TO HIS EXCELLENCY

HUGH, EARL OF NORTHUMBERLAND,

Lord WARKWORTH of Warkworth Castle,

Lord Lieutenant General and General Governor of the
Kingdom of *IRELAND*,

Lord Lieutenant and Custos Rotulorum of the Counties of MIDDLESEX
and NORTHUMBERLAND,

Knight of the Most Noble Order of the GARTER,

FELLOW OF THE ROYAL SOCIETY,

And one of the Lords of His MAJESTY'S Most Honourable Privy-Council,

This ABRIDGEMENT of the GARDENERS DICTIONARY,

Is, with the utmost Respect, inscribed, by

HIS EXCELLENCY'S most Faithful and

Obedient Humble Servant,

Philip Miller.

T H E
P R E F A C E.

THE last impression of the Abridgement of the Gardeners Dictionary, which was printed in three volumes octavo, having been long sold off, and there being yet a demand for the book, the author has been induced to publish this, which is abridged from the seventh edition in folio. But at the time he was preparing it for the press, several noblemen (for whose judgment the author had the highest regard) desired it might be printed in one volume in quarto, as they were of opinion it would be more eligible than several volumes in octavo; because the references from the *English* names to the *Latin*, or the former titles of the plants, which are here referred to those given by *Linnaeus*, would frequently occasion the turning from one volume to another, which when included in one volume would be avoided. This advice soon determined the author to print it in the manner it is now offered to the publick.

In the execution of the work, the author has been very careful not to omit any of the useful articles which are in the folio edition; and it is only the speculative parts, which are either abridged or wholly omitted. The *Latin* titles to each plant are here preserved, as being the most authentick, and therefore the more universally known; to which are added the *English* names: but where there are old *English* names to plants, by which they are more generally known among gardeners and others, who have not made botany their study, the author has chosen to adopt them, rather than to render the *Latin* titles into *English*. The synonymous titles which were added to the plants in the last folio edition are here omitted, that the work might not be too large.

The *Latin* titles of the plants are taken from Dr. *Linnaeus's* *Species of Plants*, as far as they are mentioned by that author; but there being many plants now cultivated in the *English* gardens, which are not inserted in his works, the author has given names to such as either are not to be found in *Linnaeus*, or where there is reason to believe that great botanist has not seen the plants growing, and therefore may have mistaken them.

Most of the writers on botany before *Linnaeus* have been fond of enumerating the varieties of plants, and several of them have put down varieties for different species, which had much confused the science; but *Linnaeus*, to avoid this, has too frequently gone into the opposite extreme, having, in many parts of his work, put down three or four different species, as one and the same plant. The only method to ascertain the species, is by long cultivating them from seeds; for when plants constantly keep their difference after twenty or thirty years growing from seeds, it cannot be doubted that they are distinct species.

The P R E F A C E.

The description of the species (the author believing it necessary, in order to distinguish such plants as have great resemblance to others) is here continued, but these are as much abridged as the nature of the work would admit; the particulars only being inserted in which their chief difference consists, and in every genus where there are remarkable varieties worthy notice, these are mentioned; because many of them are the greatest ornaments to the flower garden.

In treating of fruits, it is absolutely necessary to enumerate their varieties; for as most of the choice sorts have been improved by culture, the omitting the titles by which they are commonly known among gardeners, would be esteemed an unpardonable fault in a work of this kind; but in enumerating them, care has been taken not to enlarge the book, by long accounts of fruits, many of which deserve to be banished the gardens of such as have a delicate palate: therefore, the author has only recommended the best of each sort which has come to his knowledge. The directions also given, as to their choice, with the method of cultivating them thro' their different stages, are such as by long experience he has found to succeed best; and he is very certain, that whoever follows these directions, will, in a course of twenty years, find his advantage in it, whatever may have been the success of some late projects for five or six years.

The rules likewise for the management of all the esculent plants which are cultivated in the *English* gardens, are such as are now observed by those who are best skilled in the art of gardening; and where any late improvement has been made in these articles, they are carefully noticed: as also the cultivation of some roots in the open fields, which of late years have been greatly extended in *England*, and been found of very considerable benefit as a winter pabulum for cattle; as in those years when there has been a scarcity of the usual food, a supply of these roots has been of the greatest advantage to such as had store of cattle to maintain. Turneps have been long cultivated in *England* as winter fodder for cattle, and since their cultivation has been better known in the distant parts of the kingdom, have greatly improved estates; but seasons frequently happening in which these fail, every prudent person should endeavour to have a supply in case of accident. Of late years, the cultivation of two other roots has been introduced in some parts of *England*, which have fully answered this purpose; these are Carrots and Parsneps, two of the most valuable roots for fattening of cattle yet known: one acre of either of these will do more than three acres of Turneps, supposing each crop equally good; and there is scarce any cattle that will not prefer them to other food: but for swine, they are much better than any other sustenance, and the pork fatted with them the best. Another use has been made of these roots, which is the feeding of deer in parks during the winter and spring, when there is a scarcity of herbage; by this method the deer have been kept strong and sound, and so have been fat at least a month sooner than usual. The culture of both these roots is here fully treated of, with the method of preserving them through the winter for use; and it were to be wished, that such persons who have land proper for their growth would extend their culture.

The best instructions for improving natural pastures are also here given, with proper directions for laying down land which has been in tillage, so as to obtain as good sward as that of natural meadows; and likewise how to manage and improve artificial pastures, which is a part of husbandry with which the common farmers are little acquainted, though an article which deserves their greatest attention. The different methods of improving up-land, water-meadows and pastures, are also here included; the whole collected from several years experience, and not from theory, therefore the author can with safety recommend them.

The P R E F A C E.

In the articles relating to Corn of all sorts, as also in the culture of pulse, and other plants, which are sown in the open fields, several improvements are here mentioned, some of which it is to be feared will not be easily introduced, so as to become general; but however, as there is a spirit for improvements of this kind among persons of rank, it may be hoped if they begin the practice, their example may excite an emulation in their tenants and neighbours to follow them.

As the Timber of this nation is truly supposed its bulwark, so the cultivation, improvement, and preservation of it, are of the utmost consequence to the publick; yet it is greatly to be feared, that this has not been so properly attended to as it should have been, and especially by those to whom the care of the publick Timber has been entrusted; this therefore should rouse such as have large estates, to find out methods for supplying the nation with this valuable commodity, which may be done at a moderate expence, where proper care is taken in the first planting, and the after-management of Woods: in these articles the author hopes his directions will be found serviceable to all such as have inclinations and abilities to set about this work.

The directions here given for propagating all sorts of flowers being very full, it is presumed here will be found sufficient instruction to such as are desirous to improve these beauties; the choice of soils and situations for the flower-garden, and also for the nursery to raise forest-trees, fruit-trees and shrubs, is included under their several titles, whereby those who have but little experience may soon learn the methods of their culture.

As the author has been careful in this Abridgement, he hopes it will meet with the same favourable reception from the publick as his former works; for which he thinks he cannot better testify his gratitude, than by endeavouring, to the utmost of his abilities, to promote the pleasant and useful ART of GARDENING.

BELE Tree. See Populus.

ABIES, *Tourn. Pinus, Lin. Gen. Plant. 956.*
The Fir Tree.

The Characters of this genus are,

There are male and female flowers on the same tree; the male flowers have empalements of four leaves, without petals, many stamina, and naked summits. The female flowers, which are collected in a scaly cone, each scale covering two flowers, having neither petals or stamina, with one pointal, and are each succeeded by a winged nut. The distinguishing character of this genus, is the leaves arising singly from their base; whereas the Pines have two or more arising from the same point.

The Fir has always been separated from the Pine trees, by all the writers on Botany before Dr. *Linnaeus*, and were generally distinguished therefrom, by their leaves being produced singly on the branches; the leaves of the Pines being produced by pairs, threes, or fives, out of sheaths which surround their base. And as this distinction is now well known among the nursery gardeners, so it is much better to keep them separate, than to join them with the Cedar of *Libanus*, and Larch tree to the Pine, as the doctor has done, making them of one genus.

The following Species are now in the English gardens;

1. ABIES foliis emarginatis, subtus glaucis, strobilis erectis scissilibus. The Silver or Yew-leaved Fir.

2. ABIES foliis subulatis mucronatis utrinque dispositis, strobilis pendentibus. The Spruce or Norway Fir, sometimes called the Pitch tree.

3. ABIES foliis subulatis subtus glaucis, utrinque dispositis, strobilis uncialibus laxis utrinque dispositis. The small coned American Spruce Fir.

4. ABIES foliis submarginatis, subtus glaucis, utrinque dispositis, strobilis uncialibus laxis. The white Spruce Fir of North America, called Newfoundland Spruce.

5. ABIES foliis submarginatis, bifariam dispositis, strobilis subrotundis. The American Hemlock Fir.

There are some other varieties of these trees, which have been raised in England, from seeds which came from North America; but as they are believed to be only accidental va-

A B I

riations, arising from the difference of soils and situations, I shall not pretend to put them down as different species, especially as several of them have not as yet produced cones in England.

The first sort grows naturally in many parts of Germany, but the finest trees of this sort, are growing upon mount Olympus, from whence I have received some of the cones, which were of an extraordinary size. The *Strasburgh* turpentine is drawn from this tree. The wood is white and soft, and therefore not greatly esteemed. The Balm of *Gilead* Fir is so near resembling this, as scarcely to be distinguished from it, after it is grown to a large size. The young trees have their leaves growing on every side their branches, by which they may then be easily known; but as the trees advance, so their leaves become ranged only on two sides of the branches, and approach nearer to the Silver Fir: the short duration of this tree in almost every soil and situation in England, has inclined many persons to believe it a distinct species; but as I have observed the same trees to alter after some years growth, so I shall suspend my judgment of this matter, until I can determine with greater certainty.

The second sort grows naturally in the low lands of Sweden, Norway, and Denmark, as also in many other parts of Europe. This is sometimes titled *Abies rubra*, i. e. Red Fir, which has given occasion to some persons to believe, that the red deals are cut from this sort; but we now can have no doubt of the contrary, for they are cut from the *Scotch* Pine, the wood of the Spruce Fir being white. The young branches of this Fir are used to make Spruce Beer in Germany, and from thence had the title of Spruce Fir.

The third sort grows naturally in many parts of North America, from whence the cones have been brought to England. The leaves of this sort are shorter than those of the Spruce Fir, but are in shape like them, their underside being of a glaucous green colour, the cones are loose, and about an inch in length.

The fourth sort is also a native of North America, where the inhabitants make three sorts of it, by the titles of Black, White, and Red Spruce. In England, these are mostly known by the title of Newfoundland Fir, because many of their

cones have been brought from thence; but the trees are found growing in most parts of *North America*. The Black Spruce grows commonly in swamps and bogs, and rarely rises to a great height. The White Spruce is an inhabitant of the mountains and higher lands, where it grows to a large size: and in the gardens of his Grace the late Duke of *Argyle* at *Whitton*, near *Hounslow*, there are some noble trees of this sort, which are not more than thirty-six years growth from seeds. By the difference in the growth of this and the Black Spruce, we may readily suppose them to be different species; but upon examining the old branches with their cones, they approach so near as to give suspicion of their being only varieties. The red sort, as it is called in *America*, I believe to be the same with the third; for the young plants which I have raised from the seeds brought to *England* by that title, are at present so like the third sort, as not to be distinguished from them.

The fifth sort is also a native of the same country; and in the northern parts of *America*, I am informed it grows to be a very large tree; but in *England* the branches spread wide every way, so that there is no appearance of the trees ever arriving to any considerable height. The leaves of this tree are short, and shaped very like those of the Yew tree; they are ranged on two sides of the branches only, so they appear flat, like those of the Silver Fir, but are of a pale green on both sides. The cones are small, loose, and roundish. What sort of wood this tree affords I cannot say, having never seen any trees of a size fit to cut down.

From most of these Firs, the inhabitants of *North America* collect a clear fragrant turpentine, which they use for curing green wounds; and the physicians there make great use of it internally: and it is generally supposed, that what is now sold under the title of balm of *Gilead* in *England*, is this turpentine.

All the sorts of Fir are propagated by seeds; the time for sowing them is about the middle of *March* when the season is mild, otherwise it had better be deferred till the end of that month, or the beginning of *April*. The seeds which are preserved in their cones will keep good, much longer than those which are taken out; but the cones of the Silver and Balm of *Gilead* Firs generally fall to pieces in the autumn, soon after the seeds are ripe; so that if they are not carefully watched, and gathered at that time, the seeds will be lost. The cones of all the sorts of Fir open with more ease than those of the Pines, and require but little trouble to get out their seeds. If they are spread on a cloth before a fire for a few hours, their scales will open, and emit the seeds.

The seeds may be sown in pots or boxes filled with light fresh earth, covering them over about half an inch thick with the same earth; these should be placed to an east aspect, where they may have the sun till eleven in the morning; or if the seeds are sown in a bed of earth, it should be shaded with mats in the middle of the day: for when they are too much exposed to the sun, the surface of the ground will dry so fast (especially in dry seasons) as to hinder the seeds from vegetating; and when the plants begin to appear, if they are not screened from the sun, many of them will be soon destroyed. The seeds must be carefully guarded against mice and birds, who are very fond of them, but particularly when the plants begin to appear; for as they thrust up the cover of the seeds on their top, so the birds in pecking off these covers, will destroy the young plants; therefore the surest method is to cover them with nets until the plants have thrown off their husks, and expanded their seed leaves, soon after which they will be out of danger.

The plants may remain in these places where the seeds were sown till the following spring, provided they are not stunted by the stiffness of the ground, or any other cause; if

so, they had better be carefully transplanted into new beds, about the beginning of *July*; but this must be done with great care, observing to raise the plants with a trowel, so as to preserve their roots as entire as possible, and to plant them again immediately, otherwise their tender fibres will soon become dry when exposed to the air at this season, and the plants thereby destroyed. The distance for planting these young plants should be four inches row from row, and about three inches asunder in the rows: for as these beds must be arched over with hoops, that the plants may be shaded with mats in the middle of the day, so the closer they are planted, there will be less trouble and expence in their covering; and as the plants are to remain in these beds no longer than the following year, so there will be room enough for their growth during that time. These young plants must be carefully weeded, for if weeds are permitted to grow among them of any size, there will be great danger of drawing the plants out of the ground with the roots of the weeds. If the season proves very dry, it will be of service to the plants to sprinkle them over with water once or twice a week during the hot time of the year: but this should be done with caution, for too much wet will rot the shanks of these young plants and destroy them.

These plants are very rarely hurt by frost in winter, especially those in the full ground; but such as are in pots or tubs are in more danger, if they stand upon the surface of the ground; for the frost will penetrate through the sides of the pots or tubs, and thereby may injure their roots. Therefore these should either be sunk into the ground before winter, or some old tanner's bark, straw, or mulch, laid round the pots or tubs to keep out the frost.

After the young plants have remained in the seed bed one year, they may be transplanted into beds the *April* following; but as these which were not transplanted in summer from the places where they were sown, may stand two years in the beds when transplanted, so they should be allowed more room than those which were removed the preceding summer. Therefore the rows may be from five to six inches distant, and the plants in the rows four inches asunder, observing to treat them in the manner before directed. When they have grown two years in these beds, they may then be transplanted into the nursery, placing them in rows at three feet distance, and in the rows a foot asunder. The best season for removing them is in *April*, just before they begin to shoot: though they may, and often are transplanted in autumn with success; but the other time is preferable, especially if there happens to be rain soon after, otherwise they will require watering once a week for about a month.

The smaller these trees are planted out where they are to remain, the greater will be their progress, and they will grow to a much larger size than those that are removed at a much greater age; but there are few persons who have patience to wait their growth, therefore frequently plant them at the height of six or eight feet, at which size they will transplant better than most other evergreen trees; but those which are so tall, will require support, otherwise they will be in danger of being blown down by the wind. And if trees of such sizes are to be carried to a distant place, it will be expensive; for unless they have large balls of earth to their roots, there will be great hazard of their growing; and these will require more water than young plants: so that upon the whole, planting of young trees, is much preferable and less expensive. Therefore, where there are large plantations to be made, planting the trees very young is the most eligible; for the expence of cleaning these young plantations, will not be equal to that of staking and securing tall trees: and the difference of the first price, together with the carriage of the latter, will be very considerable;

ble; beside, the former will in a few years outgrow the latter. I have myself made plantations of Firs of different ages at the same time, upon the same ground; and have always found that plants of two or three years old, have in ten or twelve years, been much the best of any in the plantations; and I dare say others, who have made the like experiment, have found the same success.

In the choice of the plants, if they are to be purchased from a nursery, they should not be taken from good land to plant in a poor soil; therefore the better way is to procure them from ground, as nearly like that into which they are to be planted as possible; or if it is worse, the plants will succeed better. Indeed, where large plantations of these trees are designed, it is much the better way to make nurseries on the same ground, where the trees should be raised from seeds; for this will be a great saving of expence, and as the distance will be small to remove them, so there will be little danger of their succeeding.

But as the wood of all the sorts of Fir yet known, is much inferior to that of the Pine, so it is not adviseable to make plantations of them for their timber; therefore they are only valuable for their beauty: so that when they are planted for ornament, they should be placed so far asunder, as to admit the free air between them, otherwise the lower branches will decay, and render the trees unsightly. The great beauty of these trees are in their pyramidal form, and being furnished with lateral branches from about seven feet above the surface of the ground to their top; and these branches should be well garnished with leaves: to obtain which, the trees should not be planted nearer than eighteen or twenty feet; for when they are closer planted, the under branches soon drop their leaves and decay; and if these branches are taken off, the trees never put out new ones to supply their place. The unskilful disposition of these trees, has brought them into disrepute with many persons; whereas, if they are properly placed, they may be made very ornamental to fine seats.

In pruning off the under branches to the designed height, there must be care taken, not to cut off too many branches at the same time; one tier of branches is full enough to be displaced in a year; and if every other year this is performed, it will be sufficient; and by this gradual method of pruning, the trees will not be much retarded in their growth. The best time for this operation is in the beginning of September.

The Silver Fir requires a deep strong soil, for if it is planted in a light ground it will make but little progress; and when it is planted in a shallow ground, as soon as the roots meet with obstruction, the trees generally decay. The largest trees of this kind which I have seen, were growing in a deep loamy soil; these were upwards of ninety feet high, and were furnished with branches from ten feet above the ground to their tops, which being well garnished with leaves, made a fine appearance.

The common Spruce Fir will thrive best on the same land, but this will also do well on light ground, where the other will make little progress, so is more generally planted in England: besides, it will thrive in soils and in situations where the other will scarce live; it is also of longer duration in England.

The third sort will succeed best on a moist soil, for in light dry ground it makes but little progress, nor does it make a good appearance where the soil is not proper for its growth.

The American Spruce Fir delights in light moist ground, where the trees grow to a large size, and make a beautiful appearance; and if they are allowed room for their lower branches to spread and extend, they will be garnished with them almost to the ground, forming themselves in a pyramidal figure.

The Hemlock Fir thrives best in a strong loamy soil; those which have been planted in light dry ground, have made but little progress, especially upward, their branches taking a lateral position: so that unless the upper shoot is trained to a stake to direct its upright growth, the leading shoot will turn on one side and become flat; but in a strong loam, I have seen some of these trees which have naturally grown upright. As there are none of these trees in England, which are arrived to a size fit to cut down, so we know little of the worth of this wood.

There are some persons who are fond of propagating Fir trees from cuttings, which if properly planted will take root, but the plants so raised will never arrive to near the size of those raised from seeds: they are also never inclined to an upright growth, sending out lateral branches, and becoming bushy, therefore this practice is not worthy of imitation; and unless for sake of the multiplying a curious sort, whose seeds cannot be procured, should never be attempted; nor should the inarching of one sort upon another be practised for the same reason: for the trees so propagated will be of slow growth, and of short duration.

ABROTANUM, *Tourn. Inst.* See Artemisia.

ABROTANUM *Fœmina.* See Santolina.

ABSINTHIUM. See Artemisia.

ABRUS. See Glycine.

ABUTILON, *Tourn. Inst.* 99. Sida, *Lin. Gen. Plant.* 674. Yellow or Indian Mallow.

The Characters of this genus are,

It hath a malvaceous flower, whose stamina and styles are united at their base in one body, forming a sort of column, having a single empalement: the fruit is composed of several capsules, which contain many seeds.

Dr. *Linneus* has joined the plants of this genus to the Malvinda of *Dillenius*, including them in the same genus, under the title *Sida*. But as the Malvinda has a fruit with five capsules or cells, each containing one seed, and the fruit of *Abutilon* has many capsules and seeds, so I believe it to be right to separate them, especially as there are many species of each.

The Species of this genus now in the English gardens are,

1. ABUTILON *foliis subrotundo-cordatis acuminatis crenatis.* The common Yellow Mallow.

2. ABUTILON *foliis cordatis crenatis, capsulis scabris calyce longioribus.* The Indian Yellow Mallow.

3. ABUTILON *foliis oblongo-cordatis, inaequaliter crenatis pedunculis petiolo longioribus.* American Yellow Mallow with oblong heart-shaped leaves, and the footstalks of the flowers longer than those of the leaves.

4. ABUTILON *foliis ovato-cordatis acuminatis rugosis, floribus in thyrso terminalibus.* Yellow Mallow with oval heart-shaped rough leaves, and flowers disposed in a loose spike at the end of the branches.

5. ABUTILON *foliis cordatis subrotundis tomentosis petiolatis, pericarpis inflatis crenatis repandis.* Yellow Mallow, with downy roundish heart-shaped leaves having footstalks, and swollen covers to the fruit, which are crenated and turn backward.

6. ABUTILON *foliis cordatis acuminatis crenatis sessilibus, pericarpis inflatis tomentosis pedunculo geniculato.* Yellow Mallow, with heart shaped pointed leaves which are notched on their edges, sitting close to the stalk, and a downy swollen cover to the fruit, having a jointed footstalk.

7. ABUTILON *foliis hastatis glabris, floribus solitariis erectis, pedunculis petiolisque pilosis.* Yellow or Indian Mallow, with smooth halbert-pointed leaves, flowers standing singly and upright, with hairy footstalks to the leaves and flowers.

8. ABUTILON *foliis lobatis acutis, crenatis, subtus tomentosis, floribus terminalibus, caule fruticoso lanuginoso.* Indian Mallow

Mallow with sharp-pointed lobed leaves, woolly on their under side, flowers terminating the branches, and a downy shrubby stalk.

The first sort grows naturally in many parts of *North America*, from whence the seeds are frequently sent to *England*. It is an annual plant, which in good ground will rise four or five feet high, sending out many branches: the leaves are soft to the touch, the flowers small, of a yellow colour, so make no great appearance. The inhabitants of *North America*, use this plant for the Marsh-mallow. If the seeds of this plant are sown in a border in the spring, where the plants are to remain, they will require no other care but to keep them clean from weeds, and thin them where they are too close; and if the seeds are permitted to scatter, the plants will come up the following spring without care, and after the seeds are ripe they decay.

The fourth sort grows naturally on moist land in the *West Indies*, where it rises with a shrubby stalk, five or six feet high, sending out branches on every side, which are garnished with rough heart-shaped leaves: the flowers are disposed in loose spikes at the end of the branches, they are yellow, and shaped like those of the Mallow. This sort is propagated by seeds, which must be sown on a hot-bed, and the plants must be kept in a moderate warmth, otherwise they will not thrive in this country. The plants will continue two or three years, and produce flowers and fruit.

The eighth sort grows naturally in the *Bahama Islands*, from whence the late Mr. *Catesby* brought the seeds. It rises with a shrubby stalk to the height of seven or eight feet: the stalks are covered with a white down, the branches are garnished with leaves, having four or five lobes ending in sharp points, which are downy on their under side; the flowers are purple, and grow in loose clusters at the end of the branches. This sort is propagated by seeds, which should be sown on a moderate hot-bed; the plants must be put into pots when they are fit to transplant, and gradually inured to the open air, to which they should be exposed in summer; but in winter they must be placed in a good green-house, to secure them from frost. The plants will flower and produce seeds the second year; but will continue several years, if they are carefully managed.

All the other sorts are annual plants, which grow naturally in several parts of the *West Indies*, from whence their seeds have been brought to *England*. The seeds of these should be sown on a moderate hot-bed in the spring, and when the plants are fit to remove, they should be transplanted on another hot-bed, to bring them forward; but as the weather becomes warm, they must be hardened gradually to bear the open air; and toward the middle of *May*, if the season proves favourable, they may be taken up with balls of earth to their roots, and planted in the open borders, observing to shade and water them until they have taken new root; after which time they will require no farther care, than to keep them clean from weeds. In *June* they will begin to flower, and there will be a succession of flowers, until the cold in autumn puts a stop to them. The seeds ripen in the autumn, which should be gathered as they ripen, otherwise they will scatter.

ACACIA, *Tourn. Inst. Mimosa, Lin. Gen. Plant. 597.* The Egyptian Thorn, or Binding Bean tree.

The Characters of this genus are,

It hath male and hermaphrodite flowers collected in the same head: the male flowers have their empalements ending in five points; they have one tubulous petal, cut at the brim into five segments, and have several stamina. The hermaphrodite flowers have the same empalements and petals, with five stamina and one pointal, which afterward becomes a cylindrical pod.

Dr. *Linnaeus* has joined the *Acacia*, *Inga* and *Mimosa* together, including them in the same genus, under the title of

Mimosa. But as there are many species of *Acacia*, and that being an old medicinal title, which is still known in the shops, so it is much better to separate them, especially as there is a characteristic difference in their pods, than to join them to the *Mimosa*, of which there are also many distinct species now known in *Europe*.

The Species of this genus which we now have in the *English* gardens are,

1. ACACIA *foliis bipinnatis, foliolis aequalibus glabris, spinis geminis rectis.* *Acacia* with winged leaves, whose lobes are smooth and equal, and upright thorns by pairs.

2. ACACIA *foliis bipinnatis, foliolis exterioribus minoribus, caule aculeato.* *Acacia* with winged leaves, whose outer lobes are the least, and a prickly stalk.

3. ACACIA *foliis bipinnatis, foliolis subaequalibus spinis longis geminis rectis.* *Acacia* with winged leaves, whose lobes are almost equal, and long upright spines by pairs on the stalks.

4. ACACIA *spinis geminis patentibus foliis bipinnatis, foliolis linearibus aequalibus.* *Indian Acacia* of the *Farnese* garden.

5. ACACIA *inermis, foliis bipinnatis, foliolis linearibus glabris, floribus paniculatis, siliquis ad singula grana tumidis.* *Acacia* without thorns, winged narrow smooth leaves, and flowers disposed in panicles.

6. ACACIA *inermis, foliis bipinnatis numerosissimis, floribus globosis axillaribus.* *Acacia* with double winged leaves, having many lobes, and globular flowers rising at the wings of the stalk. 11. Dictionary.

7. ACACIA *spinis axillaribus geminis connatis, foliis bipinnatis, floribus spicatis.* Large horned *Acacia* with spiked flowers.

8. ACACIA *spinis axillaribus geminis connatis, foliis bipinnatis, floribus globosis.* Large horned *Acacia* with globular flowers. 3d Dictionary.

9. ACACIA *foliis bigeminis obtusis, spinis geminis axillaribus, floribus paniculatis staminibus longissimis.* *Acacia* with two pair of lobes to each leaf, commonly called *Doctor Long*, or *Cat's Dung*, in the *West Indies*. 5th Dictionary.

10. ACACIA *foliis bipinnatis bijugis, foliolis interioribus minoribus, petiolo lineari.* *Acacia* with double winged leaves, having two pair of lobes, the inner being smallest, and a linear stalk.

11. ACACIA *foliis conjugatis pinnatis, foliolis aequalibus, stipulis spinosis.* *Acacia* with conjugated winged leaves, whose lobes are equal, and thorny stipulae.

12. ACACIA *inermis, foliis bipinnatis, foliolis exterioribus majoribus, siliquis tumidis.* *Acacia* without thorns, doubly winged leaves, whose outer lobes are largest, and thick blunt pods.

13. ACACIA *spinis solitariis incurvis, foliis bipinnatis, floribus spicatis.* *Acacia* with single incurved spines, doubly winged leaves, and spiked flowers.

14. ACACIA *aculeata, floribus polyandris spicatis, legumine compresso laevi elliptico.* *Adanson.* Prickly *Acacia*, with spiked flowers having many stamina, and smooth compressed elliptical pods; or the true *Acacia* from which the *Gum Senegal* is taken.

15. ACACIA *spinis geminis approximatis, foliis bipinnatis, partialibus bijugatis.* *Acacia* with twin spines near each other, double winged leaves, whose wings have two pair of lobes.

The three first sorts grow naturally at the *Cape of Good Hope*, from whence the seeds are brought to *Europe*; and the plants are now in many gardens in *England* and *Holland*. These plants are not so tender as most of the other sorts, so may be preserved in a good green-house in winter, and exposed to the open air in summer. They retain their leaves all the year; but as there are not at present

any plants of an age fit for flowering, we can say nothing of their beauty as yet, but their leaves make a good appearance, and add to the variety in the green-house.

All the other sorts are natives of warmer countries, and cannot be kept in *England* through the winter without artificial heat: therefore those who have not the conveniency of a stove to preserve them, must not attempt to raise them here: for although they may grow very well in summer, yet on the first approach of winter, they will lose their leaves, and soon after decay.

They are all of them propagated by seeds, which do not ripen well in *England*, so should be procured from the countries where they grow naturally; and should be sown in small pots filled with light earth, early in the spring, which pots should be plunged into a hot-bed of a moderate temperature of heat; where (if the seeds are good) the plants will appear in about a month or five weeks after; then they should have gentle waterings two or three times a week, and fresh air should be admitted to the plants every day when the weather is warm, which will greatly strengthen them. When the plants are about three inches high, they should be each planted into a single small pot, filled with light earth, and plunged into a moderate hot-bed of tanners bark, observing to shade them every day when the sun is warm, until they have taken new root; after which they should have fresh air admitted to them, by raising of the glasses, in proportion to the warmth of the season; and they should be gently watered, when the earth of the pots is dry; but as the greater part of these plants do not draw up the moisture very fast, so they should not have too much wet.

As the plants advance in strength, they should have a greater share of air admitted to them; and when they have filled the pots with their roots, they should be shifted into pots of the next size to those in which they were before growing; but they must not be over-potted, for they will not thrive in large pots; nor if the earth is stiff will they make much progress, for they generally grow in light sandy earth.

When the plants have acquired strength, they may be exposed to the open air, during the warm season in summer, which seldom continues much longer than two months, viz. from the end of *June* to the end of *August*; during which time they should be placed in a warm situation, where they may be defended from strong winds: and soon after they are placed in the open air, they should be shifted into fresh earth, that they may be well rooted before the cold comes on in the autumn, for they must then be removed into shelter: those sorts which are the most tender should be first taken in, which are the seventh, eighth, ninth, tenth, eleventh, thirteenth and fourteenth sorts; the fourth, fifth, sixth, twelfth and fifteenth sorts may remain longer abroad, if the weather is favourable. The former sorts should be placed in a warm stove in winter, otherwise they will not thrive; but if the latter are placed in a stove kept in a moderate temperature of warmth, they will succeed very well. But the three first sorts being less tender, may remain longer in the open air; and if they are placed in a warm green-house in winter, they will do better than in a greater warmth.

All these plants may be treated with less tenderness as they acquire strength; therefore as they advance in their growth, so they should be gradually hardened: but this must be done with caution, and great care should be taken, not to let them have too much wet.

The fourteenth sort produces the Gum Senegal, of which there are great quantities consumed in *Europe*: and it is from the same tree the Gum Arabick is collected in other countries, as Mr. *Adanson* has mentioned in his *History of Senegal*. This sort is not only common in *Africa* and in *Egypt*,

but grows naturally in many parts of *India*, from whence I have frequently received the seeds. It is easily distinguished by the pods, from all the other *Acacias*, these having several isthmus in which the seeds are lodged.

The fourth sort grows naturally in both *Indies*, and also in *Africa*, and is frequently cultivated in gardens in many parts of *Europe*, for the fragrance of its flowers, which are collected into large globular heads; they are of a bright yellow colour, and very agreeable scent; these are produced from the side of the young branches, at the insertion of the leaves: so that as the shoots extend in length, new flowers are produced, whereby (in warm countries) the trees continue flowering two or three months, but in *England* there are few plants old enough for flowering: they are too tender to live through the winter in a common green-house; and if they are too much drawn in a stove, they are apt to grow weak, so rarely flower. The only method to have these trees succeed in *England*, is to keep the plants in a moderate stove in winter, where they may have air in warm mild weather, and in cold damp weather secured by a fire from both; and in the summer place them in an airy glass-case, where they may be sheltered from cold and wet, and in warm weather let them have a great share of air; for if they are placed in the open air, the summers are generally too cold for these trees; and when they are kept too close in a stove, they run up weak, so rarely produce any flowers: but by the other method I have had them produce their flowers in plenty, when the plants were of a proper age.

The other sorts are frequently preserved in the gardens of the curious for the sake of variety, some of which have frequently flowered and perfected their seeds in *England*, when they have remained in the bark stove during the whole year; but there should be particular care taken in this case, not to draw the plants so as to make them very weak.

The seventh and eighth sorts produce very large thorns upon their stems and branches, some of which were brought me from *Campeachy*, which are five or six inches long, and as large as a goose-quill; they are greatly twisted cross each other so as to make an odd appearance, having more resemblance to a work of art, than of a natural production, when separated from the tree. This sort is frequently destitute of leaves for two or three months.

ACACIA, the Common *American*. See *Robinia*.

ACAJOU, or CAJOU. See *Anacardium*.

ACALYPHA. Three-seeded Mercury.

There are three species of this genus of plants, which are preserved in curious botanic gardens for the sake of variety; but as they have no great beauty, or of any use, so they are rarely propagated in other gardens, therefore are not inserted here, as the enumeration of such plants would swell the work beyond the bounds intended.

ACANTHUS, *Tourn. Inst. Lin. Gen. Plant.* 711. Bear's-breech.

The *Characters* of this genus are,

The empalement of the flower is two-leaved and bifid; the petal has but one lip, which is turned backward, and is divided into three at the end. The capsule has two cells, each containing one seed. It is of the ringent class of flowers, whose seeds are in a capsule. In the second division of *Linnæus's* fourteenth class.

The *Species* of this genus now in the *English* gardens are,

1. ACANTHUS foliis sinuatis inermibus obtusis. Smooth Bears breech with sinuated obtuse leaves, or the common Official Bear's-breech.

2. ACANTHUS foliis sinuatis inermibus lucidis, laciniis acutis. Smooth Bear's-breech with sinuated shining leaves, having acute points.

3. ACANTHUS foliis pinnatis acutis subspinosis. Bear's-breech with acute winged leaves, having soft prickles.

4. *ACANTHUS foliis pinnatis lucidis spinosissimis*. Prickly Bear's-breech with shining winged leaves.

The first sort is the common *Acanthus*, whose leaves are taken for the ornaments of the *Corinthian* capital, and is the sort which is used in medicine. It grows naturally in *Italy*, *Sicily*, and the *Levant*.

The second sort grows naturally in *Portugal*. The leaves of this are much larger than those of the first, and are less jagged; the cuts of the leaves are more pointed, and the upper surface is lucid. This is not a variety, for the seeds constantly produce the same kind.

The third sort grows naturally in *Italy*; the leaves of this are cut into acute segments, and are shaped like winged leaves, each segment terminating with a short soft spine. The flower-stalks of this sort, rise considerably higher than those of the former sort.

The fourth sort hath large shining winged leaves, which are armed with strong spines at the end of each segment, which renders it very troublesome to handle the leaves; the flower-stalks of this rise as high as those of the third sort. This grows naturally in the *Archipelago*.

These plants have all of them thick fleshy roots, which strike deep in the ground; and those of the third and fourth sorts creep in the ground to a considerable distance, that it is difficult to keep them within proper compass. They are also less tender than the first and second sorts, so are rarely injured by the greatest cold in *England*; whereas the former are killed in severe winters where they are exposed in an open situation, therefore require a warm situation and a dry soil. These plants frequently perfect their seeds in *England*, so they may be propagated by sowing them in a bed of light earth in the spring, where the plants generally appear in about six weeks after; and if they are kept clean from weeds, it is all the care they require the first summer: but in the winter, the plants of the first and second sorts will require some protection, especially if the weather should be very sharp; therefore they should be covered with mats, pease-haulm, or some other light covering, when the frost is severe, but the covering should always be removed in mild weather.

About the beginning of *March*, if the season is mild, the young plants should be carefully taken up, and transplanted in the places where they are designed to remain. Those of the two first sorts should have a warm situation and a dry soil; they must also be covered in winter if the frost is severe, for a year or two, till they have obtained strength enough to resist the cold: but the other may be planted in the open border, where, if the ground is not too wet, they will thrive and flower very well.

But as the plants which are raised from seeds seldom flower till the third year, so few people care to wait so long, therefore generally propagate them by offsets from the roots; these are produced in great plenty by the third and fourth sorts, which send them out to a considerable distance from the mother plant, so may be had in great abundance: but the first and second sorts do not increase near so fast, therefore are less common in the *English* gardens than the other. The offsets of all these sorts, should be taken from the old plants in *March*, when the danger of the hard frost is over; for if very severe frost should happen soon after their removal, it will kill them, especially those of the two first sorts.

When the plants have taken good root in the places where they are designed to remain, the only culture they will require, is to keep them clean from weeds; and when they shoot up their flower-stalks, to put down stakes and fasten the stalks to them, to prevent their being broke down by the wind, for they generally grow four or five feet high, and their flowers being large, become heavy; but when the

seeds are formed, they are commonly too weighty for the stalks to support them. The two last sorts should have their offsets frequently taken off, to keep them within bounds.

ACER. The Maple tree. In *French*, *Erable*.

The Characters of this genus are,

It hath hermaphrodite and male flowers on the same tree; the hermaphrodite flowers have an empalement of one leaf, cut into five parts: the corolla has five petals, they have five stamina and one pointal: the flowers are succeeded by two winged capsules joined at their base; each including a single seed. The male flowers have the same characters but have no style, so are not fruitful.

The Species are,

1. *ACER foliis quinquelobis inæqualiter serratis, floribus racemosis*. *Lin. Sp. Pl.* 1054. The greater Maple, falsely called Sycamore.

2. *ACER foliis lobatis obtusis emarginatis*. *Lin. Sp. Pl.* 1055. The common or lesser Maple.

3. *ACER foliis compositis, floribus racemosis*. *Hort. Cliff.* 144. The Ash leaved Maple.

4. *ACER foliis quinquelobis acuminatis acute dentatis glabris floribus corymbosis*. *Lin. Flor. Suec.* 303. The Norway Maple.

5. *ACER foliis quinquelobis sub iis dentatis, subtus glaucis pedunculis simplicissimis aggregatis*. *Lin. Sp. Plant.* 1055. The Scarlet flowering Maple.

6. *ACER foliis quinquepartito-palmatis acuminato dentatis*. *Lin. Sp. Pl.* 1055. The American Sugar Maple.

7. *ACER foliis trilobis acuminatis serrulatis, floribus racemosis*. *Lin. Sp. Pl.* 1055. The American Mountain Maple.

8. *ACER foliis trilobis integerrimis*. *Prod. Leyd.* 459. The Montpelier Maple.

9. *ACER foliis subtrilobis serrulatis*. The *Cretan* Maple.

The first sort grows naturally in the mountains in *Germany*, but is now so common in *Britain*, as to be by some supposed to be indigenous here; for the seeds have been carried by the winds to a great distance from the trees, and the plants have risen in great plenty without care, in all places which are fenced from cattle, in the neighbourhood of the trees; so that there is generally a supply of young plants from scattered seeds without any trouble, and this may have misled many persons, to believe the tree is a native of this country.

This sort grows to a tree of a large size; the wood is soft and very white, so is used by the turners, but is not esteemed very valuable for other purposes. But as this tree will thrive better than most other sorts near the sea, so it is frequently planted to screen plantations of other sorts of trees from the spray of the sea.

The second sort is very common in most parts of *Europe*, and is generally believed to be a native of this country. The wood is very hard, so is used for gun-stocks and several other purposes; but this sort never grows to a large size.

The third sort, which is commonly known by the title of Ash leaved Maple, is a native of *North America*, but is now very common in the *English* gardens. It is of quick growth; the trees often make shoots of eight or ten feet long in one year, but the wood is soft, and the branches of these trees are frequently split off by strong winds in the summer, when they are clothed with leaves, if they are in an exposed situation. These trees abound with a sweet sap early in the spring, which, if collected, by tapping their stems at that season, and boiling it, a tolerable good sugar is produced in *North America*; but the sixth sort is that, which the inhabitants of that part of the world usually tap for that purpose. From the first sort here mentioned, *Dr. Lister* procured some sugar after the same manner in *England*; and I believe if the sap of some other species were tried, there

there might be a coarse sort of sugar produced, as there might also by boiling the sap of the Birch tree.

The fourth sort grows naturally in *Norway*, *Sweden*, and other northern parts of *Europe*; it rises to a good height, and is well furnished with branches, which are garnished with large smooth leaves of a lucid green, which are divided in shape of a hand. These have an acrid milky juice; so are rarely eaten by insects; whereas those of the first sort are frequently eaten full of holes; which render them very unfitly; for which reason, the trees have been generally neglected of late years. This fourth sort will thrive as well near the sea as the first, so is much preferable to it.

The fifth sort is a native of *North America*, from whence the seeds were brought to *England*. This is cultivated in gardens for the beauty of its red flowers, which appear early in the spring; they are formed in roundish bunches, at the bottom of the foot stalks of the leaves. There is a variety of this, which is commonly called *Sir Charles Wager's Maple*, whose flowers are produced in much larger clusters than those of the common sort, and are placed closer upon the branches; so the trees make a much better appearance than the former, though I believe it to be only a variety from it. This sort never grows to a large size in *England*.

The sixth sort is what the inhabitants of *North America* generally tap for the juice, which they boil to obtain a coarse sort of sugar, so is distinguished from the other sorts by the title of *Sugar Maple*. The leaves of this sort have some resemblance to those of the fourth sort, but are not so lucid, and are frequently eaten by insects like those of the first sort, therefore this tree is seldom cultivated for beauty. It grows large, and the wood may be used for the same purposes as those of the other species.

The seventh sort hath some appearance of the sixth, but the leaves are more pointed.

The eighth sort is a tree of low growth, never rising to a greater height than our *Lesser Maple* in its native soil. The leaves are of a thick substance, divided into three intire lobes, and are of a lucid green; they continue in beauty till late in the autumn.

The ninth sort grows naturally in the islands of the *Archipelago*; the leaves of the young plants of this sort are oval and entire, but as they advance their leaves become in shape like those of the *Ivy*; they are not of so thick consistence as those of the eighth, but are of a lucid green: and in places where the trees are well sheltered from cold, the leaves continue green most part of the year, especially while the trees are young. This sort will endure the cold of our winters in the open air.

All the sorts of *Maple* may be propagated by cuttings, which in dry ground should be planted in the autumn; but where the land is moist and cold, the spring season is preferable; if they are cut from the trees before the buds begin to swell, and the ground is not then fit to receive them, they may be wrapped in moss, and put in a cool place, where they may be kept a month or five weeks without injury, as I have frequently experienced; so that these cuttings, will bear transporting from one country to another very well. But the trees which are raised from cuttings are not so valuable as those which are propagated by seeds, because they seldom grow so large, nor so upright.

The seeds of all the sorts of *Maple* should be sown in the autumn, soon after they are ripe, for if they are kept dry till the spring, they often fail, or at least lie a whole year in the ground before they vegetate. Therefore if they cannot be sown in the autumn, they should be put into sand to preserve them, and the sand and seeds sown together early in the spring upon a common bed of earth. When the plants come up, they must be kept clean from weeds, and in the following autumn transplanted into the nursery, where they

may grow two or three years, and then may be planted where they are to remain.

ACETOSA. Sorrel. *Rumex*, *Lin. Gen.* 407.

The Characters are,

It hath male and hermaphrodite flowers on the same plant in some of the species, and in others they are on different plants; the flowers have a three-leaved empalement, and have six stamina; the hermaphrodite flowers have a three-cornered style, and these are succeeded by a three-cornered seed.

The Sorrels and Docks are by *Dr. Linnaeus* included in the same genus, under the title of *Rumex*; but as the old name of *Acetosa* or *Sorrel* is better known by physicians and in the gardens, so I have continued it under the old title.

The Species are,

1. ACETOSA floribus dioicis, foliis oblongis sagittatis. The Common Sorrel.

2. ACETOSA floribus dioicis, foliis lanceolato-hastatis. Sheeps-Sorrel.

3. ACETOSA floribus hermaphroditis, foliis cordato-hastatis. Round-leaved Garden, or Roman Sorrel.

4. ACETOSA floribus hermaphroditis digynis. *Westmoreland* Sorrel.

5. ACETOSA floribus hermaphroditis geminatis, valvularum alis maximis membranaceis reflexis, foliis indivisis. *American* Annual Sorrel.

6. ACETOSA floribus hermaphroditis distinctis, valvularum alis maximis membranaceis, foliis crotis. *Egyptian* Sorrel with Rose-coloured bladders.

7. ACETOSA floribus dioicis, valvulis lævibus, caule arboreo, foliis subcordatis. The Sorrel tree.

The first sort grows naturally in pasture lands in most parts of *England*, but is also cultivated in gardens for culinary uses. It is a perennial plant, so will continue many years without renewing, provided the roots are planted at a sufficient distance to allow room for digging the ground between the rows.

The second sort grows naturally upon dry banks, and on gravelly ground in most parts of *England*, where by its creeping roots, it spreads over the land, and is often a very troublesome weed, so is rarely admitted into gardens.

The third sort is cultivated in gardens for use, and is a much better plant for the kitchen than the common Sorrel. This spreads and increases greatly by its creeping roots, so should be planted at a good distance, and in a stony soil, will do much better than in rich land.

The fourth sort grows naturally in the northern counties of *England*, in *Wales*, and *Scotland*; it is a low plant with creeping roots, the leaves are thick in proportion to their size, and are of a glaucous colour. It is rarely propagated in gardens.

The Annual *American* Sorrel is kept in some gardens for the sake of variety, but is not of any use. It grows naturally in *America* and *Egypt*.

The sixth sort grows naturally in *Egypt*; it is an annual plant, the bladders covers of the seeds are of a fine Rose-colour. This is kept in gardens for variety, but is not cultivated for use.

The seventh sort grows naturally in the *Canary Islands*. This rises with a strong woody stalk to the height of ten or twelve feet. It is frequently kept in gardens here, but must be housed in winter, for it will not live abroad in any country where there are hard frosts in winter. This is generally propagated by cuttings, because the seeds seldom ripen well in *England*. If the cuttings are planted in a shady border any time in summer, and are duly supplied with water, they will soon put out roots; then they should be taken up carefully and planted in pots, for if they are permitted to remain in the border, they will soon grow so vigorous as to render their transplanting hazardous. When they are planted

planted into pots, they should be placed in the shade until they are rooted again; then they may be removed to enjoy the open air till *October*, when the frosts begin to be sharp; at which time they should be carried into the green-house, and treated in the same way as Myrtles, and other hardy green-house plants.

The common Sorrel is cultivated by seeds, and sometimes by parting of the roots; but the seedling plants, if they are allowed room, will have larger and more succulent leaves, than those which are propagated by slips. The plants should stand in rows about a foot asunder, to give room for digging the ground between them every spring: and if the plants are six inches distant in the rows, they may stand two or three years without removing, and only require to have the ground kept clean from weeds in summer, and slightly dug in the spring. The best time to part or transplant the roots is in autumn, which is also the best time for sowing of the seeds upon dry land.

The round-leaved, or *Roman Sorrel*, is propagated by its creeping roots. These may be transplanted either in spring or autumn, but the latter season is the best for dry ground. It thrives best on stony land, for it grows naturally on rocks. This seldom produces good seeds, especially when it is planted in light ground. The roots of this sort should be planted two feet asunder each way.

The seeds of the annual sorts should be sown the latter end of *March*, on a bed of common ground, in rows at a foot and half distance; and when the plants come up, they should be thinned so as to leave them four or five inches asunder; the ground must be kept clean from weeds, which is all the culture these plants require. In *July* they will flower, and their seeds will ripen in autumn.

ACETOSELLA. See Oxalis.

ACHILLÆA. Yarrow, Milfoil, or Nose bleed.

The Characters of this genus are,

The compound flowers have an oval scaly empalement, including many hermaphrodite florets in the disk, and from five to ten female half florets which compose the ray; the seeds are lodged in a chaffy bed, and have no down.

The Species which are kept in the *English* gardens,

1. ACHILLÆA foliis setaceis dentatis, denticulis subintegrifolulatis reflexis. *Lin. Sp. Pl.* Eastern Sneezwort, with a leaf like Lavender-Cotton, and a large flower.

2. ACHILLÆA foliis pinnatis hirsutis, pinnis linearibus dentatis, *Lin. Sp.* 897. Woolly Yarrow with yellow flowers.

3. ACHILLÆA foliis pinnatis supra decompositis laciniis linearibus distantibus. *Prod. Leyd.* 175. Tall Eastern Yarrow with leaves like Wormwood, and yellow flowers.

4. ACHILLÆA foliis pinnatifidis planis obtusis tomentosis. *Lin. Sp.* 898. Alpine umbelliferous Wormwood with silvery woolly leaves.

5. ACHILLÆA foliis lanceolatis obtusis acutè serratis. *Lin. Sp.* 898. Sweet Maudlin.

6. ACHILLÆA foliis pinnatis, foliolis obtusè lanceolatis serrato-dentatis. *Lin. Sp.* 898. Hoary Sneezwort with crested pinnule.

7. ACHILLÆA foliis lanceolatis acuminatis argutè serratis. *Lin. Sp.* 898. *Strore pleno.* Double Ptarmica, or Sneezwort.

8. ACHILLÆA foliis lanceolatis dentato-serratis, denticulatis minutè serratis. *Lin. Sp.* 898. Alpine white Maudlin with deep green leaves.

The common Yarrow, and some other species of this genus are here omitted, as they are rarely permitted to have a place in gardens. The common sort with white and purple flowers grow naturally in *England*, but the white is the most common, and is the sort which has been long used in medicine. It grows on the side of foot-ways almost every where, so may be easily procured.

The first sort here mentioned, has large yellow flowers

which stand upon pretty long footstalks singly, not in close bunches, as the common sort. It has leaves like those of Lavendar Cotton, which, when rubbed, emit a strong oily odour. This flowers in *June* and *July*.

The second sort hath woolly leaves shaped like those of the common sort, the flowers are yellow, growing in clusters at the top of the stalks, which seldom rise more than a foot high.

The third sort grows to the height of two feet and a half, having large umbels of yellow flowers on the top; the leaves are somewhat like those of the common Wormwood, and are cut into long narrow segments. This flowers in *June* and *July*.

The fourth sort is a native of the *Alps*; it is a plant of humble growth, the stalks seldom rising higher than six or seven inches; these support umbels of white flowers like those of the common Sneezwort, which appear in *April* and *May*. The leaves are silvery, and shaped like those of Wormwood, which frequently decay in the autumn or winter.

The fifth sort was used in medicine, and was some years past much cultivated in the gardens, as it was frequently used in the kitchens: but of late years it has been almost totally neglected, so was almost lost in *England* a few years since; and the markets were supplied with the eighth sort, which ignorant persons substituted in its stead, though the two plants are very different in appearance, and have very different flavours, and probably different qualities.

The sixth sort grows naturally in the *Archipelago*, but is hardy enough to live abroad in *England*, provided it is planted in a dry soil and a warm situation. It is a low plant, which puts out many heads near the roots, which are fully grnished with fine cut silvery leaves. The stalks rise from nine inches to a foot high, and are terminated by compact umbels of yellow flowers. This sort continues flowering great part of summer, so deserves a place in gardens.

The seventh sort is the common Sneezwort, of which there is a variety with double flowers, that is cultivated in gardens. The common sort, which is used in medicine, grows naturally in woods, and upon commons, in most counties in *England*. It creeps greatly at root, so that variety with double flowers should be confined, otherwise it will spread to a great distance, and will not be handsome.

The eighth sort grows naturally on the *Alps*, but is now commonly cultivated by those gardeners who supply the markets with physic herbs, and is sold for Sweet Maudlin, as is before-mentioned. This plant will rise four feet high in good land; the leaves are long, narrow, and sharply sawed on their edges; they are of a dark green, and the flowers are white: the roots creep far under ground, so they should be confined.

All the sorts of Yarrow are easily propagated by seeds, which may be sown either in the spring or autumn, upon a bed of common earth; and when the plants come up and are strong enough to transplant, they should be planted into beds in the nursery, where they may remain till autumn, at which time they should be transplanted to the places where they are designed to remain: if they are planted in a stony dry soil, they will live much longer than in rich ground.

The sorts with creeping roots propagate themselves so fast, as to render it necessary to confine them, otherwise they will spread wide on every side; and the stalks being separated to a distance from each other, the plants will make but an indifferent figure when the flowers are fully blown. The other sorts whose roots do not creep may be propagated by slipping off their heads, and planting them in a shady border; or if in an open bed, they must be shaded with mats in the day until they have taken root, after which

which they will require no farther care than to keep them clean from weeds till autumn, when they should be transplanted to the places where they are designed to remain.

ACHRAS. Mamme Sapota.

This is a large tree, which is propagated in the islands of the *West Indies*, but is supposed to have been transplanted thither from some other country. The leaves are nine or ten inches long, and five broad in the middle, drawing to points at both ends; they are smooth on their upper side, but have many slight veins running from the middle rib to the sides: the fruit is large, oval and fleshy, including one long oval-pointed nut, which is very smooth, having a longitudinal border on one side.

As I have not seen any of these trees in the *English* gardens, so I shall forbear to say any thing more of its culture, than that if the plants can be procured they must be kept in the bark-bed of the stove, and treated in the same way as other exotic plants of the same country. I have frequently received the stones of this fruit from *Jamaica*, but they were always rotten before they arrived, for not one of them ever sprouted; so that I believe, these seeds will not continue long sound after the fruit is eaten.

ACHYRANTHES. We have no proper *English* name for these plants. One of the sorts has been long in the gardens, and has been known by Father *Boccon's* title, *viz.* *Amaranthus ficulus spicatus radice perenne.* This sort grows naturally in both *Indies*, from whence I have several times received the seeds. There are three other species, whose seeds have been brought from the *Cape of Good Hope*, and the plants are preserved in curious botanic gardens, but being neither useful or beautiful, are seldom kept in other gardens, therefore they are not enumerated here.

ACINOS. See *Thymus*.

ACONITUM. Wolfsbane, or Monkshood.

The Characters are,

The flower has no empalement; it has five unequal petals, the upper is hooded and inverted; it has two forked nectariums, whose footstalks are recurved, and many small stamina which incline to the petals, with five styles terminated by reflexed stigmas. The flowers are succeeded by three or four capsules with one valve, containing many angular seeds.

The Species are,

1. ACONITUM foliis palmatis multifidis villosis. *Lin. Sp. Pl.* 532. Yellow Wolfsbane or Monkshood with hand-shaped leaves.

2. ACONITUM foliis palmatis nervosis glabris. Yellow Wolfsbane with larger smooth-veined hand-shaped leaves.

3. ACONITUM foliis multifidis, laciniis semipartitis supernè latis. *Hort. Cliff.* 24. Small Blue Wolfsbane or Monkshood with many pointed leaves.

4. ACONITUM foliorum laciniis linearibus supernè latioribus linea exaratis. *Hort. Cliff.* 214. Large Blue Wolfsbane or Monkshood, whose under leaves are cut into many narrow segments, and the upper into broader.

5. ACONITUM foliis palmatis multipartitis, spicis florum longissimis. The Common Monkshood or Blue Wolfsbane, with the longest spikes of flowers.

6. ACONITUM foliis multipartitis, laciniis linearibus incurvatis squarrosis. *Hort. Upsal.* 152. Yellow Wolfsbane of the *Pyrenees*, with leaves cut into many narrow segments which are rough.

7. ACONITUM floribus pentagynis. *Lin. Sp. Pl.* 532. Yellow wholesome Wolfsbane or Monkshood.

These sorts of Wolfsbane grow naturally upon the *Alps*, the mountains in *Germany*, *Austria*, and in *Tartary*, so require a cool shady situation, and a soil rather moist than dry; but not so wet, as to have the water standing near their roots in winter: in dry ground these plants do not thrive or flower well, especially if they are exposed much

to the sun. They may be all of them propagated by sowing their seeds in autumn, upon a north-border, where they are screened from the sun. The plants will come up the following spring, when they must be kept clean from weeds during the summer months, and in very dry seasons, if they are frequently refreshed with water, it will greatly promote their growth; the following autumn they should be transplanted into shady borders, into rows a foot asunder, and the plants at six inches distance in the rows. In this situation they may remain two years, by which time they will be strong enough to flower, so may be transplanted to the garden where they are designed to remain.

As these plants rarely flower in less time than three years from seeds, so they are generally propagated by parting of their roots; for when they are planted in a shady cool situation, the roots increase plentifully, especially the fifth sort; which, if not confined, will in a few years spread at a great distance. The autumn is the season for transplanting and parting of their roots, and if they are planted in a loamy soil to a north or east aspect, they will thrive greatly.

The roots of these plants are thick and fleshy, and in some sorts are as large as a man's thumb; these put out a great number of fibres every year, which spread to a considerable distance every way: therefore they should be allowed room, for if they have not two or three feet space, they will not produce strong flower stalks, in which their beauty chiefly consists. But the fifth sort must have much more room, because it sends out offsets in great plenty to a considerable distance every way. This has been the most commonly cultivated in the *English* gardens of all the species; and the flowers are annually brought in great plenty in *May* to the markets for flower-pots to adorn rooms; but as it is of a very poisonous quality, so it should be with great caution admitted where children frequent; there having been many instances of its dangerous effects.

Most if not all the species of this genus are hurtful in a greater or less degree, therefore should not be planted in those parts of gardens, where children are permitted to walk, lest by gathering of the leaves or flowers, and putting them in their mouths, or by rubbing either about their eyes, they should suffer by it. For the juice of the leaves will occasion great disorder, if only rubbed upon very tender flesh, but if taken inwardly will kill, unless there is timely relief. The farina of the flowers, if accidentally blown into the eyes, will occasion great pain and blindness for a time, by causing them to swell greatly, as I have myself experienced.

The Common Monkshood flowers in *May*, and is succeeded by the first and second sorts. The wholesome Wolfsbane comes after these, and the other sorts flower in *August* and *September*.

ACONITUM HYEMALE, or Winter Aconite. See *Helleborus*.

ACORUS. The Sweet Rush.

This plant grows naturally in deep standing waters, so is rarely admitted into gardens, for it will not thrive on dry land; but as the roots are used in medicine, so I would not omit the mention of it. Whoever has an inclination to propagate it, should procure some roots from the places where it grows naturally, and plant them in ditches, or close on the side of ponds, where they will thrive and increase greatly, if they are not disturbed.

ACRIVIOLA. See *Tropæolum*.

ACTÆA. Herb Christopher.

The Characters of the genus are,

The empalement of the flower is composed of four roundish concave leaves which fall off. The former has four petals which

drop off, and a great number of stamina; an oval germen with one stigma, which becomes a smooth oval berry including several roundish seeds.

The Species are,

1. *ACTÆA racemo ovato, fructibus baccatis.* Lin. Sp. 504. Common Herb Christopher.

2. *ACTÆA racemis longissimis, fructibus unicapsularibus.* Lin. Sp. 504. American Herb Christopher with the longest spikes of flowers, called Black Snakeroot in America.

3. *ACTÆA racemis paniculatis, fructibus quadricapsularibus.* Lin. Sp. 504. Herb Christopher with flowers disposed in panicles, and four capsules to each fruit.

The first sort grows naturally in shady woods, in some of the northern counties in England, particularly near Ingleborough hill in Yorkshire. It is by some curious persons preserved in gardens, for the sake of variety, but there is little beauty in the flowers to recommend it. This must have a shady situation and a moist soil, otherwise it will not thrive. It is propagated by seeds or parting of the roots; if by seeds, they should be sown in the autumn soon after they are ripe, on a shady moist border; for if the seeds are kept out of the ground till spring, they often fail, or at least lie a year before they vegetate. The time for parting and transplanting of the roots is in autumn; they require no other culture, but to keep them clear from weeds. It flowers in May, and the berries ripen in September.

The second sort is a native of North America, from whence the seeds have been brought to Europe. The fruit of this plant is frequently used in America, as an antidote to poison, and to cure the bite of venomous serpents. By some persons it is used as an emetic, and is sometimes called Ipecacuana.

The roots of this sort grow large, and multiply into several heads; and when they are planted in gardens, they should be allowed three feet every way to spread, for their leaves, which are composed of many branches, will soon cover so much room. The seeds of this plant do not ripen in England, so this is propagated by parting of the roots; the best time for transplanting and parting them is in the autumn, when the leaves begin to decay. It loves a loamy soil, not too dry. If the seeds are brought over, they should be sown as soon as they arrive, in a border of loamy earth. The seeds lie a year before they grow; the seedling plants should be transplanted in the autumn.

The stalks of this sort rise five or six feet high in moist land, and sustain very long spikes of white flowers in July and August. The plants should not be often removed, for that will prevent their flowering strong.

The third sort grows naturally in Siberia, and is at present rare in England. The leaves of this sort resemble those of the Feathered Columbine; the stalks rise little more than a foot high, supporting panicles of white flowers, which appear in May. This requires a moist loamy soil and shady situation, and may be propagated as the former.

ADANSONIA. The Sour Gourd; in French, *Pain du Singe*. Monkeys Bread.

The Characters are,

The empalement of the flower is cup-shaped, and cut into five parts at the top which turn backward. The flower has five roundish petals, fastened to the stamina at the base. It has a great number of stamina, which are joined and form a column at their base, but spread open above, and are crowned by prostrate summits. It has an oval germen, supporting a very long tubulous style which is variously intorted, crowned by several hairy stigmas spreading out in rays. The germen becomes a large oval woody capsule with many cells, filled with a mealy pulp, inclosing a great number of kidney-shaped seeds.

We know but one specie of this genus at present,

ADANSONIA. *Juss.* The Sour Gourd, or Monkeys Bread.

This tree was first described by *Prosper Alpinus*, in his book of *Egyptian plants*; but it is now known to grow in several other countries, particularly at *Senegal* in *Africa*, where there are many trees now growing, whose stems are of much greater bulk, than any other trees yet known. *Mr. Adanson*, who was four years in that country, to examine the natural productions of it, and is writing the natural history, measured the stems of several of these trees, which were from seventy-five to eighty feet in circumference; the greater branches of these trees, he says, are equal in size to the largest trees he had ever seen in *Europe*. He has not, in his account of these trees, mentioned any thing of the wood of them, or if it is used for any purposes there, but we may expect a more particular account of it, in that part of his natural history, where he is to treat of the vegetables of that country.

I have also lately received a fruit of this tree, which I was assured came from *Surinam* in the *West-Indies*, so it may probably be a native of that country. The fruit is almost as large as a man's head, the shell is woody and close, having a greenish downy coat; it is divided into ten, twelve, or fourteen cells within, which contain a good number of kidney-shaped seeds, as large as the tip of a man's little finger; these are closely surrounded with a mealy pulp of an acid taste.

The leaves of the young plants are entire, of an oblong form, about four or five inches long, and almost three broad towards the top, where they are broadest, having several veins running from the middle rib; they are of a lucid green, and stand alternately. As the plants advance in height, the leaves alter, and are divided into three parts; and afterwards into five lobes, which spread out in the shape of an hand. In some of the oldest plants, I have seen leaves with seven divisions, but these are rare in the plants which are in *England*.

The plants rise easily from fresh seeds, if they are sown in a hot bed, and are of quick growth for two or three years, but afterwards make but little progress; the lower part of their stems then begin to swell and grow much larger than the other part, after which they do not advance much in their upright growth, but put out lateral branches, which incline to an horizontal position; the branches are covered with light grey bark. The leaves fall off in the latter part of winter, and the young leaves do not come out till summer, so the branches are naked for near three months.

As this tree is a native of very hot countries, the plants will not thrive in the open air in *England*, in summer, therefore they must be constantly kept plunged in the bark-bed in the stove; and in warm weather, the fresh air should be admitted to them every day; but in winter they must be kept warm: while the plants are in a growing state, they must be frequently refreshed with water, but when they are destitute of leaves, it must be given sparingly, for too much wet will then rot their roots. It loves a light rich loamy soil.

ADENANTHERA. Bastard Flower-fence.

The Characters are,

The empalement of the flower has five indentures; the flower has five petals, ten erect stamina having prostrate summits whose points have globular glands, and an oblong germen supporting one style crowned by a single stigma; the flower is succeeded by an oblong compressed pod, inclosing four or five roundish compressed seeds.

We have but one specie of this genus in *England*, which is, *ADENANTHERA foliis utrinque glabris.* Lin. Syst. 1020. *Adenantha* with smooth leaves.

This is a native of *India*, from whence the seeds have been brought to *England*. It grows naturally in the plains near the sea in *Hiboca* and *Senalo*, where it rises to a considerable stature; it is as large as the *Tamarind* tree, spreads its branches wide on every hand, making a fine shade, so is frequently planted by the inhabitants in their gardens, and near habitations for that purpose. The leaves of this tree are doubly winged; the flowers are small and of a yellow colour, and are disposed in a long thyrse or bunch. These are succeeded by long twisted membranaceous pods, inclosing several compressed hard seeds of a fine scarlet colour, which are lodged in the pods at a distance from each other. The inhabitants perforate these seeds, and string them for the young women, who wear them about their necks.

There is another species of this tree, which is figured and described by *Rumphius*, in his *History of the Amboyna* plants, whose leaves are woolly on their underside, but this is not in our *English* gardens at present.

The sort here described requires the same treatment as the *Poinciana*, and the tender kinds of *Acacia*; to which articles the reader is desired to turn, for the culture of it: as these agree in every part so well, as that whoever can manage one, need not fear the other thriving well with the same degree of heat and management, which renders it unnecessary to insert in this place, since it would swell the work too much.

ADIANTUM. Maidenhair.

This genus is placed in *Linnaeus's* twenty-fourth class, intitled *Cryptogamia*, where he has ranged the Ferns, Maiden-hairs, *Polypodium*, &c. with the Moss, Mushroom; and all those plants, which do not produce flowers conspicuous to the naked eye; being either concealed in their fructification, or so small as not to be perceived without the help of glasses. The first order of this class is of Ferns, &c. most of which have their flowers and seeds on the back of their leaves. There are a great number of species under this genus, which grow naturally in warm countries but we have only two in the *English* gardens, viz.

1. *ADIANTUM frondibus decompositis, foliis alternis, pinnis cuneiformibus lobatis pediculatis.* *Lin. Sp. Plant.* 1096. The officinal or true Maidenhair.

2. *ADIANTUM fronde pedata, foliolis pinnatis, pinnis anticè gibbis incisè fructificantibus.* *Lin. Sp. Plant.* 1095. *Canada* Maidenhair.

The first sort is the true Maidenhair, which is directed to be used in medicine; but as it does not grow naturally in *England*, so the *Trichomanes* is usually substituted for it, which is found growing wild in great plenty in several parts of *England*. The other is a native of the south of *France*, *Italy*, and the *Levant*, from whence I received the plants. It usually grows out of the joints of walls, and the fissures of rocks, so that whoever is inclinable to keep this plant in their gardens, should plant it in pots filled with gravel and lime rubbish, in which it will thrive much better than in good earth; but the pots must be sheltered under a frame in winter, otherwise the plants are often killed by the frost.

The second sort is often preserved in gardens for the sake of variety; this should be planted in pots, and treated in the same manner as the former, for although it will live through the winter in the open air in moderate seasons, yet in severe frost it is often destroyed. This sort grows naturally in *Canada* in such quantities, that the *French* send it from thence in package for other goods, and the apothecaries at *Paris* use it for the Maidenhair in all their compositions, in which that is ordered.

ADONIS, or FLOS ADONIS. Pheasant's Eye.

The Characters are,

The flower has a five-leaved empalement, and five or eight

petals without any nectarium. It has many stamina and pointals, and the seeds are naked. It is ranged in the seventh division of *Linnaeus's* thirteenth class.

The Species are,

1. *ADONIS floribus octopetalis fructibus subcylindricis.* *Hort. Upsal.* 156. The common Adonis, or Flos Adonis, with small red flowers, of late called Red Morocco.

2. *ADONIS floribus pentapetalis fructibus ovatis.* The annual Adonis with pale yellow flowers.

3. *ADONIS floribus polypetalis, fructibus obtusis, radice perenne.* Perennial Adonis with yellow flowers, by some titled fennel-leaved black Hellebore.

The two first sorts are annual, so perish when the seeds are ripe. If the seeds are sown in the autumn, soon after they are ripe, the plants will come up the following spring; but when the seeds are not sown till spring, they rarely come up the same year. So that when the seeds are permitted to fall on the ground, they generally succeed better than when sown by art. The first sort grows naturally in *Kent*, particularly by the sides of the river *Medway*, between *Rockester* and *Maidstone*, where it is found in great plenty in the fields which are sown with wheat, but in the intermediate fields which are sown with spring corn, there is rarely a plant of it to be found, which shews the necessity of sowing the seeds in autumn; for those fields of spring corn, if suffered to remain undisturbed after the harvest, will abound with this plant the following year. For some years past great quantities of the flowers of this plant have been brought to *London*, and sold in the streets by the name of Red Morocco.

These plants will thrive best in a light soil, but may be sown in any situation, so that by sowing some in a warm situation, and others in the shade, they may be continued longer in flower. The seeds ought to be sown where the plants are to remain to flower, for they do not bear transplanting well, unless it is done when the plants are young; and therefore they should be sown in small patches in the borders of the flower garden, and when the plants come up, they should be thinned, leaving but few in each patch, which will make a better appearance than where they grow single.

The third sort hath a perennial root, and an annual stalk. This grows naturally on the mountains of *Bohemia*, *Prussia*, and other parts of *Germany*, but has been long cultivated in gardens. It produces its flowers the latter end of *March*, or the beginning of *April*, according to the forwardness of the season; the stalks rise about a foot and an half high, and when the roots are large, and have stood unremoved for some years, they will put out a great number of stalks from each root; these are garnished with fine slender leaves, which are placed in clusters at intervals. At the top of each stalk, is produced one large yellow flower, composed of an unequal number of petals, the center of which is occupied by a great number of germen, surrounded by many stamina; after the flowers drop, the germen become naked seeds, closely adhering to the footstalk, forming an obtuse spike.

This sort is propagated by seeds, which must be sown in the autumn soon after they are ripe, on an east-border, where they may have only the sun in the forenoon: when the plants come up the following spring, they must be kept clean from weeds, and in very dry weather if they are watered, it will greatly promote their growth. The following autumn the plants should be carefully taken up, and planted in a nursery-bed, at four or five inches distance, where they may remain two years to acquire strength, then may be transplanted into the pleasure-garden, where they may remain for good, because these plants do not bear transplanting well when they are old.

ADOXA. Moschatellina. Tuberos Moschatel, or Hollow Root.

This plant grows naturally in shady woods in several parts of *England*, so is seldom kept in gardens; therefore all that is necessary to be inserted of its culture is, to plant it in a shady moist part of the garden, where it will thrive fast enough.

ÆSCHYNOMENA. The false Sensitive Plant.

The Characters are,

The flower is of the butterfly kind, having ten stamina in two bodies; the cup is divided into two lips; the pod is erect, compressed, and jointed.

The Species are,

1. ÆSCHYNOMENE caule scabro leguminum articulis medio scabris. *Lin. Sp. Plant.* 713. Bastard Sensitive Plant with a rough stalk, and a jointed pod.

2. ÆSCHYNOMENE caule hispido foliis acuminatis, leguminum articulis suborbiculatis. *Prod. Leyd.* 384. Bastard Sensitive Plant with a prickly stalk, pointed leaves, and jointed pods half-rounded.

3. ÆSCHYNOMENE caule lævi arboreo leguminum articulis semicordatis glabris. *Prod. Leyd.* 384. Bastard Sensitive Plant with a smooth tree-like stalk, and smooth jointed pods.

These plants are natives of warm countries; the seeds of the two first sorts I have received from *Africa*, and those of the third from *America*, and also from *China*, and several parts of *India*.

They are generally kept in botanic gardens, but are seldom preserved in any other, as there is little beauty in their flowers, and as they are plants of no use; beside, they require a good stove to preserve them in *England*. The first and third sorts may be preserved through the winter in a bark-bed in the stove; but as their leaves and stalks are succulent, so they should have but little water given to them in cold weather, for much wet at that season will cause them to rot. The second year the plants will flower, and sometimes will perfect their seeds in *England*.

The second sort will perfect its seeds the same year it is raised, if kept under a frame, or in an airy glass-case, so is generally treated here as an annual plant, though it may be preserved through the winter in a stove.

These plants are propagated by seeds, which should be sown on a hot-bed early in the spring, and when the plants have strength enough to be removed, they should be put each into a separate small pot, filled with light earth, and plunged into a fresh hot-bed, to bring them forward; and as they advance in their growth, they should be shifted into larger pots, but great care should be taken not to overpot them, for if the pots are too large, the plants will not thrive. They must be brought forward early in the year, otherwise the second sort will not perfect its seeds.

ÆSCULUS. *Lin. Gen.* 420. The Horse Chestnut.

The title which Dr. *Linnaeus* has applied to the genus, might, with greater propriety, have been given to the Chestnut, which by that author is joined to the Beech-tree, making it only a species of that genus.

The Characters are,

The empalement of the flower is slightly cut into five segments; the flower is composed of five unequal petals, folded at their border, and waved; it has seven stamina, the empalement becomes a thick, roundish, echinated capsule, opening into three cells, in one or two of which are lodged globular seeds.

We have but one Species of this genus, viz.

ÆSCULUS floribus heptandriis. *Hort. Upsal.* 92. The Common Horse Chestnut.

The Horse Chestnut was brought from the northern parts of *Asia* about the year 1550, and was sent to *Vienna* about the year 1588. It was called *Castanea* from the shape of

its fruit, and the title of *Equini* was added to it from its being a good food for horses when ground.

This tree was in much greater esteem formerly than at present, for since it is become so very common, few persons regard it. What has occasioned its being so seldom planted, is the decay of the leaves early in summer, so that their leaves frequently begin to fall in *July*, and occasion a litter from that time, until all the leaves are fallen; but notwithstanding this inconvenience, the tree has great merit, for it affords a noble Shade in summer; and during the month of *May*, there is no tree has greater beauty, for the extremity of the branches are terminated by fine spikes of flowers, so that every part of the tree seems covered with them; which are finely spotted with a rose colour, and these being intermixed with the green leaves make a noble appearance.

As this tree is quick in its growth, so in a few years it will arrive to a size large enough to afford a good shade in summer, as also to produce plenty of flowers. I have known trees which were raised from nuts, in twelve or fourteen years, large enough to shade two or three chairs under the spread of their branches, and have been covered with flowers in the season, so that few trees make greater progress than these. But as their wood is of little value, so the trees should not be propagated in too great plenty: a few therefore of them placed at proper distances in parks for ornament, is as many as should be preserved, the wood not being fit even for burning, nor any other use that I know of.

These trees are propagated by sowing of the nuts, the best time for doing this is early in the spring; but the nuts should be preserved in sand during the winter, otherwise they are apt to grow mouldy and rot. They may indeed be planted in autumn, but then they will be in danger of rotting if the winter should prove very wet.

When the nuts succeed, and have a proper soil, the plants will shoot near a foot the first summer; so that where they grow pretty close together, it will be proper to transplant them the following autumn, when they ought to be planted in rows at three or four feet distance, and one foot and an half asunder in the rows: in this nursery they may remain two years, by which time they will be fit to plant where they are designed to be continued; for the younger these trees are planted out, the larger they will grow. But there are many who will object to their being planted out young in parks, because they will require a fence to secure them against the cattle; which will also be necessary, whatever size they are when planted; and if large, they must be well staked to prevent their being displaced by strong winds: which is another expence, so that when we consider how much faster a young tree will grow, than those which are removed at a greater age, there can be no excuse for planting large trees.

When these trees are transplanted, their roots should be preserved as entire as possible, for they do not succeed well, when torn or cut; nor should any of the branches be shortened, for there is scarce any tree, which will not bear amputation better than this; so that when any branches are by accident broken, they should be cut off close to the stem, that the wound may heal over.

There is something very singular in the growth of these trees, which is, the whole shoot being performed in less than three weeks, after the buds are opened; in which time I have measured shoots a foot and an half long, with their leaves fully expanded.

In *Turkey* the nuts of this tree are ground, and mixed with the provender for their horses, especially those which are troubled with coughs, or are broken winded; in both which disorders, they are accounted very good. Deer are very fond of the fruit, and at the time of their ripening will

will keep much about the trees, but especially in strong winds, when the nuts are blown down, which they carefully watch, and greedily devour as they fall.

There are in some gardens a few old trees now standing, which were planted single, at a great distance from any other; these are grown to a very large size, and their heads form a natural parabola, and when their flowers are in full beauty, there is not any tree yet known in *Europe*, which makes so fine an appearance. I have measured some of these trees, whose branches have extended more than thirty feet in diameter, and their heads have been so close, as to afford a perfect shade in the hottest seasons. These were planted in 1679, as appears by some writings which are in the possession of the persons, who have now the property of the land where they grow: so that although they are of quick growth, yet they are not of very short duration.

AGAVE. *Lin. Gen.* 390. Common *American Aloe*.

The *Characters* are,

The flower has no empalement, it is erect and spreads open at the brim. It has six erect stamina, crowned by narrow summits; after the flower is past, the germen becomes an oblong three-cornered seed-vessel, having three cells, which are filled with flat seeds.

Dr. *Linnaeus* has separated the plants of this genus from the *Aloe*, to which they had been joined by former botanists, because the stamina and style in these flowers, are extended much longer than the corolla, and the corolla rest upon the germen, which in the *Aloe* are not so. We may also mention another difference in the growth of the plants, by which they may be distinguished before they flower; which is, all the plants of this genus have their center leaves closely folding over each other, and embracing the flower-stem which is formed in the center; so that these never flower until all the leaves are expanded, to give the stem its liberty to advance, and when the flower is past, the plants die.

The *Species* are,

1. AGAVE *foliis dentato-spinosis scapo ramoso. Gen. Nov.* 1102. The common Great *American Aloe*, with a branching stalk.

2. AGAVE *foliis dentato-spinosis scapo simplicissimo. Lin. Sp. Plant.* 323. Great *American Aloe* with a simple stalk.

3. AGAVE *foliis integerrimis. Gen. Nov. Lin. Sp. Pl.* 323. *American Aloe* with stiff whole leaves called *Piet*.

4. AGAVE *radice tuberosâ foliis longissimis marginibus spinosis.* Smaller *American Aloe*, with a tuberos root and very long leaves, with spines on their edges.

5. AGAVE *foliis lanceolatis reflexis, marginibus dentatis.* *American Aloe* with spear-shaped reflexed leaves, whose edges are indented, called *Sobolifera*.

6. AGAVE *foliis longis erectis latè virentibus, marginibus fuscis minimè ferratis.* *American Aloe* with long deep green leaves, edged with brown, and very slightly sawed. This is called in *America* *Karattô*.

7. AGAVE *foliis oblongis marginibus spinosissimis nigricantibus.* *American Aloe* with oblong leaves, whose edges are closely beset with black spines, commonly called broad-leaved *Aloe* from *Vera Cruz*.

8. AGAVE *foliis lineari-lanceolatis integerrimis rigidis aculeo terminatis.* Narrow leaved *Aloe* from *Vera Cruz*.

The first sort here mentioned, has been long preserved in the *English* gardens, where of late years there hath been several of the plants in flower. The stems of this when the plants are vigorous, generally rise upward of twenty feet high, and branch out on every side toward the top, so as to form a kind of pyramid: the slender shoots being garnished with greenish yellow flowers, which stand erect, and come out in thick clusters at every joint.

When these plants flower, they make a fine appearance, and continue a long time in beauty, if they are protected from the cold in autumn, as there will be a succession of new flowers produced, for near three months, in favourable seasons. It has been generally believed, that this plant doth not flower until it is an hundred years old; but this is a great mistake, for the time of its flowering depends on the growth of the plants; so that in hot countries where they grow fast, and expand many leaves every season, they will flower in a few years; but in colder climates, where their growth is slow, it will be much longer before they shoot up their stem. There is a variety of this sort with striped leaves, which is now pretty common in the *English* gardens.

The plants of the second sort are so like those of the first, as not to be distinguished from them, but by good judges. The principal difference is, the leaves of this are narrower toward their extremity, and of a paler colour: the stems of this sort do not rise so high as the first, nor do they branch in the same manner, but the flowers are collected into a close head at the top; they are however of the same shape and colour. There has been three or four plants of this sort, which have lately flowered in *England*; one of which was in the *Chelsea* garden a few years past. This sort seldom puts out so many offsets as the common *Aloe*.

The seventh sort greatly resembles these, so that many persons have supposed it to be the same. But the leaves of this are much thinner, the indentures on their edges abundantly closer, and not so deep, as in either of the former; the spines too are blacker. How this differs from others in flower I know not, as none of their flowers have been produced in *England*, so far as I know.

These three sorts are hardy. I have known plants of the first sort live in the open air for some years in mild seasons, but in severe winters they are always killed, if not sheltered in that season. They are propagated by offsets, which the first sort sends out in plenty, but the third seldom puts out any; so these may be increased by taking off some of the larger roots, at the time when the plants are shifted; planting them in pots filled with light sandy earth, they will shoot out and become good plants, as I have often experienced. These should be planted in pots filled with light sandy earth, and housed in winter with *Oranges*, *Myrtles*, &c. and during that season, should have but little wet. In the summer they must be placed abroad in the open air, where they may remain till toward the end of *October*, when they should be housed again. The seventh sort being a little tenderer than the other two, should be put into the green-house before them, and may stay there a little longer in the spring.

The third sort hath long narrow stiff leaves, of a pale green colour, not indented on their edges, but frequently a little waved; the side leaves spread open, but those in the center fold closely over each other, and strictly surround the bud. The plants of this sort rarely grow more than three feet high, but the flower stem rises near twenty, and branches out much like that of the first, but more horizontally; the flowers are of the same shape, but smaller, and of a greener colour: after the flowers are past, instead of seed-vessels, young plants succeed to every flower, so that all the branches are closely beset with them. This sort never produces offsets from the root, so that it cannot be increased but when it flowers, at which time there will be plenty enough; the old plant presently after dies.

The fourth sort hath leaves somewhat like the third in shape and colour, but they are indented on the edges, and each indenture terminates in a strong thorn; the root of this sort is thick, and swells just above the surface of the ground;

ground; in other respects it agrees with the former. Dr. *Linneus* supposes this sort to be the same with the third species, but whoever sees the plants, will not doubt of their being different.

The fifth sort never grows to a large size, the leaves of it are seldom more than a foot and an half long, and about two inches and an half broad at their base; these end in a slender spine, being slightly indented on their edges; they are also reflexed backward toward their extremity, and are of a dark green colour. The flower-stem rises about twelve feet high, and branches out toward the top in the same manner as the third sort; the flowers are nearly of the same size and colour as those of the third, and after they fall off, are succeeded by young plants in the same manner.

The leaves of the sixth sort, are from two feet and an half to three feet long, and about three inches broad, being of a dark green colour ending in a black spine; the borders of the leaves are of a brownish red colour, and slightly serrated. These stand more erect than in the other species; but as this sort hath not flowered in *England*, so I cannot say how it differs from the other. The plants of it were sent me from *St. Christophers* by the title of Korato, which I suppose is given indifferently to other species of this genus; for I have frequently heard the inhabitants of *America* call the common great Aloe by the same name.

The eighth sort hath long narrow stiff leaves, which are entire, and are terminated by a stiff black spine. These leaves are seldom more than two feet long, and little more than an inch broad, being of a glaucous colour: the side leaves stand almost horizontally, but the center leaves are folded over each other, and inclose the flower-bud. This sort never puts out suckers from the root, nor have I seen any plants of this kind in flower, although there are many of them in the *English* gardens, some of which are of a considerable age.

The third, fourth, fifth, sixth, and eighth sorts, are much tenderer than the others, so cannot be preserved through the winter in *England*, unless they are placed in a warm stove; nor will they thrive if set abroad in summer, therefore they should constantly remain in the stove, observing to let them enjoy a great share of free air in warm weather. They require a light sandy earth, and should have little wet in winter; but in warm weather, may be gently watered twice a week, which is as often as is necessary; for if they have much water given them, it rots their roots, and then their leaves will decay and insects infest them. They should be shifted every summer into fresh earth, but must not be put into large pots, for unless their roots are confined, the plants will not thrive.

AGERATUM. *Lin. Gen. Plant.* 842. Bastard Hemp Agrimony.

The Characters are,

The flower has a naked receptacle, it has five bristly hairs, an oblong cup almost equal, and the style is scarce any longer.

The Species are,

1. AGERATUM foliis ovatis caule piloso. *Lin. Sp. Plant.* 839. Bastard Hemp Agrimony, with oval leaves and a hairy stalk.
2. AGERATUM foliis oppositis petiolatis crenatis, caule bifido. Bastard Hemp Agrimony, with leaves having long foot-stalks placed opposite, whose edges are bluntly indented, and a hairy stalk.
3. AGERATUM foliis ovato cordatis rugosis feralibus alternis, caule glabro. *Lin. Sp. Plant.* 839. Bastard Hemp Agrimony, with rough oval heart-shaped leaves, flower branches growing alternate, and a smooth stalk.

The two first are annual plants; the seeds of these must be sown on an hot-bed in the spring, and when the plants are come up and are strong enough to remove, they should

be transplanted into another moderate hot-bed, observing to water and shade them until they have taken root; after which time, they must have a good share of air in warm weather, otherwise they will grow up very weak. In summer, the plants will thrive in the open air. The seeds ripen in *September* and *October*, and when any of them scatter upon the ground, and the same earth happens to be put on an hot-bed the following spring, the plants will come up in great plenty, as they frequently do also in the open air. The first sort grows naturally in *Africa*, and also in the islands of *America*; for in tubs of earth which I received with plants from *Jamaica*, *Barbadoes*, and *Antigua*, I have had plenty of plants arise, from seeds which were scattered on the ground. The second sort was found growing naturally at *La Vera Cruz*, by the late Dr. *William Houslow*, who sent the seeds to *Europe*, which have so well succeeded in many gardens, as to become a weed in the hot-beds.

The third sort grows naturally in *Carolina*, but has been many years an inhabitant of the *English* gardens. This hath a perennial root, and an annual stalk, which dies in winter, but the roots put out fresh stalks in spring.

This sort is propagated by seeds, as also by parting of the roots; the latter method is commonly practised in *England*, because there are few autumns so favourable as to ripen the seeds: but the seeds are frequently brought from *North America*, where this plant is very common; for being light, they are easily waisted about to a great distance, where they come to maturity; so that where there are any plants growing, all the adjoining land is filled with the seeds of them.

The best time for paring and transplanting the roots of this plant, is in autumn, soon after their stalks decay, that they may have good root before the drying winds in spring come on, otherwise they will not flower strong, or make a good increase. The roots should be allowed three feet room every way, for as they spread and increase very much at root, so when they are cramped for room, the plants starve, and in dry seasons their leaves will hang as if they were dead.

AGERATUM, or MAUDLIN. See Achillea.

AGERATUM PURPUREUM. See Erinus.

AGNUS CASTUS. See Vitex.

AGRIFOLIUM. See Ilex.

AGRIMONIA. *Lin. Gen. Plant.* 534. Agrimony.

The Characters are,

The empalement of the flower is indented in five parts; the flower has four or five petals, which are inserted in the empalement. In the center arises a simple style resting on the germen; it has twelve slender stamina. The empalement has two cells which are compressed on both sides, and radiated length-wise.

The Species are,

1. AGRIMONIA foliis caulinis pinnatis, foliolis undique serratis omnibus minutis interstinctis fructibus hispids. *Lin.* The common Agrimony.
2. AGRIMONIA foliis pinnatis, foliolis obtusis dentatis. The white Agrimony.
3. AGRIMONIA altissima, foliis pinnatis foliolis oblongis acutis serratis. The sweet scented Agrimony.
4. AGRIMONIA foliis caulinis pinnatis, stipulis caulem obtangentibus, spica subrotunda sessili, fructibus hispids. *Lin.* Eastern Agrimony.
5. AGRIMONIA foliis caulinis ternatis fructibus glabris. *Hort. Cliff.* 179. Three-leaved Agrimony with smooth fruit.

The first sort grows naturally in several parts of *England*, by the sides of hedges, and in woods. This is the sort which is commonly used in medicine, and is brought to the markets by those who gather herbs in the fields.

The second sort is the smallest of all the species; the leaves of this have not so many pinnæ as the common sort, and the pinnæ are rounder, and the indentures on their edges blunter. The spike of flowers is slender, and the flowers smaller and of a dirty white colour. This sort grows naturally in *Italy* from whence I received the seeds, and have constantly found that the seeds of this when sown never vary.

The third sort grows near four feet high, the leaves of this have more pinnæ than either of the other, and they are longer and narrower, ending in acute points; the serratures of the leaves are sharper than any of the other, and when handled emit an agreeable odour.

The fourth sort is of humble growth, seldom rising above two feet high; the pinnæ of its leaves are longer and narrower than either of the former, and the spikes of flowers very short and thick. The roots of this are very thick, and spread widely under ground, by which it multiplies faster than either of the other.

The fifth sort greatly resembles the other in the shape of its pinnæ (or smaller leaves) but there are but three upon each foot stalk; the flower of this hath a double empalement, the outer one being fringed. *Fabius Columna*, and other writers on botany, have separated it from the Agrimony, making it a distinct genus.

All these sorts are hardy perennial plants, which will thrive in almost any soil or situation, and require no other care but to keep them clean from weeds. They may be propagated by parting their roots, which should be done in autumn, when their leaves begin to decay, that the plants may be well established before the spring. They should not be planted nearer than two feet, that their roots may have room to spread. They may also be propagated by seeds, which should be sown in autumn, for if they are kept out of the ground till spring, they seldom come up the same season.

AGROSTEMMA. *Lin. Gen. Plant.* 516. Wild Lychnis or Campion.

The Characters are,

The flower has a thick empalement of one leaf, it has five petals which are obtuse and entire, and the capsule has one cell.

The Species are,

1. AGROSTEMMA *hirsuta calycibus corollam æquantibus petalis integris nudis. Lin. Sp. Pl.* 435. Hairy wild Lychnis, commonly called Corn Campion or Darnel.

2. AGROSTEMMA *tomentosa foliis ovato-lanceolatis, petalis integris coronatis. Hort. Upsal.* 115. The single Rose Campion.

3. AGROSTEMMA *tomentosa petalis emarginatis. Lin. Sp. Pl.* 436. The umbelliferous Mountain Campion.

The first sort grows naturally in the corn fields in most parts of *England*, so is seldom admitted into gardens.

The single Rose Campion has been long an inhabitant of the *English* gardens, where, by its seeds having scattered, it is become a kind of weed. There are three varieties of this plant, one with deep red, another with flesh coloured, and a third with white flowers, but these are of small esteem; for the double Rose Campion being a finer flower, has turned the others out of most fine gardens. The single sorts propagate fast enough by the seeds, where they are permitted to scatter, for the plants come up better from self-sown seeds, than when they are sown by hand, especially if they are not sown in autumn.

The sort with double flowers never produces any seeds, so is only propagated by parting of the roots; the best time for this is in autumn, after their flowers are past; in doing of this, every head which can be slipped off with roots should be parted; these should be planted in a border of fresh undunged earth, at the distance of six inches, ob-

erving to water them gently until they have taken root, after which they will require no more, for much wet is very injurious to them, as is also dung. After the heads are well rooted, they should be planted into the borders of the flower-garden, where they will be very ornamental during the time of their flowering, which is in *July* and *August*. This is a variety of the single sort, which was first accidentally obtained from seeds.

The fifth sort grows naturally upon the *Helvetican* mountains. This is a low plant, with woolly leaves, the flower-stem rises near a foot and an half high; the flowers grow in umbels on the top of the stalk, which are of a bright red colour. This flowers in *June*, and the seeds ripen in *August* or *September*; it should have a shady situation, and will thrive best in a strong soil.

AIZOON.

This name has been by some writers applied to the House Leek, and also the Aloes.

The Characters are,

It hath a permanent empalement of one leaf, which is cut into five acute segments, with a five-cornered germen empalement, supporting five styles which are crowned, and a simple stigma. The germen afterward becomes a swelling five-cornered capsule, having five cells, in which are lodged many roundish seeds.

This genus of plants is by *Dr. Linnæus* ranged in the fifth division of his twelfth class, entitled *Icosandria pentagynia*.

The Species are,

1. AIZOON *foliis cuneiformi-ovatis floribus sessilibus. Hort. Upsal.* 127. Sempervive or Ficoidea with oval wedge-shaped leaves, and flowers without foot-stalks.

2. AIZOON *foliis lanceolatis floribus sessilibus. Lin. Sp. Pl.* 488. Sempervive with spear-shaped leaves and flowers, having no foot-stalks.

3. AIZOON *foliis lanceolatis floribus paniculatis. Lin. Sp. Pl.* 448. Sempervive with spear-shaped leaves and flowers growing in panicles.

As we have no *English* names for these plants, so I have adopted this of Sempervive, which hath been applied to the Aloe and Sedum, both which have been also titled Aizoon and Sempervivum.

The first sort is a native of the *Canary Islands*: This is an annual plant, which must be raised on a moderate hot-bed in the spring; and when the plants are fit to transplant, they should be carefully taken up, and planted each into a small pot filled with fresh light earth, and plunged into another moderate hot-bed to bring them forward; but as the weather grows warm they must be hardened by degrees to bear the open air, into which they should be removed in *June*, placing them in a sheltered situation, where they will flower, and ripen their seeds in *September*, soon after which the plants will perish.

The second sort grows naturally in *Spain*; this is also an annual plant, whose branches trail on the ground; the flowers have no beauty, so these plants are only preserved by those who are curious in collecting rare plants for the sake of variety.

The third sort grows naturally at the *Cape of Good Hope*, from whence the seeds were brought to *Europe*. This is also of humble growth, and perishes soon after the seeds are ripe.

These may be propagated in the same manner as the first, and when the plants have acquired strength, they may be planted in the full ground; but they require a poor sandy soil, for in rich ground they will grow very luxuriant in branches, but will not flower till late in the season, so rarely perfect their seeds; but when they are planted in dry sand, or lime rubbish, they will be more productive of flowers, and less vigorous in the branches.

ALATERNOIDES;

ALATERNOIDES. See *Phyllica*, *Clutia*, and *Ceanothus*.

ALATERNUS. Ever-green Privet.

The *Characters* are,

It hath male and female flowers in different plants. The male flowers have an empalement of one leaf, cut into five segments at the brim; five small petals; at the base of these petals are fastened so many stamina. The female flowers have a great resemblance to the male, but have no stamina; in the center is placed the germen, supporting a trifid style crowned by a round stigma; the germen afterward becomes a soft round berry, containing three seeds.

The *Species* are,

1. *ALATERNUS foliis ovatis marginibus crenatis glabris.* The common Alaternus.

2. *ALATERNUS foliis subcordatis serratis glabris.* Alaternus with small heart-shaped leaves.

3. *ALATERNUS foliis lanceolatis profundè serratis glabris.* Cut-leaved Alaternus.

4. *ALATERNUS foliis ovato-lanceolatis integerrimis glabris.* Broad-leaved Alaternus.

The varieties of these plants are, the first sort with variegated leaves, which is commonly called Bloatched Phillyrea by the nursery-gardeners. And the third sort with leaves striped with white, and another with yellow; these are known by the silver and gold striped Alaternus: but as these are accidental varieties, so I have omitted placing them among the number of species.

The common distinction of this genus from the Phillyrea, is in the position of their leaves, which in the plants of this are placed alternately on the branches, whereas those of Phillyrea are placed by pairs opposite; this is obvious at all seasons, but there are more essential differences in their characters, as will be explained under the article Phillyrea.

The first sort has been long cultivated in the *English* gardens, but the plain sort is now uncommon here; for the bloatched-leaved sort has been generally cultivated in the nurseries, and the other has been almost totally neglected.

The second sort was formerly in the *English* gardens, in much greater plenty than at present. This was generally called Cellastrus, or Staff-tree; the leaves of this sort are placed at greater distances than those of the first; so that their branches appear thinly covered with them, which may have occasioned their being disesteemed.

The third sort has been an old inhabitant in some gardens, but was not much propagated till of late years; the leaves of this are much longer and narrower than those of either of the other sorts, and the serratures on their edges are much deeper.

These sorts are by some supposed to be only varieties and not distinct species; but from many repeated trials, in raising them from seeds, I can affirm they do not vary, the seeds constantly producing the same species as they were taken from.

All these sorts are easily propagated by laying their branches down, as is practised for many other trees. The best time for this is in autumn, and if properly performed, the layers will have made good roots by the autumn following, when they may be cut off from the old stock, and planted either into the nursery, or in the places where they are designed to remain. When they are planted in a nursery, they should not remain there longer than two or three years; for they shoot their roots to a great distance on every side, so they do not remove with safety after several years growth. They may be transplanted either in the autumn or the spring, but in dry land the autumn planting is best, whereas in moist ground the spring is to be preferred.

The plain sorts may also be propagated by sowing their berries, which they produce in great plenty, but the birds are greedy devourers of them; so that unless the berries are guarded from them, they will soon be gone when they begin to ripen. The plants which arise from seeds, always grow more erect than those which are propagated by layers, so are fitter for large plantations, as they may be trained up to stems, and formed more like trees; whereas the layers are apt to extend their lower branches, which retards their upright growth, and renders them more like shrubs. They will grow to the height of eighteen or twenty feet, if their upright shoots are encouraged; but to keep their heads from being broken by wind or snow, those branches which shoot irregular should be shortened, which will cause their heads to be closer, and not in so much danger.

ALCEA. *Lin. Gen.* 750. The Hollyhock.

The *Characters* are,

The flower hath a double empalement, of which one is permanent, and cut into six parts. The inner is larger and slightly cut into five. In the center is placed the round germen, supporting a short cylindrical style, with many stamina joined below to the pentagonal column, and spread open at top; the germen afterwards becomes a round, depressed, articulated capsule, having many cells, in each of which is lodged one compressed kidney-shaped seed.

The *Species* are,

1. *ALCEA foliis sinuatis angulosis.* *Hort. Cliff.* 348. Hollyhock with angular sinuated leaves.

2. *ALCEA foliis palmatis.* *Hort. Cliff.* 348. Hollyhock with handed leaves.

These are distinct species, whose difference in the form of their leaves always continue. The leaves of the first sort are roundish, and cut at their extremity into angles; whereas those of the second are deeply cut into six or seven lobes, so as to resemble a hand.

The various colours of their flowers being accidental, as also the double flowers being only varieties which have risen from culture, are not by botanists deemed distinct species, so I have not enumerated them here; therefore shall only mention the various colours, which are commonly observed in their flowers; which are white, pale red, deep red, dark red, purple, yellow, and flesh colour.

Although these varieties of double Hollyhocks are not constant, yet where their seeds are carefully saved from the most double flowers, the greatest number of the plants will approach near to the plants from which their seeds were taken, both as to their colour and the fulness of their flowers; provided no plants with single or bad-coloured flowers are permitted to grow near them. Therefore as soon as any such appear, they should be removed from the good ones, that their farina may not spread into the other flowers, which would cause them to degenerate.

These plants, although natives of warm countries, yet are hardy enough to thrive in the open air in *England*, and have for many years been some of the greatest ornaments of our gardens, toward the latter part of summer: but since they have become very common, have not been so much regarded as they deserve; partly from their growing too large for small gardens, and their requiring tall stakes to secure them from being broken by strong winds, to which they are very liable by their tall growth. But in large gardens, where they are properly disposed, they make a fine appearance; for as their spikes of flowers grow very tall, so there will be a succession of them on the same stems, more than two months; the flowers on the lower part of the spike, appearing in *July*, and as their stalks advance, so new flowers are produced till near the end of *September*.

They are propagated by seeds, which, as hath been already observed, should be carefully saved from those plants whose flowers are the most double, and of the best colours. If these are preserved in their capsules until spring, the seeds will be better, provided they are gathered very dry, and care be taken that no damp comes to them in winter, for that will cause their covers to be mouldy, and thereby spoil the seeds.

The seeds should be sown on a bed of light earth, about the middle of *April*, which must be covered about half an inch deep, with the same light earth; some persons sow them in shallow drills, and others scatter the seeds thinly over the whole bed. When they are sown in the former method, the plants generally come up thick, so will require to be transplanted sooner than those which are sown thinly in broad cast. By the first, the seeds may be more equally covered, and kept clean with less trouble, because the ground between the drills may be hoed. When the plants have put out six or eight leaves, they should be transplanted into nursery-beds, at a foot distance from each other, observing to water them until they have taken good root; after which they will require no farther care, but to keep them clean from weeds till *October*, when they should be transplanted where they are to remain.

ALCHEMILLA. Ladies Mantle.

The Characters are,

The flower hath a permanent empalement of one leaf, which is cut into eight segments. It hath no petals, and each flower is succeeded by one seed wrapped up in the empalement.

Dr. *Linnaeus* ranges this genus in his fourth class of plants, entitled *Tetrandria monogynia*.

The Species are,

1. ALCHEMILLA foliis lobatis serratis, segmentis involucri acuto. The common Ladies Mantle.

2. ALCHEMILLA foliis lobatis sericeis acutè serratis, segmentis involucri subrotundis. Smaller silvery Ladies Mantle, with lobated leaves sharply serrated, and the segments of the involucrium cut into roundish segments.

3. ALCHEMILLA foliis digitatis serratis. Flor. Lapp. 62. Silvery Alpine Ladies Mantle with handed leaves.

4. ALCHEMILLA foliis quinatis multifidis glabris. Lin. Sp. Pl. 123. Smooth five-leaved Ladies Mantle, cut into many segments.

The first sort grows naturally in moist meadows in several parts of *England*, but is not very common near *London*. The leaves of this sort are used in medicine, and are esteemed to be vulnerary, drying and binding, and of great force to stop inward bleeding.

The second sort is much smaller than the first, and the leaves are much whiter and appear silky; this sort is different from the third, and always continues so when the plants are propagated by seeds, so that there can be no doubt of its being a distinct species.

The third sort grows naturally on the mountains in *Yorkshire*, *Westmoreland*, and *Cumberland*, generally upon moist boggy places. The leaves of this sort are very white, and deeply cut into five parts like a hand.

The fourth sort grows naturally in *Sweden*, *Lapland*, and other cold countries, so is only to be found in some few curious botanick gardens in this country. These are all abiding plants, which have perennial roots and annual stalks, which perish in autumn. They may be propagated by parting of their roots; the best time for doing this is in the autumn, that their roots may be established before the drying winds of the spring come on. They should have a moist soil and a shady situation, otherwise they will not thrive in the southern parts of *England*.

ALDER-TREE. See *Alnus*.

ALESANDER, or ALEXANDER. See *Smyrnum*.

ALKEKENGI. See *Physalis*.

ALLELUJAH. See *Oxalis*.

ALLIUM. Garlick.

The Characters are,

The flowers are included in one common spathe; they are composed of six concave spreading petals. It hath a three cornered capsule, opening into three parts, having three cells, filled with roundish seeds.

The Species are,

1. ALLIUM caule planifolio bulbifero, radice compositâ, staminibus tricuspидatis. Hort. Upsal. 76. Common or manured Garlick.

2. ALLIUM caule planifolio bulbifero, foliis crenulatis vaginis ancipitibus staminibus tricuspидatis. Hort. Upsal. 77. The Rocambole.

3. ALLIUM scapo nudo semicylindrico foliis lanceolatis petiolatis umbellâ fastigiatâ. Lin. Sp. Plant. 300. Broad-leaved wild Garlick or Rampsons.

4. ALLIUM caule planifolio umbellifero umbellâ globosâ staminibus tricuspидatis radice laterali. Lin. Sp. Pl. 294. Great round headed Garlick of the *Holm Islands*.

5. ALLIUM scapo nudo subcylindrico foliis lanceolatis sessilibus umbellâ fastigiatâ. Hort. Upsal. 76. The yellow Moly.

6. ALLIUM caule planifolio umbellifero ramulo bulbifero staminibus simplicibus. Lin. Sp. Plant. 296. Great broad-leaved Moly with Lilly flowers.

7. ALLIUM scapo nudo ancipiti foliis linearibus subtus convexis lævibus umbellâ subrotundâ staminibus subulatis. Hort. Upsal. 79. Greater Mountain Garlick with leaves like *Narcissus*.

8. ALLIUM scapo nudo ancipiti foliis linearibus caniculatis subtus subangulatis umbellâ fastigiatâ. Hort. Upsal. 79. Garlick with a naked stalk, narrow hollow leaves, which are angular on their lower side, and a compact umbel.

9. ALLIUM caule planifolio umbellifero foliis inferioribus hirsutis staminibus subulatis. Lin. Sp. Pl. 295. Umbelliferous Garlick with hairy under leaves, and awl-shaped stamina, commonly called *Dioscoridis* Moly.

The two first species are easily propagated by planting the cloves, or small bulbs, in the spring, in beds about four or five inches distance from each other, keeping them clean from weeds. About the beginning of *June*, the leaves of the first sort should be tied in knots, to prevent their spindling, or running to seed, which will greatly enlarge the bulb. In the middle of *July*, the leaves will begin to wither and decay, at which time they should be taken out of the ground, and hanged up in a dry room, to prevent their rotting, and may be thus preserved for winter use.

The roots of the second sort may remain in the ground till the leaves are decayed, when their bulbs may be taken up and dried, to be preserved for use during the winter season; but some of the roots may be at the same time planted again for the succeeding year. For this sort requires to be planted in autumn, especially on dry ground, otherwise their bulbs will not be large.

The third sort was formerly in greater esteem than at present, it being rarely cultivated in gardens, but is found wild in moist shady places in many parts of *England*; and may be cultivated by planting the roots in a moist shady border, at almost any time of the year; but the best season is in *July*, just as the green leaves are decaying.

The fourth sort grows naturally in the *Holm Islands*, from whence it has been transplanted into several gardens, where it is preserved more for the sake of variety than use.

The fifth sort was formerly preserved in gardens, for the sake of its yellow flowers, but having a very strong Garlick scent, most people have rooted it out of their gardens.

The sixth sort is also preserved by many persons in their gardens for the sake of variety, but as this hath a

very strong scent, so it is not very often admitted to the flower-garden.

The ninth sort is sometimes permitted to have a place in gardens for the sake of variety.

They are all of them very hardy, and will thrive in almost any soil or situation, and are easily propagated, either by their roots, or from seeds; if from the roots, the best time is in autumn, that they may take good root in the ground before the spring, which is necessary, in order to have them flower strong the following summer. If they are propagated by seeds, they may be sown on a border of common earth, either in autumn, soon after the seeds are ripe, or in the spring following, and will require no farther care, but to keep them clear from weeds; in the following autumn the plants may be transplanted into the borders where they are to remain for good.

These plants produce their flowers in *May, June, and July.*

ALMOND TREE. See *Amygdalus.*

ALMOND DWARF. See *Persica.*

ALNUS. The Alder Tree.

The Characters are,

It hath male and female flowers, which are produced at remote distances on the same plant; the male flowers are digested into a long juli, or katkin, which is loose, imbricated and cylindrical. The female flowers are collected into a conical scaly head, and are succeeded by scaly cones.

The Species are,

1. ALNUS *foliis obversè ovatis rugosis.* The common, or round-leaved Alder.

2. ALNUS *foliis ovato lanceolatis marginibus dentatis.* The long-leaved Alder.

The first sort here mentioned, is the common Alder, which is propagated in *England.* The second sort is very common in *Austria* and *Hungary,* from whence I have been furnished with the seeds. The leaves of this sort are longer, narrower, and not so glutinous as those of the first, nor are they so rough; they are also of a thinner consistence.

These two sorts delight in a moist soil, where few other trees will thrive, and are a great improvement to such lands; they are propagated either by layers, or planting of truncheons about three feet in length. The best time for this is in *February,* or the beginning of *March;* these should be sharpened at one end, and the ground loosened with an instrument before they are thrust into it, lest by the stiffness of the soil the bark should be torn off, which may occasion their miscarriage. These truncheons should be thrust into the earth at least two feet, to prevent their being blown out of the ground by strong winds, after they have made strong shoots. The plantations should be cleared from all such weeds as grow tall, otherwise they will over-bear the young shoots; but when they have made good heads, they will keep down the weeds, and will require no farther care.

If you raise them by laying down the branches, it must be performed in *October;* and by the *October* following, they will have taken roots sufficient to be transplanted out; which must be done by digging a hole, and loosening the earth in the place where each plant is to stand, planting the young tree at least a foot and an half deep, cutting off the top to about nine inches above the surface, which will occasion them to shoot out many branches.

The distance these trees should be placed (if designed for a coppice) is six feet square; and if the small lateral shoots are taken off in the spring, it will very much strengthen your upright poles, provided you leave a few small shoots at distances upon the body thereof, to detain the sap for the increase of its bulk.

These trees may be also planted on the sides of brooks

(as is usual for willows), where they will thrive exceedingly, and may be cut for poles every fifth or sixth year. This wood is in great request with the turners, and will endure a long time under ground, or to be laid in water.

ALNUS NIGRA BACCIFERA. See *Frangula.*

ALOE.

The Characters are,

The flower is of one leaf, which is cut at the top into six parts, which spread open; in the bottom of the flower is the nectarii, and the stamina are inserted in the receptacle.

This genus of plants is by *Dr. Linnæus* ranged in his sixth class, which is titled *Hexandria monogynia.*

The Species are,

1. ALOE *floribus pedunculatis cernuis corymbosis sub-cylindricis.* *Lin. Sp. Plant.* 319. The mitre-shaped Aloe.

2. ALOE *foliis dentatis erectis succulentibus planis maculatis, floribus luteis in thyrso dependentibus.* The common Barbadoes Aloe.

3. ALOE *foliis amplexicaulibus reflexis, margine dentatis, floribus cylindricis caule fruticosa.* Commonly called Sword-Aloe.

4. ALOE *foliis latioribus amplexicaulibus, margine & dorso spinosis, floribus spicatis, caule fruticoso.* Aloe with broader leaves embracing the stalks, whose edges and back are set with spines, flowers growing in spikes, and a shrubby stalk.

5. ALOE *foliis latissimis amplexicaulibus maculatis, margine spinosis floribus umbellatis.* By some called the Sops Aloe, and by others *Carolina Aloe.*

6. ALOE *foliis latioribus amplexicaulibus maculatis margine spinosis floribus spicatis.* Aloe with broad spotted leaves embracing the stalks, whose edges have spines, and flowers growing in a spike.

7. ALOE *foliis ensiformibus inermis ancipitibus floribus laxè spicatis caule fruticoso.* Aloe with sword-shaped smooth leaves, standing two ways, the flowers growing in loose spikes, and a shrubby stalk.

8. ALOE *foliis amplexicaulibus utràque spinosis, floribus spicatis.* Aloe with leaves embracing the stalks, which are prickly on every side, and flowers growing in spikes.

9. ALOE *floribus pedunculatis cernuis racemosis prismaticis ore patulo æquali.* *Lin. Sp. Plant.* 321. Aloe with hanging branching flowers, having foot stalks, and spreading equally at the brim. Commonly called Partridge-breast Aloe.

10. ALOE *foliis erectis subulatis radicans undique inerme spinosis.* *Hort. Cliff.* 131. Aloe with erect awl shaped leaves, set with soft spines on every part.

11. ALOE *floribus sessilibus infundibuli formibus bilabiatis laciniis quinque revolutis summa erecta.* *Lin. Sp. Pl.* 322. Aloe with funnel-shaped flowers, without foot-stalks, opening in two lips, and cut into five segments, which turn backward, and are erect at the top.

12. ALOE *floribus sessilibus ovatis creuatis segmentis interioribus conniventibus.* *Lin. Sp. Pl.* 322. Aloe with oval crenated flowers, without foot stalks, and the interior segments scarce appearing.

13. ALOE *sessilis foliis linguiformibus maculatis floribus pedunculatis cernuis.* This is commonly called Tongue-Aloe.

14. ALOE *floribus sessilibus bilabiatis labio superiore erecto inferiore patente.* *Lin. Sp. Pl.* 322. Commonly called large Pearl Aloe.

15. ALOE *foliis longissimis & angustissimis marginibus spinosis, floribus spicatis.* The Succotrine Aloe.

16. ALOE *caule brevi, foliis amplexicaulibus bifariam versis spinis marginibus erectis floribus capitatis.* Aloe with a short stalk, leaves standing two ways, which embrace the stalk; the spines on the edges erect, and flowers growing in a head.

17. ALOE *sessilis foliis brevioribus planis carnosissimis apice triquetris marginibus inerme spinosis.* Commonly called Cobweb Aloe.

18. *ALOE foliis ovato-lanceolatis carnosis apice triquetris angulis inermis dentatis. Hort. Cliff. 131.* Aloe with oval spear-shaped fleshy leaves, having three angles at their extremities, which are indented and set with soft spines.

19. *ALOE floribus sessilibus triquetris bilabiatis labio inferiore revolutis. Lin. Sp. Plant. 322.* Aloe with flowers divided into three parts, the under lip being turned back. Commonly called Cushion Aloe.

20. *ALOE sessilis foliis carinatis utraque verrucosis bifariam versis.* Low Aloe with keel-shaped leaves, warted on every part, and standing two ways. Commonly called Pearl-tongue Aloe.

21. *ALOE sessilis foliis carinatis verrucosis apice triquetris carnosis.* Low Aloe with fleshy, keel-shaped, spotted leaves, which are triangular at their extremities.

22. *ALOE foliis latis undulatis maculosis floribus spicatis infundibuli formibus limbo revolutis.* Aloe with broad spotted waved leaves, and funnel-shaped flowers growing in spikes, which are turned back at their brim. Commonly called Guinea Aloe.

23. *ALOE pumila, foliis longis angustis integerrimis maculatis radice repente.* Low Aloe with long narrow entire leaves, which are spotted, and a creeping root. Commonly called Ceylon Aloe.

24. *ALOE foliis amplexicaulibus nigricantibus undique spinosis.* Aloe with dark green leaves embracing the stalks, which are beset with spines on every side. Commonly, but falsely called *Aloe ferox*.

25. *ALOE floribus sessilibus reflexis imbricatis prismaticis. Lin. Sp. Plant. 323.* Aloe with reflexed flowers growing close to the stalk, in form of a prism, lying over each other like tiles on a house. Commonly called *Iris uvaria*.

The first, third, and eighteen next following sorts, are so hardy as to be kept in a warm dry green-house in winter, and may be placed in the open air in summer, in a sheltered situation; but then the plants should not have much wet, for that will rot their stems. But with this management the plants will not grow so fast, as when they are placed in a stove, though they will be stronger, and their stems will support their heads much better, nor will their leaves be so much drawn as those which are more tenderly treated, therefore this management should be preferred.

The fifth, sixth and seventh sorts grow from one to the height of two or three feet; the leaves of the fifth and sixth are generally a foot or more in length, being broad at their base, ending in acute points: they are armed with spines on their edges, and spread out on every side of their stems. The seventh has pliable blunt leaves without spines, the stalk will rise three feet high, and put out several heads. The eighth sort seldom rises more than a foot high, putting out from the stalk many clustering heads; the leaves are armed with short spines on every side, but those on the under side are short. This sort does not flower so frequently as many of the other.

The ninth, tenth, eleventh, twelfth, thirteenth, fourteenth, seventeenth, eighteenth, nineteenth, twentieth, and twenty-first sorts are plants of smaller growth; these seldom rise more than a foot high, and some of them not more than half that height; their leaves are of very different shapes, some of them have tongue-shaped leaves, and others have thick succulent leaves, for the most part terminating in an awl-shaped point. These sorts flower every year, and some of them flower two or three times in a year.

They are all of them hardy enough to live through the winter in a good green-house, provided they have not too much water; for wet in winter, will soon destroy these plants when they have no warmth in cold weather. In summer they may be exposed in the open air for about three months, during which time they should be gently watered twice a

week in dry weather. But if the autumn should prove cold and wet, they should be removed into shelter earlier than in a dry season; for if they get too much moisture, they are very apt to rot in the winter when they have no artificial heat.

The second sort is very common in the islands of *America*, where the plants are propagated upon the poorest land, for to obtain the Hepatic Aloes, which is brought to *England*, and is used chiefly for horses, being too coarse for medicine.

The leaves of this sort are about four inches broad at their base, where they are near two inches thick, and diminish gradually to a point. The leaves are of a pale sea-green colour, and when young are spotted with white. The flower-stem rises near three feet high, and the flowers stand in a slender loose spike, with very short foot-stalks, and hang downwards. This sort is too tender to live through the winter in our climate, in a common green-house; therefore it should be placed in a stove kept to a moderate degree of warmth in that season. I have known plants of this kind, which have had an oiled cloth tied about their roots, and hung up in a warm room more than two years, and afterwards planted in pots, which have grown very well, from whence the plant has been called *Sempervivum* by the inhabitants of *America*.

Although the third sort will live through the winter in a good green-house, yet it will not flower unless it is placed in a moderate share of warmth; for the flowers of this sort appear in *December*, when they make a fine appearance.

The fourth sort is somewhat like the third, but the leaves are broader, and have several spines on their backs towards their extremities. The flowers of this grow in a looser spike, and the plants never put out any suckers, so that it is very difficult to increase.

The fifteenth sort is the true Succotrine Aloe, from whence the best sort of Aloe for use in medicine is produced. This has long narrow succulent leaves, which come out without any order, and form large heads. The stalks grow three or four feet high, and have two, three, and sometimes four of these heads, branching out from it: the flowers of this sort are generally in the winter season. It will live through the winter in a warm green-house, but the plants so managed will not flower so frequently, as those which have a moderate degree of warmth in winter.

The twenty-second sort hath knobbed creeping fleshy roots, which spread over the pots; the leaves come up single, are narrow at bottom, wide in the middle, where they are waved on their edges, and decrease again at their extremities; they are about a foot and an half long, and four inches wide in their broadest part; these are of a dark green colour, marbled over with white. The flower-stem arises immediately from the root, grows about two feet high, the upper part being closely set with very white flowers which are tubulous, and cut into six parts, which are reflexed back, so as to have much of the appearance of a large single Hyacinth. This plant increases plentifully by its creeping roots, but is very tender, so must constantly remain in the stove. It usually flowers in *July*.

The twenty-third sort is a low plant with creeping fleshy roots, the leaves are about nine inches long, and one and an half broad at the bottom, gradually diminishing to the top, where it ends in a point. This sort rarely produces any flowers in *Europe*, but increases very plentifully by offsets.

The twenty-fourth sort rises to the height of eight or ten feet, with a strong stem; the leaves grow on the top, which closely embrace the stalk; these come out irregularly, and spread every way; they are near four inches broad at their base, and diminish gradually to the top, where they end in a spine. These are near two feet long, of a dark green colour,

four, and closely beset with short thick spines on every side. This sort hath not as yet flowered in *England*, nor does it put out suckers, so that it is difficult to increase. It must have a warm green-house in winter, and very little water.

The twenty-fifth sort hath very long narrow triangular leaves, shaped like those of the Bullrush; the flowers are produced in close thick spikes, upon stalks near three feet high. They are of an Orange-colour, so that when the plants are strong, and produce large spikes, they make a fine appearance. It flowers in *August* and *September*; and will live through the winter, in a warm border, close to a south-aspected wall.

The soil in which these plants thrive best, is one half fresh light earth from a common (and if the turf is taken with it and rotted, it is much better); the rest should be white sea sand and sifted lime rubbish, of each of these two a fourth part; mix these together six or eight months at least before it is used, observing to turn it over often in this time.

The middle of *July* is a very proper season to shift these plants; at which time you may take them out of the pots, and with your fingers open the roots, and shake out as much of the earth as possible, taking off all dead or mouldy roots, but do not wound or break the young fresh ones: then fill the pot about three parts full of the above-mentioned earth, putting a few stones in the bottom of the pot, to drain off the moisture; and after placing the roots of the plant in such a manner as to prevent their interfering too much with each other, put in as much of the same earth, as to fill the pot almost to the rim, and observe to shake the plant, so as to let the earth in between the roots; and then with your hand settle it close to the roots of the plant, to keep it steady in the pot; then water them gently, and set them abroad in a shady place, where they may remain for three weeks, giving them gentle waterings, if the weather should prove hot and dry.

Toward the latter end of *September*, in a dry day, remove them into the house again, observing to give them as much free open air as possible, while the weather holds warm; but, if the nights are cool, you must shut up the glasses, and give them air only in the day; and, as the cold increases, you must decrease opening the glasses, but observe to give them gentle waterings often, till the middle of *October*, when you must abate them, according to the heat of the house in which they are kept. For those plants which are placed in a stove, will require to be watered at least once a week, most part of the winter; whereas those which are kept in a green-house without artificial heat, should not be watered oftener in winter than once a month.

The tender sorts should constantly remain in the stove, or be removed in the summer to an airy glass case, where they may have free air in warm weather, but be protected from rain and cold. With this management the plants will thrive and increase, and such of them as usually flower, may be expected to produce them in beauty at their seasons.

Most of these Aloes are increased by offsets, which should be taken from the mother-plant, at the time when they are shifted, and must be planted in very small pots, filled with the same earth as was directed for the old plants; but if, in taking the suckers off, you observe that part which joined to the mother root to be moist, you must let them lie out of the ground in a shady dry place for about a week, to dry before they are planted, otherwise they are very subject to rot.

After planting, let them remain in a shady place (as was before directed in shifting the old plants) for a fortnight, when you should remove the tender kinds to a very moderate hot bed, plunging the pots therein, which will greatly facilitate their taking new root; but observe to

shade the glasses in the middle of the day, and to give them a great share of air.

Toward the middle of *August*, begin to harden these young plants, by taking off the glasses in good weather, and by raising them at other times with props, that the air may freely enter the bed, which is absolutely necessary for their growth, and to prepare them to be removed into the house, which must be done toward the end of *September*, and managed as before directed for the old plants.

The *African Aloes*, for the most part, afford plenty of suckers, by which they are increased; but those few that do not, may be most of them propagated, by taking off some of the under leaves, laying them to dry for ten days or a fortnight, as was directed for the offsets; then plant them in the same soil as was directed for them, putting that part of the leaf which did adhere to the old plant, about an inch, or an inch and an half (according to the size of the leaf) into the earth, giving them a little water to settle the earth about them; then plunge the pots into a moderate hot-bed, observing to screen them from the violence of the sun, and give them gentle refreshings with water once in a week or ten days. The best season for this is in *June*, that they may push out heads before winter.

ALOE AMERICANA MURICATA. See Agave.

ALOIDES. See Stratiotes.

ALPINIA.

The Characters are,

The flower has one stamina and one style; it is cut into six parts at the top, and has a swelling tube with three spreading lobes.

We know but one species of this genus, viz.

ALPINIA. Royen. Prod. 12. White branching Alpinia, with leaves like the flowering Reed.

This plant is a native of the *West-Indies*, from whence it has been brought into some of the curious gardens of *Europe*, where it must be preserved in a warm stove, and the pots plunged into a hot-bed of tanners bark, otherwise it will not thrive in this country. The leaves decay every winter, and are pushed out from the roots every spring, like the Ginger and Maranta; so should be managed in the same manner as is directed for those two plants, and may be propagated by parting of the roots when the leaves decay. It grows naturally in moist places in the *West-Indies*.

ALSINE. Chick-weed.

There are several species of this plant, which are common in cultivated places, and on dunghills. These being so well known to most persons, it will be needless to mention the species in this place.

ALTHÆA. Marshmallow.

The Characters are,

The flower has a double calyx; the outer is cut into nine segments. It hath several capsules, each containing one seed.

The Species are,

1. ALTHÆA foliis simplicibus acuminatis acutè dentatis tomentosis. Common Marshmallow.

2. ALTHÆA foliis trifidis piloso-hispidis. Hort. Cliff. 349. Marshmallow with trifid hairy pungent leaves.

3. ALTHÆA foliis inferioribus palmatis superioribus digitatis caule fruticoso. Hort. Upsal. 205. Marshmallow with the under leaves shaped like a hand, the upper leaves more divided, and a shrubby stalk.

The first sort is the common Marshmallow, which grows naturally in moist places in divers parts of *England*, and is frequently used in medicine. This hath a perennial root and an annual stalk, which perishes every autumn. The stalks of this plant grow erect, to the height of four or five feet; these are garnished with leaves which are hoary and soft to the touch, and placed alternately on the branches; the

the flowers come out from the wings of the leaves, which are shaped like those of the Mallow, but are smaller and of a pale colour. It may be propagated fast enough, either by seeds or parting of their roots. When it is propagated by seeds they should be sown in the spring, but if by parting of the roots, the best time is in autumn, when the stalks decay. It will thrive in any soil or situation, but in moist places will grow larger than in dry land.

The second sort grows naturally in *Spain* and *Portugal*, from both of these countries I have received the seeds. This is a low plant, whose branches trail on the ground, unless they are supported by stakes. The leaves and stalks are beset with strong hairs, the flowers come out at the wings of the stalks, and are smaller than those of the common sort, having purplish bottoms.

If the seeds of this sort are sown in *April*, the plants will flower in *July*, and the seeds ripen in *September*. They should be sown in the places where they are to remain, for as the roots shoot deep into the ground, so unless the plants are removed very young, they seldom survive transplanting.

The third sort has a woody stem, which rises to the height of four or five feet, and puts out many side branches. The flowers come out from the wings of the stalks in the same manner as the other sorts, but are not so large as those of the common Marshmallow; they are of a deeper red colour, and the empalement is much larger. This sort seldom flowers the first year, unless the summer proves warm; but when the plants live through the winter, they will flower early the following summer, so will produce good seeds. This grows naturally in *Hungary* and *Istria*, from both which places I have received the seeds.

It is propagated by seeds, which should be sown in the spring, in the place where the plants are to remain; or if otherwise, the plants must be transplanted young, else they will not succeed. They should have a sheltered situation and a dry soil, otherwise they will not live through the winter in *England*. When these plants grow in a stony soil, or in lime rubbish, they will be stunted in their growth, but they will have less sap in their branches, so will better endure the cold of this climate. This sort seldom continues longer than two years in *England*, but the seeds ripen here in kindly seasons.

ALTHÆA FRUTEX. See Hibiscus and Lavatera.

ALYSSOIDES. See Alyssum and Lunaria.

ALYSSON ALPINUM LUTEUM. See Draba.

ALYSSON SEGETUM. See Myagrum.

ALYSSON SERPILLI FOLIO. See Clypeola.

ALYSSON VERONICÆ FOLIO. See Draba.

ALYSSUM. Madwort.

The Characters are,

The flower hath four petals in form of a cross; it hath six stamina, two of which are shorter than the other four. The flower is succeeded by an indented compressed pod.

The Species are,

1. ALYSSUM caulibus frutescentibus paniculatis foliis lanceolatis undulatis integris. Prod. Leyd. 331. Madwort with shrubby stalks, flowers growing in panicles, and whole spear-shaped waved leaves.

2. ALYSSUM foliis lanceolato-linearibus acutis integerrimis caulibus procumbentibus perennantibus. Hort. Cliff. 333. Madwort with whole spear-shaped pointed leaves, and trailing perennial stalks.

3. ALYSSUM ramis senilibus spiniformibus nudis. Hort. Cliff. 332. Madwort, whose older branches have naked spines.

4. ALYSSUM ramis suffruticosis diffusis foliis punctato echinatis. Hort. Ups. 185. Madwort with shrubby diffused branches and leaves, having prickly punctures.

5. ALYSSUM caule erecto foliis lanceolatis incanis integerrimis floribus corymbosis. Hort. Cliff. 332. Hoary shrubby Madwort.

6. ALYSSUM caule erecto herbaceo filiculis sessilibus ovalibus compresso planis petalis acuminatis. Lin. Sp. Plant. 651. Madwort with an erect herbaceous stalk, pods growing close to the stalks, which are oval and compressed, and the flower leaves pointed.

7. ALYSSUM caule herbaceo foliis lanceolatis dentatis filiculis inflatis. Lin. Sp. Plant. 651. Madwort with an herbaceous stalk, spear-shaped indented leaves, and swollen seed vessels.

The first sort is a low perennial plant, with a thick fleshy stem, which seldom rises more than one foot high, but divides into many less branches which spread on the ground. The branches are garnished with long spear-shaped leaves, which are hoary and waved on their edges, and continue through the year. The flowers are produced in loose panicles, at the extremity of every branch, and are of a bright yellow colour, consisting of four petals, which are placed in form of a cross: these being numerous, make a fine appearance during their continuance. They appear the latter end of *April*, or the beginning of *May*, and if the season is moderate, will continue three weeks in beauty.

This plant is hardy, and although brought from a more southerly climate, yet, if planted in a dry, lean, or rubbishy soil, will endure our severest winters abroad. It is increased by sowing the seeds in *March* in a light sandy soil, or by planting cuttings in *April* or *May*; which are very apt to take root, if kept shaded in the heat of the day, and gently refreshed with water.

The second sort seldom continues above two or three years with us, and must therefore be often sown to preserve it; or if the seeds are suffered to fall, and remain upon the ground, the plants will rise without any trouble. It produces, at the extremity of its branches, very pretty tufts of small white flowers. This will also grow from cuttings, if planted and managed as the former.

The third sort hath lignous branches, which rise about two feet high; these are armed with small spines; the leaves are hoary, spear-shaped, and thinly placed on the stalks without any order. The flowers are white, cross-shaped, and grow in small clusters at the extremity of the branches.

This may be propagated in the same manner as the first sort, either by seeds or slips; and when the plants grow in rubbish, or on old walls, they will last much longer, and endure the cold of our winters, better than those which are in a good soil. It grows naturally in *Spain*, *Italy*, and the south of *France*.

The fourth sort hath trailing branches, which lie on the ground; these are garnished with oblong hoary leaves, which are rough to the touch. The flowers are produced in small clusters at the extremity of the branches, which are of a dark yellow colour, and are succeeded by seed vessels shaped like those of the third sort. This grows naturally upon rocks and ruins, in *Burgundy*, and some other parts of *France*, as also about *Basil*. It may be propagated in the same manner as the former sorts, and when it grows in rubbish, the plants will continue some years; but in rich ground, they seldom live through the winter in *England*.

The fifth sort grows to the height of two feet, having lignous stalks, which divide into several branches toward the top. These are garnished with hoary spear-shaped leaves, which are placed alternately on the branches: at the extremity of every shoot, the flowers are produced in round bunches, which are small, white, and cross-shaped. This plant grows naturally in the south of *France*, *Spain*, and *Italy*, chiefly on rocky or gravelly soils. It flowers in *June*, *July*, *August*, and *September*, and the seeds ripen soon after; which if permitted to scatter, the plants will come up, and require little care.

The sixth sort is a biennial plant, with oblong hoary leaves, placed alternately; the flowers come out from the wings of the stalks single; these grow very close to the stalk, and are succeeded by oval compressed seed vessels, shaped like those of the Lunaria, which contain many flat seeds. It is propagated by seeds, which must be sown upon dry ground, or lime rubbish, and treated like the former sorts.

The seventh sort is a low spreading plant, garnished with oblong hoary leaves which continue through the year: the flowers are produced in small clusters at the extremity of the branches; these are of a bright yellow colour, consisting of four petals placed in form of a cross. This sort grows naturally in the islands of the *Archipelago*, but is hardy enough to live in the open air in *England*, in a dry soil and a warm situation. It is propagated by seeds, and seldom lasts longer than two or three years.

AMARANTHOIDES. See *Gomphrena*.

AMARANTHUS. Amaranth, or Flower-gentle.

The Characters are,

It hath male and female flowers in the same plant. The flower hath no petals, but the empalement consists of three or five leaves; this is common to both sexes. The male flowers have in some species three, and in others five slender stamina. The female flowers have three short styles. The seed vessel has one cell, in which is lodged a single globular seed.

The Species are,

1. AMARANTHUS *capitellis triandris subrotundis amplexicaulibus foliis lanceolatis acuminatis. Lin. Sp. Pl. 989.* The Amaranthus tricolor.

2. AMARANTHUS *capitellis triandris subrotundis sessilibus foliis lanceolatis sparsis. Lin. Sp. Plant. 989.* Amaranthus bicolor.

3. AMARANTHUS *racemis pentandris cylindricis pendulis longissimis. Hort. Cliff. 443.* Flower-gentle with five stamina, and very long hanging cylindrical spikes.

4. AMARANTHUS *racemis cylindricis pendulis, caule erecto arboreo.* This is the tree Amaranthus.

The first sort has been long cultivated in gardens for the beauty of its variegated leaves, which are of three colours, viz. green, yellow, and red; these are very elegantly mixed, and when the plants are in full vigour, the leaves are large, and closely set from the bottom to the top of the stalks, and the branches form a sort of pyramid; so that there is not a more beautiful plant than this, when it is in full lustre. From the leaves of this plant being party-coloured, like the feathers of parrots, some botanists have separated this species from the others, and constituted a genus of it, by the title of *Psittacus*.

The second sort hath been introduced into the *English* gardens much later than the former. This grows to the same height with the former, and in the manner of its growth greatly resembles it; but the leaves have only two colours, which are an obscure purple, and a bright crimson; these are so blended as to set off each other, and when the plants are vigorous, they make a fine appearance.

The third sort grows naturally in *America*, from whence I received the seeds: this grows with an upright stem, upward of three feet high; the leaves and stalks are of a pale green colour; the spikes of the flowers are produced from the wings of the stalks, and also in clusters at the extremity of the branches: they are very long and hang downward, being of a bright purple colour. I have measured some of these spikes, which were two feet and an half long, so that many of them have reached the ground.

The fourth sort hath a strong stem, which rises to the height of seven or eight feet, sending forth many horizontal branches toward the top; these are garnished with oblong rough green leaves. At the extremity of every shoot, the

cylindrical spikes of a purple colour are produced, which hang downward, but these are seldom half the length of those of the former sort, and are much thicker. This is the sort of Amaranth, which is directed by the College to be used in medicine.

These two sorts must be raised upon a hot-bed, and in *June* they may be planted into the borders of the pleasure-garden; shading them till they have taken new root, and in dry weather they should be watered. The third sort seldom fails to ripen its seeds in the open air, but the fourth sort seldom ripens its seeds abroad when the autumn proves cold and wet; therefore one plant of this sort should be potted, to be removed to shelter early in the autumn to obtain good seeds.

The first two sorts of Amaranths must be sown on a good hot-bed in *February*, or the beginning of *March* at farthest; and in about a fortnight's time, if the bed is in good temper, the plants will rise; when you must prepare another hot-bed, covered with good rich light earth, about four inches thick; when this bed is in a proper temper to receive the young plants, you should raise them up with your finger, so as not to break off the tender roots, and prick them into your new hot-bed about four inches distance every way, giving them a gentle watering to settle the earth to their roots; but in doing this, be very cautious not to bear the young plants down to the ground by hasty watering, which rarely rise again, or at least so as to recover their former strength in a long time, but very often rot in the stems, and die quite away.

In the middle of the day keep them screened with mats from the great heat of the sun, and give them air by raising up the glasses with a small stone; and, if the glasses are wet, it will be proper to turn them every day, in good weather, that they may dry; for the moisture which is occasioned by the fermentation of the dung, and perspiration of the plants, is of a noxious quality, and very unkindly to plants; so that if the weather happens to prove bad, that you cannot turn your glasses, it will be of great service to your plants to wipe off all the moisture two or three times a day with a woollen cloth, to prevent its dropping upon the plants. When your plants are firmly rooted, and begin to grow, you must observe to give them air every day, more or less, as the weather is cold or hot, to prevent their drawing up too fast, which greatly weakens their stems.

In about three weeks or a month's time, these plants will have grown so as to meet, and will stand in need of another hot-bed, which should be of a moderate temper, and covered with the same rich earth about six inches thick, in which they should be removed, observing to take them up with as much earth about their roots as possible, and plant them seven or eight inches distance every way, giving them some water to settle the earth about their roots; but be very careful not to water them heavily, so as to bear down the plants, as was before directed; and keep them shaded in the heat of the day, until they have taken fresh roots; and be sure to refresh them often gently with water, and give them air in proportion to the heat of the weather, covering the glasses with mats every night, lest the cold chill your beds, and stop the growth of the plants.

In the beginning of *May* you must provide another hot-bed, which should be covered with a deep frame, that your plants may have room to grow. Upon this hot-bed you must set as many three-penny pots as can stand within the compass of the frame; these pots must be filled with good rich earth, and the cavities between each pot filled up with any common earth, to prevent the heat of the bed from evaporating, and filling the frame with noxious steams; then with a trowel, or some such instrument, take up your plants from the former hot-bed, with as much earth as possible to their

their roots, and place each single plant in the middle of one of the pots, filling the pot up with the earth before described, and settle it close to the root of the plant with your hands; water them gently, as before, and shade them in the heat of the day from the violence of the sun, by covering the glasses with mats; refresh them often with water, and give them a good quantity of air in the day-time.

In about three weeks more these plants will have grown to a considerable size and strength, so that you must now raise the glasses very much in the day-time; and when the air is soft, and the sun is clouded, draw off the glasses, and expose them to the open air, and repeat this as often as the weather will permit; which will harden them by degrees, to be removed abroad into the places where they are to remain the whole season; but it is not adviseable to set these plants out until a week in *July*, observing to do it when the air is perfectly soft, and, if possible, in a gentle shower of rain.

Let them at first be set near the shelter of a hedge for two or three days, where they may be screened from the violence of the sun, and strong winds, to which they must be inured by degrees. These plants, when grown to a good stature, perspire very freely, and must be every day refreshed with water, if the weather proves hot and dry; otherwise they will flint, and never produce so large leaves, as those which are skilfully treated.

This is the proper management, in order to have fine Amaranths; which, if rightly followed, and the kinds are good, in a favourable season, will produce wonderful large fine leaves, and are the greatest ornament to a good garden for upwards of two months.

There are many more species of this genus, which grow naturally in the two *Indies*, where some of them are cultivated as esculent plants; one of which the inhabitants title *Breda*, the other *Cullulu*, but as these are plants of no beauty, so they are rarely kept in gardens here.

AMARANTHUS CRISTATUS. See Celosia.

AMARYLLIS. Lily-daffodil.

The Characters are,

It hath an oblong compressed spathe, which incloses the flower-buds; it hath six awl shaped stamina with incumbent summits. The germen turns to an oval capsule, opening in three parts, having three cells.

The Species are,

1. AMARYLLIS *spathâ uniflorâ, corollâ æquali, staminibus declinatis*. Lin. Commonly called Autumnal Narcissus.

2. AMARYLLIS *spathâ uniflorâ, corollâ æquali, pistillo declinato*. Hort. Cliff. 135. Commonly called *Atamusco* Lily.

3. AMARYLLIS *spathâ uniflorâ, corollâ inæquali, genitalibus declinatis*. Hort. Cliff. 135. Commonly called *Jacobæa* Lily.

4. AMARYLLIS *spathâ multiflorâ, corollis revolutis genitalibus strictis*. Hort. Upsal. 75. Commonly called *Guernsey* Lily.

5. AMARYLLIS *spathâ multiflorâ, corollis campanulatis æqualibus, genitalibus declinatis*. Hort. Cliff. 135. Commonly called *Belladonna* Lily.

6. AMARYLLIS *spathâ multiflorâ, corollis campanulatis marginibus reflexis genitalibus declinatis*. Commonly called *Mexican* Lily.

7. AMARYLLIS *spathâ multiflorâ, corollis campanulatis æqualibus, scapo compresso longitudini umbellæ*. Flor. Leyd. 36. Lily Daffodil with many flowers in one cover; the petals equal, and the cover compressed the length of the umbel.

8. AMARYLLIS *spathâ multiflorâ, corollis campanulatis æqualibus, scapo tereti ancipiti*. Flor. Leyd. 36. Commonly called the *Ceylon* Lily.

9. AMARYLLIS *spathâ multiflorâ, foliis ciliatis*. Flor. Leyd. 37. Commonly called the *African* Scarlet Lily.

10. AMARYLLIS *spathâ uniflorâ, corollâ æquali, staminibus erectis*. Commonly called Spring yellow Lily Narcissus.

11. AMARYLLIS *spathâ multiflorâ corollis inæqualibus foliis linguiformibus*. Buttn. Lily Daffodil with many flowers in a cover, whose petals are unequal, and leaves shaped like a tongue; or the *Brunswigia* of Dr. Heister.

The first sort is a very hardy plant, which increases very fast by offsets. The season for transplanting these roots is any time from *May* to the end of *July*, when their leaves are decayed, after which it will be too late to remove them; for they will begin to push out new fibres by the middle of *August*, if the season be moist, and many times they flower the beginning of *September*; so that if they are then transplanted, it will spoil their flowering. This plant will grow in any soil or situation; but it will thrive best in a fresh light dry soil, and in an open situation, *i. e.* not under the dripping of trees, nor too near to walls. It is commonly called by the gardeners, the yellow Autumnal Narcissus, &c. and is usually sold by them with Colchicums, for autumnal ornaments to gardens; for which purpose this is a pretty plant, as it will frequently keep flowering from the middle of *September* to the middle of *November*, provided the frost is not so severe as to destroy the flowers; for although there is but one flower in each cover, yet there is a succession of flowers from the same root, especially when they are suffered to remain three or four years unremoved. The flowers seldom rise above three or four inches high; it is shaped somewhat like the flowers of the large yellow Crocus; these have their green leaves come up at the same time, like the Saffron, and after the flowers are past, the leaves increase all the winter. The roots are bulbous, and shaped like those of the Narcissus.

The tenth sort is more rare in *England* than any of the other, at present. It was formerly in several curious gardens, but as it flowers at a season when there are so many finer sorts in beauty, so it was neglected and cast out of the gardens, whereby it is almost lost in *England*: it grows naturally in *Spain* and *Portugal*, where it flowers early in *January*. This is as hardy as the first sort, and may be planted in the open borders, and treated in the same manner. It should not be taken out of the ground to transplant, till the end of *July*, or the beginning of *August*.

The second sort is a native of *Virginia* and *Carolina*, in which countries it grows very plentifully in the fields and woods, where it makes a beautiful appearance when it is in flower, which is in the spring. The flowers of this sort are produced single, and at their first appearance have a fine Carnation colour on their outside; but this fades away to a pale, or almost white, before the flowers decay. This plant is so hardy, as to thrive in the open air in *England*, provided the roots are planted in a warm situation, and on a dry soil; it may be propagated by offsets from the roots, which they put out pretty plentifully, especially if they are not transplanted oftener than once in three years.

The third sort, which is commonly called *Jacobæa* Lily, is now become pretty common in the curious gardens in *England*, the roots sending forth plenty of offsets, especially when they are kept in a moderate warmth in winter: for the roots of this kind will live in a good green-house, or may be preserved through the winter under a common hot-bed frame; but then they will not flower so often, nor send out so many offsets, as when they are placed in a moderate stove in winter. This sort will produce its flowers two or three times in a year, and is not regular to any season; but from *March* to the beginning of *September*, the flowers will be produced when the roots are in vigour. There is never more than one flower produced on the same stalk: These flowers are large, and of a very deep red; the under petals, or flower leaves, are very large; and the whole

whole flower stands nodding on one side of the stalk, making a beautiful appearance.

It is propagated by offsets, which may be taken off every year; the best time to shift and part these roots is in *August*, that they may take good root before winter; in doing of this, there should be care taken not to break off the fibres from their roots. They should be planted in pots of a middling size, filled with light kitchen garden earth; and if they are kept in a moderate degree of warmth, they will produce their flowers in plenty, and the roots will make great increase.

The sixth sort, which is commonly called the *Mexican Lily*, is not quite so hardy as the former sort, so must be placed in a warm stove; and if the pots are plunged into a hot-bed of tanners bark, the roots will thrive better, and the flowers will be strong. This sort is increased by offsets, as the others of this tribe; and it flowers usually the beginning of spring, when it makes a fine appearance in the stove; the flower-stems of this sort, seldom rise more than one foot high, each stem supports two, three, or four flowers, rarely more than that number. The flowers are large, and of a bright copper colour, inclining to red.

The eighth sort is also tender, and must be treated in the same manner as the sixth; this is more common in the gardens in *Holland* than in this country; and as it is a plant which increases but slowly, will not be very common here. This flowers usually in *June* and *July*, and sometimes the same root will flower again in autumn; for if the pots are plunged in a bed of tanners bark, the roots generally flower twice every year, but the flowers are not of long duration.

The seventh and ninth sorts are more hardy, and may be treated in the same manner as the *Jacobæa Lily*; these will increase pretty fast by offsets, when they are properly managed, especially the ninth, which sends out many offsets, so as to fill the pots with roots, but it seldom flowers in *England*. The petals of the flower turn back like those of the *Guernsey Lily*, but are of a lighter colour, rather inclining to scarlet; the roots of this are small.

The eleventh sort is figured by *Ferrarius* in his *Garden of flowers*, as also by *Morrison* in his *History of plants*; but *Dr. Heister* has separated it from this genus, and has constituted a new genus by the title of *Brunswigia*, in honour to the duke of *Brunswick*.

This grows naturally at the *Cape of Good Hope*, from whence I have received the roots, which have succeeded in the *Chelsea* garden.

This sort may be treated in the same manner, as hath been directed for the *Jacobæa Lily*, with this difference only, of placing it in winter in a stove, where there is a moderate share of warmth, for the roots of this will not endure so much cold as those, nor should they have so much water given them.

The best time to transplant these roots is about the beginning of *August*, when their leaves are quite decayed, and before they put out new fibres, for it will be very improper to remove them afterwards.

All these bulbous-rooted flowers delight in a loose sandy earth, mixed with good kitchen garden mould; and in the culture of them there should be but little water given them at those times when their leaves decay, and the roots are not in a growing state; for much moisture at that time will often cause them to rot; but when they are growing, and putting out their flower-stems, they should be frequently refreshed with water, but not given in too great quantities at a time. The pots, with the tender sorts, should constantly be kept in the stove; and in summer they should have as much free air as possible; for although some of these sorts may be kept abroad in summer, yet those do not

thrive so well, nor flower so constantly, as those which are treated in the manner here described.

The sixth sort, which is called the *Belladonna Lily*, was brought to *England* from *Portugal*, where the gardens did some years ago abound with these flowers; for the roots increase very fast, especially in such countries where they live in the open air. This plant thrives so well in *Italy*, as to need no other culture than the common *Lily*; and although it does not flower till *August*, yet it commonly produces good seeds in that country, from which they propagate them in great plenty; but with us they require more care, otherwise they cannot be preserved.

The method in which I have cultivated this plant for some years past, with great success, is as follows. I prepared a border next a south west-affected wall, of about six feet wide, in the following manner, *viz.* I removed all the earth to the depth of three feet, then I put some very rotten dung in the bottom, six inches thick, upon which I laid light garden mould about twenty inches deep; after making this level, I placed the roots at six inches distance every way, and then covered them over with light sandy earth, to the height of the border, whereby the upper part of the roots were five or six inches buried, and in the winter I covered the border all over with rotten tanners bark, three inches deep, to prevent the frost from penetrating the ground; and when the frost was very severe, I laid some mats or straw over the leaves to protect them from being killed. With this management the roots have greatly increased, and have constantly flowered every year; some of them have put out two or three stems, which grew near three feet high, and produced many flowers in each umbel, which have made a fine appearance during the month of *October*. This plant produces its flowers in *October*, and the green leaves come up soon after, and abide all the winter and spring until *June*, at which time they decay; soon after which the roots should be transplanted.

The fourth sort is supposed to come originally from *Japan*, but has been many years cultivated in the gardens of *Guernsey* and *Jersey*; in both which places, they seem to thrive as well as if it was their native country; and from those islands their roots are sent annually to the curious in most parts of *Europe*, and are commonly called *Guernsey lilies*.

When these roots come over, they should be planted in pots filled with fresh light sandy earth, mixed with a little very rotten dung, and placed in a warm situation, observing now and then to refresh the earth with water. About the middle or end of *September*, such of the roots as are strong enough to flower, will begin to shew the bud of their flower-stem (which is commonly of a red colour); therefore you should remove these pots into a situation where they may have the full benefit of the sun, and may be sheltered from strong winds: but by no means place them too near a wall, nor under glasses, which would draw them up weak, and render them less beautiful. At this season they should be gently refreshed with water, if the weather be warm and dry; but if it should prove very wet, they should be screened from it.

When the flowers begin to open, the pots should be removed under shelter, to prevent the flowers from being injured by too much wet: but they must not be kept too close, nor placed in a situation too warm, which would occasion their colour to be less lively, and hasten their decay. The flowers of this plant will continue in beauty (if rightly managed) a full month; and though they have no scent, yet, for the richness of their colour, they are justly esteemed in the first rank of the flowery race.

After the flowers are decayed, the green leaves will begin to shoot forth in length, and if sheltered from severe cold

cold, will continue growing all the winter; but they must have as much free air as possible in mild weather, and be covered only in great rains or frosts; for which purpose, a common hot-bed frame is the properest shelter for them; under which if they are placed, the glasses may be taken off constantly every day in dry open weather, which will encourage the leaves to grow strong and broad; whereas when they are placed in a green-house, or not exposed to the open air, they will grow long and slender, and have a pale weak aspect, whereby the roots will become weak, so that it seldom happens that they produce flowers under such management.

When a person is possessed of a large number of these roots; it will be troublesome to preserve them in pots, therefore there should be a bed prepared of the following earth, in some well sheltered part of the garden, *viz.* Take a third part of fresh virgin earth from a pasture ground, which is light, then put near an equal part of sea sand, to which you should add rotten dung, and sifted lime rubbish, of each an equal quantity. With this earth (when well mixed and incorporated) you should make your bed about two feet thick, raising it about four or five inches above the surface of the ground, if the situation be dry; but if the ground be wet, it should be raised eight or nine inches higher. In this bed, about the beginning of *July* (as was before directed), you should plant the roots about six or eight inches asunder each way; and in the winter, when the frost begins, you should either cover the bed with a frame, or arch it over, and cover it with mats and straw, to prevent their leaves from being pinched with cold; but in the spring the covering may be entirely removed, and the bed kept constantly clear from weeds, during the summer, observing to stir the surface of the earth now-and-then; and every year, when the leaves are decayed, you should sift a little fresh earth over the beds, to encourage the roots. In this bed the roots may remain until they are strong enough to produce flowers, when they may be taken up and planted in pots, as was before directed, or suffered to remain in the same bed to flower.

AMBROSIA.

The Characters are,

It hath male and female flowers on the same plant. The male flowers are of one leaf, funnel-shaped, and cut into five parts at the brim. The female flowers are placed under the male in the same spike: they have no petals, but an oval germen placed in the bottom of the empalement. The germen afterward becomes an oval capsule with one cell, inclosing one roundish seed.

The Species are,

1. AMBROSIA *foliis multifidis racemis solitariis pilosis.* Lin. Sp. Plant. 988. Maritime Ambrosia.
2. AMBROSIA *foliis bipinnatifidis, racemis paniculatis terminalibus glabris.* Hort. Upsal. 284. Tall unfavoury Sea Ambrosia with Mugwort leaves.
3. AMBROSIA *foliis trilobis & quinquelobis serratis.* The largest Virginian Ambrosia, with an eastern Plane Tree leaf.
4. AMBROSIA *foliis bipinnatifidis primoribus ramulorum indivisis integerrimis.* Lin. Sp. Plant. 988. Greatest unfavoury Ambrosia of Virginia, with Water Horehound leaves, which are finely divided.

5. AMBROSIA *foliis pinnatifidis hirsutis racemis solitariis terminalibus, caule fruticoso perenne, i. e.* Ambrosia with hairy winged leaves, single spikes of flowers, growing at the extremity of the branches, and a shrubby perennial stalk.

The first sort grows naturally in the east, near the sea shore; this rises about two feet and an half high, sending out many side branches, whose leaves are divided into many parts, and upon being handled emit a strong odour. The spikes of flowers are produced from the wings of the stalks, which are long, single, and hairy. After the flowers are

past, the female flowers are succeeded by hard leafy capsules having one cell, in which is included a single round seed. This is an annual plant, which seldom perfects its seeds in *England*, unless the plants are brought forward in the spring; therefore the seeds should be sown in the autumn in a warm border, and when the plants come up in the spring, they should be transplanted into another warm border, but not in rich moist land, where they grow very luxuriantly, so do not flower till late in the season, and seldom perfect their seeds. Therefore the best method to obtain good seeds, is to plant some of the plants in pots filled with light earth mixed with lime rubbish, to prevent their luxuriant growth, which will cause them to flower early, whereby good seeds may be obtained.

The second sort grows naturally in the islands of *America*, as also in *Carolina* and *Virginia*; from the two latter countries I have frequently received the seeds. This sort grows more than three feet high, dividing into many branches; these are garnished with winged leaves, in shape like those of Mugwort; at the extremity of each branch, the loose spikes of flowers are produced, composed of one long spike in the middle, and three or four shorter lateral spikes: these have male and female flowers ranged in the same manner as the former; the female flowers are succeeded by seeds of the same shape.

This sort will come up and thrive in the open air in *England*, but the plants so raised will not produce good seeds, unless the season is warm; therefore to obtain them every year, it is necessary to sow the seeds of this plant on a moderate hot-bed in *March*, and when the plants are come up two inches high, they must be transplanted into another hot-bed, observing to water them pretty well, and shade them until they have taken new root; afterward they must have a large share of fresh air every day, when the weather is warm, and frequent waterings, for they are very thirsty plants. When the plants are grown pretty strong, they must be taken up with balls of earth to their roots, and planted in *May* abroad with other hardy annual plants, among which they will make a variety. These plants will flower in *August*, and their seeds ripen in *September*.

The third sort is a native of *North America*, where it is a very common weed. This often grows eight or ten feet high; and if it is planted in a rich moist soil, or is often watered, it will grow much higher, and spread out into many branches. The seeds of this plant, when sown in the spring, seldom come up the first year, but frequently remain in the ground until the following spring; so that when the plants do not come up, the ground must not be disturbed till after the spring following, to wait for the plants coming up. When the plants come up, some of them may be transplanted into a moist soil, allowing them at least four or five feet room every way; and if they are frequently watered in dry weather, they will grow to a large size; but their branches must be supported by stakes, otherwise they are very subject to break with strong winds. These plants are only preserved by such persons as are curious in botany, for the sake of variety.

The fourth sort grows naturally in *North America*, from whence I have frequently received the seeds. The spikes of flowers in this sort are produced from the wings of the stalks, in which this differs from the second. This may be treated in the same manner as the second sort.

The fifth sort is a native of *Peru*. It grows to the height of ten or twelve feet, with a woody stem, dividing into several branches; which are garnished with hairy leaves, composed of several winged lobes, and are placed alternately upon the branches; the spikes of flowers are single, hairy, and are produced at the extremity of the branches. The female flowers are succeeded by hairy capsules, each containing a single seed.

This is a perennial plant, and may be propagated by cuttings or seeds; if by the former, they should be planted in a shady border, in either of the summer months. In a month or five weeks they will have good roots, therefore should be then taken up and potted; for when they are left longer in the full ground, they will grow very luxuriant, so will not so soon recover their removal, as those which are transplanted earlier. The plants are hardy, so may be exposed to the open air in summer; and in the winter, if they are sheltered in a common green-house, with Myrtles and other hardy exotick plants, they will live several years.

The seeds of this sort seldom come up the same year, when they are sown in spring, but those which have fallen in the autumn, have grown the following year, and so have those which have been sown at the same season.

AMETHYSTEA. *Lin. Gen.* 32. Amethyst.

The Characters are,

The flower has one leaf, which is cut into five equal pointed segments at the brim; it hath two slender stamina, which stand under the upper lip. After the flower is past, the germen becomes four naked seeds, shut up in the empalement.

We know but one Species of this genus, viz.

AMETHYSTEA. *Hort. Upsal.* 9. Mountain upright Amethyst.

This plant is a native of the mountains in Siberia, from when the seeds were sent to the imperial garden at Peterburgh.

It is annual, and hath an upright stalk, which rises about a foot high, and toward the top puts out two or three small lateral branches; these are garnished with small trifid leaves, sawed on their edges, and of a very dark green colour; at the extremity of the branches, the flowers are produced in small umbels; these are of a fine blue colour, as are also the upper part of the branches, and the leaves immediately under the umbel; so that although the flowers are small, yet from their colour, with those of the upper part of the stalks, the plants make a pretty appearance, during their continuance in flower. If the seeds of this plant are sown in the autumn, or are permitted to scatter, the plants will come up early the following spring, and these will flower the beginning of June; but those which are sown in the spring, will not flower till July.

When the plants come up, they will require no other care but to keep them clean from weeds, and where they are too close to thin them, for they do not thrive when transplanted, therefore the seeds should be sown where they are to remain.

AMMANNIA. *Houss. Nov. Gen.*

The Characters are,

It hath a bell-shaped empalement, divided at the brim into four slender parts. The flower hath no petals; it has four slender stamina which are inserted in the empalement. The empalement afterward becomes a round capsule with four cells, which are filled with small seeds.

The Species are,

1. AMMANNIA *foliis semiamplexicaulibus, caule tetragono.* *Hort. Cliff.* 344. *i. e.* Ammannia with a square stalk, and leaves embracing it half round.

2. AMMANNIA *foliis subpetiolatis caule ramosa.* *Lin. Sp. Pl.* 120. *i. e.* Ammannia with leaves having short foot-stalks and a branching stalk.

The first grows naturally in moist places in Jamaica, from whence Dr. Housloun sent the seeds to England.

It grows about a foot high, with an upright square stalk, and long narrow leaves set in form of a triangle, whose base half surround it. They are of a pale green, and of the consistence with those of Purslane; the stalks are also succulent, and of the same colour with those of that plant. The flowers come out in whorles round the stalks, at the joints where

the leaves adhere, in clusters: and are soon succeeded by round seed vessels, which are full of small seeds.

These plants must be raised on a hot-bed in the spring, and afterward removed to another hot-bed to bring them forward; when they have acquired strength, they should be transplanted into pots filled with rich light earth, and placed under a frame, or in a glass case or stove to ripen their seeds, for the plants are too tender to thrive in the open air in this country, unless the summer proves very warm.

The second sort grows naturally in Virginia and Carolina; this is an annual plant, which rises about a foot high, with red succulent stalks, putting out side branches, which grow opposite: the flowers are produced single from the wings on the lower part of the branches. These have no beauty, so are only preserved in botanick gardens for the sake of variety. This sort will perfect its seeds in the open air, if the plants are raised on a hot-bed in the spring, and planted in a warm border.

AMMI. Bishops-weed.

The Characters are,

It is an umbelliferous plant; the flowers are difform, each having five heart-shaped petals. They have five slender stamina, and two reflexed styles, crowned with obtuse stigmas. The germen afterward becomes a small round striated fruit, composed of two seeds.

The Species are,

1. AMMI *foliis inferioribus pinnatis lanceolatis serratis, superioribus multifidis linearibus.* *Hort. Upsal.* 59. *i. e.* Common Bishops-weed.

2. AMMI *foliorum omnium lacinulis lanceolatis.* *Guett.* 2. p. 433. *i. e.* Bishops-weed with all its leaves cut in a shape of a spear.

The first sort is annual; of this there is a variety, which is mentioned by John Baubin as a distinct species, under the title of *Ammi majus foliis plurimum incisus & nonnihil crispis*; but I have frequently had this variety arise from the seeds of the former, so I have not enumerated it as a different sort.

This plant is propagated by seeds, which should be sown in the autumn, in the place where it is to remain; and in the spring, the plants should be thinned, in the same manner as is practised for Carrots, leaving them four or five inches asunder; for they will grow large and cover the ground; after this they will require no farther care, but to keep them clean from weeds. In June they will flower, and their seeds will ripen in August, which should be gathered as it ripens, otherwise it will soon scatter. These seeds are used in medicine, so may be had in plenty with this management.

The second sort is a perennial plant, which is preserved in botanick gardens for variety, but having little beauty, is rarely admitted into other gardens. It may be propagated by seeds, which should be sown in the autumn, because those sown in the spring, seldom come up the same year. It will grow in any open situation, is very hardy, and thrives best on a moist soil.

AMMI PERENNE. See Sium.

AMOMUM. *Lin. Gen. Plant.* 2. Ginger.

The Characters are,

The flower is of one leaf, divided into four parts at the brim. In the bosom of the flower is situated an oblong thick nectarium. Under the receptacle of the flower is placed the round germen, which afterward becomes an oval three-cornered seed-vessel, opening in three parts, containing several seeds.

The Species are,

1. AMOMUM *scapo nudo spicâ ovato.* *Hort. Cliff.* 3. Ginger.
2. AMOMUM *scapo nudo spicâ oblongâ obtusâ.* *Hort. Cliff.* 3. Broad-leaved wild Ginger, called Zerumbet.

The first, which is the common Ginger, is cultivated for sale in most of the islands of America, but is a native of the East-Indies, and also of some parts of the West-Indies, where

it is found growing naturally without culture. The dried roots of this sort furnish a considerable export from the *British* colonies in *America*. These roots are of great use in the kitchen, as also in medicine; and the green roots preserved as a sweetmeat, are preferable to every other sort.

The roots of this sort are jointed, and spread in the ground; these put out many green Reed-like stalks in the spring, which rise to the height of two feet and an half, with narrow leaves. The flower-stems afterward arise by the side of these, immediately from the root; these are naked, ending with an oblong scaly spike; from each of these scales is produced a single blue flower, whose petals are but little longer than the squamose covering.

The second sort grows naturally in *India*; the roots of this are much larger than those of the first, but are jointed in the same manner. The stalks grow from three, to near four feet high, with oblong leaves placed alternately. The flower-stems arise immediately from the root, these are terminated by oblong blunt scaly heads; out of each scale is produced a single white flower, whose petals extend a considerable length beyond their scaly covering.

These sorts are tender, and require a warm stove to preserve them in this country. They are easily propagated by parting of their roots; the best time for doing this is in the spring, before they put out new shoots, for they should not be transplanted in summer when they are in full vigour, nor do they succeed so well when they are removed in autumn, because they remain long after in an inactive state, and during that time, if wet comes to the roots, it often causes them to rot. When the roots are parted, they should not be divided into small pieces, especially if they are designed to have flowers, for until the roots have spread to the side of the pots, they rarely put out flower-stems, for which reason they should not be planted in very large pots.

The pots with these roots should constantly remain plunged in the tan bed, for if they are taken out and placed on shelves in the stove, their fibres frequently shrink, which often occasions the roots to decay.

With this management these sorts have multiplied greatly with me, and the common Ginger has produced roots which have weighed five or six ounces, but the others have been near a pound weight.

AMOMUM PLINII. See Solanum.

AMORIS POMUM. See Lycopersicon.

AMORPHA. *Lin. Gen. Plant.* 768. Bastard Indigo.

The Characters are,

The flower is of the butterfly kind, having an oval concave standard, but no wings or keel; this is inserted between the two upper segments of the empalement: the germen afterward becomes a reflexed moon-shaped pod, having one cell, in which are lodged two kidney-shaped seeds.

We know but one Species of this genus, viz.

AMORPHA. *Hort. Cliff.* 353. Bastard Indigo.

This shrub grows naturally in *Carolina*, where formerly the inhabitants made a coarse sort of Indigo from the young shoots, which occasioned their giving it the title of Bastard Indigo.

It rises with many irregular stems, to the height of twelve or fourteen feet, with very long winged leaves, in shape like those of the common Acacia. At the extremity of the same year's shoots, the flowers are produced in long slender spikes, which are very small, and of a deep purple colour. After the flowers are past, the germen turns to a short pod, having two kidney-shaped seeds, but these do not ripen in *England*.

This shrub is become very common in all the gardens and nurseries near *London*, where it is propagated as a flowering shrub, for the ornament of the shrubbery. It is generally propagated by laying down of the young branches, which in one year will make good roots, and may then be taken

off and planted, either in the nursery, or the places where they are designed to remain. The plants must have a sheltered situation, otherwise their branches will be broken by the winds. As these shoots are large and soft, their upper parts are generally killed by frost in winter; but they put out shoots again in plenty below the dead part, the spring following.

AMYGDALUS. *Lin. Gen. Plant.* 545. The Almond Tree.

The Characters are,

It hath a tubulous empalement of one leaf, which is cut at the brim into five obtuse segments; the flower hath five oval obtuse concave petals, which are inserted in the empalement. After the flower is past, the germen becomes an oval compressed large fruit, with a thin tough hairy covering, having a longitudinal furrow; this opens and falls away, leaving an oval compressed nut.

The Species are,

1. AMYGDALUS foliis petiolatis serratis petalis forum emarginatis. Common manured Almond Tree.

2. AMYGDALUS foliis petiolatis marginibus crenatis, corollis calyce vix longioribus. The tender-shelled Almond, commonly called *Jordan* Almond.

3. AMYGDALUS foliis lanceolatis integerrimis, argenteis perennantibus petiolo brevioribus, i. e. Almond Tree with spear-shaped silvery leaves, which are entire, and continue all winter, and very short foot-stalks.

4. AMYGDALUS foliis petiolatis serratis basi attenuatis. Dwarf Almond with single flowers.

The first is the common Almond, which is cultivated more for the beauty of its flowers, than for its fruit. There are two varieties of this, one with sweet, and the other bitter kernels, which arise from the fruit of the same tree.

The second sort is commonly known by the title of *Jordan* Almonds; the nuts of this kind are frequently brought to *England*. These have a tender shell, and a large sweet kernel. The leaves of this tree are broader, shorter, and grow much closer than those of the common sort, and their edges are crenated. The flowers are very small, and of a pale colour, inclining to white.

The third sort was found growing near *Aleppo*, from whence the fruit was sent to the duke *D'Ayen* in *France*, who raised several of the plants in his curious garden at *St. Germain*. The leaves of this tree are silvery, and very like those of the Sea Purslane. These continue great part of the year, but the flowers are small, and like those of the second sort.

The fourth sort is very common in the nurseries about *London*, and is usually sold with other flowering shrubs to adorn gardens. This sort seldom rises more than four feet high, sending out many side branches. The roots of this are very subject to put out suckers, by which it may be increased in plenty; but if these are not annually taken away, they will starve the old plants. This shrub flowers in *April*, at which time all the young shoots are covered with flowers, which are of a Peach-blossom colour, and make a fine appearance when intermixed with shrubs of the same growth.

The common Almond is cultivated in all the nurseries, and the trees are generally planted for the beauty of its flowers. These often appear in *February*, when the spring is forward, but if frost comes after, the flowers are soon destroyed, so that their beauty is of short duration, and in those seasons there are few Almonds produced; whereas, when the trees do not flower till late in *March*, they seldom fail to bear plenty of fruit, many of which will be very sweet, and fit for the table when green, but they will not keep long.

They are propagated by inoculating a bud of these trees into a Plum, Almond, or Peach stock, in the month of *July*.

The next spring, when the buds shoot, you may train them up either for standards, or suffer them to grow for half-standards, according to your own fancy. The best season for transplanting these trees, if for dry ground, is in *October*, as soon as the leaves begin to decay; but for a wet soil, *February* is much preferable; observe always to bud upon Plum stocks, for wet ground; and Almonds or Peaches, for dry.

ALMOND, the dwarf, with double flowers. See *Perfica*.

ANACAMPSEROS. See *Sedum*.

ANACARDIUM. *Lin. Gen. Plant.* 467. The Cashew Nut, or Acajou.

The Characters are,

The flower is of one leaf, and cut into five parts at the top; it hath ten slender stamina. In the center is placed a round germen, with an awl-shaped style. The germen afterward becomes a large oval fleshy fruit, having a large kidney-shaped nut growing to its apex.

We have but one Species of this genus, viz.

ANACARDIUM. *Hort. Cliff.* 161. The Cashew, or Cajou.

This grows to a considerable height in its native country, which is the *West-Indies*, but in *England* the plants are with great difficulty preserved; though by their first shoot from the seeds, they appear so strong and vigorous, as to promise a much greater progress, than they are ever seen to make here.

They are easily raised from the nuts, which are annually brought from *America* in great plenty; each of these should be planted in a small pot filled with light sandy earth, and plunged into a good hot-bed of tanners bark, being careful to prevent their having wet till the plants come up, for the nuts frequently rot with moisture. The reason for my advising the nuts to be each put in a separate pot, is, because the plants seldom live when they are transplanted. If the nuts are fresh, the plants will come up in about a month after planting; and, in two months more, the plants will be four or five inches high, with large leaves; and from this quick growth, many persons have been deceived by supposing them hardy, and that they would continue the like progress, whereas they seldom advance much farther the same year.

The plants must be constantly kept in the stove, for they are too tender to live abroad in *England*, in the warmest season of the year, nor will they thrive in a common greenhouse in summer. As these plants abound with a milky acrid juice, so they should have but little water, even in summer; and in winter, if they are sparingly watered once in a month, it will be sufficient, for their roots are tender and soon perish with moisture.

The pulpy fruit, to whose apex this nut grows, is as large as an orange, and is full of an acid juice, which is frequently mixed in the making of punch in *America*. Many of these fruit have been brought to *England*, in casks of rum for the same purpose.

The nut is of the size and shape of a hare's kidney, but is much larger at the end which is next the fruit, than at the other. The shell contains an inflammable oil, which is very caustick; this will raise blisters on the skin, and has often been very troublesome to those who have incautiously put the nuts into their mouths to break the shell.

The milky juice of this tree will stain linen of a deep black, which cannot be washed out again; but whether this has the same property with that of the eastern *Anacardium*, has not yet been fully experimented, for the inspissated juice of that tree is the best sort of black, which is used for staining of black in *China* and *Japan*.

ANACYCLUS. Is a sort of Camomile of little beauty and no use, so is seldom kept in any but gardens of botany, and not worthy to be mentioned here.

ANAGALLIS. Pimpernel.

The Characters are,

The flower hath an empalement which is cut into five sharp segments. The flower is of one leaf spread open, and cut into five parts. The germen afterward becomes a globular vessel with one cell, opening horizontally, in which are lodged several angular seeds.

The Species are,

1. ANAGALLIS foliis indivisis caule procumbente. *Lin. Gen. Plant.* 148. Common Pimpernel with a red flower.

2. ANAGALLIS foliis indivisis glaucis caule procumbente flore cœruleo. Female Pimpernel with a blue flower.

3. ANAGALLIS foliis indivisis caule erecto. *Lin. Sp. Plant.* 148. Narrow-leaved Pimpernel with a blue flower.

4. ANAGALLIS foliis cordatis amplexicaulibus, caulibus compressis. *Lin. Sp. Plant.* 149. Broad-leaved Spanish Pimpernel with a blue flower.

The first sort is very common in corn fields, and other cultivated places, in most parts of *England*. The second sort is sometimes found wild in the fields, but is less common than the first in *England*. There is a variety of this with a deeper blue flower, whose seeds I received from *Nice*, and this hath retained its colour for three years, during which time I have sown it in the *Chelsea* garden.

These are all annual plants, except the third sort, which arise from seeds, and, if suffered to remain till their seeds scatter, will become weeds in the place; so that they are never cultivated, except in botanick gardens for variety. The first and second sorts are directed by the *College of Physicians* for medicinal use.

ANAGYRIS. Stinking Bean-trefoil.

The Characters are,

The flower is of the butterfly kind, the standard is heart-shaped, and much longer than the empalement; the wings are oblong, plain, and longer than the standard; as is also the keel. The germen afterward becomes a large oblong pod, in which are lodged several kidney-shaped seeds.

We have but one Species in *England*, viz.

ANAGYRIS foliis ovatis floribus lateralibus. Stinking Bean-trefoil with oval leaves, and flowers proceeding from the wings of the stalks.

This sort grows wild in the south of *France*, as also in *Spain* and *Italy*. It is a shrub which usually rises to the height of eight or ten feet, and produces its flowers in *April* and *May*, which are of a bright yellow colour, growing in spikes, somewhat like those of the *Laburnum*.

It may be propagated by laying down their tender branches in the spring, observing in dry weather to supply them with water; which if duly performed, the layers will have taken root by the following spring, when they should be cut off from the old plants, a little time before they begin to put out their leaves, and planted in a warm situation; for if they are too much exposed to cold winds, they will be in danger of being destroyed in a hard winter. This method of propagating these plants, is to supply their defect in not producing ripe seeds in this country; for the plants which are produced from seeds, will be much handsomer, and will rise to a much greater height.

If you propagate this plant from seeds, you should sow them in pots filled with light fresh earth, toward the end of *March*, and plunge the pots into a gentle hot-bed. If the seeds are good, the plants will appear in a month after they are sown; as the plants advance they should be inured to the open air, that they may be hardened before the following winter. In the autumn the pots should be placed in a hot-bed frame, to screen the plants from hard frosts, and the following spring they should be each transplanted into a separate small pot, and placed in a sheltered situation in summer, and the autumn following removed again into a frame,

frame, to shelter them in winter. The second spring after the plants come up, some of them may be shaken out of the pots, and planted in a border near a south wall, where they may remain for good.

ANANAS, the Pine-apple.

The Characters are,

The flower consists of three oval petals; these are produced from the protuberances of the pyramidal fruit. The germen is situated below the flower, which afterwards becomes a cell, in which is lodged several angular seeds.

The Varieties of this are,

1. ANANAS aculeatus, fructu ovato, carne albida. Plum. Oval-shaped Pine-apple, with a whitish flesh.

2. ANANAS aculeatus, fructu pyramidato, carne aurea. Plum. Pyramidal Pine-apple, with a yellowish flesh, called the Sugar-loaf Pine.

3. ANANAS folio vix serrato. Boerb. Ind. Alt. 2. 83. Pine-apple with smooth leaves.

4. ANANAS lucidè virens, folio vix serrato. Hort. Elth. Pine-apple with shining green leaves, and scarce any spines on their edges.

5. ANANAS fructu pyramidato olivæ colore, intus aureo. Pyramidal olive-coloured Pine-apple, with a yellow flesh.

6. ANANAS aculeatus, fructu pyramidato ex viridi flavescente. The green Pine-apple.

There are some other varieties of this fruit, which may have been obtained from seeds; and I doubt not but if the seeds were sown frequently, in the countries where they are in plenty, there may be as great variety of these fruit, as there are of apples or pears in Europe. And this I have found true by some trials which I have made by sowing of the seeds, which have always produced a variety of sorts from those of the same fruit.

The first sort is the most common in Europe; but the second sort is much preferable to it, the fruit of this being larger, and much better flavoured: the juice of this sort is not so astringent as that of the first, so that this fruit may be eaten in greater quantity, with less danger. This sort frequently produces suckers, immediately under the fruit, whereby it may be increased much faster than the common sort; so that in a few years, it may be the most common sort in England.

The third sort is preserved by some curious persons for the sake of variety, but the fruit is not worth any thing.

The sort with very smooth grass-green leaves, was raised from seeds taken out of a rotten fruit, which came from the West-Indies to the late Henry Heathcote, Esq; from whom I received one plant, which hath produced large fruit: this, I am told, is what the people of America call the King Pine. I have since raised some plants of this kind from seeds, which were brought me from Jamaica.

The plants are propagated by planting the crowns which grow on the fruit, or the suckers which are produced either from the sides of the plants, or under the fruit, both which I have found to be equally good; although by some persons the crown is thought preferable to the suckers, as supposing it will produce fruit sooner than the suckers, which is certainly a mistake; for by constant experience I find the suckers (if equally strong) will fruit as soon, and produce as large fruit as the crowns, if not better.

The suckers and crowns must be laid to dry in a warm place for four or five days, or more (according to the moisture of the part which adhered to the old plant or fruit); for if they are immediately planted, they will rot. The certain rule of judging when they are fit to plant, is by observing if the bottom is healed over, and become hard; for if the suckers are drawn off carefully from the old plants, they will have a hard skin over the lower part, so need not lie so long as the crowns, or those whose bottoms are moist. But when-

ever a crown is taken from the fruit, or the suckers from old plants, they should be immediately divested of their bottom leaves, so high as to allow depth for their planting; so that they may be thoroughly dry and healed in every part, lest when they receive heat and moisture, they should perish, which often happens when this method is not observed. If these suckers or crowns are taken off late in the autumn, or during the winter, or early in the spring, they should be laid in a dry place in the stove, for a fortnight or three weeks before they are planted, but in the summer season they will be fit for planting in a week at farthest.

As to the earth in which these should be planted, if you have a rich good kitchen garden mould, not too heavy, so as to detain the moisture too long, nor over light and sandy, it will be very proper for them without any mixture: but where this is wanting, you should procure some fresh earth from a good pasture; which should be mixed with about a third part of rotten neats dung, or the dung of an old melon or cucumber bed, which is well consumed. These should be mixed six or eight months at least before they are used; but if it be a year, it will be the better; and should be often turned, that their parts may be the better united, as also the clods well broken. This earth should not be screened very fine, for if you only clear it of the great stones, it will be better for the plants than when it is made too fine. You should always avoid mixing any sand with the earth, unless it be extremely stiff, and then it will be necessary to have it mixed at least six months or a year before it is used; and it must be frequently turned, that the sand may be incorporated in the earth, so as to divide its parts: but you should not put more than a sixth part of sand, for too much sand is very injurious to these plants.

In the summer season, when the weather is warm, these plants must be frequently watered, but you should not give them large quantities at a time: you must also be very careful, that the moisture is not detained in the pots, by the holes being stopped, for that will soon destroy the plants. If the season is warm, they should be watered twice a week; but in a cool season, once a week will be often enough: and during the summer season, you should once a week water them gently all over their leaves, which will wash the filth from off them, and thereby greatly promote the growth of the plants.

There are some persons who frequently shift these plants from pot to pot, but this is by no means to be practised by those who propose to have large well flavoured fruit; for unless the pots be filled with the roots, by the time the plants begin to shew their fruit, they commonly produce small fruit, which have generally large crowns on them, therefore the plants will not require to be new potted oftener than twice in a season: the first time should be about the end of April, when the suckers and crowns of the former year's fruit (which remained all the winter in those pots in which they were first planted) should be shifted into larger pots, *i. e.* those which were in halfpenny, or three-farthing pots, should be put into penny, or at most three halfpenny pots, according to the size of the plants; for you must be very careful not to overpot them, nothing being more prejudicial to these plants. The second time for shifting of them is in the beginning of August, when you should shift those plants which are of a proper size for fruiting the following spring, into two-penny pots, which are full large enough for any of these plants. At each of these times of shifting the plants, the bark-bed should be stirred up, and some new bark added, to raise the bed up to the height it was at first made; and when the pots are plunged again into the bark-bed, the plants should be watered gently all over their leaves, to wash off the filth, and to settle the earth to the roots of the plants. If the bark-bed be well stirred,

stirred,

stirred, and a quantity of good fresh bark added to the bed, at this latter shifting it will be of great service to the plants; for they may remain in the same tan until the beginning of *November*, or sometimes later, according to the mildness of the season, and will require but little fire before that time. During the winter season these plants will not require to be watered oftener than once a week, according as you find the earth in the pots to dry: nor should you give them too much at each time, for it is much better to give them a little water often, than to over-water them.

You must observe never to shift those plants which show their fruit, into other pots; for if they are removed after the fruit appears, it will stop the growth, and thereby cause the fruit to be smaller, and retard its ripening, so that many times it will be *October* or *November* before the fruit is ripe; therefore you should be very careful to keep the plants in a vigorous growing state, from the first appearance of the fruit, because upon this depends the goodness of the size of the fruit; for if they receive a check after this, the fruit is generally small and ill tasted.

When you have cut off the fruit from the plants, whose kind you are desirous to propagate, you should trim the leaves, and plunge the pots again into a moderate hot-bed, observing to refresh them frequently with water, which will cause them to put out suckers in plenty; so that a person may be soon supplied with plants enough of any of the kinds, who will but observe to keep the plants in health.

There is not any thing which can happen to these plants of a more dangerous nature, than to have them attacked by small white insects, which appear at first like a white mildew, but soon after have the appearance of lice: these attack both root and leaves at the same time, and if they are not soon destroyed, will spread over a whole stove in a short time; and in a few weeks will entirely stop the growth of the plants, by sucking out the nutritious juice, so that the leaves will appear yellow and sickly, and have generally a great number of yellow transparent spots all over them. These insects, after they are fully grown, appear like bugs, and adhere so closely to the leaves, as not to be easily washed off, and seem to have no local motion. They were originally brought from *America* upon the plants which were imported from thence, and I believe they are the same insects which have destroyed the sugar canes of late in some of the *Leeward Islands*; for upon some sugar canes which were sent me from *Barbadoes* there were great numbers of the same insects. Since they have been in *England*, they have spread greatly in such stoves, where there has not been more than ordinary care taken to destroy them. They have also attacked the Orange trees in many gardens near *London*, and have done them incredible damage; but I do not find they will endure the cold of our climate in winter, so that they are never found on such plants as live in the open air. The only method I have yet been able to discover for destroying these insects, is by washing the leaves, branches, and stems, of such plants as they attack, frequently with water, in which there has been a strong infusion of tobacco stalks, which I find will destroy the insects, and not prejudice the plants. But this method cannot be practised on the *Ananas* plants, because the insects will fasten themselves so low between the leaves, that it is impossible to come at them with a sponge to wash them off; so that if all those which appear to sight are cleared off, they will soon be succeeded by a fresh supply from below, and the roots will be also equally infested at the same time. Therefore, whenever these insects appear on the plants, the safest method will be, to take the plants out of the pots, and clear the earth from the roots; then prepare a large tub, which should be filled with water, in which there has been a strong infusion of tobacco stalks; into this tub you should put the

plants, placing some sticks cross the tub, to keep the plants immersed in water. In this water they should remain twenty-four hours; then take them out, and with a sponge wash off all the insects from the leaves and roots, which may be easily effected when the insects are killed by infusion; then cut off all the small fibres of the roots, and dip the plants into a tub of fair water, washing them therein, which is the most effectual way to clear them from the insects. After which you should pot them in fresh earth, and having stirred up the bark-bed, and added some new tan to give a fresh heat to the bed, the pots should be plunged again, observing to water them all over the leaves (as was before directed) and this should be repeated once a week during the summer season; for I observe these insects always multiply much faster where the plants are kept dry, than in such places where the plants are sometimes sprinkled over with water, and kept in a growing state.

As these insects are frequently brought over from *America* on the *Ananas* plants which come from thence, those persons who procure their plants from thence, should look carefully over them when they receive them, to see they have none of these insects on them; for if they have, they will soon be propagated over all the plants in the stove where these are placed: therefore, whenever they are observed, the plants should be soaked (as before directed) before they are planted into pots.

The stoves which are erected for preserving of these plants are built in different ways, according to the fancy of the contriver. Some persons build them with upright glasses in front, about four feet high, and sloping glasses over these, which rise about six feet high, so that there is just height enough for persons to walk upright on the back-side of the bark-bed. Others make but one slope of glasses, from the top of the stove down to the plate, which lies about six or eight inches above the bark pit, in the front of the stove; so that in this stove, there is no walk made in the front between the bark pit and the glasses; but the inconveniency of watering the plants, as also of coming near those plants which are placed in the front of the stove to clean them, has, in some measure, brought them into disesteem, so that few persons now build them, though the expence is much less than of the other kind of stoves; but of both these stoves, the figures and descriptions which are hereafter exhibited under the article of *STOVE*, will be sufficient for any person to build either of the sorts. One of these stoves about twenty-five feet long in the clear, with the pit for the tan reaching from end to end, and six feet and an half wide, will contain about an hundred plants; so that whoever is desirous to have this fruit, may easily proportion their stove to the quantity of fruit which they are willing to have.

But it will be also necessary to have a bark pit under a deep frame, in order to raise the young plants in summer; for in this bed you should plunge the suckers, when they are taken from the old plants, as also the crowns which come from the fruit, so that this frame will be as a nursery to raise the young plants to supply the stove: but these plants should not remain in these frames longer than till the beginning of *November*, unless the frame is built with brick-work with flues in it to warm the air (in the manner hereafter described and figured), which are very useful, as nurseries, to keep the young plants till they are of a proper size to produce fruit; and the air in this frame may be kept either warmer or cooler than the stove, according as the plants may require, so that the stove may be every autumn filled only with bearing plants, whereby a much greater quantity of fruit may be annually produced, than can be where young and old plants must be crowded
into

into the same stove: but where there are no conveniencies of this kind, the young plants, about the middle or latter end of *October*, must be removed into the stove, and being small, may be crowded in among the larger plants; for as they will not grow much during the winter season, so they may be placed very close together. The end of *March*, where there is no nursery for the young plants, they must be removed out into the hot bed again, which should be prepared a fortnight before, that the tan may have acquired a proper heat: but you should be careful that the tan be not too hot, for that might scald the fibres of the plants, if they are suddenly plunged therein. Therefore if you find the bark too hot, you should not plunge the pots above two or three inches into the tan, letting them remain so until the heat of the tan is a little abated, when you should plunge the pots down to their rims in the bed. If the nights should continue cold after these plants are removed into the bed, you must carefully cover the glasses with mats; otherwise by coming out of a warm stove, they may receive a sudden check, which will greatly retard their growth, which must be carefully avoided; because the sooner the plants are set growing in the spring, the more time they will have to gain strength, in order to produce large fruit the following season.

You should not plunge the pots too close together in this frame, but allow them a proper distance, that the lower part of the plants may increase in bulk, for it is on this that the magnitude of the fruit depends; because when the plants are placed too close, they draw up very tall, but do not obtain strength; so that when they are taken out of the bed, the leaves are not able to support themselves; but all the outward long leaves will fall down, leaving the smaller middle leaves naked, and this sometimes will cause them to rot in the centre. You must also observe, when the sun is very warm, to raise the glasses of the hot-bed in the heat of the day with props, in order to let out the steam of the bed, and to admit fresh air; for one neglect of this kind, in a very hot day, may destroy all the plants, or at least so scald them, that they will not get over it in many months. It will be also very proper, in extreme hot weather, to shade the glasses in the middle of the day with mats; for the glasses, lying so near to the leaves of the plants, will occasion a prodigious heat at such times.

There are some persons who regulate the heat of their stoves by thermometers in summer, but at that season this is unnecessary, for the outward air in hot weather is frequently greater than the Ananas heat marked on the thermometers, so that the heat of the stoves at that season will be much greater. The use of the thermometer is only in winter, during the time the fires are continued, by which it is easy to judge when to increase or diminish the fires; for at that season, the stoves should not be kept to a greater warmth than five or six divisions above Ananas, nor suffered to be more than as many divisions below it. When the plants are placed into the tan for the winter season (which should be done about the middle of *October*), the tan bed should be renewed, adding two thirds of new tan, to one third of the old. If this be well mixed, and the new tan is good, the bed will maintain a proper degree of warmth till *February*, at which time it will be proper to stir up the bed, and add a load or two of new tan, so as to raise the bed as much as it sunk since the autumn; this will give a fresh heat to the bed, and keep the plants growing; and, as the fruit will now begin to appear, it will be absolutely necessary to keep the plants in a growing state, otherwise the fruit will not be large; for if they receive any check at this time, it will greatly injure them.

In *April* it will be proper to stir up the tan again, and if the bed has sunk since the last stirring, it will be proper to

add some fresh tan to it; this will renew the warmth of the bed, and forward the fruit. And if the tan bed is constantly kept in a good temper, and a sufficient quantity of air admitted every day to the plants, they will succeed much better than in a cool bed kept too close.

Those plants which shew their fruit early in *February*, will ripen about *June*; some sorts are at least a month or five weeks longer in ripening their fruit than others, from the time of the appearance of the fruit: but the season in which the fruit is in greatest perfection is from the beginning of *June* to the end of *September*; though in *March*, *April*, and *October*, I have frequently eaten this fruit in pretty good perfection; but then the plants have been in perfect health, otherwise they are seldom well flavoured.

The method of judging when the fruit is ripe, is by the smell, and from observation; for as the several sorts differ from each other in the colour of their fruit, that will not be any direction when to cut them; for should they remain so long as to become soft to the touch before they are cut, they become flat and dead, as they do also when they are cut long before they are eaten: therefore the surest way to have this fruit in perfection, is to cut it the same day it is eaten: but it must be cut early in the morning, before the sun has heated the fruit, otherwise it will be hot, observing to cut the stalk as long to the fruit as possible, and lay it in a cool, but dry place, preserving the stalk and crown unto it, until it is eaten.

That sort with green fruit, if suffered to ripen well, is of an olive colour; but there are some persons who cut them before they are ripe, when they are not fit to be eaten, for no other reason, but to have them green: and although many persons have much recommended this sort for its excellent flavour, yet I think the sugar loaf sort is to be preferred to it.

ANAPODOPHYLLON. See Podophyllum.

ANASTATICA. *Lin. Gen. Plant.* 175. (Rose of *Jericho*.)

The Characters are,

The flowers hath four roundish petals placed in form of a cross. The seed vessel in this is blunt-pointed, bordered, and crowned, and the valves open oblique to the style.

We know but one Species of this genus, viz.

ANASTATICA. *Hort. Cliff.* 328. Rose of *Jericho*.

This plant grows naturally on the sands near the borders of the *Red Sea*, and in many parts of *Syria*. It is a low annual plant, dividing into many irregular woody branches near the root; at each joint is placed a single, oblong, hoary loaf, and at the same places come out small single flowers of a whitish green colour, composed of four small leaves, placed in form of a cross, like the other plants of this class. These are succeeded by short wrinkled pods, having four small horns; these open into two cells, in each of which is lodged a single brown seed.

It hath had the epithet of *Rosa Mariae* given to it by the monks, who have superstitiously supposed that the flowers open on the night that our Saviour was born. But the truth is, that the dry woody plant being set for some time in water, will dilate and open so as to disclose the seed vessels and seeds. This I have seen done when the plants have been many years gathered, so that there are several curious persons who preserve them in their repositories of curiosities, for the singularity of this property.

This plant is propagated by seeds, which should be sown the beginning of *April*, on a border of light sandy earth, where it is designed to remain, for it will not bear transplanting. When the plants come up, they should be thinned, leaving them about six inches distant from each other, and observe to keep them clean from weeds, this is all the care they require. If the season proves favourable, the plants

plants will flower in *August*, but unless the autumn proves warm and dry, they will not ripen their seeds in *England*; nor could I rarely procure seeds from those plants which were raised in autumn, for if much rain happens when the plants are in flower, they never perfect any seeds.

ANCHUSA. *Lin. Gen.* 167.

The Characters are,

The flower is of one leaf, having a cylindrical tube; at the brim it is cut into five obtuse segments, which spread open. The germen afterward becomes four oblong blunt seeds shut up in the empalement.

The Species are,

1. ANCHUSA foliis lanceolatis birsutis, floribus capitatis axillaribus pedunculis longissimis. The greater Garden Bugloss.

2. ANCHUSA racemis subnudis conjugatis. *Prod. Leyd.* 408. Perennial wild Borage with a Carmine flower.

3. ANCHUSA strigosa foliis linearibus dentatis pedicellis bractea minoribus calycibus fructiferis inflatis. *Læf. Lin. Sp. Plant.* 133. Portugal Bugloss with a waving Viper's Bugloss leaf.

4. ANCHUSA ramis floribusque alternis axillaribus bracteis ovatis. *Lin. Sp. Plant.* 133. Eastern Bugloss with a yellow flower.

5. ANCHUSA floribus sparsis caule glabro. *Lin. Sp. Plant.* 133. Small yellow Alkanet of *Virginia*, called by the inhabitants *Puccoon*.

6. ANCHUSA pedunculis diphyllis capitatis. *Lin. Sp. Plant.* 134. Broad-leaved Ever green Borage.

7. ANCHUSA foliis lanceolatis verrucosis semiamplexicaulis, floribus capitatis, caule procumbente. Warty Bugloss of *Crete*.

8. ANCHUSA foliis lanceolatis spicis imbricatis secundis. *Hort. Cliff.* 46. Greater *Candia* Bugloss with a purplish blue flower.

9. ANCHUSA foliis longis birsutis, floribus capitatis reflexis, pedunculis longissimis. Wild *Cretan* Borage with an azure flower.

The first sort is the Bugloss, whose flowers are ordered to be used in medicine.

The roots of this sort seldom continue longer than two years, especially in good ground, for they are subject to rot in winter, unless when they happen to grow in rubbish, or out of an old wall, where they will live three or four years; for in such places the plants are stunted in their growth, so their branches are firmer and not so full of juice as those which grow in better soil. The plants may be easily propagated by seeds, which may be sown either in the spring or autumn, upon a bed of light sandy earth; and when the plants are strong enough to remove, they should be planted into beds at two feet distance, observing, if the season proves dry, to water them till they have taken root, after which time they will require no farther care but to keep them clean from weeds. The plants which come up in the autumn, will flower the following *June*, and ripen their seeds in *August*; but those which are sown in the spring, do not often flower the same year, or if they do, it is late in the season, so will not ripen their seeds. If the seeds of this plant are permitted to scatter, the plants will rise in plenty, which may be managed in the manner before directed.

The second sort grows to the height of two feet when cultivated in gardens, but in the places where it grows wild, is rarely more than a foot and an half high. The leaves of this are narrow, and less hairy than those of the first; the spikes of flowers come out double, and have no leaves about them; the flowers are small, and of a red colour. The roots will continue two years in poor land.

The third sort is a biennial plant, which perishes soon after the seeds are ripe. This grows two feet high, and sends out many lateral branches. The flowers are of a bright blue colour, and grow in an imbricated spike; and after these fall, the empalement turns to a swollen vessel inclosing the seeds.

The fourth sort is a perennial plant, with long trailing branches which lie on the ground. The flowers are yellow, and about the size of the common Bugloss; and there is a succession of these on the same plants great part of the year. This, though a native of the *Levant*, is hardy enough to live in the open air in *England*, if it hath a dry sandy soil. It may be propagated by seeds in the same manner as the first sort, and if the seeds are permitted to scatter, the plants will rise without care, and will continue several years.

The fifth sort is a native of *North America*, where it grows naturally in the woods, and being an early plant, generally flowers before the new leaves come out on the trees; so that in some of the woods, where this plant abounds, the surface of the ground seems covered with its bright yellow flowers. It is known in that country by the title of *Puccoon*. It is a perennial plant, which seldom rises a foot high in good ground, but not above half that height, where the soil is poor; the flowers grow in loose spikes, upon a smooth stalk. This is propagated by seeds, which if sown in the spring, seldom grow the first year.

The sixth sort is a very hardy perennial plant, with weak trailing branches; the flowers are blue, and come out between the leaves on the spike, like the fourth sort; the plants frequently grow out of the joints of old walls, in those places where any of the plants have been near; for when the seeds are permitted to scatter, there will be an abundant supply of the plants. These flower great part of the year.

The seventh sort is a low trailing annual plant, whose branches seldom extend more than six inches. The flowers are small, of a bright blue colour, and are collected into small bunches at the extremity of the branches. The plants perish soon after their seeds are ripe, which if permitted to scatter, the plants will come up better than when they are sown.

The eighth sort rises near as high as the first, to which it bears great resemblance in its leaves and branches; but the flowers grow on long spikes coming out imbricatum, like the tiles on a house, in which it differs from that. It grows naturally in the *Levant*, but is equally hardy with the first species, and may be cultivated in the same manner.

The ninth sort is a perennial plant, with broad rough leaves, like those of the sixth; the branches grow more erect, and the flowers which are of a bright azure colour, are collected into spikes, coming out singly from between the leaves. This is a hardy plant, and may be propagated in the same manner as the other sorts.

ANCHUSA RADICE RUBRA. See *Lithospermum*.

ANDRACHNE. Bastard Orpine.

The Characters are,

There are male and female flowers on the same plant. The male flower hath a five-leaved empalement. The flower has five slender petals. It hath five slender stamens. The female flowers come out from the wings of the stalk near the male. These have a five-leaved empalement, but no petals; it has three slender styles which are inserted in the rudiment, and a globular capsule having three cells, in each of which are lodged two triangular obtuse seeds.

We have but one Species of this genus, viz.

ANDRACHNE procumbens herbacea. *Lin. Sp. Plant.* 1014. Bastard Orpine with trailing branches and a white flower.

This is a low plant, whose branches trail upon the ground. The leaves are small, of an oval shape, smooth, and of a sea-green colour. It is found wild in some parts of *Italy*, and in the *Archipelago*; and being a plant of no great beauty, it is seldom cultivated but in botanick gardens for variety. If the seeds of this plant are sown on a bed of common earth in the autumn, soon after they are ripe, the plants

plants will come up the spring following, and produce flowers and seeds; but if it is sown in the spring, the seeds will often remain in the ground until the next year, before they come up. It should be sown where it is designed to remain; and will require no other culture, but to keep the plants clear from weeds. It should have a light dry soil and a warm situation; this seldom continues longer than two years.

ANDROMEDA. *Lin. Gen. Plant.* 485. We have no *English* name for this plant.

The *Characters* are,

The empalement of the flower is cut into five small acute segments. The flower is of one leaf, is oval and bell-shaped, and divided into five parts at the brim, which are reflexed. It hath ten stamina. The germen afterward turns to a round pentagonal vessel having five cells, which are filled with small round seeds.

The *Species* are,

1. ANDROMEDA *pedunculis aggregatis, corollis ovatis, foliis alternis lanceolatis revolutis.* *Lin. Sp. Plant.* 393. *i. e.* Andromeda with aggregate foot-stalks, oval petals, and spear-shaped leaves growing alternately.

2. ANDROMEDA *pedunculis aggregatis corollis cylindricis foliis alternis ovatis integerrimis.* *Lin. Sp. Plant.* 393. Andromeda with aggregate foot-stalks, cylindrical flowers, and oval entire leaves placed alternately.

3. ANDROMEDA *racemis fecundis nudis paniculatis, corollis subcylindricis foliis alternis oblongis crenulatis.* *Lin. Sp. Pl.* 394. Andromeda with naked fruitful loose spikes, cylindrical flowers, and oblong crenated leaves placed alternately.

4. ANDROMEDA *racemis fecundis nudis, corollis rotundo-ovatis.* *Lin. Sp. Plant.* 394. Andromeda with naked fruitful spikes, and oval roundish flowers; commonly called Sorrel Tree in *Carolina*.

5. ANDROMEDA *racemis fecundis foliaceis corollis subcylindricis, foliis alternis lanceolatis obtusis punctatis.* *Lin. Sp. Pl.* 394. Andromeda with leafy fruitful spikes, cylindrical flowers, and obtuse spear-shaped leaves, with punctures placed alternately.

The first sort is a low plant which grows naturally on bogs in the northern countries, but is with difficulty preserved in gardens; and having little beauty, is seldom cultivated except in botanick gardens. I received the seeds from *Petersburgh*, which came up in the *Chelsea* garden, but did not continue more than one year.

The second sort grows naturally in *North America*: this is a low shrub, which sends out many woody stalks from the root, which are garnished with oval leaves placed alternately; the flowers are collected in small bunches: these are shaped like those of the Strawberry tree, and are of an herbaceous colour. They appear in *June* and *July*.

The third sort is also a native of *North America*. This shrub grows about four feet high, sending out several branches, which are clothed with oblong leaves placed alternately; the flowers grow in loose spikes from the ends of the branches; these are of the pitcher-shape, like those of the *Arbutus*, but are a little longer. They appear in *July*.

The fourth sort grows naturally in *Virginia* and *Carolina*; in the latter it is much larger than in the former, the climate being warmer; so many of the trees and shrubs grow to a much greater height there. In *Virginia*, this is a shrub growing ten or twelve feet high, but in *Carolina* it rises twenty feet. The flowers grow in long naked spikes, coming out from the sides of the branches, which are of an herbaceous colour, and are ranged on one side of the stalk; they are oval, and shaped like a pitcher.

The fifth sort grows naturally in *Siberia*, and also in *North America*; it is a low shrub which grows on mossy land, so is very difficult to keep in gardens. The leaves are shaped

like those of the Box tree, and are of the like consistence, having several small punctures on them; the flowers grow in short spikes from the extremity of the branches: these are produced single between two leaves, they are white, and of a cylindrical pitcher-shape.

All the sorts, except the fourth, are very hardy plants, which delight in moist ground; they increase by their creeping roots, which put up suckers at a distance, and may be taken off with roots, and transplanted where they are designed to remain, for they do not bear to be often removed.

The fourth sort requires to be sheltered from hard frost in winter, but in the summer should be frequently watered. It is a difficult plant to keep in gardens, as it grows naturally on boggy places, and requires a greater heat than that of this climate. It may be propagated by seeds, which should be procured from *America*, where it is known by the name of Sorrel tree.

ANDROSACE. We have no *English* name for this plant.

The *Characters* are,

The flowers grow in an umbel set in an involucre; the flower is of one leaf, having an oval tube, inclosed by the empalement, and is divided into five parts. It hath five small stamina within the tube; the empalement afterward becomes a round capsule of one cell, which is full of round seeds.

The *Species* are,

1. ANDROSACE *perianthiis maximis.* *Hort. Upsal.* 36. Common broad-leaved annual Androsace.

2. ANDROSACE *foliis lanceolatis dentatis glabris perianthiis angulatis corollâ brevioribus.* *Flor. Suec.* 160. Spring Chickweed with heads like Androsace.

3. ANDROSACE *foliis pilosis perianthiis hirsutis.* *Lin. Sp. Plant.* 142. Hairy Housleek of the *Alps* with a milk white flower.

The first sort grows naturally in *Austria* and *Bohemia* amongst the corn: this hath broad leaves which spread near the ground, from the center of these the foot-stalks arise, which are terminated by the umbel of flowers, like those of the *Auricula*; under the umbel of flowers is a large empalement, which is permanent; the flowers are composed of five small white petals; these appear in *April* and *May*, and the seeds ripen in *June*, and the plants soon after perish.

The other sorts are much smaller than this, some of them seldom growing more than three inches high, and have very small flowers, so make little appearance. They grow naturally on the *Alps* and *Helvetian* mountains, as also in *Siberia*, from whence I have received the seeds of three or four species. These are only preserved in botanick gardens for the sake of variety, and all the sorts except the first should have a shady situation.

The seeds of these sorts should be sown soon after they are ripe, otherwise they seldom grow the same year. Their seeds are ripe the end of *May*; which, if permitted to scatter, will come up, and often succeed better than those which are sown.

ANDROSÆMUM. See *Hypericum*.

ANDRYALA. *Lin. Gen. Plant.* 820. Downy Sowthistle.

The *Characters* are,

It hath a short round hairy empalement; the flowers are composed of many hermaphrodite flowers, which are uniform, and are of one leaf, stretched out like a tongue on one side. The germen is situated at the bottom of each floret. The germen afterward becomes a single oval seed, crowned with down.

The *Species* are,

1. ANDRYALA *foliis integris.* *Guett. Hort. Upsal.* 240. Downy Sowthistle with whole leaves.

2. ANDRYALA *foliis dentato-basistatis.* *Lin. Sp. Pl.* 808. Downy Sowthistle with indented spear-shaped leaves.

The first is an annual plant, which grows naturally in the south of *France*, *Spain*, and *Italy*, and is preserved in botanick gardens for the sake of variety. This grows one foot and an half high, with woolly branching stalks. The flowers are produced in small clusters at the top of the stalks, which are yellow, and like those of the Sowthistle, so do not make any great appearance. It is easily raised by seeds, which should be sown in the spring, in the place where the plants are to remain, and will require no other culture but to thin them where they are too close, and keep them clean from weeds. It flowers in *July*, and the seeds ripen in *September*.

The second is a perennial plant, which grows naturally in *Spain*, from whence I received the seeds, as I have also from the *Cape of Good Hope*. The leaves of this plant are extremely white, and are much indented on their edges; the flower-stalks grow about a foot high, having small clusters of yellow flowers, which appear in *July*; the seeds sometimes ripen in *England*, but not every year. They love a light dry soil, in which they will live in the open air in this country.

ANEMONE. Wind-flower.

The Characters are,

The flower is naked having no empalement, and consists of two or three orders of leaves or petals, which are oblong, and disposed in three series over each other. It hath many germen collected into a head, which afterward become so many seeds inclosed with a down which adhere to the foot-stalk, and form an obtuse cone.

The Species are,

1. ANEMONE *pedunculo nudo seminibus subrotundis hirsutis*. *Lin. Sp. Pl.* 540. Wild Anemone with a large white flower.
2. ANEMONE *seminibus acutis foliolis incisus caule unifloro*. *Hort. Cliff.* 224. Wild or Wood Anemone with a large flower.
3. ANEMONE *seminibus acutis foliolis incisus petalis lanceolatis numerosis*. *Lin. Sp. Plant.* 541. Wood Anemone with a blue flower.
4. ANEMONE *pedunculis alternis longissimis fructibus cylindricis seminibus hirsutis*. *Lin. Sp. Plant.* 540. Small white flowering *Virginia Anemone*.
5. ANEMONE *foliis radicalibus ternato-decompositis, involucri foliis*. *Lin. Sp. Plant.* 539. Narrow-leaved Anemone with a single flower.
6. ANEMONE *foliis digitatis*. *Lin. Sp. Plant.* 540. Broad-leaved Garden Anemone.

The first sort grows naturally in many parts of *Germany*; this approaches near to our wood Anemone, but the seeds of it are round and hairy; the flower is large and white, but having little beauty, is seldom planted in gardens.

The second sort grows wild in the woods in many parts of *England*, where it flowers in *April* and *May*, making a pretty appearance in those places where they are in plenty. The roots of this may be taken up when their leaves decay, and transplanted in wildernesses, where they will thrive and increase greatly, if they are not disturbed; and in the spring, before the trees are covered with leaves, they will have a very good effect, in covering of the ground and making a pleasing variety at that season.

The third sort is found growing naturally in some parts of *England*, but particularly at *Wimbledon* in *Surrey*, in a wood near the mansion-house, in great plenty; but it is not certain that they were not originally planted there, as they are not found in any other place in that neighbourhood.

The fourth sort grows naturally in *North America*, from whence the seeds are frequently sent to *England*. This is a very hardy plant, and produces plenty of seeds in *England*, but having little beauty, scarce deserves a place in gardens, unless for the sake of variety.

The fifth and sixth sorts are natives of the East, from whence their roots were brought originally; but have been

so greatly improved by culture, as to render them some of the chief ornaments to our gardens in the spring. The principal colours of these flowers are red, white, purple, and blue, and some are finely variegated with red, white, and purple. There are many intermediate shades of these colours; the flowers are large and very double, and, when properly managed, are extremely beautiful.

The soil in which these flowers will thrive extremely, may be composed in the following manner: Take a quantity of fresh untried earth (from a common or some other pasture land) that is of a light sandy loam, or hazel mould, observing not to take it above ten inches deep below the surface; and if the turf be taken with it the better, provided it hath time to rot thoroughly before it is used: mix this with a third part of rotten cow dung, and lay it in a heap, keeping it turned over at least once a month for eight or ten months, the better to mix it, and rot the dung and turf, and to let it have the advantages of the free air. In doing this work, be careful to rake out all great stones, and break the clods; but by no means sift or screen the earth, which I have found very hurtful to many sorts of roots.

This earth should be mixed twelve months before it is used, if possible; but if you are constrained to use it sooner, you must turn it over the oftener, to mellow and break the clods; and observe to rake out all the parts of the green sward, that are not quite rotten, before you use it, which would be prejudicial to your roots, if suffered to remain. The beginning of *September* is a proper season to prepare the beds for planting (which if in a wet soil, should be raised with this sort of earth six or eight inches above the surface of the ground, laying at the bottom some of the rakings of your heap to drain off the moisture; but in a dry soil, three inches above the surface will be sufficient): this compost should be laid at least two feet and an half thick, and in the bottom there should be about four or five inches of rotten neats dung, or the rotten dung of an old melon or cucumber bed, so that you must take out the former soil of the beds to make room for it.

And observe in preparing your beds, to lay them (if in a wet soil) a little round, to shoot off the water; but in a dry one, let it be nearer to a level; in wet land, where the beds are raised above the surface, it will be proper to fill up the paths between them in winter, either with rotten tan or dung, to prevent the frost from penetrating into the sides of the beds, which otherwise may destroy their roots. Your earth should be laid in the beds at least a fortnight or three weeks before you plant the roots, and a longer time would be yet better, that it may settle; and when you plant them, stir the upper part of the soil about six inches deep, with a spade; then rake it even and smooth, and with a stick draw lines each way of your bed at six inches distance, so that the whole may be in squares, that your roots may be planted regularly: then with three fingers make a whole in the center of each square, about three inches deep, laying therein a root with the eye uppermost; and when you have finished your bed, with the head of a rake draw the earth smooth, so as to cover the crown of the roots about two inches thick.

The best season for planting these roots, if for forward flowers, is about the latter end of *September*; and for those of a middle season, any time in *October*; but observe to perform this work, if possible, at or near the time of some gentle showers; for if you should plant them when the ground is perfectly dry, and there should no rain fall for three weeks or a month after, the roots will be very apt to grow mouldy upon the crown; and if once they get this distemper, they seldom come to good after.

You may also reserve some of your Anemone roots till after *Christmas*, before you plant them, lest by the severity

of the winter your early planted roots should be destroyed, which does sometimes happen in very hard winters, especially in those places where they are not covered to protect them from frost: these late planted roots will flower a fortnight or three weeks after those which were planted in autumn, and many time blow equally as fair, especially if it prove a moist spring, or that care be taken to refresh them with water.

But then the increase of these roots will not be near so great as those of your first planting, provided they were not hurt in winter; and it is for this reason all those who make sale of these roots, are forward in planting; but in such gardens where these flowers are preserved with care, there is always provision made to cover them from the injuries of the weather, by arching the beds over with hoops, or frames of wood, and covering them with garden mats or cloths, in frosty nights, and bad weather, especially in the spring of the year, when their buds begin to appear; for otherwise, if you plant the best and most double flowers, the black frosts and cutting winds in *March* will often cause them to blow single, by destroying the thrum that is in the middle of the flower; and this many times hath occasioned many people who have bought the roots, to think they were cheated in the purchase of them, when it was wholly owing to their neglect of covering them, that their flowers became single.

Toward the latter end of *June*, the leaves of your first blown roots will begin to decay; soon after which time you must take them out of the ground, clearing them from decayed stalks, and washing them, to clean the earth from the roots; then spread them on a mat in a dry shady place till they are perfectly dried, when you may put them up in bags, and hang them out of the reach of mice, or other vermin, which will destroy many of the roots if they can come at them.

As all the fine varieties of these flowers were first obtained from seeds, so no good florist, that hath garden room, should neglect to sow them; in order to which, they should provide themselves with a quantity of good roots of the single (or what the gardeners call Poppy Anemonies) of the best colours, and such as have strong stems and large flowers, but especially such as have more leaves than common, and also other good properties; these should be planted early, that they may have strength to produce good seeds, which will be ripe in three weeks or a month's time, after the flowers are past; when you must carefully gather it, otherwise it will be blown away in a short time, it being inclosed in a downy substance. You must preserve this seed till the beginning of *August*, when you may either sow it in pots, tubs, or a well prepared bed of light earth: in the doing of it you must be careful not to let your seeds be in heaps, to avoid which is a thing little understood, and is what I have been informed of by the late *Mr. Obadiab Lowe*, gardener at *Battersea*, who for several years raised large quantities of these flowers from seeds: his manner was thus:

After having levelled his bed of earth, in which he intended to sow his seeds, he rubbed his seeds well between his hands, with a little dry sand, in order to make them separate the better; then he sowed them as regularly as possible over the bed; but as these seeds will still adhere closely together by their down, so he made use of a strong hair brush, with which he gently swept over the whole bed, observing not to brush off the seeds; this brush will so separate the seeds, if carefully managed, as not to leave any entire lumps; then gently sift some light earth, about a quarter of an inch thick over the seeds; and, if it should prove hot dry weather, it will be advisable to lay some mats hollow upon the bed in the heat of the day, and now and then

give them a little water; but this must be given gently, lest by hastily watering you wash the seeds out of the ground; but be sure to uncover the bed at all times when there are gentle showers, and every night, that the seeds may have the benefit of the dews; and as the heat of the weather decreases, you may begin to uncover your bed in the day time also.

In about two months after sowing, your plants will begin to appear, if the season has proved favourable, or your care in management hath not been wanting, otherwise they many times remain a whole year in the ground. The first winter after their appearing above ground, they are subject to injuries from hard frosts, or too much wet, against both of which you must equally defend them; for the frost is very apt to loosen the earth, so that the young plants are often turned out of the ground, after which a small frost will destroy them; and too much wet often rots their tender roots, so that all your former trouble may be lost in a short time for want of care in this particular; nor do I know of any thing more destructive to these tender plants, than the cold black frosts and winds of *February* and *March*, from which you must be careful to defend them, by placing a low reed fence on the north and east sides of the bed, which may be moveable, and only fastened to a few stakes to support it for the present, and may be taken quite away as the season advances, or removed to the south and west sides of the bed, to screen it from the violence of the sun, which often impairs these plants when young.

As the spring advances, if the weather should prove dry, you must gently refresh them with water, which will greatly strengthen your roots; and when the green leaves are decayed, if your roots are not too thick to remain in the same bed another year, you must clear off all the weeds, and decayed leaves, from the bed, and sift a little more of the same prepared good earth, about a quarter of an inch thick over the surface, and observe to keep them clear from weeds during the summer season, and at *Michaelmas* repeat the same earthing; but as these roots so left in the ground, will come up early in the autumn, the beds should be carefully covered in frosty weather, otherwise their leaves will be injured, whereby the roots will be weakened, if not destroyed. If your roots succeed well, many of them will flower the second year, when you may select all such as you like, by marking them with a stick; but you should not destroy any of them till after the third year, when you have seen them blow strong, at which time you will be capable to judge of their goodness; for until the roots have acquired strength, the flowers will not shew themselves to advantage.

The single (or Poppy) Anemonies will flower most part of the winter and spring, when the seasons are favourable, if they are planted in a warm situation, at which time they make a fine appearance, therefore deserve a place in every flower garden, especially as they require little culture. There are some fine blue colours amongst these single Anemonies, which, with the scarlets and reds, make a beautiful mixture of colours; and as these begin flowering in *January* or *February*, when the weather is cold, they will continue a long time in beauty, provided the frost is not too severe. The seeds of these are ripe by the middle or end of *May*, and must be gathered daily as it ripens, otherwise it will soon be blown away by the winds

ANEMONOIDES. See Anemone.

ANEMONOSPERMOS. See Arctotis.

ANETHUM. Dill.

The Characters are,

It is an umbelliferous plant with many umbels, which are uniform. The flowers have five spear-shaped petals; under the flower is situated the germen, which afterward becomes two compressed seeds having borders.

We have but one *Species* of this genus, *viz.*

ANETHUM fructibus compressis. Hort. Cliff. 106. Garden or common Dill.

This plant is propagated by sowing the seeds in autumn, soon after they are ripe; for if they are kept out of the ground till spring, they frequently miscarry; or if any of the plants do come up, they often decay before they have perfected their seeds. They love a light soil, and will not bear to be transplanted, but must be sown where they are to remain; for if the plants are removed, they will not produce good seeds; therefore the best way is, when the plants are come up, to hoe them out, as is practised for Onions, Carrots, &c. leaving the plants about eight or ten inches asunder every way, observing to keep them clear from weeds, when the seeds are ripe; the heads or umbels should be cut, and spread upon a cloth to dry, and then beat out for use; and if you let some seeds fall upon the ground, they will arise the next spring without any care, so that the trouble of sowing their seeds may be spared.

ANGELICA.

The *Characters* are,

It is an umbelliferous plant, the greater umbel being composed of many small ones; the empalement of the flowers are indented in five parts. The flowers of the whole umbel are uniform. The germen is situated below the flower, which afterward becomes a roundish fruit splitting into two, and composed of two seeds, which are plain on one side and convex on the other, and are bordered.

The *Species* are,

1. *ANGELICA foliorum impari lobato.* Flor. Lapp. 101. Common Garden Angelica.

2. *ANGELICA altissima foliorum lobatis maximis serratis.* Commonly called Archangelica.

3. *ANGELICA foliis æqualibus ovato-lanceolatis serratis.* Hort. Cliff. 97. Greater wild Angelica.

4. *ANGELICA extimo foliorum pari coadunato folio terminali petiolato.* Prod. Leyd. 103. Dark Purple Angelica of Canada.

5. *ANGELICA foliis æqualibus ovatis inciso-serratis.* Hort. Cliff. 97. Shining Angelica of Canada.

The first sort is the common Angelica, which is cultivated in the gardens for medicinal use, as also for making a sweet-meat, which is by some greatly esteemed. This grows naturally by the side of rivers in Lapland, and other northern countries.

The second sort grows naturally in Hungary, and some parts of Germany.

The third sort grows naturally in moist meadows, and by the sides of rivers in many parts of England, so is seldom admitted into gardens.

The fourth and fifth sorts grow naturally in North America, from whence their seeds were sent to Europe, where the plants are preserved in gardens for the sake of variety; but as they are of no use, and have little beauty, so they are not admitted into many gardens. They are both very hardy plants, and may be easily propagated by seeds, which should be sown in autumn, and afterward the plants should be transplanted into a moist soil, and have a shady situation, allowing them room on every side. They grow near four feet high, and put out many shoots from the root, especially the second year from seed, when they will flower in June, and the seeds ripen in September. The roots of these sorts seldom continue longer than three or four years.

The common Angelica delights to grow in a very moist soil; the seeds of this plant should be sown soon after they are ripe, for if they are kept until the spring, seldom one seed in forty will grow. The best place for this plant is upon the sides of ditches, or pools of water, where being planted about three feet asunder, they will thrive exceedingly. The second year after sowing, they will shoot up to flower; therefore if you have a mind to continue their

roots, you should cut down these stems in May, which will occasion their putting out heads from the sides of the roots, whereby they may be continued for three or four years; whereas if they had been permitted to feed, their roots would perish soon after.

The gardeners near London, who have ditches of water running through their gardens, propagate great quantities of this plant, for which they have a great demand from the confectioners, who make a sweet-meat with the tender stalks of it, cut in May.

This plant is also used in medicine, as are also the seeds; therefore where it is cultivated for the seeds, there should be new plantations annually made to supply the places of those which die, for when they are permitted to feed, they last but two years.

ANGUINA. See *Tricofanthes.*

ANGURIA. The Water Melon, or Citrul.

The *Characters* are,

It hath male and female flowers growing separate on the same plant; the flowers of both sexes, are of the open bell-shaped kind, of one leaf. The male flowers have three short stamina, which are joined together. The female flowers rest upon an oval germen, which afterward becomes an oblong fleshy fruit, having five cells filled with compressed seeds, which are rounded at their extremity.

We have but one *Species* of this genus, *viz.*

ANGURIA foliis multipartitis. Water Melon, called Citrul.

Of this there are several varieties, which differ in the form and colour of their fruit. But as these vary annually from seeds, so it is needless to enumerate them here.

This fruit is cultivated in Spain, Portugal, Italy, and most other warm countries in Europe; as also in Africa, Asia, and America; and is by the inhabitants of those countries, greatly esteemed for their wholesome cooling quality; but in England the fruit is not so universally esteemed, though there are some few persons who are very fond of them.

To have this fruit good, you must first provide yourself with some seeds, which should be three or four years old; for new seeds are apt to produce vigorous plants, which are seldom so fruitful as those of a moderate strength. The best sorts to cultivate in England, are those with small round fruit, which come from Astracan, for those with very large fruit, seldom ripen in this climate. Having provided yourself with good seed, you may sow it in the hot-bed for early cucumbers; then you should prepare a heap of new dung the beginning of February, which should be thrown in a heap for about twelve days to heat, as is practised for early cucumbers. When the dung is of a proper temper, the bed should be made in the same manner as for the Musk Melon, covering the dung about three inches thick with loamy earth; for the plants may be raised fit to plant out for good, in the same bed with the early Cucumbers, so the bed here mentioned is where they are to remain for good. But as these plants require much more room than either Cucumbers or common Melons, so there should be but one plant put into a three light frame: therefore a hill of the same loamy earth should be raised a foot and an half high in the middle light of each frame, into which when the bed is of a proper temper for heat, the plants should be carefully planted, observing to water and shade them until they have taken good root.

After these plants are placed in these beds, you must be careful to admit fresh air to them by raising of the glasses in proportion to the weather; and as their branches extend you should lead the shoots as they are produced, so as to fill each part of the frame, but not to crowd each other; and be careful to keep them clear from weeds; they must also be frequently watered, but do not give it them in great quantities. In short, there is little difference to be observed in the

the management of these, from that of Musk Melons, but only to give them more room, earthing the beds to the same depth, and adding to the sides of the beds for the roots of the plants to run into it, and to keep the beds to a good temperature of heat; and when the fruit appears, to admit air freely to the plants, in order to set their fruit; but when the nights are cold, the glasses must be covered with mats to keep the beds warm, without which this fruit will seldom come to be good in this country.

ANIL. The Indigo Plant.

The Characters are,

The flower is of the butterfly kind. The standard is open, bordered, and reflexed. The wings are oblong, blunt, and spread open, as is also the keel, which turns backwards. In the center is situated a cylindrical germen, which afterward becomes a taper pod, filled with kidney-shaped seeds.

The Species are,

1. ANIL *leguminibus arcuatis incanis racemis folio brevioribus caule fruticoso perenni.* The Jamaica wild Indigo.
2. ANIL *leguminibus sessilibus arcuatis glabris foliis impari pinnatis foliolis ovatis obtusis.* The Guatimala Indigo.
3. ANIL *leguminibus tercibus brevibus foliis pinnatis quinifve, spicis florum longissimis laxis, radice perenne.* This is the Carolina wild Indigo.

The first and second sorts are annual plants with us; the seeds of these must be sown on a hot bed early in the spring of the year; and when the plants are come up two inches high, they should be transplanted into small pots filled with good fresh earth, and the pots plunged into a hot-bed of tanners bark; as the plants obtain strength, they must have a great share of a free air, by raising the glasses in the day time; in June they may be exposed to the open air, by which time they will begin to produce their flowers, which will be succeeded by pods in a short time after, and in August their seeds will be perfected, if the plants are brought forward in the spring.

The third sort grows to the height of five or six feet, and will abide two or three years, if it is preserved in a very warm stove in winter; this produces spikes of flowers from the wings of the leaves on the sides of the stems of the plant, and doth sometimes perfect its seeds in England. This must be raised in a hot-bed, as was directed for the former, but must not be wholly exposed to the open air, even in the hottest weather.

The second and third sorts are supposed to be promiscuously used to make the Indigo, but the second is the common sort which is cultivated in the English plantations in America; but I have been assured by a person of great credit, that he has made as good Indigo from the first sort, as any that was produced in our plantations; and this being a much larger plant, will afford a greater quantity from the same compass of ground, than any one of the other species; and this sort will grow on poorer land, so may be cultivated in such places where the first sort will not thrive; by which means improvements may be made with this plant in our American plantations. But the French chiefly cultivate the second sort, which is generally called Guatimala Indigo; but there are some other sorts of this plant, which are natives of India, from which this commodity is made; two of which I have had growing in the garden at Chelsea, both which are very different in their leaves and pods from either of the American sorts. I have also received seeds from India of the third sort, which is the same species of Indigo which grows naturally in South Carolina, and which was greatly esteemed some years ago by the Indigo planters of that country, for the beauty of the commodity which it produced; but the plants being slender, and thinly garnished with leaves, which were small, they did not furnish a quantity of Indigo, in proportion to their bulk, so of late this sort has not been

much cultivated there; though the account which I receiv'd with the seeds was, that it was what the best Indigo of India was made from.

The whole process of making the Indigo, would swell this volume beyond the intended size, so is omitted here.

ANISUM, or ANISE. See Pimpinella.

ANNONA. *Lin. Gen. Plant.* 613. The Custard Apple.

The Characters are,

The flower hath in some species three, and in others six petals, three large and three alternately smaller. The germen afterward becomes an oval, or oblong fruit, having a scaly rind, and one cell, in which are lodged many oval smooth seeds.

The Species are,

1. ANNONA *foliis lanceolatis fructibus ovatis reticulato-arcolatis.* *Lin. Sp. Plant.* 537. The Custard Apple.
2. ANNONA *foliis ovali-lanceolatis glabris nitidis planis pomis muricatis.* *Hort. Cliff.* 222. The Sour Sop.
3. ANNONA *foliis oblongis fructibus obtuse subsquamatis.* *Lin. Sp. Plant.* 537. The Sweet Sop.
4. ANNONA *foliis oblongis obtusis glabris, fructu rotundo, cortice glabro.* The Water Apple.
5. ANNONA *foliis latissimis glabris, fructu oblongo squamato, seminibus nitidissimis.* This is called Cherimolhas by the Spaniards.
6. ANNONA *foliis ovato-lanceolatis pubescentibus fructu glabro subcaeruleo.* The Sweet Apple.
7. ANNONA *foliis lanceolatis glabris nitidis secundum nervos sulcatis.* *Hort. Cliff.* 222. The Purple Apple.
8. ANNONA *foliis lanceolatis fructibus trifidis.* *Lin. Sp. Pl.* 537. The North American Annona, called by the inhabitants Papaw.

The first sort usually grows to the height of twenty-five feet, or upwards, in the West-Indies, and is well furnished with branches on every side; the leaves are oblong, pointed, and have several deep transverse ribs or veins, and are of a light green colour; the fruit is of a conical form, and as large as a tennis ball, of an Orange colour when ripe, having a soft sweet yellowish pulp, of the consistence of a custard, from whence this name was given to it.

The second sort does not grow so large as the first, rarely rising above twenty-five feet high, and not so well furnished with branches; the leaves are broader, and have a smooth surface without any furrows, and are of a shining green colour; the fruit is large, of an oval shape, irregular, and pointed at the top, being of a greenish yellow colour, and full of small knobs on the outside.

The third sort is a tree of humbler growth, seldom rising so high as twenty feet, and is well furnished with branches on every side; the leaves of this sort have an agreeable scent when rubbed; the fruit is roundish and scaly, and when ripe turns of a purple colour, and hath a sweet pulp.

The fourth sort commonly grows from thirty to forty feet in the West-Indies. This hath oblong pointed leaves, which have some slender furrows, and when rubbed have a strong scent; the fruit of this sort is seldom eaten but by the negroes.

The fifth sort is much cultivated in Peru for the fruit. This grows to be a very large tree in its natural country, and is well furnished with branches, which are garnished with leaves of a bright green colour, and much larger than those of any of the other sorts. The fruit is oblong, and is scaly on the outside, and of a dark purple colour when ripe.

The sixth and seventh sorts grow in some of the French islands, as also in Cuba, in great plenty; these grow to the height of thirty feet or more; their fruit are esteemed by the inhabitants of those islands, who frequently give them to sick persons, as they reckon them very cooling and wholesome.

The

The eighth sort grows plentifully in the *Bahama Islands*, where it seldom rises to more than ten feet high, having several stems; the fruit of this sort are shaped like a pear inverted. This is seldom eaten but by the negroes, and is the food of guanas, and other animals.

This sort will thrive in the open air in *England*, if it is planted in a warm sheltered situation; but the plants should be trained up in pots, and sheltered in winter, for two or three years, until they have acquired some strength; then they may be turned out of the pots in the spring, and planted in the full ground, where they are to remain. This sort flowers in many curious gardens. The seeds of this are frequently brought to *England* from *North America*; and many plants have been lately raised in the gardens near *London*. The seeds of this sort are very different in shape, from any of those which I have yet seen, which have been brought from the islands of the *West-Indies*, and the shape of the leaves are also different; this casts its leaves in autumn, whereas all the others retain their leaves until the spring, when the new leaves come out. The fruit is very different from those of the other species, two or three growing, together joined at their foot-stalks.

All the sorts, which are natives of the warm parts of *America*, are too tender to live in this country, if they are not preserved in warm stoves; they come up very easily from the seeds which are brought from *America*, if they are fresh; but the seeds must be sown on a good hot-bed, or in pots of light earth, and plunged into a hot-bed of tanners bark, pretty early in the spring; because if the plants come up early, they will have time to get strength, before the cold weather comes on in the autumn.

If these plants are kept in the bark stove, and carefully managed, they will make great progress; but in warm weather they should have plenty of fresh air admitted to them; for when the air is excluded from them too much, they are apt to grow sickly; when they will soon be attacked by vermin, which will multiply and spread over the whole surface of the leaves, and cause them to decay; but if the plants are carefully managed, their leaves will continue green all the winter, and make a very good appearance in the stove at that season.

They must constantly remain in the tan bed, otherwise they will make but little progress; for although they will live in a dry stove, yet they will not thrive, nor will their leaves appear so fine, as when they are preserved in a vigorous growing state; and it is more for the beauty of their leaves, than any hopes of their producing fruit in this country, that they are preserved in stoves; for though there has been some of the sorts which have produced flowers in *England*, yet none have ever shewn their fruit here.

ANTHEMIS. *Lin. Gen. Plant.* 870. Chamomile.

The Characters are,

It is a plant with a compound flower. The border, or rays of the flower, is composed of many female flowers, whose petals are stretched out like tongues on one side. The middle, or disk of the flower, is composed of many hermaphrodite florets, which are funnel shaped, erect, and cut into five parts at the top. The germen is situated at the bottom, which after-ward becomes an oblong naked seed.

The Species are,

1. ANTHEMIS foliis pinnato-compositis linearibus acutis subvillosis. *Lin. Sp. Pl.* 894. Common, or noble Chamomile.
2. ANTHEMIS receptaculis conicis paleis setaceis seminibus coronato-marginatis. *Flor. Suec.* 704. Wild Chamomile, or May Weed.
3. ANTHEMIS receptaculis conicis paleis setaceis seminibus nudis. *Lin. Sp. Plant.* 894. Stinking May Weed.
4. ANTHEMIS forum paleis rigidis pungentibus. *Flor. Leyd.* 172. Chamomile with stiff pungent chaff between the flowers.

5. ANTHEMIS erecta foliorum apicibus subspinosis. *Lin. Sp. Plant.* 893. Spanish Chamomile with a large flower.

6. ANTHEMIS foliis pinnatis denticulatis carnosis caule ramoso. *Lin. Sp. Plant.* 893. Sea Chamomile.

7. ANTHEMIS foliis pinnatifidis obtusis planis, pedunculis hirsutis, foliosis calycibus tomentosus. *Hort. Cliff.* 415. Hoary Sea Chamomile with a thick Wormwood leaf.

8. ANTHEMIS foliis simplicibus dentato-laciniatis. *Lin. Sp. Plant.* 894. Broad-leaved Portugal Chamomile, with a buck's horn leaf.

9. ANTHEMIS foliis pinnato-multifidis planis, laciniis linearibus acutis trifidis, pedunculis longissimis. *Hort. Cliff.* 415. Eastern Chamomile with a Wormwood leaf.

10. ANTHEMIS foliis simplicibus ovato-lanceolatis repando crenatis. *Lin. Sp. Plant.* 895. Portugal Chamomile with a Maudlin leaf.

11. ANTHEMIS caulibus unifloris decumbentibus foliis pinnato-multifidis. *Lin. Hort. Cliff.* 414. Pellitory of Spain.

12. ANTHEMIS foliis bipinnatis laciniis linearibus integris, pedunculis nudis longissimis. *Flor. Leyd. Prod.* 171. Alpine Ox Eye with a Wormwood leaf.

13. ANTHEMIS foliis bipinnatis serratis subtus tomentosus caule corymbofo. *Lin. Sp. Plant.* 896. Alpine Ox Eye with a white flower.

14. ANTHEMIS foliis pinnatis acutè serratis subtus tomentosus, pedunculis florum longissimis. Ox Eye with Tan'ey leaves.

15. ANTHEMIS foliis ovatis integris sessilibus floribus umbellatis sparsis. Eastern Ox Eye with a winged woolly leaf.

The first sort is the common Chamomile, which grows in plenty upon commons, and other waste land. It is a trailing perennial plant, which puts out roots from the branches as they lie on the ground, whereby it spreads and multiplies greatly; so that whoever is willing to cultivate this plant, need only procure a few of the slips in the spring, and plant them a foot asunder, that they may have room to spread, and they will soon cover the ground. The flowers of this sort are ordered for medicinal use, but the market people generally sell the double flowers, which are much larger, but not so strong as the single. The double sort is equally hardy, and may be propagated in the same manner.

The second sort is a common annual weed, which grows among corn; it flowers in *May*, so was called *May Weed*, though some have applied that title improperly to the *Cotula fatida*, which rarely flowers till late in *June*. This is the third sort here enumerated, of which there is a variety with double flowers, which is preserved by often planting the slips and cuttings; so that although the plant is naturally an annual, yet by this method it may be continued.

The fourth, fifth, and eighth sorts are annual plants, which grow naturally in *Spain*, *Portugal*, *Italy*, and the south of *France*; the plants are preserved in botanick gardens for the sake of variety, but are seldom allowed a place in others. They flower in *July*, and their seeds ripen in *September*.

The sixth, seventh, ninth, tenth, twelfth, thirteenth, fourteenth, and fifteenth sorts are perennial plants; these grow naturally in *Spain*, *Portugal*, and *Greece*, the plants are preserved in some curious gardens for the sake of variety. They are hardy, and may be propagated either by seeds or slips; if by seeds, they should be sown in the spring upon poor land, where the plants will continue much longer than in good ground. The slips may be planted during any of the summer months, observing to plant them in a shady border, and water them until they have taken root. In the autumn they may be removed to the places where they are to remain, and will require no other care but to keep them clean from weeds. These plants do not grow tall, but are bushy, so should be allowed room. They continue in flower from *July* to *October*, and the seeds ripen in autumn.

The

The eleventh sort is the Pellitory of *Spain*, the roots of which are used for the tooth-ach, being extremely warm; when they are applied to the part affected, they draw out the cold rheum, and are often serviceable. This is a perennial plant, with a long taper root like a Carrot, which grows naturally in *Spain* and *Portugal*, from whence the roots are brought to *England*. The branches of this trail upon the ground, and spread a foot or more on every side, and have fine winged leaves, like those of the common Chamomile; at the extremity of each branch is produced one large single flower like Chamomile, but much larger, the rays of which are of a pure white within, but purple on their outside. It flowers in *June* and *July*, and the seeds are ripe in *September*; but unless the season is warm and dry, the seeds do not ripen in *England*, for the wet falls between the scales, and rots the seeds in embryo.

The twelfth and thirteenth sorts are perennial plants, which do not rise more than two feet high; the leaves are hoary, and have some resemblance to those of the common Wormwood.

These sorts are propagated by seeds, which they produce in plenty, and may be sown on a bed of common earth in the spring; when the plants are strong enough to remove, they may be transplanted into large open borders, near shrubs, where they may have room to grow, for they spread out on every side, therefore require three feet distance from other plants; in these large open spots, they will make a pretty variety from *June* to *November*, during which time they continue in flower: some of these are white, others are of a sulphur, and some have yellow flowers, but these vary from seed.

ANTHERICUM. *Lin. Gen. Plant.* 380. Spiderwort.

The Characters are,

The flower hath no empalement, and is composed of six petals, which spread open. It hath six upright stamina. The germen, which is situated in the center is three-cornered, which after-ward becomes an oval smooth capsule, having three furrows, opening in three cells, which are filled with angular seeds.

The Species are,

1. ANATHERICUM foliis planis scapo ramoso corollis revolutis. *Lin. Sp. Plant.* 310. Asphodel, with rough compressed leaves and a spreading stalk.

2. ANATHERICUM foliis planis scapo ramoso corollis planis. *Lin. Sp. Pl.* 310. Branching Spiderwort with a small flower.

3. ANATHERICUM foliis planis scapo simplicissimo. *Hort. Upsal.* 83. Branchless Spiderwort with a small flower.

4. ANATHERICUM foliis carnosis teretibus caule fruticoso. *Lin. Sp. Plant.* 310. Cape Spiderwort with stalks and pulpy Onion leaves.

5. ANATHERICUM foliis carnosis subulatis planiusculis. *Hort. Upsal.* 83. Low Cape Spiderwort, with Aloe-shaped pulpy leaves.

6. ANATHERICUM foliis carnosis subulatis semiteretibus stricis. *Hort. Upsal.* 83. Low Asphodel, with awl-shaped succulent leaves.

7. ANATHERICUM foliis carnosis subulatis teretibus. *Hort. Upsal.* 83. Small yellow African Spiderwort, with narrow leaves.

8. ANATHERICUM caule foliis carnosis teretibus spicis florum longissimis laxis. *Fig. Plant. pl.* 39. Low African Spiderwort with taper fleshy leaves and very long loose spikes of flowers.

9. ANATHERICUM sessile foliis linearibus planis caule decumbente. *Fig. Plant. pl.* 39. f. 2. Low Spiderwort with narrow plain leaves and a trailing stalk.

10. ANATHERICUM foliis ensiformibus filamentis lanatis. *Flor. Succ.* 268. Marsh yellow Asphodel.

11. ANATHERICUM foliis ensiformibus perianthiis trilobis filamentis glabris. *Flor. Succ.* 269. Marsh Alpine Spiderwort, with an Iris leaf.

The first sort grows near two feet high; the stalk branches out on every side, each branch being terminated by a loose spike of flowers, which are white, and the petals are turned backward to their foot-stalk. The leaves of this sort are flat, and the root is perennial, but the branches decay in autumn.

The second sort hath a perennial root, but an annual stalk, which decays in autumn; the stalks of this rise about the same height as the former, sending out many lateral ones in like manner, which are terminated by loose spikes of flowers, which are white, but the petals are plain, and do not turn back as in the other sort.

The third sort hath plain leaves and an unbranching stalk, in which it chiefly differs from the former. The root of this is perennial, but the stalks decay in winter.

These three sorts grow naturally in *Spain*, *Portugal*, and other warm countries; they were more common some years ago in the *English* gardens, than at present; for the severe winter in 1740, killed most of their roots. These flower in *June* and *July*, and their seeds are ripe in *September*. They are propagated by seeds, which should be sown in autumn: these should be sown in a bed of light sandy earth, in a warm situation; when the plants come up, they must be kept clean from weeds during the summer, and in autumn, when their leaves decay, they should be carefully taken up, and transplanted, in the borders of the flower-garden, where they will last several years, if they are not killed by frost; to prevent which, some rotten tan should be laid over the roots in winter, which will always secure them.

The fourth sort has been long preserved in many gardens near *London*, and was formerly known among the gardeners, by the title of Onion-leaved Aloe. This plant produces many lignous branches from the root, each having a plant with long taper leaves, in shape of those of the Onion, which are full of a yellow pulp very juicy. It grows naturally at the *Cape of Good Hope*, and requires a little shelter in the winter, but in some mild seasons I have had plants live without any cover, which were planted close to a warm wall.

The fifth and sixth sorts grow close to the ground, never rising with any stalk. The fifth hath broad, flat, pulpy leaves, resembling those of some sorts of Aloe. The leaves spread open flat on the ground, and the flowers are produced on loose spikes, like the former, but they are shorter. The flowers are yellow, and appear at different seasons. This is propagated by offsets, which are put out in plenty, and must be planted in pots filled with light sandy earth, and in winter placed in the green-house, and treated as other hardy succulent plants, which come from the *Cape of Good Hope*.

The sixth sort hath long narrow pulpy leaves, which are almost taper, but flated on their upper side; this sends out many offsets, by which it may be increased plentifully. It must be treated in the same manner as the former.

The seventh sort is annual: this is a low plant growing close to the ground, having pretty long succulent leaves, which are taper, but flated on their upper side; the flowers grow in loose spikes, which are shorter than either of the other sorts. They are yellow, and are succeeded by round seed vessels, like those of the former sorts; the plants perish soon after their seeds ripen. The seeds of this sort should be sown on a warm border of light earth, in *April*, where they are to remain, and will require not other care but to keep them clean from weeds, and to thin them where they are too close.

The eighth sort never rises to a stalk, but the leaves come out close to the ground. These are long, taper, succulent, and of a sea-green colour, growing erect; the flower-stems rise between the leaves, and are near three feet long.

long. The plants are seldom long destitute of flowers. It must be treated in the same manner as the fourth, fifth, and sixth sorts.

The ninth sort is a native of *Jamaica*, where it grows naturally in moist places; this is a very low plant, having many long narrow leaves like those of grass; from between these come out the flower-stalks, which are five or six inches in length, falling to the ground; at the top the flowers are collected into small heads; these are yellow, and shaped like those of the former. They appear in *June* and *July*, and their seeds ripen in *August* and *September*. This is tender, so must be placed in a stove, otherwise the plants will not live in this country: it may be easily propagated by seeds, which should be sown on a hot-bed in the spring.

The tenth and eleventh sorts grow naturally on bogs in most of the northern countries; the tenth is common in many parts of *England*, but particularly in *Lancashire*, from whence it had the title of *Lancashire Asphodel*; it also grows on a bog upon *Putney-beath*. The other grows naturally in *Denmark*, *Sweden*, and *Lapland*. The flower-stems rise about six inches high, being terminated by a loose spike of small yellow flowers. These plants, growing naturally upon bogs, are with difficulty preserved in gardens.

ANTHOLYZA. We have no *English* name for this plant.

The Characters are,

It hath an imbricated sheath, which is permanent; the flower is of one leaf, and opens above with compressed jaws. The under lip is trifid and short; the middle segment turns downward. Under the flower is situated the germen, which afterward becomes a roundish three-cornered vessel having three cells, in which are lodged many triangular seeds.

The Species are,

1. ANTHOLYZA *flamine unico declinato*. *Lin. Sp. Plant.* 37. Antholyza with one stamen declining.
2. ANTHOLYZA *foliis linearibus sulcatis floribus albis uno versu dispositis*. *Fig. Plant. pl.* 40. Strange Corn-flag with narrow furrowed leaves, and white flowers ranged on one side of the stalk.

The first sort hath round red bulbous roots, from which arise several rough furrowed leaves, which are near a foot long, and half an inch broad; between these come out the flower-stem immediately from the root, which rises two feet high, is hairy, and hath several flowers coming out on each side. These are of one leaf, cut into six unequal parts at the top: the margins are waved and closed together, wrapping up the three stamens. These flowers are red, and appear in *June*, and the seeds ripen in *September*.

The roots of the second sort are in shape and size like those of the vernal *Crocus*, but the outer skin is thin and white; from this arises five or six long narrow leaves, which are deeply furrowed. Between these arise the flower-stem, which is a foot and an half high; the flowers come out, ranged on one side, standing erect. These have each a spathe, or sheath, of one leaf, divided into two, ending in points. The flower is of one leaf, having a long tube, but is divided into six unequal segments at the top, which spread open. After the flower is past, the germen becomes a three-cornered seed vessel, opening in three cells, which are filled with triangular seeds.

They are propagated by offsets, which the bulbous roots send forth in pretty great plenty; or by seeds, which are sometimes perfected in *Europe*. These seeds should be sown soon after they are ripe; if the seeds are sown in pots of light earth, and plunged into an old bed of tan which has lost its heat, and shaded in the middle of the day in hot weather, the seeds will come up the following winter; therefore they must be kept covered with glasses to screen them from cold. In summer, after the leaves are decayed, the

root should be taken up, and planted each into a separate small pot filled with light earth. In summer the pots may be placed in the open air in half-sun, but in winter they must be placed under a hot-bed frame, for they are not very tender; but where any damp arises, it is very apt to occasion a mouldiness upon their leaves. The roots shoot up in autumn, and the flowers begin to appear in *May*; the seeds ripen in *August*, and soon after their leaves and stalks decay. The roots may be easily transported from one country to another at the time when they are taken up. These flowers are a great ornament to the green-house when they are in flower, and as they require but little culture, so deserve a place in every good garden.

ANTHOSPERMUM. Amber Tree, *vulgò*.

The Characters are,

It is male and female in different plants; the male flowers have no petals. The female flowers have the same structure as the male, but have no stamens; instead of which there is an oval germen, situated in the bottom, which afterward becomes a roundish capsule having four cells, which contain several angular seeds.

We know but one Species of this genus, *viz.*

ANTHOSPERMUM *mas & femina*. *Hort. Cliff.* 455. Male and female Amber Tree.

It is preserved in many curious gardens, which have collections of tender plants, and is easily propagated by planting cuttings during any of the summer months, in a border of light earth; which will take root in six weeks time, provided they are watered and shaded as the season may require: then they should be taken up, with a ball of earth to their roots, and planted into pots filled with light sandy earth, and may be exposed to the open air until *October*; at which time they should be removed into the conservatory, where they should be placed as free as possible from being over-hung with other plants; and, during the winter season, they must be often refreshed with water, but should not have too much given them each time.

The beauty of this shrub is in its small ever-green leaves, which grow as close as heath; and, being bruised between the fingers, emit a very fragrant odour. The plants must be frequently renewed by cuttings, for the old plants are very subject to decay, seldom continuing above three or four years.

It is but of late years there have been any of the female plants in the gardens, for all those which were formerly in the gardens, were the male; which being propagated by cuttings had been continued, so that no seeds were ever produced in *England* till within a few years past, when I received some seeds from the *Cape of Good Hope*, from which I raised many plants of both sexes, and a few among them which have hermaphrodite flowers, which have seeds, from which many plants have been raised.

ANTHYLLIS. *Lin. Gen. Plant.* 773. Ladies Finger.

The Characters are,

The flower is of the butterfly kind, having a long standard reflexed on both sides beyond the empalement; the two wings are short; the keel is of the same length, and compressed. In the center is situated an oblong germen, which afterward becomes a small roundish pod included by the empalement, having one or two seeds.

The Species are,

1. ANTHYLLIS *herbacea foliis quaterno-pinnatis floribus lateralibus* *Hort. Upsal.* 221. Five-leaved Woundwort.
2. ANTHYLLIS *herbacea foliis pinnatis inæqualibus capitulo duplicato*. *Lin. Sp. Pl.* 719. Low Woundwort with a scarlet flower.
3. ANTHYLLIS *herbacea foliis pinnatis foliolis inæqualibus caulinis lineari lanceolatis floribus capitatis simplicibus*. Rustick Woundwort, or Ladies Fingers.

4. ANTHYLLIS herbacea foliis pinnatis æqualibus capitulo terminali. *Lin. Sp. Plant.* 719. Purple Milk Vetch.

5. ANTHYLLIS herbacea foliis pinnatis inæqualibus capitulis solitariis. *Lin. Sp. Pl.* 719. Herbaceous Woundwort, with unequal winged leaves and a single head.

6. ANTHYLLIS fruticosa foliis pinnatis æqualibus floribus capitatis. *Hort. Cliff.* 371. Jupiter's Beard, or Silver Bush.

7. ANTHYLLIS fruticosa foliis ternatis inæqualibus calycibus lanatis lateralibus. *Lin. Sp. Plant.* 720. Hoary Cytifus with a longer middle leaf.

8. ANTHYLLIS fruticosa spinosa foliis simplicibus. *Lin. Sp. Plant.* 720. Prickly Broom with duckmeat leaves and bluish purple flowers.

The first sort grows naturally in *Spain, Italy, and Sicily*. This is an annual plant, with trailing branches, which spread flat on the ground; the flowers, which are yellow, come out in clusters on the sides of the stalks, having large swelling empalements, and are succeeded by short pods inclosed in the empalement. It flowers in *June and July*, and the seeds ripen in *September*. The seeds of this sort should be sown on a bed of light earth in *April*, where the plants are to remain, and will require no other care, but to thin them to the distance of two feet, and keep them clean from weeds.

The second sort grows naturally in *Spain and Portugal*, from both which countries I have received the seeds; it also grows wild in *Wales*, and the *Isle of Man*. This is a biennial plant, having single leaves at bottom, which are oval and hairy; but those which grow out of the stalks are winged, each being composed of two or three pair of lobes terminated by an odd one: the flowers are collected into heads at the top of the stalks; these are of a bright scarlet colour, so make a pretty appearance: it flowers in *June and July*, and the seeds ripen in *October*. When the plants of this sort grow on poor land, they will sometimes continue three years, but in gardens they seldom last longer than two.

The third sort grows naturally upon chalky grounds in many parts of *England*, so is rarely admitted into gardens. The heads of flowers in this species are single, whereas the other has generally double heads.

The fourth sort is a perennial plant with trailing branches; at the extremity of the branches, the flowers are produced in heads; these are of a purple colour, and globular form. It grows naturally on mountains, in the south of *France and Italy*. It is propagated by seeds, which may be sown either in the autumn or spring: those which are sown in the autumn, will rise the following spring, and more certainly grow, than those which are sown in the spring, which seldom grow the same year. When the plants come up, they must be kept clean from weeds; and where they are too close together, they must be thinned. The following autumn, they should be transplanted to the places where they are to remain, and will require no particular management afterward. This sort flowers in *June and July*, and the seeds ripen in *October*.

The fifth sort approaches near to the third, but the leaves are hoary, and the flowers are produced on the side of the branches; these are yellow, and collected into small heads. This may be propagated by seeds as the former.

The sixth sort is the *Barba Jovis*, or *Jupiter's Beard*, by many called Silver Bush, from the whiteness of its leaves. This is a shrub which often grows ten or twelve feet high, the leaves are very white and hairy; the flowers are produced at the extremity of the branches, collected into small heads; these are of a bright yellow colour, and appear in *June*. It is propagated either by seeds or cuttings; if by seeds, they should be sown in the autumn, in pots filled with light earth, and placed under a frame in winter to protect them from frost. The following spring the plants will

rise, and when they are strong enough to remove, they should be each planted in a small pot filled with light earth, and placed in the shade, till they have taken new root; after which, they may be placed with other hardy exotick plants, in a sheltered situation, where they may remain till *October*, when they must be removed into shelter. These plants are too tender to live in the open air here in winter, though I have had some of them live abroad two or three years, which were planted against a south-west aspect wall. It may also be propagated by cuttings, which may be planted during any of the summer months, observing to water and shade them until they have taken root.

The seventh sort is a low shrub, seldom rising above two feet high, but sends out many slender branches, which are garnished with hoary leaves; they are sometimes single, but generally have three oval lobes, the middle being longer than the other two; the flowers are white, and come out from the side of the branches, three or four joined together having woolly empalements, but these are rarely succeeded by seeds in *England*. It may be propagated by cuttings, in the same manner as the former sort, and treated as hath been directed for that.

The eighth sort grows naturally in *Spain and Portugal*. This is a shrub which grows nine or ten feet high, having the appearance of one sort of *Gorse or Whin*, but it hath round leaves growing single. It will live in the open air in mild winters, but hard frost will destroy it. It is propagated by seeds only.

ANTIRRHINUM, Snap-dragon, or Calves-snout.

The Characters are,

The flower is ringent, having an oblong tube, and divided at the top into two lips, which are closed at the jaw. In the bottom is situated an obtuse nectarium, which is not prominent. In the center is placed a roundish germeu, which afterward becomes a round obtuse capsule having two cells, which are full of small angular seeds.

To this genus *Linnaeus* has joined the *Linaria* and *Afarina*; but as the flowers of the *Linaria* have spurs to their petals, and the nectarium being very prominent, which are not so in this genus, so it should be separated from it; especially as there are many species of both kinds, which cannot so well be distinguished when both genera are joined in one.

The Species are,

1. ANTIRRHINUM foliis lanceolatis obtusis alternis caule ramosissimo diffuso. *Hort. Cliff.* 324. The least Field Snap-dragon.

2. ANTIRRHINUM foliis lanceolatis petiolatis calycibus corollâ longioribus. Greater Field Snap-dragon.

3. ANTIRRHINUM foliis lanceolatis petiolatis calycibus brevissimis racemo terminali. *Vir. Cliff.* 61. Another great Snap-dragon with a longer leaf.

4. ANTIRRHINUM foliis lanceolatis glabris, calycibus hirsutis racemo longissimo. Broad-leaved Snap-dragon with a large pale flower.

5. ANTIRRHINUM foliis lineari-lanceolatis hirsutis racemo brevioris. Greater Italian long-leaved Snap-dragon with a large snowy flower.

6. ANTIRRHINUM foliis linearibus floribus petiolatis axillaribus. Sicilian Snap-dragon with a Toad-flax leaf and a snow white flower.

The two first sorts grow naturally on arable land in many parts of *England*, so are seldom admitted into gardens; these are both annual plants, which come up from scattered seeds. They flower in *June and July*, and their seeds are ripe in *September*.

The third sort is not a native of *England*, but having been first brought into gardens, the seeds have scattered about in so great plenty, that it is become very common upon walls and old buildings in many parts of *England*. Of this sort there are several varieties, which differ in the colour of their

flowers, some having red flowers with white mouths, some with yellow mouths, others have white flowers, with yellow and white mouths. There is also one with striped leaves. The last is propagated by slips and cuttings, which readily take root any time in the spring or summer. The different colours of the flowers are variable from seeds.

The fourth sort grows naturally in the islands of the *Archipelago*. The leaves of this are much broader, the flowers greatly larger, and the spikes longer, than in any of the other sorts. The colours of the flowers are as changeable in this sort as the former, when raised from seeds; but as this is the most specious kind, so it better deserves propagating than the common sort, especially as it is equally hardy.

The fifth sort hath long narrow leaves, which are hairy; the flowers are large, and the spike is shorter than the former.

The sixth sort is an annual plant, which seldom grows more than a foot high; the leaves of this are very narrow and smooth; the flowers come out from the wings of the leaves single, standing on long foot-stalks; these are very white, with a dark bottom.

The third, fourth, and fifth sorts are raised from seeds, which should be sown in a dry soil, which is not too rich, either in *April* or *May*; and in *July* the plants may be planted out into large borders, where they will flower the spring following; or they may be sown early in the spring, for flowering the same autumn, but then they are not so likely to endure the winter; and if the autumn prove bad, they will not perfect their seeds.

These plants grow extremely well upon old walls or buildings, in which places they will endure for several years; whereas those planted in gardens seldom last longer than two years, unless they are planted in a very poor soil, and the flowers often cropped, and not suffered to seed; but any of these sorts may be continued, by planting cuttings in any of the summer months, which will easily take root.

Wherever these plants are designed to grow on walls, or on a rocky barren soil, the seeds should be sown the beginning of *March*, where they are designed to remain; for if the plants are first raised in a better soil, and afterward transplanted into those places, they seldom succeed well.

APARINE, Goose-grass, or Clivers.

There are three or four sorts of this which are preserved in botanick gardens for variety, but are not worthy of a place in other gardens.

APHACA, Vetchling.

The Characters are,

The flower is of the butterfly kind; the standard being large and heart-shaped, the wings are shorter and obtuse; the keel is the length of the wings, and divided slightly in the middle. The germen, which is situated in the center; afterward becomes a short pod, containing two or three round seeds.

We have but one Species of this plant, viz.

APHACA *Lob. Icon.* 70. Yellow Vetchling.

This plant is found wild in divers parts of *England*, on arable land, but is seldom preserved in gardens. It is an annual plant, which perishes soon after the seeds are perfected. The surest method to cultivate this plant, is to sow the seeds on a bed of light earth in autumn, soon after they are ripe; for if they are kept out of the ground until spring, they seldom grow; and if some of the plants come up at that season, they seldom perfect their seeds so well as those which were sown in autumn. These seeds should be sown where the plants are designed to remain, for they seldom succeed well if they are transplanted. All the culture these plants require, is to keep them clear from weeds, and to thin them where they come up too close, leaving them about ten inches or a foot asunder.

APIOS. See Glycine.

APIUM, Parsley.

The Characters are,

It is a plant with an umbelliferous flower; each flower has five stamina. Under the flower is situated the germen, which afterward becomes an oval channelled fruit, dividing into two parts, having two oval seeds channelled on one side, and plain on the other.

The Species are,

1. APIUM *foliolis caulinis linearibus.* Hort. Cliff. 108. Common Parsley.

2. APIUM *foliis radicalibus amplioribus crispis caulinis ovato-multifidis.* Curled Parsley.

3. APIUM *foliis radicalibus trifidis, serratis petiolis longissimis.* The large rooted Parsley.

4. APIUM *foliolis caulinis cuneiformibus.* Hort. Cliff. 107. Smalage or Water Parsley.

5. APIUM *foliis erectis, petiolis longissimis foliolis quinque lobatis serratis.* Upright Celery.

6. APIUM *foliis patulis, petiolis brevibus, foliolis quinque serratis, radice rapacea.* Celeriack or Turnep-rooted Celery.

The first sort is the common Parsley, which is generally cultivated for culinary use; and is what the *College of Physicians* have directed to be used in medicine, under the title of *Petroselinum*; for when *Apium* is prescribed, the Smalage is always intended.

The second sort may be constantly preserved, if the seeds are carefully saved from plants, whose leaves are well curled, the seeds will produce the same; but there are few persons who will be at the trouble to save the seeds so carefully, as not to have some of the common sort mixed with it: therefore the only method to have it good, is to separate all those plants which have plain leaves from the curled, as soon as they are distinguishable, leaving only such as are of the right kind. It will be a very safe method for such persons, who cannot well distinguish the common Parsley from the lesser Hemlock, to sow the seeds of this curled leaved Parsley, which is easily known at first sight from Hemlock; for where the latter has been used by mistake, it has been attended with bad consequences.

The third sort is chiefly cultivated for their roots, which are now pretty commonly sold in the *London* markets; the leaves of this sort have much longer foot-stalks, and the subdivisions of these are not so numerous as in the common Parsley; the lobes of the leaves are much larger, and of a darker green, so that it is easily distinguished from the common sort by its leaves, but the roots are six times as large as the common Parsley can be brought to with the utmost culture. This sort was many years cultivated in *Holland*, before the *English* gardeners could be prevailed on to sow it. I brought the seeds of it from thence in 1727, and would then have persuaded some of the kitchen gardeners to make trial of it, but they refused to accept of it, so that I cultivated it several years before it was known in the markets.

The fourth sort is commonly known by the title of Smalage. This is what the physicians intend when they prescribe *Apium*. This plant grows naturally by the sides of brooks and ditches in many parts of *England*, so is rarely cultivated in gardens.

The fifth sort is the common Celery, and the sixth sort was supposed to be a degenerate species from it, but I cannot agree to this opinion; for from many years trial, I have never found it vary. The leaves of this sort are short, when compared with those of the other, and spread open horizontally, and the roots grow as large as common Turneps. All the difference which I have observed to arise from culture, has been only in the size of the roots; those on rich ground, which were properly cultivated, were much larger than those on poorer land, but the leaves and outward appearance of the

the plants were never altered, so that I make no doubt of its being a different species.

The common Parsley should be sown early in the spring; for the seeds remain a long time in the earth, the plants seldom appearing in less than six weeks after the seeds are sown. This sort is generally sown in drills by the edges of borders in the kitchen gardens near *London*, because it is much easier to keep it clear from weeds, than if the seeds are sown promiscuously on a border, and the Parsley is much sooner cut for use: but when the roots are desired for medicinal use, then the seeds must be sown thin; and when the plants are come up, they should be hoed out single, as is practised for Carrots, Onions, &c. observing also to cut up the weeds: if this be observed, the roots will become fit for use by *July* or *August*.

The common Parsley is, by some skilful persons, cultivated in fields for the use of sheep, it being a sovereign remedy to preserve them from the rot, provided they are fed twice a week for two or three hours each time with this herb; but hares and rabbits are so fond of it, that they will come from a great distance to feed upon it; and in countries where these animals abound, they will destroy it, if it is not very securely fenced against them; so that whoever has a mind to have plenty of hares in their fields, by cultivating Parsley, will draw all the hares of the country to them.

The best time for sowing it in the fields is about the middle or latter end of *February*; the ground should be made fine, and the seeds sown pretty thick, in drills drawn at about a foot asunder, that the ground may be kept hoed between the drills, to destroy the weeds, which, if permitted to grow, will soon over-run the Parsley. Two bushels of seed will sow one acre of land.

The great Garden Parsley is now more known to us in *England*, than it was some years ago: in *Holland* it has been long very common in all their markets: they bring these roots in bunches, as we do young Carrots, to market, in summer; and the roots are much of the same size: it is called *Petroseline Wortle* by the *Dutch*, who are very fond of it for *Water Souche*.

It may be cultivated by sowing the seeds in good ground early in the spring; and in *April*, when the plants are up, cut them out with a hoe (as is practised for young Carrots) to about five or six inches square, and keep them constantly clean from weeds, and in *July* the roots will be fit to draw for use, and may be boiled and eaten as young Carrots; and are very palatable and wholesome, especially for those who are troubled with the gravel.

But where these plants are cut out, to allow them more room, if the soil is good, the roots will grow to the size of a middling Parsnep, by *September*; and the roots may be preserved for use all the following winter, in the same manner as Carrots.

The seeds of the two sorts of Celery should be sown at two or three different times, the better to continue it for use through the whole season without running up to seed. The first sowing should be in the beginning of *March*, upon a gentle hot-bed; the second may be at the end of the same month, which ought to be in an open spot of light earth, where it may enjoy the benefit of the sun; the third time of sowing should be the latter end of *April*, or beginning of *May*, on a moist soil; and if exposed to the morning sun only, it will be so much the better; but it should not be under the drip of trees.

The seeds which are sown on the hot-bed will come up in about three weeks or a month after sowing, when you must carefully clear it from weeds; and if the season prove dry, you must frequently water it; and in about five or six weeks after it is up, the plants will be fit to transplant: you must therefore prepare some beds of moist rich earth, in a

warm situation, in which you should prick these young plants, at about three inches square, that they may grow strong; and if the season should prove cold, the beds must be covered with mats, to screen the plants from morning frosts, which would retard their growth: you must also observe, in drawing these plants out of the seed-beds, to thin them where they grow too thick, leaving the small plants to get more strength before they are transplanted, by which means one and the same seed-bed will afford three different plantings, which will accordingly succeed each other for use.

The middle of *May* some of the plants of the first sowing will be fit to transplant for blanching; which should be planted in a moist rich light soil, upon which this first planted Celery will often grow to be twenty inches long in the clean blanched parts, which upon a poor or dry soil seldom rises to be ten inches.

The manner of transplanting it is as follows: After having cleared the ground of weeds, you must dig a trench by a line about ten inches wide, and eight or nine inches deep, loosening the earth in the bottom, and laying it level; and the earth that comes out of the trench should be equally laid on each side the trench, to be ready to draw in again to earth the Celery as it advances in height. These trenches should be made at three feet distance from each other; then plant your plants in the middle of the trench, at about four or five inches distance, in one strait row, having before trimmed the plants, and cut off the tops of the long leaves; and as they are planted, you must observe to close the earth well to their roots with your feet, and to water them plentifully until they have taken new root. As these plants advance in height, you must observe to draw the earth on each side close to them, being careful not to bury their hearts, nor ever to do it but in dry weather, otherwise the plants will rot.

When your plants have advanced a considerable height above the trenches, and all the earth, which was laid on the sides thereof, hath been employed in earthing them up; you must then make use of a spade to dig up the earth between the trenches, which must also be made use of for the same purpose, continuing from time to time to earth it up, until it is fit for use.

The first of your planting out will, perhaps, be fit for use by the end of *July*, and will be succeeded by the after plantations; and if the latter sowings are rightly managed, there will be a succession of it till *April*; but you should observe, to plant the last crop in a drier soil, to prevent its being rotted with too much wet in winter; you will do well to cover your ridges of Celery with some Pease-haulm, or some such light covering, when the frost is very hard, which will admit the air to the plants; for if they are covered too close, they will be very subject to rot; by this means you will preserve your Celery till spring; but you must remember to take off the covering whenever the weather will permit, otherwise it will be apt to cause the Celery to pipe, and run to seed. By this method of covering the Celery, the frost will be kept out of the ground, so it may be always taken up for use when it is wanted; which, if neglected, it cannot be taken up in hard frost. The Celery, when fully blanched, will not continue good above three weeks or a month before it will rot or pipe: therefore, in order to continue it good, you should have, at least, six or seven different seasons of planting; so that if it be only intended to supply a family, there need not be much planted at each time; but this must be proportioned according to the quantity required.

The other sort of Celery, which is commonly called *Celериac*, is to be managed in the same manner as is directed for the *Italian Celery*, excepting that this should be planted upon the level ground, or in very shallow drills; for this plant seldom grows above eight or ten inches high, so requires but little earthing up; the great excellency of this being in

the size of the root, which is often as large as ordinary Turneps. It should be sown about the end of *March*, or beginning of *April*, upon a rich border of earth; and, in dry weather, constantly watered, otherwise the seeds will not grow: when the plants are large enough to transplant out, they should be placed eighteen inches asunder, row from row, and the plants six or eight inches distant in the rows; the ground must be carefully kept clean from weeds; but this sort will require only one earthing up, which should not be performed until the roots are nearly grown to their size: both these sorts of Celery delight in a rich light moist soil, where they will grow to a much larger size, and will be sweeter and tenderer than on a poor or dry ground.

The best method to save this seed, is to make choice of some long good roots of the upright Celery, which have not been too much blanched, and plant them out at about a foot asunder in a moist soil, early in the spring; and when they run up to seed, keep them supported with stakes, to prevent their being broken down with the wind: and in *July*, when this seed begins to be formed, if the season should prove very dry, it will be proper to give some water to the plants, which will greatly help its producing good seeds. In *August* these seeds will be ripe, at which time it should be cut up, in a dry time, and spread upon cloths in the sun to dry; then beat out the seeds, and preserve it dry in bags for use.

APIUM MACEDONICUM. See Bubon.

APIUM ANISUM DICTUM. See Pimpinella.

APIUM PYRENAICUM. See Crithmum.

APOCYNUM. *Tourn. Inst. R. H. 91; Lin. Gen. Plant.* 269. Dogsbane.

The Characters are,

The flower is of one leaf, cut into five acute segments at the top, which turn backward; in the bottom of the flower are situated five nectariums, which surround the germen: there are five stamina, scarce visible. In the center are two oval germen, which afterward become two large pointed capsules, having one cell, which is filled with compressed seeds, lying over each other like tiles on a house, and furnished with long feathery down.

The Species are,

1. APOCYNUM caule rectiusculo herbaceo foliis ovatis utrinque glabris cymis terminalibus. *Lin. Sp. Plant.* 213. Canada Dogsbane with greater Tutsan leaves.

2. APOCYNUM caule rectiusculo herbaceo foliis oblongis cymis lateralibus. *Lin. Sp. Plant.* 213. Greatest Canada Dogsbane with the least herbaceous flower.

3. APOCYNUM caule rectiusculo herbaceo foliis ovato lanceolatis. *Prod. Leyd.* 411. Venetian maritime Dogsbane with a Willow leaf and a purple flower.

4. APOCYNUM foliis ovatis petiolatis, superne glabris, floribus amplis pediculis longis hirsutis caule fruticoso. Shrubby upright Dogsbane with a very large and beautiful yellow flower.

5. APOCYNUM foliis oblongo-cordatis rigidis floribus lateralibus, caule fruticoso volubili. Climbing Dogsbane with a Citron leaf and spotted pods.

6. APOCYNUM caule erecto frutescente foliis lanceolato-ovalibus corollis acutis fauce villosis. *Flor. Zeyl.* 114. Dogsbane with an upright woody stalk, and oval pointed leaves.

7. APOCYNUM caule volubili perenne foliis ovatis venosis. *Prod. Leyd.* 412. Dogsbane with a perennial twining stalk, and oval veined leaves.

8. APOCYNUM caule volubili foliis ovatis rigidis obliquis cymis lateralibus tubo floris longissimo. Greater climbing Dogsbane with roundish leaves.

9. APOCYNUM caule fruticoso scandente foliis ovatis nervosis cymis lateralibus flore luteo magno tubo longissimo. Dogsbane with a climbing shrubby stalk, oval veined leaves; the flowers growing in bunches from the sides of the stalks, and a large yellow flower with a very long tube.

10. APOCYNUM foliis oblongo-cordatis, mucronatis sessilibus floribus lateralibus, caule scandente. Climbing Dogsbane with oblong pointed leaves, and large yellow open flowers.

11. APOCYNUM foliis cordatis glabris floribus villosis lateralibus petiolis longioribus caule scandente. Climbing Dogsbane with large yellow hairy flowers, and swelling angular pods, which are smooth.

The first sort grows naturally in *North America*. This hath an annual stalk, and a perennial root; the stalks rise about three feet, grow upright, and are garnished with smooth oval leaves, growing opposite. These, as also the stalks, abound with a milky juice, which flows out when they are broken; the flowers are collected in a kind of umbel, growing at the top of the stalks. These are white, and the nectariums in the bottom, have a purplish cast; these are seldom succeeded by pods in *England*, but the plant is propagated by parting of the roots. It is hardy, so will thrive in the full ground, but the soil should be light or dry, otherwise the roots are apt to rot in winter. The best time to part the roots is in *March*, before they begin to put out new stalks.

The second sort is a native of the same countries; the roots of this sort creep far in the ground, so that when it is planted in a garden, it is apt to spread so much, as to be troublesome. The stalks of this sort grow about two feet high, are red, and have oblong smooth leaves, set on by pairs opposite. Towards the upper part of the stalk, the flowers come out from the wings of the leaves, collected in small bunches, which are of an herbaceous white colour, and very small, so make no great appearance. This is very hardy, and propagates too fast by its creeping roots. Both these sorts flower in *July*, and in autumn their stalks decay to the root.

The third sort grows upon a small island in the sea, near *Venice*, but is supposed to have been originally brought from some other country. The roots of this creep pretty much, by which it is propagated, for it never produces any seeds either in the gardens where it is cultivated, or at *Venice* where it grows without care, as I have been informed by a very curious botanist, who resided many years at *Venice*, and constantly went to the spot several times in the season, to procure the seeds, if there had been any produced; but he assured me, he never could find any pods formed on the plants. The stalks of this sort decay in autumn, and new ones are sent out from the roots in the spring. The flowers grow at the top of the stalks in small umbels, which are shaped like those of the former sorts, but are much larger, so make a pretty appearance; it flowers in *July* and *August*. The best time to remove and part the roots is in the spring, just before they begin to push out new stalks.

The fourth sort grows naturally in *Jamaica*, in the *Savannas*, from whence it had the title of *Savanna* flower, by which it is chiefly known in that island. This rises three or four feet high, having woody stalks, which send out a few lateral branches, which are garnished with oval leaves, placed by pairs opposite; they are smooth, and of a shining green colour on their upper sides, but are pale, and veined underneath; the flowers are produced from the side of the branches, upon long foot-stalks; they are very large, having a long tube, which spreads open very wide at the top, and are of a bright yellow, so make a fine appearance in the places where the plants grow naturally, being most part of the year in flower. This plant is too tender to thrive in *England* without the assistance of a stove. It is propagated by seeds, which must be procured from *Jamaica*. When the seeds are obtained, they should be sown in pots filled with light sandy earth, and plunged into a hot-bed of tanners bark. If the seeds are good, the plants will appear in a month or five weeks after, when they should be treated in

the same manner as other tender plants from the same country, with this difference only, to be sparing in watering them; for these plants which abound with a milky juice, require very little wet, being soon destroyed by moisture. They should be constantly kept in the tan bed in the stove: there must be great care not to over pot them, for unless their roots are confined, the plants will not thrive. The second year the plants will flower, if they have been skilfully managed, when they will make a fine appearance in the stove: the usual time of their flowering in *England*, is in *July* and *August*.

The fifth sort was discovered by father *Plumier*, in some of the *French* islands in *America*, who made a drawing of the plant. It was afterwards found by the late Mr. *Robert Millar*, surgeon, growing plentifully near *Carthagena*, in *New Spain*. It hath twining stalks, by which it mounts to the tops of very tall trees; and stiff, oblong, heart-shaped leaves, which are smooth, of a shining green colour. The flowers are produced in small clusters from the side of the branches, and are of an herbaceous colour, so do not make any great appearance.

The sixth sort grows naturally in *India*, *Ceylon*, and upon the coast of *Guinea*. This plant rises with a woody stem to the height of five or six feet, garnished with oblong pointed leaves, very smooth, and of a shining green above, but pale underneath. From the wings of the leaves the flowers are produced in loose bunches. These are small, tubulous, and of a purple colour. It is a very tender plant, so must be constantly kept in a hot house, and plunged in the tan bed, otherwise it will not thrive in *England*. This plant must be sparingly watered, especially in winter, and should be planted in light sandy earth.

The seventh sort grows naturally in *India*. This plant hath a twining stalk, by which it rises to a considerable height, and is garnished with oblong leaves, which are much veined. It is tender, so requires to be constantly preserved in the stove, otherwise it will not thrive in this country.

The eighth sort grows naturally in *Jamaica*. This hath a climbing stalk, by which it fastens to the neighbouring trees, and rises ten or twelve feet high. The leaves are oval, stiff, and oblique to the foot-stalk; the flowers are of a purplish colour, and have very long tubes, but spread open wide at the top. It is tender, so must constantly remain in the stove, and should have very little water.

The ninth sort hath a climbing woolly stalk, and rises to a considerable height, by the support of neighbouring trees. The leaves grow by pairs opposite; the flowers come out from the wings of the leaves, each standing upon a separate long foot-stalk; they are large, and of a bright yellow colour, with very long tubes, and spread open wide at the top; they are succeeded by long compressed pods, which have borders on one side, and are filled with long channelled seeds, which are crowned with long plumes of soft down. This is propagated by seeds, which must be procured from the country where it grows naturally, for the seeds do not ripen in this country; and the plants should be treated in the same manner, as hath been before directed for the fourth sort. It flowers in *August* and *September*, in *England*.

The tenth and eleventh sorts were discovered at *La Vera Cruz*, in *New Spain*, by the late Dr. *William Houstoun*. These plants have both climbing stalks, by which they mount to the tops of the tallest trees, where they grow naturally. The tenth sort has produced flowers in *England* several times; but the eleventh, which grows more luxuriantly than the other, never had any appearance of flowers. These are both propagated by seeds, which should be sown as the fourth sort, and the plants must be treated in the same manner afterward. The pods of all the sorts are filled with seeds, which are, for the most part compressed, and lie over each

other (*imbricatum*) like tiles on a house: these have each a long plume of a cottony down fastened to their crowns, by which, when the pods are ripe and open, the seeds are wafted by the wind to a considerable distance; so that in the countries where these plants naturally grow, they are some of the most troublesome weeds.

The down of these plants is in great esteem in *France*, for stuffing of easy chairs, making very light quilts, which are warm, and extremely light, so are very proper covering for persons afflicted with the gout; for the down is so extreme light and elastick, that it occasions no weight. This the *French* call *Delawad*, and in the southern parts of *France*, where some of the sorts will thrive in the open air, and perfect their seeds, there are many plantations made of these plants for the sake of the down.

The other sorts, which have been ranged under this genus, are now referred to the following genera, to which the reader is desired to turn, for such of them as are not here enumerated, *viz.* *Asclepias*, *Cynanchum*, and *Periploca*.

APPLE TREE. See *Malus*.

APPLES of LOVE. See *Lycopersicon* and *Solanum*.

MAD APPLES. See *Melongena*.

APRICOT, or ABRICOT; or, in *Latin*, *Malus Armeniaca*. See *Armeniaca*.

AQUIFOLIUM. See *Ilex*.

AQUILEGIA, Columbine.

The Characters are,

The flower hath no empalement, but is composed of five equal oval petals, which are plain, and spread open within, and have five equal nectariums, ranged alternately with the petals, each of the horns widening upward. It hath many awl-shaped stamina, and five oval germen, which afterward become five cylindrical vessels, which are filled with oval shining seeds.

The Species are,

1. AQUILEGIA nectariis rectis petalo lanceolato brevioribus. *Lin. Sp. Pl.* 533. Wild Columbine.

2. AQUILEGIA nectariis rectis, petalis ovatis longioribus. Mountain Columbine with a large flower.

3. AQUILEGIA nectariis incurvis. *Hort. Upsal.* Columbine with a double inverted flower.

4. AQUILEGIA nectariis rectis staminibus corollâ longioribus. *Hort. Upsal.* 153. Early dwarf Canada Columbine.

The first sort is found growing wild in the woods in some parts of *England*. I have frequently gathered it in the woods near *Bexley* in *Kent*, and also between *Maidstone* and *Rockesfer*. The flowers of this are blue, and the petals are short. The second sort I found growing naturally near *Ingleborough Hill*, in *Yorkshire*. The flowers of this are much larger than those of the Garden Columbine, and the seeds which I sowed of this in the garden at *Chelsea*, produced the same species without the least variation.

The third is the Garden Columbine, of which there are great varieties, not only in the colour and fulness of their flowers, but also in their form. In some there are no visible nectariums, but in place of them a multiplicity of petals, so that the flowers are as double as those of the Larkspur. These are commonly called Rose Columbines; the colours of these are Chestnut, blue, red, and white, and some are finely variegated with two colours.

There are others with sharp pointed petals, which expand in form of a star; of these there are single and double flowers, of the several colours as the former. But as the sorts with variegated flowers are the greatest beauties, so those persons, who are desirous to have them in perfection, should root out all those plants whose flowers are not well marked, or cut off their stems so soon as their flowers appear, leaving only the most beautiful to seed.

They are all raised by sowing the seeds, or parting the old roots, but the former method is chiefly practised; for the old

roots are very apt to degenerate after they have blown two or three years, and become quite plain.

The seeds should be sown in a nursery bed in *September*, for the seeds which are kept till spring seldom grow well, or at least remain in the ground a whole year. In the spring following your young plants will appear above ground, you must therefore clear them from weeds, and if the season should be dry, refresh them with water, that they may gather strength.

In the middle or latter end of *May*, these plants will be strong enough to transplant; you must therefore prepare some beds of good fresh undunged earth, planting them therein at eight or nine inches distance every way, keeping them clear from weeds.

At *Michaelmas* you may remove them into the borders of your flower garden, and the *May* following they will produce flowers; but if you intend to maintain their roots, you should not suffer them to seed, but crop off all their flower-stems as soon as the flowers are past.

In order to keep up a succession of good flowers, you should sow fresh seeds every year; and if you can meet with a friend, at some distance, who is furnished with good flowers of this kind, it will be very advantageous to both parties, to exchange seeds once in two years, by which means they will not be so apt to degenerate into plain colours.

The *Canada* Columbine flowers almost a month before the other sorts; for which reason it is preserved in the gardens of the curious, though there is no very great beauty in the flowers. There is another variety of this sort, with taller flower-stems, which flowers a little after the other, but doth not differ, either in the shape of its flowers or leaves from this.

The first sort is that which is directed for medicinal use in the Dispensaries, but at present is very rarely ordered.

ARABIS. *Lin. Gen. Pl.* 732. Bastard Tower Mustard.

The Characters are,

The flower hath four petals in form of a cross, which spread open; at the bottom of which is situated a reflexed nectarium; between these arise six upright stamina. In the center is situated a taper germen, which afterward becomes a narrow long compressed pod, having two valves and a thin partition, between which is lodged a row of flat seeds.

The Species are,

1. ARABIS foliis petiolatis lanceolatis integerrimis. *Vir. Cliff.* 64. Bastard Tower Mustard, with whole spear-shaped leaves having foot-stalks.

2. ARABIS foliis amplexicaulibus dentatis. *Hort. Cliff.* 335. Bastard Tower Mustard, with indented leaves embracing the stalks.

3. ARABIS foliis amplexicaulibus siliquis ancipitibus linearibus calycibus subpilosis. *Hort. Upsal.* 191. Broad-leaved hairy Tower Mustard, with hanging pods.

4. ARABIS foliis amplexicaulibus siliquis decurvis planis linearibus, calycibus subrugosis. *Hort. Upsal.* 192. Bastard Tower Mustard, with narrow plain hanging pods and rough flower cups.

The first sort is a low plant, which seldom rises more than four or five inches high, branching on every side; having small white flowers growing alternately, which have each four petals in form of a cross, that are succeeded by long slender pods, filled with small round seeds. It grows naturally on sandy dry ground, in many parts of *England*.

The second sort grows naturally in *Istria*, and also upon the *Alps*, and other mountainous countries. It is a perennial plant, which increases very fast by its creeping roots, which run obliquely near the surface of the ground, and send down roots at every joint. The leaves are whitish, and indented on their edges; the flower-stalks grow near a foot high, and are garnished with leaves placed alternately, which

closely embrace the stalks: the flowers grow in loose bunches on the top; these are white, and have leaves in form of a cross, which are succeeded by long flat pods, opening lengthways.

This is a very hardy plant, so will thrive in any situation. It produces seeds in plenty, but as it multiplies so fast by its creeping roots, so few persons are at the trouble to sow the seeds. It flowers early in the spring.

The third sort grows naturally in *Siberia*. This is a perennial plant, which grows near a foot high; the leaves are broad, hairy, and indented on their edges. The flowers grow alternately in loose spikes, and are of a dirty white colour. These are succeeded by long narrow pods, which are filled with flat brown seeds. This is a biennial plant, which is very hardy, so will thrive in any situation.

The fourth sort grows naturally in *Hungary*, *Sicily*, and *France*, as also upon some old walls at *Cambridge* and *Ely*, but the seeds might probably come out of the gardens where they were first planted. The plants of this kind, which grow on walls or ruins, continue much longer than those which are sown in gardens, where they seldom live longer than two years; the stalks rise about a foot and an half high. Toward the top of the stalks grow long loose spikes of flowers, which are of a dirty white colour. After the flowers are past, the germen become long flat pods, which open lengthways, and have two rows of flat bordered seeds of a dark brown colour.

This sort is easily propagated by seed, which should be sown in the autumn. When the plants are strong enough to remove, they may be transplanted into a shady border, or in rural plantations, where no other care will be necessary, but to prevent their being overgrown by weeds.

ARACHIS, Earth, or Ground Nut.

The Characters are,

The empalement of the flower opens in two parts. The flower is of the butterfly kind; it hath ten stamina, nine of which coalesce, and the upper one stands off. In the center is situated an oblong germen, which afterward turns to an oblong pod, containing two or three oblong blunt seeds.

We have but one Species of this plant, viz.

ARACHIS. *Lin. Hort. Cliff.* 353. Earth, or Ground Nut.

The native country of this plant I believe is *Africa*, though at present, all the settlements in *America* abound with it; but many persons who have resided in that country affirm, they were originally brought by the slaves from *Africa*.

It multiplies very fast in a warm country, but being impatient of cold, it cannot be propagated in the open air in *England*; therefore, whoever has an inclination to cultivate this plant, must plant the seeds in a hot-bed in the spring of the year; and when the weather proves warm, they may be exposed to the open air by degrees. The branches of this plant trail upon the ground, and the flowers (which are yellow) are produced single upon long foot-stalks; and as soon as the flower begins to decay, the germen is thrust under ground, where the pod is formed and ripened; so that unless the ground is opened, they never appear: the roots of this plant are annual, but the nuts or seeds sufficiently stock the ground in a warm country, where they are not very carefully taken up.

ARALIA, Berry-bearing Angelica.

The Characters are,

It is an umbelliferous plant with a globular umbel, having a small involucre; the flower hath five oval petals, and five short styles. The germen afterward turns to a roundish channelled berry, having five cells, each containing one oblong hard seed.

The Species are,

1. ARALIA caule folioso herbaceo laevi. *Hort. Upsal.* 70. *Canada* Berry-bearing Angelica.

2. *ARALIA caule nudo*. Hort. Cliff. 113. Berry-bearing Angelica with a naked stalk.

3. *ARALIA arborescens caule foliolisque aculeata*. Vir. Cliff. 26. Angelica Tree, vulgò.

The first sort is pretty common in many gardens near London, but the second is at present more rarely met with. Both these plants grow naturally in North America. They are perennial plants, whose stalks decay in autumn, and new ones arise from their roots in the spring. The first grows about four or five feet high, and divides into many irregular branches, having ramose leaves, placed alternately; at the wings of these the flower-stalks are produced, which are terminated by round umbels of small flowers, of a whitish colour; these are succeeded by round channelled berries, which when ripe, are black. This plant flowers in June, and the seeds ripen in October.

The second sort rises to near the same height as the former; the leaves of this divide into two or three parts, each ending with three or five large lobes, which are sawed on their edges. The flower-stalks arise between these immediately from the root, being naked, and are terminated by round umbels of flowers, in shape and colour like the first, but the berries are smaller. This flowers toward the end of June, and the seeds ripen late in the autumn.

Both these sorts are easily propagated by seeds, which are generally produced in plenty. These should be sown in the autumn soon after they are ripe. When the plants appear, they must be kept clean from weeds during the summer; and in the autumn following, when their leaves decay, the roots may be taken up, and transplanted where they are to remain. They are very hardy plants, so may be planted in any situation; and as they grow naturally in woods, so they may be planted in wilder's quarters, under trees.

The third sort rises with a woody stem to the height of eight or ten feet, dividing into several branches; these are garnished with branching leaves, which are compounded of many divaricated wings; the ribs of the leaves, as also the branches and stems of the plants, are armed with strong crooked spines, which render the places very difficult to pass through where they grow in plenty. The flowers of this sort are produced in large loose umbels, at the extremity of the branches, and are of an herbaceous colour, so make no great figure, but the plants are preserved in most of the curious gardens in England. It flowers in August, but the seeds do not ripen in this country.

This is propagated by seeds, which are easily procured from North America; but as they seldom arrive here till toward the spring, so the plants never come up the first year, but the following spring. When the plants come up, they should be frequently refreshed with water, and constantly kept clean from weeds, and in summer they should be inured to the open air. These plants should not be disturbed the first season; but as they are often injured by frost when young, so in the first winter the plants should be screened from hard frosts, but in mild weather should be constantly opened to enjoy the free air. The leaves of these plants fall away in the autumn. In the spring, before the plants begin to push, they should be transplanted; a few of them should be planted singly into small pots, and the others may be planted in a bed of light earth in a warm situation. If those which are planted in the small pots are plunged in a moderate hot-bed, it will greatly forward their growth; but they must be early inured to bear the open air, otherwise they will draw up weak, and the spring following they may be planted where they are designed to remain. As these plants do not come out very early in the spring, so they often continue growing pretty late in the autumn, which causes the extreme parts of their shoots to be very tender, whereby they often suffer from the early

frosts in autumn, which frequently kill the upper parts of the shoots; but as their woody stems are seldom injured, so they put out new branches below: and if in very severe winters the stems are destroyed, yet the roots will remain, and put out new ones the following summer, therefore they should not be destroyed.

This plant may also be propagated by its roots, for as they spread far in the ground, so they will put out young plants at a distance from the stems, which may be taken off before they begin to shoot in the spring.

ARBOR CAMPHORIFERA. See Laurus.

ARBOR CORAL. See Erythrina.

ARBOR JUDÆ. See Cercis.

ARBUTUS, the Strawberry tree.

The Characters are,

The flower hath a small obtuse empalement, which is cut into five parts, upon which the germen sits! The flower is of one leaf, shaped like a pitcher; at the bottom of the flower is situated the globular germen, which afterward becomes an oval or round berry, having five cells, which are filled with hard seeds.

The Species are,

1. *ARBUTUS foliis glabris serratis, baccis polyspermis, caule erecto arboreo*. The common Strawberry tree.

2. *ARBUTUS foliis glabris integerrimis, baccis polyspermis caule erecto arboreo*. The Oriental Strawberry tree, called Adrachne.

3. *ARBUTUS caulibus procumbentibus foliis ovatis subserratis floribus sparsis baccis polyspermis*. Lin. Sp. Pl. 395. Arbutus with trailing stalks, oval leaves somewhat indented, flowers growing loosely, and many seeds.

4. *ARBUTUS caulibus procumbentibus foliis rugosis serratis*. Flor. Lap. 161. Arbutus with trailing stalks and rough sawed leaves.

5. *ARBUTUS caulibus procumbentibus foliis integerrimis*. Flor. Lat. 162. Arbutus with trailing stalks and entire leaves; called Uva ursi, or Bearberries.

The first sort grows naturally in Italy, Spain, and also in Ireland; and is now very common in the English gardens. Of this sort there are the following varieties, viz. one with an oblong flower and oval fruit; another with a double flower, and a third with red flowers; but these being only femal varieties, I have not mentioned them as species.

The second sort grows naturally in the East, particularly about Magnesia, where it is so plenty, as to be the principal fuel used by the inhabitants of the country. The leaves are large and oval, somewhat like those of the Bay tree, but not quite so long; they are smooth and entire, having no serratures on their edges; the flowers are shaped like those of the common Arbutus, but grow thinly on their branches. The fruit is oval, and of the same colour and consistence with the common sort, but the seeds of this are flat, whereas those of the common sort are pointed and angular.

The common Strawberry tree is one of the greatest ornaments in the months of October, November, and frequently great part of December; that being the season when the trees are in flower, and the fruit of the former year is ripe, for the fruit is a whole year growing to perfection; so that the fruit which is produced from the flowers of one year, do not ripen till the blossoms for the succeeding year are fully blown; so they make a goodly appearance, and at a season when most other trees are past their beauty.

The sort with double flowers is a curiosity, but as the flowers have only two rows of leaves, so they make no great appearance; nor do the trees produce fruit in any plenty, therefore the other is more preferable. The sort with red flowers makes a pretty variety, when intermixed with the other; for the outside of the flowers are of a fine red colour at their first appearance, and afterward they change to purple before they fall off. These varieties are preserved by inarching

inarching or grafting them upon the common Arbutus, for the seeds of either do not produce the same kind.

The best method to propagate the Arbutus is from seeds; therefore when the fruit is perfectly ripe, it should be gathered and mixed with dry sand, to preserve them till the middle or latter end of *March*, which is a proper season for sowing of them, in order to have strong plants before winter; they must be sown in pots, which should be plunged into a moderate hot-bed, which will greatly forward their vegetation; and, if they are properly managed, will grow eight or ten inches high before winter. In the summer, if the pots are plunged into an old tan bed, it will preserve the earth in the pots from drying too fast; and if the plants are screened from the sun in the heat of the day, it will greatly forward them. The beginning of *October*, these plants may be shaken out of the pots, and their roots carefully separated, planting them singly in small pots filled with light earth; then plunge the pots into an old bed of tanners bark, under a common frame, where they should remain during the winter, observing to expose the plants to the open air, at all times when the weather is favourable, but in frosty weather they must be covered. The spring following, they may be plunged into the ground, in a sheltered situation, observing to water them frequently in dry weather, which will keep them growing all the summer: but it will be advisable to screen them from the frost the following winter, by covering them with mats in bad weather.

The following spring you may shake them out of the pots into the open ground in the places where they are to remain, that they may have taken good root before the winter.

These trees are tolerably hardy, and are seldom hurt, except in extreme hard winters, which many times kill the young and tender branches, but rarely destroy the trees; therefore, however dead the trees may appear after a hard winter, yet they should be suffered to remain till the succeeding summer has sufficiently demonstrated what are living and what are dead; for the winters *Anno 1728-9*, and *1739-40*, gave us great reason to believe most of the trees of this kind were destroyed; and many people were so hasty, as to dig up or cut down, many of their trees; whereas all those people who had patience to let them remain, found that scarce any of them failed to come out again the next summer, and made handsome plants that season.

The very best season for transplanting of the Arbutus is in *September*, at which time the blossoms are beginning to appear; and at that season, if it should prove very dry and they are kept moist, they will take root very soon; but toward the beginning of *November*, their roots should be well covered with mulch, to keep out the frost.

The third sort grows naturally in *Acadia*, and other northern parts of *America*, upon swampy land, which is frequently overflowed with water; this is a low bushy shrub, with slender trailing branches, which are garnished with oval leaves, a little sawed on their edges; the flowers come out from the wings of the leaves, growing in thin loose bunches: it is with great difficulty the plants of this sort are kept alive here.

The fourth sort grows naturally on the *Alps*, and the *Helvetian* mountains, also in *Lapland* and *Siberia*. This sends out from the roots many slender branches, which trail upon the ground; which are garnished with oblong rough leaves, of a pale green colour; the flowers are produced from the wings of the leaves, upon long slender foot-stalks; and are succeeded by berries about the size of the common black Cherry, which are first green, afterward red, and when ripe they are black. This is also a very difficult plant to keep alive in gardens, for it is an inhabitant of bogs, growing among moss, where the ground is never dry.

The fifth sort grows naturally upon the mountains in

Spain, and some other parts of *Europe*. It rises little more than a foot high, dividing into many branches, which are closely garnished with smooth thick leaves of an oval form; the flowers are produced in small bunches toward the extremity of the branches, which are shaped like those of the common sort, but are smaller; and are succeeded by berries, of the same size with those of the former sort, which are red when ripe.

The true Adrachne is not at present in *England*, but there is a broad-leaved sort from the *Lewant*, whose leaves are sawed on their edges, which passes for it. The seeds of this must be procured from the *Lewant*, where the trees grow in plenty. The seeds may be sown, and the plants treated in the same way as the Arbutus, but the plants are much tenderer. As the leaves of this tree are larger than those of the common Arbutus, so the trees make a fine appearance, and deserve our care to cultivate them; therefore they should be preserved in pots three or four years, till they have obtained strength, and may then be planted in a warm situation and on a dry soil, for this sort will not thrive in wet ground.

ARCTIUM. *Lin. Gen.* 830. Burdock.

The Characters are,

The flower is composed of many florets, which are tubulous and uniform, cut into five narrow segments at the top: the germen is situated at the bottom of the tube, which afterward becomes a single pyramidal angular seed, crowned with down.

The Species are,

1. ARCTIUM foliis cordatis inermibus petiolatis capitulis majoribus sparsis. Burdock with heart-shaped leaves, without prickles, having foot-stalks, and large heads growing scatteringly.

2. ARCTIUM foliis cordatis inermibus, capitulis minoribus compactis. Burdock with heart-shaped leaves without spines, and small heads growing close together.

3. ARCTIUM foliis cordatis inermibus, capitulis tomento-reticulatis. Burdock with heart-shaped leaves without spines, and woolly netted heads.

The two first sorts are common weeds, growing on the sides of roads and foot-paths in most parts of *England*, so are not admitted into gardens. The first is ordered for medicinal use by the *College of Physicians*, therefore I have inserted it here.

The leaves of the third sort are like those of the common, but are whiter on their under side; the heads are more compact, and the florets are of a bright red colour; but the greatest difference is in their heads, which in this sort are beautifully netted with a fine down all over.

As these plants are seldom admitted into gardens, so it is needless to say any thing of their culture; but where they are troublesome weeds, it may not be amiss to mention, that their roots last but two years, so they may be destroyed with less trouble than such as have abiding roots; for the plants which come up from seed, do not flower till the second year, and when the seeds are perfected their roots decay.

ARCTOTIS, or ANEMONOSPERMOS.

The Characters are,

The common empalement is scaly and silvery; the flower is composed of many female florets, which are ranged round the border; the germen afterward becomes a single roundish seed, covered with a soft down. The middle or disk of the flower is composed of hermaphrodite florets; in the center is placed a small germen, supporting a cylindrical style with a single stigma. These flowers are abortive.

The Species are,

1. ARCTOTIS foliis pinnatis, caule herbaceo, petalis radii profundè trifidis. *Flor. Leyd.* 179. Anemonospermus of *Africa*, with hoary Dandelion leaves.

2. *ARCTOTIS foliis lanceolato-linearibus integris denticulatis.* *Lin. Hort. Cliff.* 412. *Arctotis* with narrow spear-shaped leaves, which are indented on the sides.

3. *ARCTOTIS foliis pinnato-sinuatis, laciniis oblongis dentatis.* *Lin. Hort. Cliff.* 412. *Arctotis* with sinuated winged leaves, with long indentures, and a beautiful Orange-coloured flower.

4. *ARCTOTIS foliis ovatis dentatis, petiolis longissimis, superne dentatis, caule ramoso.* *Lin. Hort. Cliff.* 412. *Arctotis* with oval indented leaves, with long foot-stalks, whose upper side is indented, and a branching stalk.

5. *ARCTOTIS ramis decumbentibus foliis lineari-lanceolatis rigidis subtus argenteis flore magno aureo pedunculo longissimo.* *Fig. Pl. Tab.* 49. *Arctotis* with trailing branches, narrow, stiff; spear-shaped leaves, white on their under side, and a large golden flower, with a very long foot-stalk.

6. *ARCTOTIS foliis pinnato-sinuatis subtus argenteis sessilibus, flore magno aurantio.* *Arctotis* with sinuated winged leaves, lying close to the stalk, white on their under side, and a large Orange-coloured flower.

7. *ARCTOTIS foliis ovatis nervosis marginibus crenatis petiolis longissimis.* *Arctotis* with nervous heart-shaped leaves, whose edges are indented, and very long foot-stalks.

8. *ARCTOTIS foliis pinnato-laciniatis undatis caule racemoso fruticoso.* *Arctotis* with winged jagged leaves, which are waved, and a branching shrubby stalk.

These plants are natives of the country about the *Cape of Good Hope*, from whence they have been brought to some curious gardens in *Holland* and *England*.

The first sort here mentioned is an annual plant, which may be sown upon a warm border of light earth in the open air, in the middle of *April*, where they are designed to remain; and require no farther care, but to thin the plants where they are too close, and keep them clean from weeds. They will flower in *August*, and perfect seeds very well in autumn.

The fifth, sixth, and seventh sorts are low plants, seldom rising in stem above four or five inches, their leaves spreading near the surface of the ground; the flowers are produced upon single naked foot-stalks arising from the root of the plants; these flower in *April* or *May*, at which time they make a fine appearance; but they seldom perfect their seeds in *England*; therefore are propagated by cuttings, which take root freely in the summer months. In winter the plants may be preserved under a good frame, where they may have a large share of free air, when the weather is mild; for if they are drawn weak by being kept in a green-house, they seldom produce many flowers.

The second, third, fourth, and eighth sorts, grow to the height of four or five feet, and the eighth, sometimes to six or seven, sending forth many branches; therefore will require to be frequently pruned, to keep the plants in tolerable order; for it sends forth strong rambling shoots, when their roots are not too much confined in the pots, but more so when they are duly watered.

The fifth and sixth sorts flower in *May* and *June*; these have very large beautiful flowers, especially the fifth, whose bottom is finely chequered with black and white, and the rays being of a deep gold colour, are set off by the other colours.

The shrubby sorts are propagated by planting cuttings in a bed of light fresh earth, in any of the summer months, observing to shade them from the heat of the sun until they have taken root; then they may be planted into pots filled with the like fresh earth, setting the pots in a shady place until the plants are settled in their new earth, after which time you should expose them to the open air until the latter end of *October*, or later, according as you find the weather is favourable; when you must remove the pots into the green-house, where they should be placed as near the window as possible, that they may have a good quantity of free air at all times when the weather is mild; you must also frequently refresh them with

water, giving them it plentifully in mild weather, otherwise their leaves and branches will hang down and wither. They will require to be shifted into other pots two or three times at least, every summer, and the pots should be frequently removed, to prevent the plants from striking their roots through the holes of the pots into the ground, which they are very apt to do, and then they will shoot very vigorously.

All these plants should be frequently renewed by cuttings, because the old plants are subject to decay in winter; therefore if young plants are not annually raised, the species may soon be lost.

ARGEMONE, Prickly Poppy.

The Characters are,

The flower hath five roundish petals, which spread open, and are larger than the empalement; in the center is situated an oval five-cornered germen. This is attended by a great number of stamina; the germen afterward becomes an oval seed-vessel, having five angles, and so many cells, which are filled with small rough seeds.

There is but one Species of this plant known, which is,

ARGEMONE Mexicana. *Tourn.* The Prickly Poppy.

This is an annual plant, which is very common in most parts of the *West-Indies*; and is, by the Spaniards, called *Fico del Inferno*, or the Devil's Fig; there is no great beauty or use of this plant amongst us, that I know of; but whoever hath a mind to cultivate it, should sow it on a bed of light earth, in the spring, where it is to remain; and if it comes up too thick, the plants must be thinned out to four inches distance, where, when once it has shed its seed, there will not want a supply of plants for several years after.

ARIA THEOPHRASTI. See *Cratægus*.

ARISARUM. See *Arum*.

ARISTOLOCHIA, Birthwort.

The Characters are,

The flower is of one leaf, which is unequal; the base is swelling and globular, afterward is extended in a cylindrical tube, which spreads open at the brim, where the lower part is stretched out like a tongue. The oblong angular germen fits under the flower, which afterward turns to a large seed-vessel, differing in form, which opens in six cells, which are filled with seeds, for the most part compressed.

The Species are,

1. *ARISTOLOCHIA foliis cordatis, subsessilibus obtusis, caule infirmo, floribus solitariis.* *Lin. Sp. Plant.* 962. Round-rooted Birthwort with a black purple flower.

2. *ARISTOLOCHIA foliis cordatis petiolatis integerrimis obtusiusculis, caule infirmo floribus solitariis.* *Lin. Sp. Plant.* 962. The true long-rooted Birthwort.

3. *ARISTOLOCHIA foliis cordatis caule erecto floribus axillaribus confertis.* *Hort. Upsal.* 279. Upright or climbing Birthwort.

4. *ARISTOLOCHIA foliis cordatis, crenulatis petiolatis, floribus solitariis.* *Lin. Sp. Pl.* 962. Birthwort, called Pistolochia.

5. *ARISTOLOCHIA foliis cordato-oblongis undatis, caule infirmo, floribus solitariis.* *Lin. Sp. Pl.* 961. Ever-green Birthwort of Crete.

6. *ARISTOLOCHIA foliis cordato-oblongis planis, caulibus infirmis flexuosis, teretibus floribus solitariis.* *Lin. Sp. Plant.* 961. The Virginia Snakeroot.

7. *ARISTOLOCHIA foliis cordato-lanceolatis caule erecto fruticoso.* *Lin. Sp. Pl.* 960. Virginia Birthwort with eared leaves.

8. *ARISTOLOCHIA foliis cordato-oblongis caule volubili pedunculis multifloris.* *Flor. Zeyl.* 323. The Contrayerva of Jamaica.

9. *ARISTOLOCHIA hirta floribus solitariis pendulis recurvatis sublabiatis.* *Lin. Sp. Plant.* Long-rooted hairy Birthwort with an oblong leaf and a large flower.

The first and second sorts grow naturally in the south of *France*, in *Spain*, and *Italy*, from whence they are brought for medicinal use. The roots of the first sort are roundish,

and grow to the size of small Turneps; and are in shape and colour like the roots of the common Cyclamen, the roots of which are frequently sold in the markets for those of the round Birthwort, which at first may have been occasioned by the supposed virtues of the roots of the Cyclamen. This sort hath three or four weak trailing branches, which lie on the ground where they are not supported, and extend to the length of two feet; the leaves are heart-shaped, and rounded at their extremity; the flowers come out singly, at every leaf, toward the upper part of the stalk. They are of a purplish black colour, and shaped like those of the other sorts, and are frequently succeeded by oval seed-vessels, having six cells, which are full of flat seeds.

The second sort hath long tap roots, shaped like those of Carrots; this has weak trailing branches, which extend little more than a foot; the leaves of this sort are paler, and have longer foot-stalks than the first; the flowers come out from the wing of the leaves, like the other, and are of a pale purple colour: they are sometimes succeeded by oblong seed-vessels, having six cells filled with compressed seeds.

They are both propagated by seeds, which should be sown in the autumn, in pots filled with light earth, and placed under a frame, to be screened from the frost. If these pots are put into a gentle hot-bed in *March*, it will bring up the plants much sooner than they otherwise would rise. When the plants come up, they should be inured by degrees to bear the open air; in summer they must have gentle refreshings of water in dry weather; but in the autumn, when their stalks begin to decay, they must have little wet: in the winter the pots must be sheltered under a frame, and in *March*, before the roots begin to shoot, they should be transplanted into separate small pots filled with light earth, when they may be removed into the open air, and treated in the same manner as in the former summer, and sheltered also the following winter. The next spring they may be turned out of the pots, and planted in a warm border; where, in the autumn, when their stalks are decayed, if the border is covered with old tanners bark to keep out the frost, the roots will be secured; but where this care is not taken, the roots are frequently killed by frost.

When the seeds of these plants are sown in the spring, the plants will not appear till the spring following; so that a whole season is lost, and many times they fail, therefore it should always be sown in the autumn.

The third sort grows naturally in *France, Spain, Italy, and Hungary*, but is preserved in some of the *English* gardens because it is sometimes used in medicine. This is a mischievous plant for creeping at the root; so that if once it has taken in a garden, it will be difficult to extirpate again: it will thrive in almost any soil or situation.

The fourth sort grows wild in *Spain, Italy, and the south of France*; but in *England* it is preserved, for variety, in botanick gardens. The plants of this sort must be planted in pots filled with light earth, and sheltered from severe cold in winter, but they should have as much free air as possible in mild weather.

The fifth sort grows naturally in *Crete*. The root of this sort is perennial, and sends out many trailing branches, which extend to about one foot and an half in length, with oblong heart-shaped leaves, which are evergreen. The flowers are shaped like the others of this genus, of a dark purple colour, but never produce seeds in *England*, so are propagated by parting of the roots: this sort is too tender to thrive in the open air in winter, so is preserved in pots, and placed under a common frame in winter, where they should have as much free air as possible in mild weather.

The sixth sort is the Snakeroot, which is greatly used in medicine; these roots are brought over from *Virginia and Carolina*. There are some of these plants preserved in

the gardens of those who are curious, but as they are sometimes killed by frost in winter, so they are not very common in the *English* gardens. This sort is propagated by seeds, which should be sown in the autumn, and afterward treated in the same manner as hath been directed for the two first sorts, with which management they will produce their flowers, and perfect their seeds every year.

The seventh sort grows naturally in *North America*, and is by some called Snakeroot, but is not near so strong as the former; the branches of this grow erect, and are perennial, whereas those of the other sort decay to the root every winter: this rises about two feet high; the branches are not woody, but are strong enough to support themselves; the leaves are oblong and heart-shaped. This sort will live abroad in warm borders, with a little protection in hard frosts. It is propagated by seeds as the former, and may also be increased by parting of the roots.

The eighth sort grows naturally in *Jamaica*, where it is called Contrayerva; the roots are there used as such: this hath long trailing branches, which climb upon the neighbouring plants, and rise to a considerable height; the flowers are produced in small clusters, toward the upper part of the stalks, which are of a dark purple colour. This plant is tender, and in winter should have very little wet, therefore must be constantly kept in the stove, otherwise it will not live in *England*.

The ninth sort was discovered by Dr. *Tournefort* in the *Levant*. This hath some resemblance to the second sort, but the leaves are not so deeply eared at bottom, and are hairy; the flowers of this are also much larger. This may be propagated by seeds, in the same manner as hath been directed for the first and second sorts, and the plants so treated will thrive very well here.

ARMENIACA, the Apricot.

The Characters are,

The flower is composed of five large roundish petals which spread open, whose base is inserted in the empalement; in the center is placed a round germen, attended by upward of twenty awl-shaped stamina. The germen afterward becomes a roundish pulpy fruit, having a longitudinal furrow inclosing a roundish nut, which is a little compressed on the sides.

The specific title given by *Linnaeus* to the Apricot is, *Prunus floribus subsessilibus foliis subcordatis. Sp. Plant. 474.*

The Varieties are,

1. The Masculine Apricot.
2. The Orange Apricot.
3. The *Algier* Apricot.
4. The *Roman* Apricot.
5. The *Turkey* Apricot.
6. The *Breda* Apricot.
7. The *Brussels* Apricot.

The Masculine is the first ripe of all the Apricots; it is a small, roundish fruit, of a red colour towards the sun; as it ripens, the colour fades to a greenish yellow on the other side. The tree is very apt to be covered with flowers, but as they come out early in the spring, they are frequently destroyed by the cold, unless the trees are covered to protect them.

The Orange is the next ripe Apricot; this fruit is much larger than the former, and as it ripens, changes to a deep yellow colour. The flesh of this is dry, and not high flavoured, it is better for tarts than for the table.

The *Algier* is the next in season; this is of an oval shape, a little compressed on the sides; it turns to a pale yellow, or straw colour, when ripe; the flesh is dry, and not high flavoured: this, and what is by some persons called the common Apricot, are often confounded.

The *Roman* is the next ripe Apricot; this is a larger fruit than the former, and not compressed so much on the sides; the colour is deeper, and the flesh is not so dry as the former.

The

The *Turkey Apricot* is yet larger than either of the former, and of a globular figure; the fruit turns to a deeper colour than the former; the flesh is firmer, and of a higher flavour than either of the former.

The *Breda Apricot* (as it is called from its being brought from thence into *England*) was originally brought from *Africa*: this is a large roundish fruit, changing to a deep yellow when ripe; the flesh is soft, full of juice, and of a deep Orange colour within side; the stone is rounder and larger than any of the other sorts: this is the best Apricot we have, and when ripened on a standard, is preferable to all other kinds.

The *Brussels* is the latest ripe of all the Apricots, for when it is planted against a wall, it is generally the beginning of *August* before it is ripe, unless when it is planted to a full south aspect; which is what should not be practised, because the fruit is never well tasted which grows in a warm exposure. This fruit is of a middling size, rather inclining to an oval figure; red on the side next the sun, with many dark spots, and of a greenish yellow on the other side; the flesh is firm, and of an high flavour; the fruit often cracks before it is ripe.

Most people train these trees up to stems of six or seven feet high, or bud them upon stocks of that height; but this is a practice I would not recommend to the publick, because the higher the heads of these trees are, the more they are exposed to the cutting winds in the spring, which too frequently destroy the blossoms; and the fruit is also more liable to be blown down in summer, especially if there should happen to be much wind at the time when the fruit is ripe; which by falling from a great height, will be bruised and spoiled; therefore I prefer half standards, of about two and an half, or three feet in the stem, to those which are much taller.

These fruits are all propagated by budding them on Plum stocks, and will readily take upon almost any sort of Plum, provided the stock be free and thriving (except the *Brussels* kind, which is usually budded on a sort of stock, commonly called the *St. Julian*, which better suits this tree, as being generally planted for standards, than any other sort of Plum will). The manner of raising the stocks, and budding these trees, shall be treated of under their particular articles, to which I refer the reader, and shall proceed to their planting and management.

These trees are all (except the two last sorts) planted against walls, and should have an east or west aspect; for if they are planted full south, the great heat causes them to be mealy before they are well eatable.

The borders under these walls should be six feet wide, at least, and if it were more, the better, but I would never advise the making of them so deep as is the general custom; for if the earth be two feet deep, or two and an half at most, it is enough.

If your ground is a wet cold loam or clay, you should raise your borders as much above the level of the surface as it will admit, laying some stones or rubbish in the bottom, to prevent the roots from running downwards; but if you plant upon a chalk or gravel, it will be better to raise the borders to a proper thickness, with good loamy earth, than to sink the borders by removing the chalk or gravel; for although these are removed the whole breadth of the border, which we may allow to be eight feet, and this trench filled with good earth, yet the roots of the trees will in a few years extend this length, and then meeting with the chalk or gravel, will occasion the leaves of the trees to turn pale, and fall off early in the season; the fruit will be small, dry, and ill flavoured, and the shoots of the trees will be weak. But where the borders are raised above the chalk to their full height, the roots will not strike down into the gravel or

chalk, but rather extend themselves near the surface, where they will meet with better soil: and as these trees are of long duration, and old trees being not only more fruitful than young, but the fruit is also better flavoured; therefore the providing for their continuance is absolutely necessary.

The soil I would in general advise to be used for these, and all other sorts of fruit trees, is fresh untried earth, from a pasture ground, taken about ten inches deep, with the turf, and laid to rot and mellow at least twelve months before it is used; and this must be kept often turned, to sweeten and imbibe the nitrous particles of the air.

Your borders being prepared, make choice of such trees as are but of one year's growth from budding; and if your soil is dry, or of a middling temper, you should prefer *October* as the best season for planting, especially having at that time, a greater choice of trees from the nurseries, before they have been picked and drawn over by other people. The manner of preparing these trees for planting is the same in common with other fruit trees. But do not cut off any part of the head at that time, unless there are any strong foreright shoots which will not come to the wall, which may be taken quite away.

Your trees being thus prepared, you must mark out the distances they are to stand, which in a good strong soil, or against a low wall, should be twenty feet or more; but in a moderate soil, and against taller walls, eighteen feet is a good reasonable distance; then make a hole where each tree is to stand, and place its stem about four inches from the wall, inclining the head thereto; and after having fixed the tree in the ground, nail the branches to the wall, to prevent their being shaken. In this state the trees may remain till the middle of *March*, when, if the weather is good, you must unnailed the branches of your trees, so as not to disturb their roots; and, being provided with a sharp knife, put your foot close to the stem of the tree; and having placed your left-hand to the bottom of the tree, to prevent its being disturbed, with your right-hand cut off the head of the tree, if it has but one stem, or where it may have two or more shoots, each of them must be shortened, to about four or five eyes above the bud, so that the sloping side may be toward the wall.

In the spring, if the weather proves dry, you must now-and-then give your trees a gentle refreshing with water, all over their heads, which will greatly help them; and also lay some turf, or other mulch, round their roots, to prevent their drying during the summer season; and as new branches are produced, observe to nail them to the wall in a horizontal position; and such shoots as are produced foreright, must be entirely displaced. This must be repeated as often as is necessary, to prevent their growing from the wall, but by no means stop any of the shoots in summer.

At *Michaelmas*, when the trees have done growing, you must unnailed their branches, and shorten them in proportion to their strength; a vigorous branch may be left eight or nine inches long, but a weak one should not be left above five or six.

When you have shortened the shoots, be sure to nail them as horizontally as possible, for upon this it is that the future good of the tree chiefly depends.

The second summer observe, as in the first, to displace all foreright shoots, as they are produced, nailing in the other close to the wall horizontally, so that the middle of the tree may be kept open; and never shorten any of the shoots in summer, unless to furnish branches to fill vacant places on the wall; and never do this later than *April*. At *Michaelmas* shorten these shoots, as was directed for the first year; the strong ones may be left nine or ten inches, and the weak ones six or seven at most.

The following year's management will be nearly the same with this, but only observe, that Apricots produce their blossom buds, not only upon the last year's wood, but also upon the cursons, or spurs, which are produced from the two years wood; a great care should therefore be had in the summer management, not to hurt or displace them; observe also to shorten your branches at the winter pruning, so as to furnish bearing wood in every part of the tree.

These few rules, well executed, together with a little observation and care, will be sufficient; and to pretend to prescribe particular directions for all the different accidents, or manner of treating fruits, would be impossible.

The *Brussels* and *Breda* Apricots, being, for the most part, planted for standards, will require very little pruning or management; only observe to take out all dead wood, or such branches as cross each other; this must be done early in autumn, or in the spring, after the cold weather is past, that the part may not canker where the incision is made.

ARMERIUS, Sweet-William. See *Dianthus*.

ARNICA. *Lin. Gen. Plant.* 784. Leopardbane.

The Characters are,

It hath a compound flower, the border or rays being composed of many female florets, which spread open; the disk, or middle, has many hermaphrodite flowers, which are tubulous, and have each five short stamina. In the hermaphrodite flowers the germen is situated below the flower, which after-ward becomes a single oblong seed, crowned with long slender down.

The Species are,

1. ARNICA foliis ovatis integris, caulinis geminis oppositis. *Lin. Sp. Plant.* 884. Arnica with entire oval leaves, and those on the stalks growing opposite by pairs.

2. ARNICA foliis alternis serratis. *Hall. Helvet.* 737. Arnica with sawed leaves growing alternately.

The first sort grows naturally upon the *Alps*, and also upon many of the mountains in *Germany*, and other cold parts of *Europe*, and is greatly esteemed by the *Germans* for its medicinal qualities, where it is prescribed by this title of Arnica.

The roots of this plant, when placed in a proper soil and situation, do greatly increase, for they send out thick fleshy roots, which spread very far under the surface; these put out many oval entire leaves, from between which the flower-stems arise, which grow about a foot and an half high; the top is terminated by a single yellow flower, composed of many florets, like those of *Dandelion*. These are succeeded by oblong seeds, which are crowned with down.

This plant delights in a moist shady situation; it may be propagated by parting of the root in autumn, when the stalks begin to decay, or by the seeds sown in autumn, soon after they are ripe, for those sown in the spring often fail.

The second sort grows naturally on the mountains of *Bohemia*, as also in *Siberia*. The roots of this sort are much jointed, and divide into many irregular fleshy offsets, which are variously contorted; from whence many superstitious persons have been led to imagine, that the roots would expel the poison of scorpions, and cure the wounds made by the bite of that animal. It is a very hardy plant, and is propagated in the same manner as the former.

ARTEDIA. *Lin. Gen. Plant.* 249. We have no *English* name for this genus.

The Characters are,

It is an umbelliferous plant; the rays of the large umbel are difform, the flowers of the small ones in the disk are male, and the rays are hermaphrodite. These have each five slender stamina; those flowers which compose the rays, have a small germen at bottom, which after-ward becomes a roundish compressed fruit, with a leafy border, which splits into two, and contains two oblong seeds, with scaly borders.

The Species are,

1. ARTEDIA seminibus squamatis, *Hort. Cliff.* 89. Artedia with squamose seeds.

2. ARTEDIA seminibus aculeatis. *Hort. Cliff.* 89. Artedia with prickly seeds.

The first is a native of the east, *Rawwolf* found it growing upon mount *Libanus*. It is an annual plant, whose stalks rise about two feet high, sending out a few side branches, which are garnished with narrow compound leaves resembling those of *Dill*; the extremity of the stalk is terminated by a large umbel of white flowers, composed of five unequal petals. These are succeeded by roundish compressed fruit, each having two seeds, whose borders are scaly.

The second sort grows upon the *African* shore in the *Mediterranean*, as also in *Spain*. This is also an annual plant, with an upright stalk near three feet high, and puts out many side shoots; the leaves are hairy, and greatly resemble those of the common *Carrot*; the stalks are terminated by umbels of large white flowers, shaped like those of the former, and are succeeded by a prickly fruit, composed of two seeds.

Both these plants decay as soon as they perfect their seeds, and many times before they are ripe, in *England*; for unless the seeds are sown in autumn, and the plants come up before winter, they rarely produce good seeds here. The seeds should be sown on a warm border where the plants are to remain, for they will not bear transplanting.

ARTEMISIA, Mugwort.

The Characters are,

The flower is composed of hermaphrodite and female florets; the hermaphrodite flowers compose the disk, or middle. In the center is placed the germen, which is accompanied by five hairy stamina; the germen after-ward becomes a single naked seed, sitting upon a naked placenta.

The Species are,

1. ARTEMISIA foliis pinnatifidis planis incisus subtus tomentosus, racemis simplicibus floribus ovatis radio quinquefloro. *Lin. Sp. Plant.* 348. Common Mugwort.

2. ARTEMISIA foliis lanceolatis subtus tomentosus integerrimis dentatisque. *Lin. Sp. Plant.* 848. Mugwort with spear-shaped leaves which are entire, and indented on their edges, and their under side woolly.

The first sort grows naturally on banks, and by the side of foot paths, in most parts of *England*, so is rarely admitted into gardens, for the roots creep far under the surface of the ground; so that unless they are stopped, they will soon spread over a large space of ground. This flowers in *June*, at which time the herb is in perfection for use.

The Moxa, so famous in the eastern countries for curing the gout by burning of the part affected, is the lanugo, or down, which is on the under part of the leaves of Mugwort.

The second sort grows naturally in *Siberia*; it rises up with single stalks about two feet high; the flowers come out from the wings of the leaves in small loose spikes, and near the top they are often single; these are larger than those of the common sort, and are of a pale yellow colour.

This sort is as hardy as the common sort, and multiplies as fast, but is only preserved in botanick gardens for the sake of variety.

ARTICHOKE is called by the *Latins* Cinara.

As this plant is much better known by its *English* title than the *Latin*, I shall treat of it under this head, and refer for its characters to the *Latin* title of Cinara, under which the other species will be exhibited.

We have two sorts of Artichokes, which are cultivated in the *English* gardens, which we shall distinguish here only by the names they are generally known among the gardeners.

The best sort is what the gardeners call the globe Artichoke. This hath large heads, with broad brown scales, which turn inward; the fleshy part at the bottom of the scales is very thick, therefore is much preferred to the other, which is called the *French* Artichoke. The stalks of which

do generally grow taller, and the heads are smaller, and shaped more conical than those of the globe. The scales are narrower, of a greener colour, and frequently turned outward. The fleshy part which is eaten is not near so thick, and hath a disagreeable perfumed taste; this was almost totally rooted out of the *English* gardens before the hard frost in 1739-40, when the greatest part of the roots of the other sort were destroyed, so many persons were supplied the following spring with plants from *Guernsey*, where they cultivate only the latter sort; but since the other has been increased again, this green sort has been in most gardens rooted out, to make way for the globe Artichoke.

The manner of propagating this plant is from slips, or suckers taken from the old roots, in *February* or *March*, which, if planted in a good soil, will produce large fair fruit the autumn following; but as this is a plant which few gardeners, that have not been bred in the kitchen gardens near *London*, understand to manage well, I shall be the more particular in my directions about it.

About the beginning of *March*, according to the earliness of the season, or forwardness of the old Artichoke stocks, will be the proper time for dressing them, which must be thus performed: with your spade remove all the earth from about your stock, down below the part from whence the young shoots are produced, clearing the earth from between the shoots, so as to be able to judge of the goodness of each, with their proper position upon the stock; then make choice of two of the clearest, straightest, and most promising plants that are produced from the under part of the stock, which are much preferable to the strong thick plants which generally grow upon the crown of the roots, for these have hard woody stems, so do never produce good fruit, but generally are what the market gardeners call rogues, which have very little bottom, and the scales of their heads are irregularly placed; in slipping off the other shoots, you must be careful not to injure the plants which you are to let remain for a crop; then with your thumb force off all the other plants and buds close to the head of the stock, from whence they are produced, being very careful not to leave any of the buds, and with your spade draw the earth about the two plants which are left, and with your hands close it fast to each of them, separating them as far asunder as they can conveniently be placed without breaking them, observing to crop off the tops of the leaves which hang down, with your hands; your ground being levelled between the stocks, you may sow thereon a small crop of Spinage, which will be taken off before the Artichokes will cover the ground; and toward the latter end of *April*, or the beginning of *May*, when your plants begin to shew their fruit, you must carefully look over your stocks, and draw up all young plants from them, which may have been produced from the roots since their dressing, and cut off all suckers which are produced from the stems of the Artichokes, leaving only the principal head, by which means your fruit will be larger; when your Artichokes are fit to gather, you must break, or cut them down close to the surface of the ground, that your stocks may make strong fresh shoots by the middle of *November*, which is the season for earthing; or, as the gardeners term it, landing them up, which is thus done:

Cut off all the young shoots quite close to the surface of the ground; then dig between every stock, raising all the earth between each row of stocks into a ridge, as is done in the common method of trenching ground, in such manner as that the row of Artichokes may be exactly in the middle of each ridge; this will be sufficient to guard them against common frost; and I would here recommend it to the publick, as infinitely preferable to long dung, which is by the unskilful often used to cover the roots, and is the occasion of their fruit being small, and almost without any bottoms

to them; for there is not any thing so hurtful to these roots, as new dung being either buried near, or laid about them. Observe, that although I have mentioned *November* as the season for earthing them, yet if the weather proves mild, it may be deferred till any time in *December*.

As we have experienced, that, in very severe frosts, these roots are sometimes destroyed, therefore it is proper to give some directions to prevent it; although this rarely happens in dry ground, in which we have but few instances of their being killed, except in the hard frosts of 1683, and 1739-40. In these two winters most of the Artichokes were destroyed in *England*; in the last of these winters, it happened from the little care which was taken of them, there having been no severe frost for so many years before, which had injured them, that few people used any care to preserve them; but since that hard frost, many people have run into the other extreme, of covering all their roots of Artichokes with long dung every winter, which is a very bad method, because the dung lying near the roots, is very apt to rot the best plants; therefore I would advise the earthing (or as it is called by the gardeners, landing) of the Artichokes to be deferred till the latter end of *November*, provided the season continues mild; and towards *Christmas*, if there is any danger of severe frosts, to lay a quantity of long dung, pease-haulm, tanners bark, or any other light covering over the ridges of earth, which will keep out the frost; and this being at a distance from the roots, will not injure them; but this covering should be carefully taken off the beginning of *February*, or sooner, provided the season is mild, or at least so soon as the weather is so, otherwise the plants will be injured by its lying too long upon them.

When you have thus earthed them up, you have nothing more to do till *March*, by which time the plants will have grown through the ridge of the earth; therefore when the weather is proper, the roots must be dressed as was before directed.

When you have a mind to make a new plantation of Artichokes, after having digged and buried some very rotten dung in the ground you have allotted for that purpose, make choice of such of your plants as were taken from your old stocks, which are clear, sound, and not woody, having some fibres to their bottom; then with your knife cut off that knobbed woody part, which joined them to the stock; and if that cuts crisp and tender, it is a sign of its goodness, but if tough and stringy, throw it away as good for nothing; then cut off the large outside leaves of the plants intended for planting pretty low, that the middle, or heart leaves, may be above them: Your plants being thus prepared (if the weather is very dry, or the plants have been any time taken from the stocks, it will be convenient to set them upright in a tub of water for three or four hours before they are planted, which will greatly refresh them), you must then proceed to planting, which must be done by ranging a line across the ground, in order to their being placed exactly in a row, and, with a measure-stick, plant them at two feet distance from each other in the rows, and if designed for a full crop, five feet distance row from row; your plants must be set about four inches deep, and the earth closed very fast to their roots, observing, if the season proves dry, to keep them watered two or three times a week, until they are growing, after which they do not require any.

N. B. You may sow a thin crop of Spinage upon the ground before you plant your plants, observing to clear it from about them after it is come up.

These plants, in a kindly season, or on a moist soil, will produce the largest and best Artichokes some time in *August* and *September*, after all those from the old stocks are past; so that if you intend to continue your Artichokes through the whole season, you must make a new plantation every year, otherwise.

otherwise you cannot possibly have fruit longer than two or three months.

If any of the plants which are planted in the spring, should not fruit in autumn, you may, at the season of earthing up your roots, tie up the leaves with a small willow twig, &c. and lay the earth up close to it, so that the top of the plant may be above ground, and when the frost comes on, if you will cover the top with a little straw, or pease-haulm, to prevent their being killed by frost, these plants will produce fruit in winter, or early in the spring.

But in those plantations where you intend to plant other things between your Artichokes, you must allow nine or ten feet between the rows, as is often practised by the kitchen gardeners near London, who sow the ground between with Radishes or Spinage, and plant two rows of Cauliflowers, at four feet distance row from row, and two feet and an half distance in the rows between them; so that there are always five feet allowed for the Artichokes to grow; and in May, when the Radishes or Spinage are taken off, they sow a row of Cucumbers for pickling, exactly between the two rows of Cauliflowers, and at three feet distance from each other; and between the rows of Cauliflowers and the Artichokes, plant a row of Cabbages or Savoys for winter use, which, when the Cauliflowers are drawn off, and the Artichokes gathered, will have full liberty to grow; and by this means the ground is fully employed through the whole season. This has long been the practice of the kitchen gardeners near London, who pay large rents for their land, so are obliged to get as many crops in a year from it as possible.

If in the spring you find your stocks shoot very weak, which may have been occasioned either by hard frost, or too much wet, you must then uncover them, and with your spade loosen and break the earth about them, raising a small hill about the plants of each stock, levelling the rest between the rows, which will greatly help them; and in three weeks, or a month's time after, they will be fit to slip.

Those Artichokes which are planted in a moist rich soil, will always produce the largest and best fruit; so that where such a soil can be obtained, it will be proper to make a fresh plantation every spring, to succeed the old stocks, and supply the table in autumn. But the roots will not live through the winter in a very moist soil, so that your stocks which you intend should remain, to supply the table early, and to furnish plants, should be in a drier situation. You should always observe to plant these in an open spot of ground, not under the drip of trees, where they will draw up very tall, and produce small insignificant fruit.

ARTICHOKES of Jerusalem. See Helianthus.

ARUM, Wake Robin, or Cuckow Pint.

The Characters are,

The flower hath a long oblong spathe; the spadix is single, shaped like a club at the top, upon which the germen are situated. It hath no petals nor stamina, but many four-cornered summits, sitting close to the germen. There are many germen which surround the upper part of the spadix, which are oval, having no styles, but have bearded stigma: the germen afterward become globular berries, with one cell, having round seeds.

The Species are,

1. ARUM *acaule foliis hastatis integerrimis spadice clavato.* Hort. Cliff. 434. The common Arum, or Wake Robin, with spotted and plain leaves.

2. ARUM *acaule foliis hastatis acutis petiolis longissimis spathe maximâ erectâ.* Largest Italian Arum, with white veins.

3. ARUM *acaule foliis hastatis spathe declinatâ filiformi subulata.* Lin. Sp. Plant. 966. Friars Cowl with a flower ending in a slender tail.

4. ARUM *acaule foliis cordato-oblongis spathe bifidâ spadice incurvo.* Hort. Cliff. 435. Greater broad-leaved Friars Cowl.

5. ARUM *acaule foliis lanceolatis spadice setaceo declinato.*

Hort. Cliff. 345. Narrow-leaved Friars Cowl of Dioscoridis.

6. ARUM *acaule foliis hastato-cordatis acutis angulis obtusis.* Hort. Cliff. 434. Arum without stalk, pointed spear heart-shaped leaves, with obtuse angles.

7. ARUM *acaule foliis ternatis.* Flor. Virg. 113. Three-leaved Arum without stalk.

8. ARUM *foliis pedatis, foliolis lanceolatis integerrimis æquantibus spathe spadice longiorem.* Prod. Leyd. 7. Common Dragon.

9. ARUM *foliis pedatis, foliolis lanceolatis integerrimis superantibus spathe spadice breviorum.* Prod. Leyd. 7. Smaller dwarf Arum with many leaves.

10. ARUM *acaule foliis trilobis flore sessile.* Flor. Zeyl. 326. Broad-leaved low Arum of Ceylon with a scarlet pistil.

11. ARUM *acaule foliis peltatis ovatis repandis basi semibifidis.* Hort. Cliff. 434. Greatest Egyptian Arum, vulgarly called Colocasia.

12. ARUM *acaule foliis cordatis nervosis floribus sessilibus.* American Arum with a Beet leaf called Scunk Weed.

13. ARUM *acaule foliis cordatis angulatis divaricatis.* Lin. Sp. Pl. 966. Arum without stalk, and spear-shaped leaves.

14. ARUM *acaule foliis cordatis obtusis mucronatis angulis rotundatis.* Hort. Cliff. 435. Arum without stalk, blunt heart-shaped leaves, which are pointed, and the angles rounded. This is commonly called Edder in America.

15. ARUM *acaule foliis peltatis ovatis integerrimis basi semibifidis.* Hort. Cliff. 453. Eatable Arum with a Water Lily leaf.

16. ARUM *acaule foliis sagittatis acuminatis nervosis.* Greatest Egyptian Arum, or Colocasia with blackish stalks.

17. ARUM *acaule foliis hastatis acuminatis spathe mucronatâ revolutâ.* Dwarf broad-leaved Arum of Ceylon with a purple pistil.

18. ARUM *caulescens foliis sagittatis spathe declinatâ clausâ.* Tree-like Arum with lance-shaped leaves, commonly called Dumb Cane.

The first sort grows naturally in woods, and on shady banks in most parts of England, so is seldom admitted into gardens; but being a medicinal plant, it is here inserted to introduce the other species. There are two varieties of this, one with plain leaves, and the other hath leaves full of black spots; but these are only accidental varieties, which arise from the same seeds. The roots of this are ordered by the College of Physicians to be used in a powder which bears the title of the plant; but these roots are generally gathered in the spring, when the leaves are in full vigour, so that the roots shrink and soon loose their pungent quality; but those which are taken up when the leaves decay, will continue good a whole year, and retain their pungency the same as when first taken up. The not observing this, has brought the medicine into disrepute. It flowers in April, and the seeds ripen in July, when is the best time to take up the roots.

The second sort grows naturally in Italy, Spain, and Portugal. The leaves of this sort rise a foot and an half high, are very large, running out to a point; these are finely veined with white, interspersed with black spots, which, together with the fine shining green of their surface, make a pretty variety. The flowers grow near a foot high, and have very long upright spathe, which are of a pale green, inclining to white; these appear the end of April, or beginning of May; this propagates very fast by offsets from the root, and will thrive in any soil or situation. The best time to transplant them is from the time the seeds are ripe, to the end of October.

The third, fourth, and fifth sorts hath been generally separated from this genus, and were distinguished by the title of Arisarum, or Friar's Cowl, from the resemblance the flower has in shape to the hoods or cowls worn by the people of that order. These are very low plants, their leaves having very short foot-stalks, and the flowers grow close to

the ground. They flower in *April*. The time for transplanting the roots is the same as for the former.

The sixth and seventh sorts grow naturally in *Virginia* and *Carolina*; these never rise with stalks, but their leaves arise immediately from the roots, having short foot-stalks; the flowers come up between their leaves, which have short foot-stalks; they appear in *May*, but have little beauty, so the plants are only kept in botanick gardens for the sake of variety.

The eighth sort is the common Dragon, which is used in medicine, and has been generally ranged in a separate genus from this under the title of *Dracunculus*.

This sort is used in medicine, so is preserved in some gardens, to supply the markets: it grows naturally in most of the southern parts of *Europe*, from whence it was first obtained. It hath a strait stalk three or four feet high, which is spotted like the belly of a snake; at the top it spreads out into leaves, which are cut into several narrow segments, almost to the bottom, and are spread open like a hand; at the top of the stalk the flower is produced, which is in shape like the common *Arum*, having a very long spathe of a dark purple colour, standing erect, with a large pistil of the same colour, so that when it is in flower, it makes no unpleasing appearance; but the flower hath so strong a scent of carrion, that few persons can endure it; for which reason it hath been banished most gardens; but was it not for this, a few of the plants might merit a place in gardens, for the oddness of the flower. It is very hardy, so will grow in any soil or situation, and propagates fast by offsets from the root. There is a variety of this with variegated leaves and stalks, which is preserved in the gardens of some persons who are fond of striped leaved plants.

The ninth sort grows naturally in moist places in *Virginia* and *New England*, but is very difficult to preserve long in a garden, especially if the soil is dry. The leaves of this sort are divided like those of the former, but are smaller, and rarely grow more than nine inches high; the flowers are like those of the common *Arum*.

The tenth sort grows naturally in *Ceylon*, and some other parts of *India*, so is very impatient of cold: it is a plant of humble growth; the flower rises immediately from the root, standing on a very short foot-stalk; the spathe is long, erect, and of a fine scarlet within, as is also the pistil. This plant must be placed in the tan bed of the bark stove, otherwise it will not thrive in *England*. It is propagated by offsets from the root, which come out in plenty when the plants are in health.

The eleventh, thirteenth, fourteenth, fifteenth, and sixteenth sorts, have mild roots, which are eaten by the inhabitants of all the hot countries, where they grow naturally, and some of the sorts are cultivated by the inhabitants of the Sugar colonies, as esculent plants, their roots being constantly eaten; as also are the leaves of some of the sorts, particularly the fifteenth, which they call *Indian Kale*: the leaves of this are boiled, and supply the want of other greens. It is esteemed a wholesome green; and in those countries where many of the common *European* vegetables are with difficulty produced, this proves a good succedaneum. The sixteenth sort has not been many years introduced among them, for it came originally from the *Spanish West-Indies*, where it grows in great plenty. Both these have larger roots than the fifteenth, for which reason they are preferred to it.

All these sorts are preserved in the gardens of those persons, who are curious in collecting exotic plants, for the variety of their leaves; for their flowers have very little beauty, nor do they often appear in this country. The plants are propagated easily by offsets from their roots, which they put out plentifully: these must be planted in pots filled with rich earth, and plunged into a hot-bed; and

if they are afterward continued in the bark stove, they will make great progress, and their leaves will be very large.

The roots of the seventeenth sort I received from *India*; this annually flowers in *May*; the leaves grow near the ground, having short foot-stalks; the flower comes up immediately from the root, upon a short foot-stalk, and is of a very deep purple colour, and smell almost like the flower of *Dragon*. It is tender, so must be constantly kept in the bark stove, otherwise it will not thrive in *England*.

The eighteenth sort grows naturally in the Sugar islands, and other warm parts of *America*, chiefly in the low grounds; the whole plant abounds with an acrid juice, so that if a leaf or part of the stalk is broken, and applied to the tip of the tongue, it occasions a very painful sensation, and occasions the salivary ducts to swell, and brings on a great defluxion of saliva; the stalks of this plant are sometimes applied to the mouths of the negroes by way of punishment. This sort is propagated by cutting off the stalks into lengths of three or four joints, which must be laid to dry six weeks or two months; for if the wounded part is not perfectly healed over before the cuttings are planted, they will rot and decay: these should be planted in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tan, being careful that they have little wet, until they have made good roots; some of them may be placed in a dry stove, and others plunged into the tan bed in the bark stove, where they will make the greatest progress, and produce more flowers than the others.

ARUM ÆTHIOPICUM. See *Calla*.

ARUM SCANDENS. See *Dracontium*.

ARUNDO. *Lin. Gen. Plant.* 76. The Reed.

The Characters are,

It is of the grass tribe; the flowers grow in spikes, and are included in a chaff which opens with two valves. The petals of the flowers are bivalve, having a down at their base, and hath three hairy stamina: in the center is situated an oblong germen, with two slender styles. The germen afterward becomes an oblong pointed seed, with long down adhering to its base.

The Species are,

1. ARUNDO *calycibus quinquefloris paniculâ laxâ. Prod. Leyd.* 66. The common Marsh Reed.

2. ARUNDO *calycibus trifloris paniculâ diffusâ. Prod. Leyd.* 66. The manured Reed, or *Donax* of *Dioscorides*; this is sometimes called by gardeners the Ever-green Reed.

3. ARUNDO *Indica Laconica versicolor. Mor. Hist.* 3. p. 219. The Indian variegated Reed of *Theophrastus*.

4. ARUNDO *caule arboreo foliis acuminatis sulcatis, basi rotundioribus.* Another species of *Bambu*.

5. ARUNDO *caule arboreo foliis utrinque acuminatis.* Reed with a tree-like stalk, and leaves which are pointed at both ends.

6. ARUNDO *Orientalis tenuifolia caule pleno ex quâ Turcæ calamos parant. Tourn. Cor.* 39. Eastern Reed with a narrow leaf and a full stalk, of which the *Turks* made their writing pens.

The first sort is so very common by the sides of rivers and large standing waters in divers parts of *England*, that it is needless for me to say any thing of its culture. This is cut in autumn, when the leaves begin to fall, and the stems are changed brown, for making hedges in kitchen gardens, and for many other uses.

The second sort, although a native of a warm country, yet will bear our cold of the severest winters, in the open ground; it dies to the surface in autumn, and rises again the succeeding spring; and if kept supplied with water in dry weather, will grow ten or twelve feet high the same summer. This is propagated by parting the roots early in the spring, before they begin to shoot, and will, in a year or two, if the ground be good, make very large stools.

stools, from each of which you may have twenty or thirty large canes produced.

The stalks of this sort are brought from *Portugal* and *Spain*, and are used by the weavers, as also to make fishing rods.

The third sort is supposed to be a variety of the second, differing therefrom only in having variegated leaves. This plant will not grow so large, nor will it resist the cold so well, therefore will not live in the open air through the winter in *England*; so the plants must be kept in pots, and housed in the autumn.

The two sorts of *Bambu* are of great service to the inhabitants of *India*, who make most of their common utensils of the stems of these canes, which grow to a prodigious magnitude in those countries.

We have plants of the fourth sort in the *English* gardens, which are more than twenty feet high; and if the stoves in which they are kept were high enough to admit them, they would, according to appearance, rise to twice that height. Some of these stems are as large as a man's wrist, but in general as big as walking-sticks, and when dried are as fit for that purpose, as those which are imported. The leaves of this sort are much broader than those of the fifth, particularly at their base; these leaves are generally put round the tea-chests in their package, and are fastened together so as to form a kind of mat.

The fifth sort is more rare at present in *Europe*, though it is the most common on the coast of *Malabar*.

They are both tender plants, so will not live in this country, unless they are preserved in a warm stove; and as their roots spread very wide, so they should not be confined: therefore to have them produce strong stems, they must be planted in large tubs, filled with rich earth, and plunged into the tan bed in the bark stove; and as they naturally grow in marshy low places, so they require plenty of water, especially when the roots have filled the tubs in which they were planted. When the tubs decay, the boards may be removed, and the plants permitted to root into the tan, which will encourage them to grow to a larger size; but then there must be care taken when the bed is refreshed with new tan, to leave a sufficient quantity of old tan about the roots of the plants; for if they are too much bared, and the new tan laid near them, when that heats, it will scorch their roots, so that the plants are sometimes destroyed by it.

The sixth sort is what the *Turks* make their writing pens withal; this grows in a valley near mount *Athos*, as also on the banks of the river *Jordan*, but there are none of the plants in *England*. At present this sort may be managed as the *Bambu*.

ARUNDO SACCHARIFERA. See Saccharum.

ASARINA. *Tourn. Inst. R. H.* 171. tab. 76. Bastard Asarum.

The Characters are,

The flower is of one leaf, of the grinning kind, divided at the top into two lips, the upper one is divided into two parts. The lower lip is slightly cut into three obtuse parts; the two lips join close together, so as to form a kind of snout. It hath four stamina. In the center is placed a round germen, which afterward turns to a round husk, divided into two cells, which are full of roundish seeds.

The Species are,

1. ASARINA caule decumbente foliis oppositis reniformibus crenatis. Asarina, or Rock Ground-Ivy.
2. ASARINA caule erecto foliis lanceolatis amplexicaulibus paniculâ dichotomâ. Bastard Asarum with an upright stalk, spear-shaped leaves which embrace the stalks, and spikes of flowers coming out from the division of the branches.

The first sort is a low trailing annual plant, the branches extend little more than a foot each way, and are weak, so

that unless they are supported, they lie upon the ground; at the wings of the leaves the flowers come out singly on each side the stalk, which are shaped like those of Snap-dragon, but have a long tube; they are of a worn-out purple colour at the top, but below of an herbaceous colour. The seeds should be sown soon after they are ripe, or permitted to scatter, for when they are sown in the spring they seldom grow. The plants should remain where they are sown, and require no other care but to thin them where they grow too close. It grows naturally in *Italy* and the south of *France*.

The second sort grows naturally in *North America*. This plant hath upright stalks, which grow a foot and an half high, and put out several side branches; the leaves grow opposite, and embrace the stalks at their base; the flowers come out in short loose spikes from the divisions of the stalks, which are shaped like those of the former, but are less, and of a purple colour.

The seeds of this sort should be sown in the autumn, for those which are sown in the spring, seldom grow the same year, but remain in the ground till the following spring; the second year the plants will flower and perfect their seeds. The roots seldom last above two years, so that young plants should be annually raised.

ASARUM, Asarabacca.

The Characters are,

The flower hath no petals, but a thick coloured empalement and twelve short stamina. At the bottom of the empalement is inclosed a thick germen, which afterward turns to a thick capsule having six cells, containing several oval seeds.

The Species are,

1. ASARUM foliis reniformibus obtusis binis. *Lin. Sp. Plant.* 442. Common Asarabacca.
2. ASARUM foliis reniformibus mucronatis. *Lin. Sp. Plant.* 442. Canada Asarabacca.
3. ASARUM foliis cordatis obtusis glabris petiolatis. *Flor. Virg.* 162. *Virginia* Asarabacca, with round Pistolochia leaves marked like those of Sowbread.

The first sort hath thick fleshy roots which are jointed; the leaves grow singly upon short foot-stalks, arising immediately from the root; the flowers grow upon very short foot-stalks close to the ground, so are hid under the leaves. They have a bell-shaped empalement, of a worn-out purple colour, which is cut into three at the top, where it turns backward.

The leaves of the second sort are much larger than those of the first, and stand on longer foot-stalks; these are pointed and hairy. The flowers are like those of the other sort, growing close to the root, but are somewhat inclining to green on their outside, in all other respects they agree.

The third sort hath smooth blunt heart-shaped leaves, standing on long foot-stalks; these are veined, and spotted on their upper surface like those of the autumnal Cyclamen; the flowers of this are shaped like the others, but stand on longer foot-stalks, and are of a darker purple colour.

The first of these sorts is very common, and hath been found wild in some parts of *England*, though but rarely; it delights in a moist shady place, and is increased by parting the roots in autumn. This is the sort which is used in medicine.

The *Canada* sort is tolerably hardy, and will endure our common winters in the open ground, being rarely hurt but by great frosts, or being planted in a wet soil, which often occasions the roots to rot in winter. This is propagated as the other.

The third sort will live in the open air in *England*, being seldom injured by frost; but if the plants are too much exposed to the sun in summer, they seldom thrive well; therefore they should be planted in a border where they may have only the morning sun, in which situation they will spread and increase.

ASCLEPIAS, Hirundinaria, or Swallow-wort.

The Characters are,

The flower hath a petal of one leaf, divided into five oval parts. In the center is situated five nectariums which encompass the parts of generation; the stamina are joined in a truncated body inclosed by five scales, and are scarce visible. It hath two oval pointed germen, which afterward become two large oblong swelling pods ending in a point, which open with two valves, which are filled with compressed seeds, lying over each other like tiles on a house, and are crowned with a soft down.

The Species are,

1. ASCLEPIAS foliis ovatis acuminatis caule erecto umbellulis proliferis. *Lin. Sp. Plant.* 216. Common Swallow-wort with a white flower.

2. ASCLEPIAS foliis lanceolatis acutis caule superne subvolubili. *Lin. Sp. Pl.* 216. Swallow-wort with a black flower.

3. ASCLEPIAS foliis ovatis acutis caule infirmo, umbellis simplicibus. Narrow-leaved Swallow-wort with a yellow flower.

4. ASCLEPIAS foliis revolutis linearibus verticillatis caule erecto. *Lin. Sp. Pl.* 217. Upright Dogbane of Maryland, with narrow Toadflax leaves and flowers growing in an umbel.

5. ASCLEPIAS foliis ovalibus subtus tomentosus caule simplicissimo umbellis nutantibus. *Lin. Sp. Plant.* 214. Greater upright Syrian Dogbane.

6. ASCLEPIAS foliis ovatis subtus pilosiusculis caule simplicibus umbellis nectariisque erectis. *Lin. Sp. Plant.* 214. Dogbane with fine purple flowers and upright horns.

7. ASCLEPIAS foliis ovatis subtus villosis caule simplici umbellis erectis nectariis resupinatis. *Lin. Sp. Pl.* 214. Upright Dogbane of New York, with leaves less hoary, and a worn-out palish purple coloured flower.

8. ASCLEPIAS foliis ovatis rugosis nudis caule simplici umbellis subsessilibus pedicellis tomentosis. *Lin. Sp. Plant.* The old American Dogbane called Witank.

9. ASCLEPIAS foliis lanceolatis caule superne diviso umbellis terminalibus congestis. *Lin. Sp. Plant.* 215. Smaller upright Dogbane of Canada.

10. ASCLEPIAS foliis villosis caule decumbente. *Lin. Sp. Pl.* 216. Hairy Orange-coloured Dogbane of Carolina.

11. ASCLEPIAS foliis alternis lanceolatis caule divaricato piloso. *Lin. Sp. Pl.* 217. Hairy New England Dogbane with a tuberose root, and an Orange-coloured flower, commonly called Orange Apocynum.

12. ASCLEPIAS foliis lineari-lanceolatis glabris caule fruticoso umbellis lateralibus. Upright African Dogbane with a hairy fruit, and a narrow, smooth, Willow leaf.

13. ASCLEPIAS foliis lanceolatis glabris umbellis simplicibus lateralibus caule fruticoso. Upright African Dogbane with a broad, smooth, Willow leaf.

14. ASCLEPIAS foliis lanceolatis villosis acutis umbellis simplicibus erectis caule fruticoso. Upright African Dogbane with hairy fruit, and a broad hairy Willow leaf and hairy fruit.

15. ASCLEPIAS caule erecto fruticoso, foliis subrotundis amplexicaulis, umbellis congestis. Upright shrubby Dogbane with a roundish sea-green leaf.

16. ASCLEPIAS foliis lanceolatis glabris caule simplici umbellis erectis lateralibus solitariis. *Lin. Sp. Pl.* 215. American Dogbane with longer Almond leaves.

17. ASCLEPIAS foliis lanceolatis petiolatis glabris caule simplici umbellis erectis solitariis. *Lin. Sp. Pl.* 215. Dogbane with a fibrous root, and scarlet petals with Saffron-coloured horns, called Bastard Ipecacuana.

18. ASCLEPIAS foliis amplexicaulis oblongo-ovalibus. *Flor. Zeyl.* 112. Greater upright broad-leaved Indian Dogbane, and the *Beid el ossar.* *Alp. Ægypt.* 85.

19. ASCLEPIAS foliis ovato-lanceolatis glabris caule simplici umbellis erectis terminalibus. Upright Dogbane with oblong pointed leaves, and white flowers growing in an umbel.

The first sort is the common Swallow-wort of the shops. This is called Vincetoxicum and Hirundinaria, in *Engliso* Swallow-wort, or tame Poison, from its supposed virtue, being accounted a mighty counter poison. The root is the only part which is used, which is composed of many strong fibres, connected at the top, like those of Asparagus, from which arise many stalks, in number proportional to the size of the roots; which grow two feet high, and are very slender at the top; the leaves are placed opposite by pairs. The flowers are white, growing in umbels near the top of the stalk, from which are sent out smaller umbels. After the flower is past, the two germen become two long pointed pods, inclosing many compressed seeds, which are crowned with a soft white down. It flowers in *June*, and the seeds ripen in *September*. It grows naturally in the south of *France*, *Spain*, and *Italy*.

The second sort agrees with the first, in the shape of its roots, leaves, and flowers, but the stalks extend to a greater length, and toward their upper part twist round any sticks, or other plants near it, and the flowers of this are black.

The third differs from both the other in the narrowness of its leaves, and weakness of its stalks; the umbels of flowers are single, and of a yellow colour. There is a variety of this with broader leaves, which may have come from the seeds of this.

These plants are generally propagated by parting their roots, especially the first sort, which seldom produces seeds in *England*. The best time for this is in autumn, when their stalks begin to decay. They should not be planted nearer together than three feet, for the fibres of their roots extend to a considerable distance. They are very hardy plants, so will thrive in any situation, but love a dry soil.

The fourth sort grows naturally in *North America*. This rises with slender upright stalks, which are garnished with very narrow leaves, growing in whorles: at the top of the stalks grow umbels of small, white, starry flowers, which appear in *July*, but are never succeeded by pods in *England*, so are only propagated by parting of the roots, which should be done in the spring before they put out new shoots.

The fifth sort creeps greatly at the root; this sends up strong stems upward of five feet high, which have thick oval leaves placed opposite, and hoary on their under sides. Towards the top of the stalks the umbels of flowers come out on the side; these are of a worn-out purple colour, smelling sweet, and nod downward; sometimes they are succeeded by large oval pods, filled with flat seeds, crowned by a long soft down. This propagates fast enough by its creeping root, and will grow in any soil or situation. It may be transplanted any time after the stalks decay, and before the roots shoot in the spring.

The sixth sort hath a perennial root, which sends up several upright stalks in the spring, about two feet high, garnished with oval leaves growing opposite; at the top of the stalks the umbels of flowers are produced, which are of a bright purple colour, making a pretty appearance, but are not succeeded by pods in *England*; this must be treated as the fourth sort.

The seventh sort grows naturally in *North America*. This hath a perennial root, which sends out single stalks, near three feet high, which have oval leaves placed opposite; the flowers grow in erect umbels at the top, and the nectariums are declining. It is very hardy, and propagates fast by its creeping roots, but never produces seeds in *England*.

The eighth sort resembles the seventh, but the leaves are rough, and the umbels of flowers are more compact, and come out on the side of the stalk; these are of an herbaceous colour: it is propagated by roots as the former sort.

The ninth sort came first from *Canada*, but hath since been found growing naturally in several other parts of *America*. It

hath a perennial root, which puts out several upright stalks about two feet high, with oblong smooth leaves placed by pairs; at the top are produced close umbels of purple flowers. It is propagated by parting of the roots, which do not increase very fast, so that it is not very plenty in the gardens; but it is hardy enough to live abroad, if it is planted in a dry soil.

The tenth sort is a native of *North America*, but is hardy enough to live abroad in *England*, if it is planted in a warm situation, and in a dry soil. This hath declining stalks, which are a foot and an half long, and hairy; the leaves are narrow, hairy, and placed opposite; the umbels grow at the extremity of the branches, which are compact, and the flowers are of a bright Orange colour. It is propagated by seeds, which should be sown upon a hot-bed to bring up the plants. When they are of a proper strength to remove, they should be shaken out of the pots, and planted in a warm border a foot asunder, being careful to shade them from the sun, until they have taken fresh root, but they must have very little water given them, for they are milky plants, which rot with much wet. When their stalks decay in autumn, some rotten tan should be laid over the ground to keep out the frost, which should be removed in the spring before the plants put out new shoots. The second spring the roots may be transplanted where they are to remain; the roots will then be strong enough to flower in summer, and will last several years, especially if they are covered with tan to keep out the frost in winter, but they should not be afterward removed; for when the roots are large, they will not bear transplanting.

The eleventh sort is a native of the same countries, and is much like the former, but differs in having upright stalks, and the leaves growing alternate. The roots of this grow to a large size, so will not bear transplanting. It is propagated by seeds, which should be treated in the manner directed for the former. These flower the latter end of *July*, and in *August*. Neither of these plants will live long in pots, for which reason I have recommended their being planted in the full ground; but they should have a warm situation.

The twelfth, thirteenth, and fourteenth sorts grow naturally at the *Cape of Good Hope*. These rise with upright shrubby stems to the height of eight or ten feet, and divide into many branches. The flowers of all the sorts are white, and grow loosely on the umbel; these are frequently succeeded by short, thick, swelling pods, ending in a point, which are thick set with hairs, and are filled with compressed seeds, crowned with a soft down.

The thirteenth sort differs from the twelfth, in having much broader leaves, which are of a darker green; the umbels of flowers are smaller, grow upon shorter foot-stalks, and the single flowers are larger.

The fourteenth sort doth not rise so high as either of the former, and the branches grow at a much greater distance; the leaves are shorter, and are covered on both sides with short hairs.

These are propagated by seeds, which may be sown in *April* on a bed of light earth in the open air; and when the plants are three or four inches high, they should be each planted in a small pot filled with light earth, and shaded until they have taken new root, then they may be placed with other exotick plants in a sheltered situation; in *October* they must be removed into the green-house, and during the winter should have but little water, for as they abound with a milky juice, much wet will rot them.

These three sorts may also be propagated by cuttings, which, if planted in *July* or *August*, in a shady border, will soon take root, and may then be taken up and planted in pots, and managed as the seedling plants. The thirteenth sort has lived in the open air in mild winters in the *Chel-*

sea garden, but in cold winters they are constantly destroyed.

The fourteenth sort grows with an upright shrubby stalk to the height of six or seven feet, dividing toward the top into three or four branches, with stiff roundish leaves, which closely embrace them. Toward the upper part, the flowers are produced on their sides, growing in short compact umbels. They are of an herbaceous colour, and make but little appearance; they come out chiefly in autumn and winter. This requires the same culture as the former sorts.

The fifteenth sort grows naturally in the warm parts of *America*. - This rises with single stalks near two feet high, which are garnished with smooth spear-shaped leaves, ending in a point; toward the top of the stalk the umbels of flowers are produced from the wings of the leaves, which are white, and stand erect; and are succeeded by oblong pointed pods, filled with compressed seeds, crowned with soft down. It flowers in *June* and *July*, and the seeds ripen in *October*.

This plant is tender, so must be raised in a hot-bed, and constantly remain in the stove, otherwise the plants will not thrive here.

The sixteenth sort is also a native of the warm parts of *America*, the roots of which have been sent to *England* for *Ipecacuana*. There have been many accounts of the bad effects of the use of these roots, as also of the poisonous quality of the plant, so that the publick should be cautioned not to make use of it, and also to be careful not to let the milky juice of the plant mix with any thing which is taken inwardly.

The plant rises five or six feet high, with upright stems, and smooth oblong leaves placed opposite; toward the top of the branches, the umbels of flowers come out, which stand erect; the petals of the flowers are of a scarlet colour; and the horny nectariums in the middle are of a bright Saffron colour, which make a pretty appearance; there is commonly a succession of these flowers on the same plant, from *June* to *October*. The flowers are succeeded by long taper pods filled with seeds crowned by a soft down, which ripen late in the autumn.

It is propagated by seeds, which must be sown on a hot-bed in the spring; and the plants should be treated in the same manner, as is before directed for the former sort; the roots of this sort may be continued three or four years, but after the second year, the plants grow naked, and do not produce so many flowers as the young plants.

The seventeenth sort rises with upright stems, six or seven feet high, with thick oval leaves placed opposite. The umbels of flowers are produced from the wings of the leaves; the flowers are white, of a star figure, having five points; the pods of this sort are very large, in shape like an ox's testicles, and are filled with flat seeds lying over each other, like tiles on a house.

This plant is tender, so must be preserved constantly in the stove, and treated in the same manner as the two former sorts, and should have very little wet, especially in the winter.

The eighteenth sort approaches near to the fifteenth, from which it differs in the leaves, being broader, and the umbels of flowers terminating the stalks, whereas those of the fifteenth are produced at the wings of the leaves. This is tender, so must be managed as the fifteenth sort. It flowers in *August*, and the seeds ripen in *October*.

The nineteenth sort I received from *Carthage*; this hath climbing stalks, which fasten themselves to the neighbouring plants, and rise to the height of ten or twelve feet, with spear-shaped hairy leaves, growing opposite upon very short foot-stalks; the umbels of flowers, come out from the wings of the leaves, which are very compact, and the flowers are of a sulphur colour.

This plant is tender, so must be constantly preserved in the stove, and treated in the same way as is directed for the former sorts.

ASCYRUM. *Lin. Gen. Plant.* 737. St. Peterwort.

The Characters are,

The flower hath four oval petals, the two outer are large and placed opposite, the two inner are small. In the center is situated an oblong germen, attended by a great number of bristly stamina, which are reduced at their base to four bodies. The germen afterward becomes an oblong pointed seed-vessel, filled with small round seeds.

The Species are,

1. ASCYRUM *foliis ovatis caule tereti paniculâ dichotomâ. Lin. Sp. Pl.* 787. Bastard St. Johnswort of Maryland, with small yellow flowers called St. Andrew's Crosses.

2. ASCYRUM *foliis hirsutis caule stricto. Lin. Sp. Pl.* 788. Shrubby hairy St. Johnswort of Virginia.

3. ASCYRUM *foliis ovatis caule compresso. Lin. Sp. Plant.* 788. Upright shrubby Bastard St. Johnswort with a yellow flower.

The first sort is a low plant, whose stalks seldom rise more than six inches high; these have small oval leaves, placed by pairs; the stalks are slender, and divide into two toward the top. From between the division of the branches, the loose spikes of flowers are produced, which are yellow, but very small, so make no appearance; therefore the plant is scarce worthy of a place in gardens, but for the sake of variety. The root is perennial, and the plant may be propagated by laying down its branches; it loves a moist soil, and a shady situation.

The second sort grows about three feet high, with upright stalks, and hairy oblong leaves; the flowers are produced at the ends of the stalks, which are of the shape and colour with common St. Johnswort, but have only four leaves. This hath a perennial root, but the stalks decay every autumn. It may be propagated by parting the roots in autumn, when the stalks decay, and should be planted in a loamy soil.

The third sort grows naturally in *South Carolina*. This plant rises a foot and an half high, with flat stalks, which are garnished with oval smooth leaves growing opposite; the stalks are terminated by three or four yellow flowers, growing close together, which are larger than those of the common St. Johnswort, and the petals of the flowers are hollow. It may be propagated by cuttings, made of the young shoots in *May*; which, if planted in pots, and plunged into a very moderate hot-bed, will take root in five or six weeks, when they may be transplanted into a warm border, where they will endure the cold of our ordinary winters.

These plants have little beauty, so are seldom cultivated but in botanick gardens, for the sake of variety.

ASCYRUM BALEARICUM.

ASCYRUM MAGNO FLORE. } See Hypericum.

ASCYRUM VULGARE.

ASH TREE. See Fraxinus.

ASPALATHUS. *Lin. Gen. Plant.* 767. African Broom.

The Characters are,

The flower is of the butterfly kind. The standard is hairy, compressed, and blunt pointed; the wings are blunt, moon-shaped, and spread open, and are shorter than the standard; the keel is bifid, and of the same length as the wings. In the bottom is situated an oval germen, which afterward becomes an oval oblong pod, inclosing one or two, kidney-shaped seeds.

The Species are,

1. ASPALATHUS *foliis confertis subulatis mucronatis bispidis floribus capitatis. Lin. Sp. Pl.* 711. Yellow African Broom, with hairy flowers collected in woolly heads, and prickly Asparagus leaves which are hairy.

2. ASPALATHUS *foliis quinatis sessilibus. Lin. Sp. Pl.* 712.

Indian shrubby Trefoil, with single red flowers, an oblong foot-stalk, and a small pod.

3. ASPALATHUS *foliis trinis linearibus sericeis stipulis simplicibus mucronatis floribus sparsis tomentosis. Lin. Sp. Pl.* 713. Narrow-leaved African silvery Cytisus, with a silky down and flowers in a spike like a hare's foot.

These plants grow naturally about the *Cape of Good Hope*. The first is a low shrub growing about three feet high, with slender branches, having many trifoliate leaves growing in clusters; at the ends of the branches the flowers come out, which are yellow, collected in woolly heads; these are rarely succeeded by pods in *England*. It is propagated by seeds, which must be obtained from the country where the plants grow naturally; it should be sown in pots filled with light earth as soon as they arrive: if this happens in the autumn, the pots should be plunged into an old tan bed whose heat is spent, where they may remain till spring, when they should be removed into a moderate hot-bed, which will bring up the plants. But when the seeds arrive in the spring, the pots in which the seeds are sown should be then plunged into a moderate hot-bed. Those seeds which are sown in the spring, seldom grow the same year; therefore in the autumn, the pots should be put into an old tan bed, as was directed for those sown in autumn, and afterward put on a hot-bed the following spring. When the plants come up, and are strong enough to remove, they should be each planted into a separate small pot filled with light earth, and plunged into a moderate hot-bed, to encourage their rooting again; and so soon as they are established in the pots, they should by degrees be inured to the open air, into which they should be removed in summer, placing them in a sheltered situation, where they may remain till autumn, when they must be carried into the green-house, and in winter should have but little water.

The second sort grows about five feet high, with slender branches, which are garnished with leaves growing by fives close to the branches; the flowers come out singly upon long foot-stalks, which are of a pale red colour. This is propagated as the former, and requires the same treatment.

The third sort rises about four feet high, with a shrubby stalk dividing into slender branches, with silky white leaves, coming out by threes; the flowers are yellow, downy, and grow thinly on the branches. This is propagated as the two former, and must be treated in the same way as is directed for the first sort. It flowers late in the summer.

ASPARAGUS, Asparagus, Sparagus, or Sperage; corruptly called Sparrowgrafs.

The Characters are,

The flower is naked, having no empalement, and is of the bell-shaped kind spread open and reflexed at the top. These are male and hermaphrodite, sometimes in different plants, and at other times on the same stalks. The hermaphrodite flowers have a germen, which afterward becomes a round berry having three cells; in each of them is lodged one or two seeds. The male flowers have six stamina, but no germen or style, nor are succeeded by any berries.

The Species are,

1. ASPARAGUS *caule herbaceo erecto, foliis setaceis, stipulis paribus. Flor. Suec.* 272. Garden Asparagus.

2. ASPARAGUS *caule inermi herbaceo foliis teretibus longioribus fasciculatis.* Maritime Asparagus with a thicker leaf.

3. ASPARAGUS *foliis aciformibus pungentibus caule fruticoso inermi. Sauv. Monf.* 45. Asparagus with sharp pointed leaves.

4. ASPARAGUS *aculeis solitariis ramis flexuosis foliis brevioribus fasciculatis.* Prickly Asparagus with horrid spines.

5. ASPARAGUS *aculeis solitariis ramis reflexis retrofractisque, foliis fasciculatis. Lin. Sp. Pl.* 313. Narrow leaved African Asparagus with slender twigs, and many leaves growing

from a point like those of the Larch tree, and spread in form of a star.

6. *ASPARAGUS aphyllus spinis fasciculatis inæqualibus divergentibus.* Hort. Cliff. 122. Another prickly Asparagus, with three or four spines rising from the same point.

7. *ASPARAGUS caule iuxta ramis declinatis foliis fetaceis.* Prod. Leyd. 29. Asparagus with a smooth stalk, declining branches, and bristly leaves.

8. *ASPARAGUS aculeis solitariis caule erecto foliis fasciculatis, ramis filiformibus.* Lin. Sp. Plant. 313. Asparagus with single spines, an upright stalk, leaves growing in clusters, and very slender branches.

9. *ASPARAGUS spinis lateralibus terminalibusque, ramis aggregatis foliis fasciculatis.* Lin. Sp. Pl. 314. Asparagus with spines growing on the sides and ends of the branches, which are in bunches, and leaves coming out in clusters.

10. *ASPARAGUS foliis solitariis lineari lanceolatis caule flexuoso aculeis recurvis.* Flor. Zeyl. 124. The great prickly Asparagus of Ceylon, with bushy stalks.

The first sort is the common Asparagus, which is cultivated for the use of the table, and may have probably been brought by culture to the perfection it now is, from the wild sort, which grows naturally in the fens of *Lincolnshire*, where the shoots are no larger than straws; but if so, it must have been from very long culture and good management; for a friend of mine, who procured some seeds of the wild sort, which he cultivated with great care, in very rich ground, yet could not bring the roots to produce shoots more than half the size of the garden kind, which grew on the same ground; but he always found the wild sort came up a week or ten days earlier in the spring, and the shoots were exceeding sweet.

This Asparagus is propagated by seeds, in the procuring of which, there should be particular care to get it from a person of skill, who may be depended upon for his choice of the shoots, and integrity in supplying with the best seeds. But where a person is in possession of some good beds of Asparagus, it is much the best way to save it himself; in order to which, a sufficient number of the fairest buds should be marked early in the spring, and permitted to run up for seeds; because those which run up after the season for cutting the Asparagus is over, are generally so backward, as not to ripen the seeds unless the summer is warm, and the autumn very favourable. In the choice of the buds to be left for seeds, there must great regard be had to their size and roundness, never leaving any that are inclinable to be flat, or that soon grow open-headed, always choosing the roundest, and such as have the closest tops. But as several of these produce only male flowers which are barren, so a greater number of buds should be left, than might be necessary, if there could be a certainty of their being all fruitful, but this never happens. When the buds are left, it will be proper to thrust a stake down by each, but there must be care had in the doing of this, not to injure the crown of the root. These stakes will not only serve as marks to distinguish them from the others when they are all run up, but also to fasten the shoots to, when they are advanced in height, and put out lateral branches; to prevent their being broken by wind, which frequently happens where this is not observed; before the other shoots are permitted to run up, after which there is little danger of it, because they will then be screened by the other stalks. Toward the end of *September* the berries will be fully ripe, when the stalks should be cut off, and the berries stripped in a tub, in which they may remain three weeks or a month to sweat, by which means the outer husks will be rotten; then fill the tub with water, and with your hands break all the husks by squeezing them between your hands. These husks will all swim upon the water, but the seeds will sink to the bottom; so that by pouring off the

water gently, the husks will be carried along with it; and by putting fresh water two or three times, and stirring your seed about, you will make it entirely clean: then spread your seed upon a mat or cloth, and expose it to the sun and air in dry weather, until it is perfectly dry; when you may put it into a bag, and hang it up in a dry place till the beginning of *February*; at which time you must prepare a bed of good rich earth made very level, whereon you must sow your seeds (but not too thick, which will cause your plants to be small); then tread the bed all over to bury your seed in the ground, and rake it over smooth.

In the following summer, keep it diligently cleared from weeds, which will greatly add to the strength of your plants; and toward the latter end of *October*, when the haulm is quite withered, you may spread a little rotten dung over the surface of the ground, about an inch thick, which will preserve the young buds from being hurt with the frosts, &c.

The spring following, your plants will be fit to plant out for good (for I would never choose plants of more than one year's growth, having very often experienced them to take much better than older, and to produce finer roots): you must therefore prepare your ground by trenching it well, burying therein a good quantity of rotten dung at the bottom of each trench, that it may lie at least six inches below the surface of the ground; then level your whole plot very exactly, taking out all large stones: but this should not be done long before you intend to plant your Asparagus, in which you must be governed according to the nature of your soil or the season; for if your soil is dry and the season forward, you may plant toward the end of *March*; but in a very wet soil, it is better to wait till the middle of *April*, which is about the season that the plants are beginning to shoot. I know many people have advised the planting of Asparagus at *Michaelmas*, but this I have experienced to be very wrong; for in two different years I was obliged to transplant large quantities at that season, but I had better have thrown away the plants, for upon examination in the spring, I found most of the roots were grown mouldy, and decaying; and I am sure, not one in five of them succeeded, and those which did were so weak, as not to be worth their standing.

The season being now come for planting, you must with a narrow pronged dung-fork, carefully fork up your roots, shaking them out of the earth, and separating them from each other; observing to lay their heads even, for the more convenient planting them, which must be performed in this manner:

Your plot of ground being levelled, you must begin at one side thereof, ranging a line very tight cross the piece; by which you must throw out a trench exactly strait, and about six inches deep, so as not to turn up the dung, into which you must lay your roots, spreading them with your fingers, and placing them upright against the back of the trench, that the buds may stand forward, and be about two inches below the surface of the ground, and at twelve inches distance from each other; then, with a rake, draw the earth into the trench again, laying it very level, which will preserve the roots in their right position; then remove your line a foot farther back, and make another trench in the like manner, laying therein your plants as before directed, and continuing the same distance row from row; only observing between every four rows, to leave a distance of two feet and an half, for an alley to go between the beds to cut the Asparagus, &c.

Your plot of ground being finished and levelled, you may sow thereon a small crop of Onions, which will not hurt your Asparagus, and tread in your seeds, raking your ground level.

There are some persons who plant the seeds of Asparagus in the place where the roots are to remain, which is a very good method, if it is performed with care. The way is this:

this: After the ground has been well trenched and dunged, they lay it level, and draw a line cross the ground (in the same manner as is practised in planting of the young plants); then with a dibble make holes at a foot distance, into each of which you must drop two seeds, for fear one should miscarry; these holes should not be more than half an inch deep; then cover the seeds, by striking the earth in upon it, and go on removing the line a foot back for another row; and after four rows are finished, leave a space for an alley between the beds, if it is designed to stand for the natural season of cutting; but if it is to be taken up for hot-beds, there may be six rows planted in each bed, and the distance in the rows need not be more than nine inches. This should be performed by the middle of *February*, because the seeds lie long in the ground; but if Onions are intended to be sown upon the ground, that may be performed a fortnight or three weeks after, provided the ground is not stirred so deep as to disturb the Asparagus seeds, in raking the Onion seed into the ground.

As the roots of Asparagus always send forth many long fibres which run deep into the ground, so when the seeds are sown where they are to remain, these roots will not be broken or injured, as those must be which are transplanted; therefore they will shoot deeper into the ground, and make much greater progress, and the fibres will push out on every side, which will cause the crown of the root to be in the center; whereas in transplanting, the roots are made flat against the side of the trench.

When your Asparagus is come up, and the Onions have raised their seed leaves upright (which will be in a month or six weeks after planting), you must with a small hoe cut up all the weeds, and thin your crop of Onions where they may have come up in bunches: but this must be done carefully, and in dry weather, that the weeds may die as fast as they are cut up, being careful not to injure the young shoots of Asparagus, as also to cut up the Onions which grow near the shoots. This work must be repeated about three times, which, if well done, and the season not too wet, will keep the ground clear from weeds until the Onions are fit to be pulled up, which is commonly in *August*, and is known when their greens fall down and begin to wither. When you have drawn off your Onions, you must clean your ground well from weeds, which will keep it clean till you earth the beds; which must be done in *October*, when the haulm begins to decay; for if you cut off the haulm while green, the roots will shoot fresh again, which will greatly weaken them. This young haulm should be cut off with a knife, leaving the stems two or three inches above ground, which will be a guide for you to distinguish the beds from the alleys; then with a hoe clear off the weeds into the alleys, and dig up the alleys, burying the weeds in the bottom, and throw the earth upon the beds, so that the beds may be about five inches above the level of the alleys: then you may plant a row of Coleworts in the middle of the alleys, but do not sow or plant any thing upon the beds, which would greatly weaken your roots; nor would I ever advise the planting of Beans in the alleys (as is the practice of many) for it greatly damages the two outside rows of Asparagus. In this manner it must remain till spring, when you must hoe over the beds to destroy all young weeds; then rake them smooth, and observe all the succeeding summer to keep them clear from weeds, and in *October* dig up the alleys again, as was before directed, earthing the beds, &c.

The second spring after planting, you may begin to cut some of your Asparagus, though it will be much better to stay until the third; therefore now you must fork up your beds with a flat pronged fork, made on purpose, which is commonly called an Asparagus fork: this must be done before the buds shoot in the spring, and with care, lest you

fork too deep, and bruise the head of the root; then rake the beds over smooth, just before the buds appear above ground, which will destroy all young weeds, and keep your beds clean much longer than if left unraked, or done so soon as forked; and when your buds appear about four or five inches above ground, you may then cut them, but it should be done sparingly, only taking the large buds, and suffering the small to run up to strengthen the roots; for the more you cut, the greater will be the increase of buds, but they will be smaller and the roots sooner decay. When you cut a bud, you must open the ground with your knife (which should be very narrow and long in the blade, and filled with teeth like a saw) to see whether any more young buds are coming up close by it, which might be either broken or bruised in cutting the other, then with your knife saw it off about three inches under ground. This may appear a very troublesome affair to people unacquainted with the practical part, but those who are employed in cutting Asparagus, will perform a great deal of this work in a short time; but care in doing it is absolutely necessary to be observed by all who cut Asparagus.

The manner of dressing your Asparagus beds is every year the same as directed for the second, *viz.* clearing them from weeds, digging the alleys in *October*, and forking the beds toward the end of *March*, &c. only observe every other year to lay some rotten dung (from a Melon or Cucumber bed) all over your beds, burying some in the alleys also, at the time for digging them up. This will preserve the ground in heart to maintain your roots in vigour, and by this management, a plot of good Asparagus may be continued for ten or twelve years in cutting, and will produce good buds, especially if it is not cut too long each season; for when it is not left to run up pretty early in *June*, the roots will be greatly weakened, so the buds will be smaller: therefore, in those families where Asparagus is required late in the season, a few beds should be set apart for that purpose, which will be much better than to injure the whole plantation, by cutting it too long.

I cannot help taking notice of a common error that has long prevailed with most people, which is, that of not dunging the ground for Asparagus, believing that the dung communicates a strong rank taste to the Asparagus; which is a great mistake, for the sweetest Asparagus is that which grows upon the richest ground, and poor ground occasions that rank taste, so often complained of; the sweetness of Asparagus being occasioned by the quickness of its growth; which is always proportionable to the goodness of the ground, and the warmth of the seasons: but in order to prove this, I planted two beds of Asparagus, upon ground which had dung laid a foot thick; and these beds were every year dunged extremely thick, and the Asparagus produced from these beds was much sweeter than any I could procure, though they were boiled together in the same water.

The quantity of ground necessary to be planted with Asparagus, to supply a small family, should be at least five or six rods, less than that will not do; for if you cannot cut one hundred at a time, it will scarcely be worth while; for you must be obliged to keep it after it is cut two or three days, to furnish enough for one mess; but for a larger family, twelve rods of ground should be planted, which, if a good crop, will furnish two or three hundred each day in the height of the season.

But as there are several people who delight in having early Asparagus, which is become a very great trade in the kitchen gardens near *London*, I shall give proper directions for the obtaining it any time in winter.

You must first be provided with a quantity of good roots (either of your own raising, or purchased from such gardeners as plant for sale), that have been two or three years planted.

planted out from the seed bed; and having fixed upon the time you would willingly have your Asparagus fit to cut, about six or seven weeks before, you should prepare a quantity of new stable horse-dung, which should be thrown in a heap for ten or twelve days to ferment, mixing some sea-coal ashes with it; it should be turned over to mix it well, then it will be fit for use. Then dig out a trench in the ground where you intend to make the bed, the width of the frames that are designed to cover it, and the length in proportion to the quantity you intend to have (which if designed only to supply a small family, three or four lights at a time will be sufficient): then lay down your dung into the trench, working it very regularly, and beat it down very tight with a fork, laying it at least three feet in thickness or more, when the beds are made in *December*; then put your earth thereon about six inches thick, breaking the clods and laying it level; and at one end, begin laying your roots against a little ridge of earth, raised about four inches high: your roots must be laid as close as possible one to the other, in rows, with their buds standing upright; and between every row lay a small quantity of fine mould, observing to keep the crown of the roots exactly level. When you have finished laying your bed with roots, you must lay some stiff earth up to the roots, on the outsides of the bed, which are bare, to keep them from drying; and thrust two or three sharp pointed sticks, about two feet long, down between the roots, in the middle of the bed, at a distance from each other. The use of these sticks is to let you know what temper of heat your bed is in, which you may find by drawing up the sticks, and feeling the lower part; and if, after the bed has been made a week, you find it doth not heat, you may lay a little straw or litter round the sides, or upon the top, which will greatly help it; and if you find it very hot, so as to endanger scorching of the roots, it will be advisable to let it remain wholly uncovered, and to thrust a large stick into the dung, on each side of the bed, in two or three places, to make holes for the great steam of the bed to pass off, which in a short time will reduce the bed to a moderate heat.

After your bed has been made a fortnight, you must cover the crowns of the roots with fine earth, about two inches thick; and when the buds appear above ground through that earth, you must again lay on more earth, about three inches thick; so that in the whole, it may be five inches above the crowns of the roots, which will be sufficient.

Then you must make a band of straw (or long litter), about four inches thick, which you must fasten round the sides of the bed, that the upper part may be level with the surface of the ground: this must be fastened with strait sticks about two feet long, sharpened at the points, to run into the bed; and upon this band you must set your frames, and put your glasses thereon; but if, after your bed hath been made three weeks, you find the heat decline, you must lay a good lining of fresh hot dung round the sides of the bed, which will add a fresh heat thereto; and in bad weather, as also every night, keep the glasses covered with mats and straw; but in the day time, let it be all taken off, especially whenever the sun appears; which, shining through the glasses, will give a good colour to the Asparagus.

A bed thus made, if it works kindly, will begin to produce buds, for cutting, in about five weeks after it is made, and will hold about three weeks in cutting; which, if rightly planted with good roots, will produce, in that time, about three hundred buds in each light; so that, if you would continue your Asparagus until the season of the natural being produced, you must make a fresh bed every three weeks, until the beginning of *March*, from the season of your first bed being made; for if your last bed is made about a week in *March*, it will continue till the season of natural Asparagus; and the last beds will come a fortnight sooner to cut

than those made about *Christmas*; and the buds will be larger, and better coloured, as they will then enjoy a greater share of the sun.

If you intend to follow this method of forcing early Asparagus, you must keep planting every year a quantity, which you shall judge necessary (unless you intend to buy the roots from some other garden); the quantity of roots necessary to plant one light, is commonly known by the measure of the ground where they grow; for in a good crop, where few roots are missing, one rod of ground will furnish enough for a light; but this calculation is made from the ground planted with roots, which are designed to be taken up after two or three years growth for forcing, in which there are six rows in a bed, at but ten inches distance, and the plants eight or nine inches asunder in the rows; but where there is a greater space between the rows, and fewer rows in a bed, then there must be a greater quantity of ground allotted for each light. Most of the kitchen gardeners about *London*, take up their Asparagus roots after two years growth from planting; but where the land is not very good, it will be better to let it have three years growth, for if the roots are weak, the buds of Asparagus will be very small, so not worth the trouble of forcing. The best ground for planting Asparagus, to have large roots for hot-beds, is a low moist rich soil; but for those that are to remain for a natural produce, a middling soil, neither too wet nor too dry; but a fresh sandy loam, when well dunged, is preferable to any other.

The second sort is mentioned to grow naturally in *Wales*, and also near *Bristol*, but this I have great doubts about; for those who have mentioned it, say it does not differ from the garden kind, which is only altered by culture. But I have lately received specimens of this, which were gathered near *Montpelier*, by which I am convinced that it is a different species from that which grows in *Wales*, for the leaves of the wild maritime kind, are taper and thick, and are thinly placed on their branches, nor do the stalks branch out so much.

This sort is propagated by seeds in the same manner as the garden kind, but must have a warmer situation, and the roots should be well covered in winter, to prevent the frost from penetrating of the ground, which will destroy it.

The third sort hath white crooked shrubby stalks, which rise six or eight feet high, but have no spines on them; the leaves come out in clusters from the same point, like those of the Larch tree; these are very short, and end in sharp prickles, so that they are troublesome to handle. This sort grows naturally in the south of *France*, *Spain*, and *Portugal*. It is propagated by seeds as the former sorts, but is too tender to live abroad in *England*, so the roots should be planted in pots, and sheltered in winter.

The fourth hath shrubby stalks, three or four feet high, with very white bark, and are armed with thorns which are single, coming out just below each tuft of leaves. These stalks continue several years, and put out many branches, which are garnished with narrow short leaves. These continue green all the winter, if the plants are screened from severe frost.

It is propagated by seeds as the former, which may be procured from the *Mediterranean*, where it grows naturally; the plants should be kept in pots, that they may be sheltered in winter.

The fifth sort grows naturally at the *Cape of Good Hope*. This hath very crooked irregular stalks, which rise eight or ten feet high, and are shrubby, putting out several side branches, which are weak. These have long narrow leaves coming out in clusters like those of the Larch tree; under each of these clusters is placed a single sharp thorn. The stalks continue several years, and the leaves keep green all the year. It is commonly propagated by parting of the roots, because the plants do not seed in this country; the best time

time for this is in *April*. The roots must be planted in pots, and removed into the green-house in autumn, for these plants will not live abroad in *England*.

The sixth sort grows naturally in *Spain*, *Portugal*, and *Sicily*, generally in rocky places. This sends up many weak irregular shoots, which have no leaves, but instead thereof, are armed with short stiff thorns, which come out four or five together from the same point, and spread from each other every way. The flowers are small, of an herbaceous colour; the berries are larger than those of the common sort, and are black when ripe. This is tender, so must be treated as the third sort.

The seventh sort grows naturally at the *Cape of Good Hope*. This sends up from the root several slender stalks, which put out weak branches, which decline downward; these are closely garnished with bristly leaves, like those of garden *Asparagus*, which continue green through the year. It is propagated by parting of the roots, as the fifth sort, and the plants should be treated in the same manner.

The eighth sort grows naturally at the *Cape of Good Hope*; this sends up many weak shoots growing in clusters, which are armed with sharp spines, both on the side and end of the shoots; the leaves come out in small clusters, which continue green all the year. This is propagated as the fifth sort, and requires the same treatment.

The tenth sort sends out from the root many weak climbing branches which rise five or six feet high, which are garnished with narrow spear-shaped leaves coming out single; the shoots are armed with short crooked spines, which are so closely set on, that it is difficult to handle the branches. This is propagated by parting the root; but the plants must be placed in a moderate stove, otherwise it will not thrive in this country. It grows naturally in the island of *Ceylon*.

These plants are preserved in the gardens of the curious, where they add to the variety; being not difficult to manage, where there is conveniency to house them in winter. They should have a place among other exotic plants.

ASPARAGUS SCANDENS. See *Medeola*.

ASPEN TREE. See *Populus*.

ASPERUGO, Small Wild Bugloss.

The Characters are,

The flower is of one leaf, with a short cylindrical tube; it hath five short stamina in the center, with four compressed germen, which afterward become four oblong seeds, inclosed in the empalement.

We know but one Species of this genus, which is,

ASPERUGO. *Flor. Lapp.* 76. Small Wild Bugloss, Great Goose Grass, or German Madwort.

This is an annual plant, which is found wild in some parts of *England*, as near *Newmarket*, at *Boxley* in *Suffex*, and in *Holy Island*. It is preserved in the botanick gardens for variety: it may be easily propagated by seeds, which should be sown in autumn; and when the plants come up, they require no other culture but to keep them clear from weeds, and in *May* they will flower: in *June* their seeds will be perfected.

ASPERULA, Woodroof.

This plant grows wild in shady woods in many parts of *England*, and flowers in *April* or *May*, and is sometimes used in medicine; but as this grows wild in *England*, it is rarely admitted into gardens.

ASPHODELUS, King's Spear.

The Characters are,

The flower has no empalement; it is of one leaf, cut into six parts, which spread open; at the bottom is inserted a globular nectarium, having six valves; it hath six stamina, which are inserted in the valves of the nectarium. Between the nectarium is placed a globular germen, which afterward becomes a fleshy seed-vessel, having three cells, which are filled with triangular seeds.

The Species are,

1. ASPHODELUS caule folioso, foliis triquetris fistulosis. *Hort. Cliff.* 127. Common yellow King's Spear.

2. ASPHODELUS caule nudo ramoso foliis ensiformibus laciniatis. Male branching King's Spear with white flowers.

3. ASPHODELUS caule nudo simplici foliis lineari-ensiformibus. White unbranched King's Spear.

4. ASPHODELUS foliis ensiformibus carinatis scapo ramoso-patulo. King's Spear with sword-like, keel shaped leaves, and a branching spreading stalk.

5. ASPHODELUS caule nudo foliis subulatis fistulosis radice annua. Annual branching Spiderwort with a small flower and fistular leaves.

6. ASPHODELUS foliis planis, caule ramoso, floribus sparsis. King's Spear with plain leaves, a branching stalk, and flowers placed thinly.

The first sort is the yellow *Asphodel*, which is directed for use in medicine; this hath roots composed of many thick fleshy fibres, which are yellow, and are joined into a head at the top; from whence arise strong round single stalks, near three feet high, garnished on the upper part of the stalk with yellow star-shaped flowers, which appear in *June*, and the seeds ripen in autumn.

The second sort hath roots composed of many thick fleshy fibres; to each of which is fastened an oblong tuber, as large as small *Potatoes*; the leaves are long and flexible, having sharp edges; between these come out the stalks, which rise more than three feet high, sending out several side branches; the upper part of these are adorned with many white star-shaped flowers, which grow in long spikes, flowering gradually upward. They come out the beginning of *June*, and the seeds ripen in autumn.

The third sort hath roots like the second, but the leaves are longer and narrower; the stalks of this are single, never putting out any side branches; the flowers are of a purer white, and grow in longer spikes. This flowers at the same time with the former.

The fourth sort hath roots composed of smaller fibres than the two last, nor are the knobs at bottom half so large; the leaves are long, almost triangular, and hollow like the keel of a boat; the stalks seldom rise above two feet high, and divide into several spreading branches; these are terminated by loose spikes of white flowers, which are smaller than those of the former.

The fifth sort is an annual plant; the roots of this are composed of many fleshy fibres, which are yellow; the leaves are spread out from the crown of the root, close to the ground, in a large cluster; these are convex on their under side, but plain above; the flower-stalks rise immediately from the root, and grow about two feet high, dividing into three or four branches upward, which are adorned with white starry flowers, with purple lines on the outside. These flower in *July* and *August*, and their seeds ripen in *October*.

The yellow sort multiplies very fast by roots, and will soon overspread a large border, if suffered to remain unre-moved, or the side roots are not taken off: but the other sorts are not so productive of shoots from their sides, and are much better kept within bounds.

These sorts of *Asphodel* are very pretty ornaments for a flower garden, and require very little trouble to cultivate them, so are more acceptable. They may be all propagated by seeds, which should be sown soon after they are ripe, on a border of light fresh earth: in the spring the plants will appear, and will have strength enough to be transplanted by the *Michaelmas* following, when they should be planted in the flower nursery, at about six inches distance every way; observing to plant them so low, as that the top of the roots may be three or four inches under the surface of the bed; and some old tan, or dung, should be spread over the surface

of the ground, to keep out the frost: in this bed they may remain one year; then the roots having acquired strength enough to produce flowers the following year, they should, at *Michaelmas*, when their leaves are decayed, be carefully taken up, and transplanted into the flower garden, in the middle of the borders, amongst other hardy kind of flowers, where being properly intermixed, they will make an agreeable variety, and continue a long time in flower.

The fifth sort is annual, so is only propagated by seeds; these should be sown in the autumn, in the places where they are to remain for good. If the seeds of this plant are permitted to scatter, the plants will come up without care.

The sixth sort was raised from seeds in the *Chelsea* garden, *Anno 1751*, where it produced flowers the following year. The seeds came from the *Cape of Good Hope*, where this plant naturally grows.

The roots of this plant are composed of many tubers, or fangs, each about the size of a little finger, toward the upper part, where they are largest, and diminish gradually downward to the size of a small straw. These are joined together at the crown (like the roots of *Asparagus*), where the buds are formed; from whence the leaves are produced, which are generally seven or eight in number, and are nine or ten inches in length, and an inch and an half broad in the middle, lessening gradually to both ends. They are smooth, and of a glaucous or sea-green colour. From the center of the root arises the flower-stem, which grows about two feet and an half high, and divides into several branches. The flowers are produced thinly on the branches, forming a loose spike, or thyrsus. These are white, and consist of one leaf, which is deeply cut into six parts. The germen becomes a roundish seed-vessel, opening in three cells, which are filled with triangular seeds.

This plant is too tender to live through the winter in the open air in *England*, so must be kept in pots, and housed in winter, or placed under a hot-bed frame, where the frost is kept out by covering; in which management, the plants will thrive better than in a common green-house. In winter these plants must have little wet, for much moisture, at that season, is apt to rot their roots.

ASPLENIUM, or Ceterach.

This plant is nearly allied to the Fern, and grows upon old moist shady walls in divers parts of *England*; but is rarely cultivated in gardens.

ASTER, Starwort.

The Characters are,

It hath a compound flower, composed of several female and hermaphrodite florets, which are included in one common scaly empalement; the rays of the flower are composed of female florets; the hermaphrodite florets form the disk or middle; these are funnel-shaped, and have each five short slender stamina; in the bottom is placed a germen, which afterward becomes an oblong seed, crowned with down.

The Species are,

1. *ASTER foliis lanceolatis hirtis, radicalibus obtusis, caule simplicissimo unifloro. Lin. Sp. Pl. 872.* Blue Mountain Starwort with a large flower, and oblong leaves.

2. *ASTER foliis lanceolatis obtusis scabris trinervis integris, pedunculis nudiusculis corymbosis squamis calycinis obtusis. Lin. Sp. Plant. 873.* Common *Attick* Starwort, vulgarly called *Italian* Starwort.

3. *ASTER foliis lanceolatis integerrimis carnosis glabris ramis inæquatis, floribus corymbosis. Lin. Sp. Plant. 872.* Sea Starwort called *Tripolium*.

4. *ASTER foliis linearibus acutis integerrimis, caule corymboso ramosissimo. Hort. Cliff. 408.* Starwort with a flower of *Tripolium*, and a very narrow thin leaf.

5. *ASTER foliis lanceolatis alternis integerrimis semiamplexicaulibus floribus terminalibus. Hort. Cliff. 408.* Tallest

hairy *New England* Starwort with large purple Violet flowers.

6. *ASTER foliis cordato-lanceolatis undulatis floribus racemosis adscendentibus. Hort. Cliff. 408.* Purple *New England* Starwort with the appearance of golden rod, and waved leaves.

7. *ASTER foliis semiamplexicaulibus lanceolatis serratis scabris, pedunculis alternis subunifloris calycibus disco superantibus. Hort. Cliff. 408.* Broad-leaved *American* Starwort with purplish stalks.

8. *ASTER floribus ovatis disco radii longiore. Lin. Sp. Pl. 877.* Starwort like *Heath*, and the disk of the flower like *Wild Melilot*.

9. *ASTER foliis lanceolatis subserratis sessilibus caule paniculato ramulis unifloris solitariis calycibus squarrosis. Hort. Cliff. 408.* Broad-leaved umbellated Starwort of *New Holland*, with pale Violet flowers.

10. *ASTER foliis lanceolato-linearibus subcarnosis integerrimis planis floribus corymbosis fastigiatis pedunculis foliolosis. Lin. Sp. Plant. 874.* Starwort with the *Tripolium* flower.

11. *ASTER caule simplicissimo foliis ovatis sessilibus integerrimis racemo terminali. Flor. Virg. 178.* Starwort with single stalks, oval entire leaves growing close to the stalks, which end in a loose spike.

12. *ASTER caule paniculato pedunculis racemosis pedicellis foliosis foliolis linearibus integerrimis. Flor. Virg. 100.* Bushy *Heath* like Starwort.

13. *ASTER foliis cordatis serratis petiolatis, caule paniculato. Hort. Cliff. 408.* Broad-leaved autumnal Starwort.

14. *ASTER foliis lanceolato-linearibus medio serratis pedunculis foliosis caule racemoso calycibus erectis. Hort. Cliff. 408.* *American* Starwort with leaves like *Summer Cypress*, and bluish white flowers growing in very long spikes.

15. *ASTER caule corymboso foliis lanceolatis reflexis, floribus solitariis, calycibus patulis. Flor. Leyd. 168.* *Pyramidal Virginia* Starwort with rough *Hyssop* leaves, and leafy scales to the empalement.

16. *ASTER foliis lanceolatis scabris integris, caule ramofo, pedunculis foliosis, calycibus obtusis.* Another *Attick* Starwort of the *Alps*.

17. *ASTER foliis oblengo lanceolatis acutis serratis caule ramofo floribus terminalibus calycibus linearibus erectis.* Starwort with smooth jagged leaves, growing scatteringly like those of the *Peach tree*, and pale blue flowers.

18. *ASTER foliis oblongis acutis basi latioribus semiamplexicaulibus, caule ramofo floribus terminalibus plerumque solitariis.* Late blue shrubby Starwort of *John Tradescant*, commonly called *Michaelmas Daisy*.

19. *ASTER caule erecto hirsuto foliis oblongis acutis scabris acutè dentatis semiamplexicaulibus floribus corymbosis, calycibus hirsutis erectis.* Early *Pyrenean* Starwort with a large blue flower.

20. *ASTER caule altissimo hirsuto simplicissimo foliis oblongis acutis basi latioribus semiamplexicaulibus floribus tribus sessilibus terminalibus.* Starwort with a very tall unbranched stalk, oblong pointed leaves, which are broader at the base, and half embrace the stalks, which are terminated by three flowers sitting very close.

21. *ASTER caule ramocissimo patulo, foliis lineari-lanceolatis rigidis, floribus seriatim positus pedunculis foliosis.* Starwort with a very branching spreading stalk, narrow spear-shaped stiff leaves, flowers placed one above another, and leafy foot-stalks.

22. *ASTER foliis lanceolatis acutis scabris, caule simplici floribus umbellatis terminalibus.* Starwort with rough pointed spear-shaped leaves, and a single stalk, terminated by flowers, growing in an umbel.

23. *ASTER foliis nervosis acutis linearibus lanceolatis, caule simplici floribus terminalibus quasi umbellatim dispositis.* Starwort with narrow pointed nervous leaves, and a single stalk, terminated by flowers growing almost in an umbel.

24. *ASTER*

24. *ASTER foliis inferioribus ovatis basi semiamplexicaulibus, superioribus lanceolatis parvis caule paniculato, ramis unifloris pedunculis foliosis.* Starwort with the lower leaves oval, whose base half embraces the stalks, the upper leaves small and spear-shaped, a stalk terminated by a loose spike, with a single flower on each branch, and a leafy foot stalk.

25. *ASTER floribus terminalibus solitariis foliis linearibus alternis.* Flor. Virg. 98. Starwort with single flowers at the ends of the branches, and very narrow leaves placed alternately.

26. *ASTER foliis linearilanceolatis acutis sessilibus caule paniculato, ramis unifloris pedunculis foliosis linearibus.* Starwort with narrow, pointed spear-shaped leaves, growing close to the stalks, which end in loose spikes, and branches ending with a single flower, whose foot-stalks have narrow leaves.

27. *ASTER foliis linearilanceolatis glabris trinerviis floribus corymbosis terminalibus.* Starwort with smooth, narrow, spear-shaped leaves, with three veins, and flowers in a corymbus, which terminate the stalks.

28. *ASTER foliis linearibus integerrimis caule paniculato.* Hort. Cliff. 408. New England Starwort with Toad-flax leaves, and a Chamomile flower.

29. *ASTER foliis lanceolatis sessilibus integerrimis caule paniculato pedunculis foliosis.* Broad-leaved Starwort of New Holland, with deep Violet flowers growing in loose spikes.

30. *ASTER caule ramofo scabro perenni, foliis ovatis oppositis pedunculis nudis unifloris.* Fig. Pl. Tab. 76. Starwort with a rough perennial branching stalk, oval leaves growing opposite, and naked foot-stalks with one flower.

31. *ASTER foliis linearibus fasciculatis punctatis, pedunculis unifloris nudis, caule fruticoso rugoso.* Hort. Cliff. 409. Shrubby African Starwort, with narrow leaves growing in clusters.

32. *ASTER foliis ovatis angulatis dentatis, petiolatis calycibus terminalibus patentibus foliosis.* Hort. Cliff. 407. Annual Starwort with a goose-foot leaf, and a large beautiful flower, commonly called China Aster, or Queen Marguerette.

33. *ASTER foliis pinnatis.* Hort. Cliff. 407. Starwort with winged leaves.

The first sort grows naturally upon the Alps, where it seldom rises more than six inches high, and when transplanted into a garden, not above nine or ten. It sends up a single stalk from the root, at the top of which is one large blue flower, somewhat like those of the Italian Starwort. The root is perennial, but must be planted in a shady situation, and a moist soil.

The second sort is the Italian Starwort, which was some years past more common in the gardens than at present; for since the great variety of American Starworts have been introduced into England, this sort hath not been so much cultivated, though it is by no means inferior to the best of them; and, in some respects, preferable to most of them; for it is not so subject to creep by the root, as many of the American sorts do, whereby they often become troublesome in small gardens, nor do the stalks of these seldom grow more than two feet high, and are very strong, so are very rarely broken by the wind. They are terminated with large flowers having blue rays, with a yellow disk. It flowers in October, and, in mild seasons, will often continue till the middle of November; during which time they are very ornamental plants in a garden. This sort is propagated by parting of the roots; the best time for doing it is soon after they are out of flower, for those which are removed in the spring will not flower so strong the succeeding summer. These roots should not be removed oftener than every third year, where they are expected to produce many flowers.

It grows naturally in the vallies of Italy, Sicily, and Narbonne, and is generally supposed to be the Amellus mentioned by Virgil in his fourth Georgick, to grow in the pastures;

the leaves and stalks being rough and bitter, the cattle seldom browse upon it, so that whenever there are any of these roots in the fields, they send up a thick tuft of stalks, which, being left after the grass is eaten bare, these being full of flowers, make a fine appearance, and therefore might engage the poet's attention.

The third sort grows naturally in salt marshes, which are flowed by the tides, and is seldom admitted into gardens. It flowers in July and August.

The fourth sort is a native of North America. It sends up many strong shoots from the root every spring, which rise between four and five feet high, with oblong leaves, which half embrace the stalk with their base with a single flower; terminating the stalk, of a blue colour. This flowers in August and September; it is easily propagated by parting of the roots, soon after the flowers are past, and will thrive in almost any soil or situation.

The fifth sort sends up many stalks from the root, which rise five feet high, with spear-shaped leaves which are entire, and half embrace the stalks, which are terminated by large purple Violet flowers, growing in a loose panicle: it flowers in August, and is very hardy, so may be planted in any soil or situation, and is propagated by parting the roots.

The sixth sort grows naturally in North America. This hath broad heart-shaped waved leaves at the bottom; the stalks rise between two and three feet high, upon which the flowers come out in loose spikes, which are of a very pale blue colour, inclining to white. This flowers in the same season as the former, and may be propagated in the same manner.

The seventh sort sends up several strong stalks, upward of two feet high, which are of a purple colour, with spear-shaped smooth leaves, whose base embraces the stalks half round; the flowers grow upon single foot-stalks, forming a corymbus at the top, and are of a pale blue colour; these appear the latter end of September. This may be propagated in the same way as the former.

The eighth sort rises with slender stalks, upward of three feet high, garnished with very small leaves; the flowers come out on short foot-stalks, on every side of the branches, which are small, with white rays and a yellow disk. These appear in November, and often continue part of December. This may be propagated as is before directed.

The ninth sort rises near four feet high, having broad leaves at the bottom; the flowers are produced in a loose kind of umbel at the top of the stalks, which are of a pale blue colour, and appear the latter end of August. This is hardy, and may be propagated as the former.

The tenth sort grows three feet high; the stalks of this divide into a great number of branches, which divide again toward the top into several smaller, which are garnished with very narrow leaves; the flowers grow in large clusters at the top, forming a sort of corymbus; they are of a pale bluish colour, and appear the beginning of August. This is hardy, and may be propagated by parting of the roots, as the former.

The eleventh sort rises four feet high, with a single stalk, and oval leaves growing close to the stalks, which are terminated by slender loose spikes of pale blue flowers, which appear about Michaelmas. This is propagated as the sorts above-mentioned.

The twelfth sort sends up slender stalks three feet high; these are garnished with very narrow leaves their whole length, and are terminated by single flowers.

The thirteenth sort grows about two feet high, having slender stalks, with oblong pointed heart shaped leaves, which are sharply sawed on their edges, and are terminated by white flowers growing in loose panicles. This flowers in September, and may be propagated as the former.

The fourteenth sort sends up stalks five feet high, with narrow spear-shaped leaves, and are terminated by spikes of small white flowers, which appear the end of *October*. This sort spreads greatly at the root, so is apt to over-run the borders.

The fifteenth sort hath narrow oblong hairy leaves at the bottom; the stalks rise three feet high, with small narrow rough leaves which turn backward; the stalks are terminated by a single large blue flower. This sort flowers the end of *October*, and continues most part of *November*, when it makes a fine appearance. It doth not multiply fast by its roots, but may be propagated in plenty, by cuttings made from the young shoots in *May*, which, if planted in a bed of light earth, and shaded from the sun, will take root: it is called by the gardeners *Catesby's Starwort*.

The sixteenth sort sends up several stalks a foot and an half high, with rough spear-shaped leaves; these are terminated for the most part by one large blue flower, somewhat like those of the *Italian Starwort*, but paler and comes earlier to flower. It is propagated by parting of the root.

The seventeenth sort rises to the height of five feet, with branching stalks, and oblong spear-shaped leaves, which are sawed on their edges; the stalks are terminated by large pale blue flowers, and are in beauty in *October*. This is propagated by parting the roots, as the sorts before-mentioned.

The eighteenth sort was brought from *Virginia* many years ago, by Mr. *John Tradescant*, who was a great collector of rarities. It is generally known by the title of *Michaelmas Daisy*, from its flowering about old *Michaelmas* day. The stalks of this sort are numerous, and rise about four feet high, with oblong leaves ending in a point, whose base half embraces the stalks. The branches are terminated by pretty large flowers, which are of a very pale bluish colour, tending to white. The roots of this multiply very fast, so that it propagates so much as often to be troublesome; it will thrive in any situation.

The nineteenth sort sends up several strong hairy stalks, which rise a foot and an half high, having many oblong rough leaves ending in a point, whose base half embraces the stalks, which are terminated by one large blue flower, having a very hairy empalement. This flowers the latter end of *July*. This should have a moist soil and a shady situation. It is propagated by parting of the roots.

The twentieth sort rises with strong hairy stalks, to the height of eight or nine feet, which are upright, unbranched, and garnished with oblong hairy leaves ending in a point; their base half surrounds the stalks, which are for the most part terminated by three large purple flowers inclining to red, and sit close to the top of the stalk, surrounded by a few narrow leaves. This sort flowers in *November*. It is propagated by parting of the roots, and delights in a moist soil.

The twenty-first sort hath slender purplish stalks, which rise about three feet high, sending out many side branches, which spread horizontally, and are garnished with narrow small spear-shaped leaves; the flowers are produced in a sort of loose spike, growing one above another on each side the stalk. These are small, and of a pale purplish colour, and appear in *November*. It is easily propagated by parting of the roots.

The twenty-second sort sends up stiff channelled stalks about two feet high, which are garnished with rough spear-shaped leaves ending in a point; the flowers are white, and grow in a sort of umbel at the top of the stalks. It flowers the end of *September*, and is propagated by parting of the roots.

The twenty-third sort hath much the appearance of the former, but the leaves are narrower, whiter on their under side, and have three longitudinal veins; the flowers are also

larger and whiter. It grows about the same height, and flowers at the same time with the former.

The twenty-fourth sort rises four feet high; the bottom leaves are oval and half surround the stalk at their base, the upper leaves are small and spear-shaped; the stalks are terminated by one large blue flower, with a leafy foot-stalk; this flowers about the end of *October*, and is propagated by parting of the roots.

The twenty-fifth sort sends up from the root several slender stalks near three feet high, with very narrow leaves, and puts out side branches, each being terminated by one white flower. This flowers in *November*, and is easily propagated by parting of the roots.

The twenty-sixth sort rises about a foot and an half high, with very narrow spear-shaped leaves which are smooth; the stalks are terminated by one pale blue flower, having a leafy foot-stalk.

The twenty-seventh sort grows about two feet high, with erect stalks, with narrow smooth spear-shaped leaves, which come out irregularly in clusters; the upper part of the stalks are garnished with very narrow leaves; the flowers are produced in form of a corymbus at the end of the stalks, which are of a pale blue colour, and appear in *September*. This is propagated by parting of the roots.

The twenty-eighth sort rises with slender stalks about three feet high, with very narrow leaves, and are terminated by loose panicles of flowers, whose rays are white and their disks yellow. This flowers in *October*, and is propagated by parting of the roots.

The twenty-ninth sort sends out many strong stalks from the root, which rise about three feet high, with spear-shaped leaves growing close to the branches, which are terminated by loose spikes of dark blue flowers, which appear in *October*. This is propagated by parting of the roots.

The thirtieth sort grows naturally at the *Cape of Good Hope*. The plant has many fibrous roots, from which arise a purplish rough stalk, which divides into many branches near the root, so as to form a low bushy plant, with oval leaves about an inch long, and a third part of an inch broad; they are pretty thick and succulent, and are rough to the touch, having no foot-stalks: toward the upper part of the branches, the foot-stalks of the flower arise, which are from four to six inches long, and naked, each supporting a single radiated flower.

The rays of the flower are of a fine sky-blue colour, which, after they have been some time expanded, turn back toward the empalement; the disk of the flower is yellow. After the flower falls away, each of the florets which compose the disk is succeeded by a single seed, crowned with a soft down. The whole plant is a little acid to the taste.

This plant is never destitute of flowers the whole year, for in the winter season, there will always be a number of them in beauty, though at that time they are not so numerous, or quite so large as in summer; but the plants will not live in the open air in this country. It perfects its seeds very well, so may be propagated by sowing them in *April*, in a bed of light earth; and when the plants are large enough to transplant, they should be each put into a separate small pot, and may continue in the open-air till toward the end of *October*, at which time they should either be removed into the greenhouse, or put under a hot-bed frame to screen them from the frost in winter. It may also be propagated by cuttings, which should be planted in a shady border any time in summer, and when rooted must be treated as the seedlings.

The thirty-first sort rises with a woody stem about three feet high, sending out many side branches which are lignous, with narrow leaves coming out in clusters from one point, like those of the Larch tree; the flowers are produced from the side of the branches, upon long slender foot-stalks singly; these

these are of a pale blue colour, and appear the beginning of *March*; as this plant never produces seeds in *Europe*, so it is only propagated by cuttings, which may be performed any time in the summer. When the plants are rooted, they may be placed in the open air till the end of *October*, when they should be removed into shelter. This sort is at present but in few *English* gardens.

The thirty-second sort is a native of *China*, from whence the seeds were sent to *France* by the missionaries, where the plants were first raised in *Europe*. The seeds came by the title of *La Reine Marguerette*, or *Queen of Daisies*, by which title the *French* still call it. In 1752, I received seeds of the double flowers both red and blue, and in 1753, the seeds of the double white sort, which have retained their difference from that time without variation, yet as they are generally supposed to be only varieties, so I have not inserted them as different species.

As these are annual plants, so they are only propagated by seeds, which must be sown in the spring upon a gentle hot-bed, just to bring up the plants; for they should be inured to the open air as soon as possible, to prevent their being drawn up weak: when the plants are big enough to remove, they should be carefully taken up and planted in a bed of rich earth at six inches distance each way. In this bed they may remain a month or five weeks, by which time they will be strong enough to transplant into the borders of the flower garden, where they are designed to remain; the plants should be taken up carefully, with large balls of earth to their roots, and the ground dug up and well broken with the spade, where the holes are made to receive the plants: this work should, if possible, be done when there is rain, for then the plants will soon take new root, after which time they will require no other care.

In *August* these plants will flower, by which time if the ground is rich in which they are planted, they will be two feet high, and furnished with many side branches, each of which is terminated by a large radiated flower, some white, some red, and others blue. The seeds ripen the beginning of *October*, which should be gathered when it is perfectly dry; and in order to preserve the kinds with double flowers, those which grow upon the side branches, which are commonly fuller of leaves than the flowers on the main stem, should always be preserved for seeds.

The thirty-third sort is an annual plant, which rises with an upright stalk about one foot high, with winged leaves, each consisting of two or three pair of lobes terminated by an odd one: at the top of the stalk is produced one large Orange-coloured flower, having a single empalement, cut into many slender segments which end in points: after the flower is past, each floret is succeeded by an oblong angular seed, crowned with long down. This plant is propagated by seeds, which should be sown on a moderate hot-bed in the spring; and when the plants are fit to remove, they must be each planted into a separate small pot filled with rich earth, and plunged into the tan bed, where they may remain to flower and perfect their seeds, for they will not thrive in the open air. This sort flowers in *July*, and the seeds ripen in *September*.

ASTERISCUS. See *Bupthalmum*.

ASTEROIDES, Bastard Starwort. See *Inula*.

ASTRAGALOIDES. See *Phaca*.

ASTRAGALUS, Wild Liquorice, Liquorice Vetch, or Milk Vetch.

The Characters are,

It hath a butterfly flower. The standard (or vexillum) is upright, blunt, and reflexed on the sides; the wings are oblong, and shorter than the standard; the keel is the same length with the wings, and bordered. At the bottom of the flower is situated a taper germen, which afterward becomes a pod having two cells, each having a row of kidney-shaped seeds.

The Species are,

1. ASTRAGALUS caulescens prostratus leguminibus subtriquetris arcuatis foliis ovalibus pedunculo longioribus. *Lin. Sp. Pl.* 758. Common wild perennial trailing Milk Vetch with yellow flowers, sometimes called Wild Liquorice.

2. ASTRAGALUS caulescens procumbens, leguminibus subulatis recurvatis glabris. *Hort. Upsal.* 226. Yellow annual Milk Vetch of *Montpelier*, with trailing stalks.

3. ASTRAGALUS caulescens, spicis cylindricis subsessilibus, calycibus leguminibusque lanatis. *Lin. Sp. Pl.* 755. Taller Foxtail Milk Vetch of the *Alps*.

4. ASTRAGALUS caulescens prostratus, leguminibus subglobosis inflatis mucronatis pilosis. *Hort. Upsal.* 226. Yellow perennial Milk Vetch, with a round double pod resembling a bladder.

5. ASTRAGALUS caulescens procumbens, leguminibus capitatis cordatis acutis reflexis complicatis. *Lin. Sp. Plant.* 759. Larger *Spanish* Milk Vetch, with pods like the epiglottis, and a purple flower.

6. ASTRAGALUS subcaulos scapis folio longioribus, floribus laxè spicatis erectis. *Prod. Leyd.* 392. Milk Vetch, or Cock's-head with large Vetch flowers of a purplish blue colour, and Goat's-thorn leaves.

7. ASTRAGALUS caulescens procumbens, spicis pedunculatis leguminibus prismaticis erectis triquetris apice uncinatis. *Hort. Upsal.* 225. Trailing maritime annual Milk Vetch, with broad leaves and flowers sitting upon foot-stalks.

8. ASTRAGALUS subcaulescens procumbens floribus subracemosis erectis foliis tomentosis. *Lin. Sp. Plant.* 759. Small hoary purple Milk Vetch.

9. ASTRAGALUS acaulos scapis folia æquantibus leguminibus inflatis subglobosis nudis. *Lin. Sp. Plant.* 760. Low Milk Vetch with swelling globular pods.

10. ASTRAGALUS caulescens erectus floribus glomeratis subsessilibus ex omnibus axillis foliaceis. *Lin. Sp. Pl.* 755. Greatest hoary upright eastern Milk Vetch, with flowers coming out from the bottom to the top of the stalk.

11. ASTRAGALUS caulescens scapis folio longioribus floribus laxè spicatis erectis, leguminibus arcuatis. *Egyptian* Milk Vetch, with spikes of purple flowers and incurved pods.

12. ASTRAGALUS caulescens diffusus capitulis subsessilibus lateralibus leguminibus erectis subulatis acumine reflexis. *Hort. Cliff.* 361. Annual Milk Vetch with hairy leaves and pods, many of them growing close to the wings of the leaves.

13. ASTRAGALUS caule recto paniculato pedunculis folio longioribus floribus sparsis. *Hort. Cliff.* 362. Tallest eastern Milk Vetch with a Goat's-rue leaf, and a small yellowish flower.

14. ASTRAGALUS acaulos scapo erecto foliis longiore leguminibus subulatis inflatis villosis erectis. *Hort. Upsal.* 226. Hairy white unbranched Milk Vetch, with purple Violet flowers growing in spikes.

15. ASTRAGALUS caulescens erectus lævis pedunculis spicatis leguminibus ovato-cylindricis stylo acuminatis. *Lin. Sp. Pl.* 757. Taller untrailing Milk Vetch, with a yellowish green flower.

16. ASTRAGALUS caulescens diffusus leguminibus subcylindricis mucronatis foliolis subtus subvillosis. *Lin. Sp. Pl.* 757. Canada Milk Vetch with a yellowish green flower.

17. ASTRAGALUS caulescens erectus pilosus floribus spicatis leguminibus subulatis pilosis. *Lin. Sp. Pl.* 756. Upright hairy Milk Vetch, with yellow flowers growing in spikes.

18. ASTRAGALUS incanus caulibus procumbentibus scapis folio æquantibus floribus glomeratis. *Supine* Milk Vetch with hairy glomerated pods.

19. ASTRAGALUS caulescens incanus, leguminibus subulatis recurvatis incanis. Hoary Milk Vetch with a crooked pod.

20. ASTRAGALUS caulescens capitulis globosis, pedunculis longissimis, foliolis emarginatis. *Hort. Cliff.* 360. A most hairy eastern Milk Vetch, with rounder heads and purple flowers.

The first fort grows wild upon chalky ground in many parts of *England*, so is not often admitted into gardens. The root of this is perennial, but the stalks decay every autumn: it creeps at the root, so that it is too apt to spread where it is suffered to grow. It flowers in *June*, and the seeds ripen in *September*.

The second fort is annual; the branches of this trail upon the ground, which are striated; the leaves are composed of about eight pair of lobes, terminated by an odd one: the foot-stalk of the flowers arise from the wings of the leaves, which is about three inches long, garnished toward the top with a few pale yellow flowers rising one above another; these are succeeded by oblong pods, which bend in form of a fickle. It flowers in *June*, and the seeds ripen in *September*. The seeds of this should be sown in *April*, in the place where they are to remain.

The third fort is a biennial plant. This rises with an upright hairy stalk near three feet high, with long winged leaves, each having eighteen or twenty pair of oval lobes, terminated by an odd one. The flowers are produced in large cylindrical spikes from the wings of the leaves, sitting very close to the stalks, which are entirely covered with down, out of which the yellow flowers just peep; these are succeeded by oval pods shut up in the woolly empalements. It flowers in *June* and *July*, and the seeds ripen in the autumn, soon after which the plants decay. The seeds of this should be sown on an open border, where the plants are designed to remain in *April*.

The fourth fort hath a perennial root, which sends out several striated stalks near three feet long, which, if not supported, prostrate themselves toward the earth, with winged leaves placed alternately, which are composed of about ten pair of oval small lobes, terminated by an odd one. The flowers arise from the wings of the leaves, upon foot-stalks two inches long, in small loose spikes, which are yellow, and shaped like the rest of this genus, and are succeeded by hairy globular swelling pods ending with a sharp point. It flowers in *July*, and the seeds ripen in the autumn. It is easily propagated by seeds, which should be sown upon an open border in the spring, in the place where they are to remain. One or two of these plants in a garden by way of variety, may be admitted, but they have little beauty.

The fifth fort is annual. This sends out from the root two or three hairy trailing branches, which are garnished with leaves, composed of ten or twelve pair of blunt lobes, terminated by an odd one: the flowers come out from the wings of the leaves upon naked foot-stalks, four or five inches long, and are gathered into a round head; these are shaped like the others, but are pretty large, and of a deep purple colour, which are succeeded by short pods rough on their outsides, and when opened are shaped like a heart, ending in a sharp point, containing three or four seeds.

The seeds of this should be sown on an open border in *April*, where the plants are to remain, and treated as the other annual forts before-mentioned.

The sixth fort is a perennial plant, seldom rising with a stem more than three inches high, with leaves, which are composed of many pairs of narrow lobes, set very close together on the midrib, terminated by an odd one. The flowers grow upon long foot-stalks, which rise above the leaves; these are large and of a purple colour, growing in a loose spike, and stand erect, and are succeeded by oblong crooked pods opening in two cells, filled with square seeds. This is propagated by seeds, which should be sown, and the plants treated in the same manner as the fourth fort, but should have a shady situation and a stronger soil.

The seventh fort is annual; it hath trailing branches near two feet long, with winged leaves, composed of about ten pair of blunt lobes, set thinly on the midrib, terminated by

an odd one: at the wing of the leaf comes out a foot-stalk near two inches long, sustaining four or five yellow flowers at the top, which are succeeded by triangular brown pods, shaped like a prism, growing erect, and opens in two cells filled with greenish square seeds. This may be treated in the same manner as the second.

The eighth fort is a perennial plant, which grows in several parts of *England*, particularly in the north. It is a low plant, seldom rising more than two or three inches high, with leaves composed of narrow woolly lobes, placed close on the midrib; the flowers are pretty large, of a purple colour, growing in loose spikes. It flowers in *June*, and the seeds ripen in *August*. This should have a shady situation.

The ninth fort hath a perennial creeping root, with leaves composed of many pair of oval lobes, terminated by an odd one; the flower-stalks are as long as the leaves, which support a cylindrical spike of yellow flowers, which are succeeded by swollen pods, opening into two cells, containing several greenish seeds. This may be propagated as the fourth fort, and must have a shady situation.

The tenth fort sends up stalks near three feet high, which are large at bottom, and gradually diminish to the top; the leaves at bottom are very long, and diminish upward, so as to form a sort of pyramid; these are composed of many large oval pair of lobes, which are placed thinly on the midrib, and are terminated by an odd one; the flowers come out in clusters from the wings of each leaf. These are large, of a bright yellow colour, and are succeeded by cylindrical pods opening in two cells, filled with square yellow seeds. It flowers in *July*, and in very favourable seasons will perfect seeds in *England*. It is propagated by seeds, which should be sown, and the plants afterward treated, as hath been directed for the fourth fort. The third year from seed the plants will flower, and continue many years in a proper soil.

The eleventh fort is an annual plant, which rises with upright stalks a foot and an half high, which are thinly garnished with leaves, composed of about twelve pair of oval lobes, terminated by an odd one; the foot-stalks of the flowers arise from the wings of the leaves, and are extended beyond them; these are terminated by loose spikes of yellow flowers, which are succeeded by fickle-shaped pods. It flowers in *July*, and the seeds ripen in autumn. It may be propagated by seeds, in the same manner as hath been before directed for the annual forts.

The twelfth fort is an annual plant, which sends out several weak stalks without any order, having leaves, composed of ten or twelve pair of lobes, and sometimes terminated by an odd one; at the foot-stalks of the leaves the flowers come out in small clusters, sitting close to the sides of the stalks, which are of a copper colour, and are succeeded by awl-shaped pointed pods growing erect, reflected at their points. This is propagated by seeds, in the same manner as the other annual forts before-mentioned.

The thirteenth fort hath a perennial root, which sends out many upright stalks upward of five feet high, which are garnished with leaves, composed of about fourteen pair of oval lobes, terminated by an odd one; from the wings of the leaves the foot-stalks of the flowers arise, which are garnished with small yellow flowers, growing in loose spikes, and are extended beyond the leaves; these are succeeded by very short triangular pods, ending in a point, which open in two cells, filled with Ash-coloured square seeds. It is propagated by seeds, which, if suffered to fall on the ground, the plants will come up and require no farther culture. The roots of this fort will abide many years.

The fourteenth fort never rises with a stalk, but sends out leaves from the root, which are composed of many blunt lobes, placed by pairs, and terminated by an odd one; the

foot-stalks of the flowers arise immediately from the root, and are longer than the leaves, being terminated by spikes of blue flowers, which are succeeded by swelling awl-shaped pods, that are erect and hairy, having two cells which are filled with greenish seeds. It flowers in *July*, and the seeds ripen in autumn. The root is abiding, and the plant is propagated by seeds as the fourth sort, but should have an open situation.

The fifteenth sort hath a perennial root, but an annual stalk; from the root arise several upright stalks three feet high, which are garnished with leaves, composed of eighteen or twenty pair of oval smooth lobes, and terminated by an odd one; from the wings of the leaves arise the foot-stalks, which are terminated by spikes of greenish yellow flowers, which are succeeded by oval cylindrical pods, to which adhere the style, which extend beyond the pods in a point. This flowers in *August*, but unless the season is warm, the plants seldom ripen their seeds in *England*. It is propagated by seeds, which should be sown upon a moderate hot-bed in the spring; and when the plants come up they must be inured to the open air, into which they should be removed the end of *May*, and planted in a warm border, where they will thrive and flower; and if the winter proves very severe, a little old tan should be laid over the roots, which will effectually preserve them.

The sixteenth sort hath a perennial root, which sends out many irregular stalks about two feet long, with leaves, composed of many pair of oval lobes, which are hairy on their under side; from the wings of the leaves come out the foot-stalks, supporting spikes of greenish yellow flowers; which are succeeded by cylindrical pods, ending in a point.

The seventeenth sort rises with upright stalks two feet high, which are hairy, and garnished with leaves, composed of many pair of oval woolly lobes, terminated by an odd one; from the wings of the leaves arise the foot-stalks, which are terminated by close spikes of yellow flowers, which are succeeded by hairy awl-shaped pods, having two cells, filled with brown seeds. It is a perennial plant, and propagated by seeds, in the same manner as the fourth sort.

The eighteenth sort is a biennial plant, with many trailing stalks, which are divided into many smaller branches, with leaves composed of many pair of narrow lobes, terminated by an odd one; the flowers are collected into heads, which terminate the foot-stalks, and are white; the foot-stalks are about the same length as the leaves; the pods are short and triangular, and the whole plant is covered with a silvery down. The seeds of this should be sown upon an open bed of light earth, where the plants are to remain, and the plants afterward treated in the manner before directed for the annual sorts.

The nineteenth sort sends up an upright stalk, seldom more than six inches high, with small winged hoary leaves; the foot-stalks arise from the wings of the leaves, supporting three or four pale flowers, which are succeeded by sickle-shaped hoary pods. This is a biennial plant, and should be treated in the same manner as the last.

The twentieth sort sends up several erect stalks, garnished with leaves, composed of several pair of lobes, which are indented at the top: from the wings of the leaves come out long foot-stalks, supporting a globular head of purple flowers; these are rarely succeeded by pods in *England*. It flowers the end of *July*.

ASTRANTIA, Masterwort.

The Characters are,

It is a plant whose flowers grow in an umbel; the involucre of the general umbel is composed of two large trifid leaves, and two entire, and in another species of several small leaves: the flower is composed of five petals, which are bifid: it hath five stamens. The oblong germen is situated below the receptacle, which after-

ward becomes an oval blunt channelled fruit, divided into two parts, having two oblong oval seeds inclosed in the cover.

The Species are,

1. ASTRANTIA foliis radicalibus quinquelobatis serratis, caulibus trilobatis acutis. Greatest Masterwort with a purplish involucre.

2. ASTRANTIA foliis quinquelobatis lobis tripartitis. Haller: Helv. 439. Greater Masterwort with a white involucre.

3. ASTRANTIA foliis digittatis serratis. Lin. Sp. Pl. 255. Smaller black Hellebore with a Sanicle leaf.

The first sort hath many spreading leaves rising from the root, composed of five large lobes, sawed pretty deep on their edges; from between these the stalks arise near two feet high, having at each joint one leaf deeply cut into three sharp pointed lobes; at the top of the stalk is produced the umbel of flowers, at the bottom of which is situated the general involucre, composed of two long trifid leaves, and two entire ones of the same length, which extend beyond the rays, and are of a purplish colour.

The second sort hath much the appearance of the first, but it differs from that in having five lobes to the leaves of the stalks, which are much shorter, and rounder at the point, than those of the other. The general involucre of the umbel is composed of short narrow leaves, and those of the smaller umbels are shorter and white.

The third sort seldom rises a foot high; the foot-stalks of the leaves are four inches long; the leaves are divided into eight segments to the bottom, and spread out like a hand; the involucre of the general umbel is composed of several very narrow leaves; the foot stalks of the separate umbels are very long and slender, and toward the top often divide into three, each having a small umbel. The involucre of these small umbels are short and white.

These plants are very hardy; they may be propagated either by sowing of their seeds, or parting their roots. The seeds should be sown in the autumn, soon after they are ripe, on a shady border; when the plants come up, where they are too close, some of the plants should be drawn out, to allow room for others to grow until *Michaelmas*, when they should be transplanted where they are to remain; which should always be in a moist soil, and a shady situation. The distance these plants should be placed, is three feet, for their roots will spread to a considerable width, if they are permitted to remain long in the same place. These plants are seldom preserved but in botanick gardens, there being no great beauty in their flowers.

ATHAMANTA. Lin. Gen. Plant. 301. Spignel.

The Characters are,

It is a plant with an umbellated flower; the involucre of the great umbel is composed of many narrow leaves, which are shorter than the rays; those of the small ones are narrow, and equal with the rays: each flower hath five slender stamens, of the same length with the petals; the germen is situated below the receptacle, which afterward becomes an oblong channelled fruit, divided into two parts, each containing one oval channelled seed.

The Species are,

1. ATHAMANTA foliolis capillaribus, seminibus glabris striatis. Hort. Cliff. 93. Spignel with Dill leaves.

2. ATHAMANTA foliolis linearibus planis hirsutis, petalis bipartitis, seminibus oblongis hirsutis. Lin. Mat. Med. 143. Candy. Carrot with very slender Fennel leaves.

3. ATHAMANTA foliis inferioribus nitidis, umbellis primordialis subsessilibus, seminibus pilosis. Hort. Upsal. 60. The second Sicilian Carrot with a Flixweed leaf.

The first sort is the common Spignel used in medicine. It grows naturally in *Westmoreland*, and by the inhabitants there is called Bald-Money, or Bawd-Money; by some it is called Meu. This is a perennial plant, the stalks rise a foot and an half high, and are channelled; the leaves are very ramose,

and composed of many fine hair-like leaves, set pretty close, and are of a deep green; the stalk is terminated by an umbel of white flowers, which are succeeded by oblong smooth seeds.

This may be propagated by parting of the roots at *Michaelmas*, or from seeds sown soon after they are ripe; the plants should have a shady situation and a moist soil.

The second sort is the *Daucus Creticus*, of which there are two sorts, whose seeds are indifferently used in the shops, one of which is annual; but that here mentioned is a perennial plant, whose leaves are composed of numbers of slender narrow leaves like those of Fennel, irregularly disposed. The flower-stalk rises about two feet high, sending out many branches, with the same compound capillary leaves, and at the top are terminated by compound umbels, composed of near twenty small ones; these have white flowers with five petals, which are succeeded by oblong, hairy, channelled fruit, divided into two parts, containing one oblong hairy seed.

This sort is propagated by seeds, which should be sown in autumn on an open bed of light dry ground; the following autumn the plants should be carefully taken up, and planted at about a foot distance in a bed of light sandy earth, where the roots will continue several years, and annually flower, and produce ripe seeds. It flowers in *June*, and the seeds are ripe in *September*.

The third sort is a perennial plant, which sends up from the root several upright stalks, near three feet high, which are terminated by compound umbels. The flowers are composed of five white petals, which are not quite equal, and are succeeded by oblong woolly fruit, divided into two parts, each containing one oblong channelled seed.

This may be propagated in the same manner as the former, and is equally hardy.

ATRACTYLIS. *Lin. Gen. Pl.* 837. Distaff Thistle.

The Characters are,

It hath a radiated, compound flower, composed of many hermaphrodite florets, which are included in a common scaly empalement, which hath no spines. The hermaphrodite florets compose the rays, or border, and are stretched out on one side like a tongue. Those which compose the disk are funnel-shaped; in those of the disk is situated a short crowned germen, which afterward becomes a turbinated compressed seed, crowned with a plume of down, stout up in the empalement.

The Species are,

1. *ATRACTYLIS involucris cancellatis ventricosus, linearibus dentatis calycibus ovatis, floribus fuscis.* *Lin. Sp. Plant.* 830. Small Cnicus with a netted head, and woolly seed.

2. *ATRACTYLIS foliis dentato-sinuatis, flore radiato ovalato involucro patente, caule herbaceo.* *Lin. Sp. Plant.* 829. Lower purple prickly Cnicus.

3. *ATRACTYLIS flore acaule.* *Lin. Sp. Plant.* 829. Prickly gum-bearing Cnicus without stalk, and a Carline Thistle leaf.

4. *ATRACTYLIS foliis oblongo ovatis denticulatis spinosis calycibus patentibus caule fruticoso.* *Hort. Cliff.* 295. Shrubby African Bastard Saffron with an Ilex leaf, and a golden flower.

The first sort is an annual plant, which seldom rises more than eight or nine inches high, with a slender stem, garnished with narrow hoary leaves, having spines on their edges; at the top of the stalk there are two or three slender branches sent out, each being terminated by a head of flowers, like those of the Thistle, with an involucre composed of several narrow leaves, armed with spines on their side, and are longer than the head of the flowers. The empalement is curiously netted over, and is narrow at the top, but swelling below, containing many florets of a purplish colour. These are each succeeded by a single downy seed, which in cold years never perfect here.

It is propagated by seeds, which must be sown upon an open bed of light earth, where the plants are to remain, and thin the plants where they come up too close together.

The second sort rises with a stalk near a foot high, with indented leaves, having small spines on their edges; the upper part of the stalk is divided into two or three slender branches, each supporting a head of purple flowers, having rays inclosed in a scaly empalement. The roots of this will live two or three years; it flowers in *June*, but unless the summer is warm and dry, it will not perfect seeds in *England*. The seeds of this sort should be sown where they are to remain, and will require no other culture than the former.

The third sort is what the *College of Physicians* have placed among the medicinal simples, by the title of Carline Thistle; the root of this is perennial, and sends out many narrow leaves, which are deeply sinuated, and armed with spines on their edges. These lie close on the ground, and between them the flower is situated, without stalk, having many florets, inclosed in a prickly empalement. Those on the border are white, but those which compose the disk of a yellowish colour. It flowers in *July*, but never perfects seeds in *England*.

The fourth sort rises with a shrubby stalk, near three feet high, with oblong leaves, indented on their edges, which have weak spines at each indenture; there are several weak branches sent out on the sides, each of which are terminated by a single head of flowers, inclosed in a common empalement which spreads open, and are of a golden colour, but are never succeeded by seeds in *England*. This is propagated by slips, or heads, taken from the flower-stalks in *June*; when these have taken root, they may be exposed in the open air till *October*, when they must be removed into shelter, and, during the winter, should have little water, but in summer should be exposed with other hardy exotick plants in a sheltered situation.

ATRAPHAXIS. *Lin. Gen. Plant.* 405. We have no *English* name for this.

The Characters are,

The flower hath a permanent empalement. It hath two roundish sinuated petals larger than the empalement, which are permanent; it hath six capillary stamina; in the center is situated a compressed germen, which afterward becomes a roundish compressed seed, stout up in the empalement.

The Species are,

1. *ATRAPHAXIS ramis spinosis.* *Hort. Cliff.* 138. Shrubby prickly *Atraphaxis* of the east, with a fair flower.

2. *ATRAPHAXIS inermis.* *Lin. Sp. Plant.* 333. African creeping shrubby *Atraphaxis*, with leaves curled on their sides.

The first is a shrub which rises four or five feet high, sending out many weak lateral branches, which are armed with spines, with small spear-shaped leaves of an Ash colour, which are smooth. The flowers come out at the ends of the shoots in clusters, composed of two white leaves tinged with purple, and are included in a two-leaved empalement of a white herbaceous colour; these appear in *August*. The plant is propagated by cuttings, and must be screened from hard frost, which commonly destroys those which are planted in the open air.

The second sort sends out many slender branches, which trail on the ground when they are not supported, with small oval leaves, about the size of those of the Knot-grass, but are waved and curled on their edges, embracing the stalk half round at their base. The flowers come out from the wings of the leaves, and have much the appearance of an apetalous flower, being composed of four herbaceous leaves, two of which are the empalement, the other two the petals. It flowers in *June* and *July*. This is a native of the country about the *Cape of Good Hope*. It may be easily propagated by cuttings any time in the summer, and in winter the plants must be screened from frost.

ATRIPLEX, Orach, or Arach.

The Characters are,

It hath female and hermaphrodite flowers on the same plant. The hermaphrodite flowers have a permanent empalement of five leaves, with membranaceous borders. In the center is placed the orbicular germen, which afterward becomes an orbicular compressed seed, shut up in the five-cornered empalement.

The Species are,

1. *ATRIPLEX caule erecto herbaceo foliis triangularibus.* Hort. Cliff. 469. Pale, green, or white Garden Orach.
2. *ATRIPLEX caule fruticoso foliis deltoidibus integris.* Hort. Cliff. 469. Broad-leaved Orach, or shrubby Halimus, commonly called Sea Purslane Tree.
3. *ATRIPLEX caule fruticoso foliis obovatis.* Flor. Suec. 829. Shrubby Sea Orach, or Halimus, called Sea Purslane, with a narrow leaf.

There are several other species of this genus, some of which grow naturally in *England*, but as they are plants of no beauty, so they are rarely admitted into gardens, for which reason I shall not enumerate them here.

The first of these plants was formerly cultivated in the kitchen gardens, as a culinary herb, being used as Spinage, and is now, by some persons, preferred to it; though, in general, it is not esteemed amongst the *English*; but the *French*, at present, cultivate this plant for use.

There are three or four different varieties of this, whose difference is only in the colour of the plants; one of which is of a deep green, another of a dark purple, and a third with green leaves and purple borders. These are generally supposed to be only accidental varieties which have come from the same seeds, but in thirty years which I have cultivated these sorts, I have never yet observed them to vary.

These plants are annual, so must be sown for use at *Michaelmas*, soon after the seeds are ripe; at which time it generally succeeds better than when it is sown in the spring, and will be fit for use at least a month earlier. They require no other culture, but to hoe them when they are about an inch high; to cut them down where they are too thick, leaving them about four inches asunder, and to cut down all the weeds. When your plants are grown about four inches high, it will be proper to hoe them a second time, in order to clear them from weeds; and, if you observe the plants are left too close in any part, you must then cut them out. Where these plants are sown on a rich soil, and allowed a good distance, the leaves will be very large, in which the goodness of the herb consists. This must be eaten while it is young; for, when the stalks become tough, it is good for nothing. The first sort is ordered by the *College of Physicians* for medicinal use.

The second sort was formerly cultivated in gardens as a shrub; and, by some persons, were formed into hedges, and constantly sheared, to keep them thick; but this plant is by no means fit for such purposes, on many accounts, for it grows too vigorous; the shoots, in one month, at the growing season of the year, will be two feet long, provided they have a good soil; so that a hedge of this plant cannot be kept in tolerable order, nor will it ever form a thick hedge. But a worse inconvenience attends this plant; for, in very hard winters, it is often destroyed.

It may be propagated by cuttings, which may be planted in any of the summer months, on a shady border, they will soon take root, and be fit to transplant the *Michaelmas* following, when they should be planted where they are to remain.

The third sort grows wild in divers parts of *England*, on the sea side, from whence the plants may be procured; or it may be propagated by cuttings, in the same manner as the former sort. This is a low under shrub, seldom rising above two feet and an half, or at most three feet high, but becomes very bushy. This may have a place amongst other low shrubs; and, if planted on a poor gravelly soil, will abide several years, and make a pretty diversity.

ATROPA. Lin. Gen. Plant. 222. Deadly Nightshade:

The Characters are,

The flower is bell-shaped, and divided into five equal parts. It hath five stamina rising from the base of the petal. In the center is situated an oval germen, which afterward becomes a globular berry having three cells, sitting on the empalement, and filled with kidney-shaped seeds.

The Species are,

1. *ATROPA caule herbaceo, foliis ovatis integris.* Lin. Sp. Plant. 181. Common Deadly Nightshade.
2. *ATROPA caule fruticoso.* Lin. Sp. Plant. 182. Deadly Nightshade with a shrubby stalk.

The first sort grows wild in many parts of *England*, but is not very frequent near *London*. This plant hath a perennial root, which sends out strong herbaceous stalks of a purplish colour, which rise to the height of four or five feet, with oblong entire leaves, which toward autumn change to a purplish colour; the flowers come out between the leaves singly, upon long foot-stalks; these are large, bell-shaped, and of a dusky brown colour on their outside, but are purple within. After the flower is past, the germen turns to a large round berry, a little flatted at the top, and is first green, but when ripe turns to a shining black, sitting close upon the empalement, and contains a purple juice of a nauseous sweet taste, and full of small kidney-shaped seeds. In some places this plant is called *Dwale*, but in general *Deadly Nightshade*, from its quality. It should not be suffered to grow in any places where children resort, for it is a strong poison; there has been several instances within a few years past, of its deadly quality, by several children being killed with eating the berries.

There is also an instance of the direful effects of this plant recorded in *Buchanan's History of Scotland*, wherein he gives an account of the destruction of the army of *Sveno*, when he invaded *Scotland*, by mixing a quantity of the juice of these berries with the drink which the *Scots* by their truce were to supply them with; which so intoxicated the *Danes*, that the *Scots* fell upon them in their sleep, and killed the greatest part of them, so that there were scarcely men enough left to carry off their king.

The second rises with a shrubby stem to the height of six or eight feet, divided into many branches, garnished with round leaves, in shape like those of the *Storax* tree. The flowers come out between the leaves upon short foot-stalks, which are shaped like those of the former, but are much less, of a dirty yellowish colour, with a few brown stripes; these are never succeeded by berries in *England*. It grows naturally in *Spain*, and is only propagated by seeds. The plants are too tender to live abroad in winter, therefore at the end of *October* they must be removed into the greenhouse, and treated as other plants from the same country. It flowers in *July* and *August*.

AVENA. Lin. Gen. Plant. 85. Oats.

The Characters are,

The flowers are collected in a loose panicle, and have a bivalvular empalement, swelling in the middle. The petal of the flower is bivalve, having a spiral beard, twisting, jointed, and reflexed. There are two oval nectariums sitting upon the upper side of the germen; they have three slender stamina: the germen afterward becomes an oblong swelling seed, having a longitudinal furrow, and closely shut up in the cover or chaff.

AVENA calycibus dispermibus seminibus levibus. Hort. Cliff. 25. Oats with two smooth seeds in each empalement.

There are three varieties of these oats cultivated in *England*, viz. the white, the black, and the brown or red Oat, but where they have been many years separately cultivated, I have never observed them to alter. However, as their principal difference is in the colour of the grain, I shall not enumerate them as distinct species. There is also a naked Oat, which

which is sometimes cultivated in the distant parts of *England*, but is rarely seen near *London*.

The white sort is the most common about *London*; the black is more cultivated in the northern parts of *England*, and is esteemed a very hearty food for horses; but the first makes the whitest meal, and is chiefly cultivated where the inhabitants live much upon oat cakes.

Oats are a very profitable grain, and absolutely necessary, being the principal grain which horses love; and are esteemed the most wholesome food for those cattle, being sweet, and of an opening nature; other grains being apt to bind, which is injurious to labouring horses: but if you feed them with this grain soon after they are housed, before they have sweat in the mow, or are otherwise dried, it is as bad on the other hand, for they are then too laxative.

This grain is a great improvement to many estates in the north of *England*, *Scotland*, and *Wales*; for it will thrive on cold barren soils, which will produce no other sort of grain; it will also thrive on the hottest land: in short, there is no soil too rich or too poor for it, too hot or too cold for it; and in wet harvests, when other grain is spoiled, this will receive little or no damage; the straw and husks being of so dry a nature, that if they are housed wet, they will not heat in the mow, or become mouldy, as other grain usually do; so is of great advantage in the northern parts of *England*, and in *Scotland*, where their harvest is generally late, and the autumns wet.

The best time for sowing of Oats is in *February* or *March*, according as the season is early or late; and sometimes I have known it sown in *April* upon cold land, and has been early ripe. The black and red Oats may be sown a month earlier than the white, because they are hardier.

Oats are often sown on land which has the former year produced Wheat, Rye, or Barley. The common method is to plough in the stubble about the beginning of *February*, and sow the Oats, and harrow them in; but then they must be harrowed the same way as the furrows lay, for if it be done crossways, the stubble will be raised on the surface; but this is not a good method of husbandry, for when people have time to plough the stubble in autumn, it will rot in winter; and then giving the land another ploughing and a good harrowing just before the oats are sown, it will make the ground finer and better to receive the grain. Most people allow four bushels of Oats to an acre, but I am convinced two bushels are more than enough; the usual produce is about twenty-five bushels to an acre, though I have sometimes known more than thirty-five bushels on an acre.

Oats are also sown upon land when it is first broken up, before the ground is brought to a tilth for other grain, and is frequently sown upon the sward with one ploughing; but it is much better to give the sward time to rot before the Oats are sown, for the roots of the grass will prevent those of the corn from striking downward.

AURANTIUM, the Orange Tree.

The Characters are,

The flower hath five oblong spreading petals, and many stamens, which are frequently joined in small separate bodies at bottom. In the center is situated the germen, which after-ward becomes a globular fleshy fruit, compressed at both ends, having a thick fleshy pulp, and divided into several cells, each containing two oval callous seeds.

The Species are,

1. AURANTIUM foliis ovato-lanceolatis glabris. The common *Seville* Orange.

2. AURANTIUM foliis lanceolatis acutis glabris. The *China* Orange.

3. AURANTIUM foliis lineari lanceolatis glabris. Orange Tree, with narrow leaves called Willow-leaved Orange, and by some the *Turkey* Orange.

4. AURANTIUM foliis ovato-lanceolatis crassis lucidis, fructu maximo. The Pampelmoes, or Shaddock.

5. AURANTIUM pumilum foliis ovatis floribus sessilibus. The Dwarf or Nutmeg Orange.

There are many varieties of this, as there is of most other fruits which have arisen from culture; but those here enumerated may strictly be allowed to be distinct species. The varieties in the *English* gardens are, 1. The yellow and white striped leaved Orange. 2. The curled leaved Orange. 3. The horned Orange. 4. The double flowering Orange. And, 5. The hermaphrodite Orange.

The *China* Orange is not so hardy as the *Seville*, therefore must be treated more tenderly to have good fruit in *England*.

The dwarf Orange is also tender, and the leaves are very small, growing in clusters. This sort, when in flower, is proper to place in a room or gallery, to adorn them; the flowers being very sweet, but these are seldom to be found in good health, because they must be treated with more care than the common Orange and Lemon trees; as must also the Shaddock, otherwise the fruit will always drop off in winter. The Pampelmoes were brought from the *East* to the *West-Indies*. But the inhabitants have greatly degenerated the fruit since it has been in the *West-Indies*, by raising the trees from seeds; the greatest part of which produce harsh sour fruit, greatly inferior to the original sort; the flesh or pulp of which is red, whereas the greater part of the trees in *America* produce fruit with a pale yellow flesh; and by constantly raising these trees from seeds, they degenerate the fruit continually; whereas if they would bud from the good sort, they might have it in as great plenty as they pleased.

All the sorts of Orange and Lemon trees with striped leaves are tender, therefore must be placed in a warm part of the green-house in winter, and must be treated with more care than the common sort, otherwise they will not thrive.

The horned Orange differs from the other sorts, in the fruit dividing into parts, and the rind expanding in form of horns: this and the distorted Orange, are preserved by some curious persons for variety. There is also a great variety of sweet Oranges both in the *East* and *West-Indies*; some of which are much more esteemed than those we now have in *Europe*.

If you purpose to raise stocks for budding of Oranges, you should procure some Citron seeds which were duly ripened; for the stocks of this kind are preferable to any other, both for quickness of growth, as also that they will take buds of either Orange, Lemon, or Citron; next to these are the *Seville* Orange seeds. The best seeds are usually to be had from rotten fruits, which are commonly easy to be procured in the spring of the year; then prepare a good hot-bed, of either horse dung or tanners bark; the last of which is much the better, if you can easily procure it. When this bed is in a moderate temper for heat, you must sow your seeds in pots of good rich earth, and plunge them into the hot-bed. In three weeks or a month the plants will come up, and if they are not stunted, either for want of proper heat or moisture, they will be in six weeks after their appearance, fit to transplant into single pots: you must therefore renew your hot-bed, and having prepared a quantity of small halfpenny pots, fill these half full of fresh loamy earth, mixed with very rotten cow dung; and then shake out the young plants from the seed pots, with all the earth about them, that you may the better separate the plants without tearing their roots; put a single plant into each of the pots; then fill them up with the same earth as before directed, plunging the pots into the new hot-bed, giving them a good watering to fix the earth to their roots, and screen them from the sun in the heat of the day. In this method, with due care, your plants will grow to be two feet high by the end of *July*, when you must begin to harden them by degrees, in raising your glasses very

very high, and when the weather is good, take them quite off; but do not expose them to the open sun in the heat of the day, but rather take off the glasses, and shade the plants with mats, which may be taken off when the sun declines; for the violent heat in the middle of the day would be very injurious to them in hot weather, especially while young. Toward the end of *September* you must house them, observing to place them near the windows of the green-house, to prevent the damps from moulding their tender shoots. During the winter season they may be often refreshed with water. If the plants are plunged into a gentle hot-bed in the spring, it will greatly forward them; but they should be hardened by the beginning of *June*, that they may be in right order to bud in *August*; when you should make choice of cuttings from trees that are healthy and fruitful, of whatever kinds you please, observing that the shoots are round; the buds of these being much better and easier to part from the wood, than such as are flat. When you have budded the stocks, you should remove them into a green-house, to defend them from wet, turning the buds from the sun; but let them have as much free air as possible, and refresh them often with water. In a month's time after budding, you will see which of them has taken; you must then untie them, that the binding may not pinch the buds, and let them remain in the green-house all the winter; then in the spring, prepare a moderate hot-bed of tanners bark; and, after having cut off the stocks about three inches above the buds, plunge their pots into the hot-bed, observing to give them air and water, as the heat of the weather shall require; but be sure to screen them from the violence of the sun during the heat of the day. With this management, if your buds shoot kindly, they will grow to the height of two feet or more, by *July*; at which time you must begin to harden them before the cold weather comes on, that they may the better stand in the green-house the following winter. In the first winter after their shooting, you must keep them warm; for, by forcing them in the bark bed, they will be somewhat tenderer; however, it is very necessary to raise them to their height in one season, that their stems may be strait: for such trees, which are two or more years growing to their heading height, their stems are generally crooked. In the succeeding years, their management will be the same as in full grown trees, which will be hereafter treated of: I shall, therefore, now proceed to treat of the management of such trees as are brought over every year in chests from *Italy*; which is, indeed, by much the quicker way of furnishing a green-house with large trees; for those which are raised from seeds in *England*, will not grow so large in their stems under eighteen or twenty years, as these will have when brought over; and although their heads are small when we receive them, yet in three years, with good management, they will have large heads, and produce fruit.

In the choice of these trees, observe first, the difference of their shoots and leaves (if they have any upon them) to distinguish their different sorts, for the Shaddock and Citrons always make much stronger shoots than the Orange; for which reason, the *Italian* gardeners, who raise these trees for sale, generally propagate those sorts, so that they bring few of the *Seville* Orange trees over, which are much more valuable, both for their flowers and fruit; also prefer those that have two good buds, one on each side of the stock (for many of them have but one, so will always have an irregular head): the straitness of the stem, freshness of the branches, and plumpness of the bark, are necessary observations.

When you have furnished yourself with a parcel of these trees, you must prepare a moderate hot-bed of tanners bark in a forcing frame, in length and breadth according to the number of trees to be forced; then put your trees into a

tub of water upright, about half way of the stems, leaving the head and upper part of the stem out of the water, the better to draw and imbibe the moisture. In this situation they may remain two or three days (according to their plumpness when you received them); then take them out, and clean their roots from all filth, cutting off all broken or bruised roots, and all the small fibres, which are quite dried by being so long out of the earth; and scrub the stems with a hard hair brush, cleaning them afterwards with a cloth; then cut off the branches about three inches from the stem, and having prepared a quantity of good fresh earth, mixed with very rotten neats dung, plant your trees therein, observing never to put them into large pots; for if they are big enough to contain their roots, it is sufficient at first planting; and be sure to put some potsherds and large stones in the bottom of each pot, to keep the holes at the bottom of the pots from being stopped with earth, that the water may freely pass off, and wrap some haybands round their stems, from bottom to top, to prevent the sun from drying their bark: then plunge these pots into the bark bed, watering them well to settle the earth to their roots, frequently repeating the same all over their heads and stems, being very careful not to over water them, especially before they have made good roots; and observe to screen the glasses of your hot-bed from the sun in the heat of the day.

If your trees take to grow kindly (as there is little reason to doubt of, if the directions given be duly observed), they will have made strong shoots by the beginning of *June*; at which time you should stop their shoots, to obtain lateral branches to furnish their heads; and now you must give them air plentifully, and begin to harden them, that in the middle of *July* they may be removed into the open air, in some warm situation, defended from the great heat of the sun, and from winds, that they may be hardened before winter. About the end of *September* you should house these plants, sitting them at first in the front of the green-house, near the glasses, keeping the windows open at all times when the weather will permit; and about the latter end of *October*, when you bring in the Myrtles, and other less tender trees, you must set your Oranges in the warmest and best part of the house, placing lower plants or trees in the front, to hide their stems. During the winter, let your waterings be frequent, but give them not too much at a time; for now their heads are but small, and therefore incapable to discharge too great a quantity of moisture; and take great care to guard them from frost.

In the spring, when you begin to take out some of your hardiest sorts of plants, to thin your house, wash and cleanse the stems and leaves of your Orange trees, taking out the upper part of the earth in the pots, filling them up again with good fresh rich earth, laying thereon a little rotten neats dung round the outside of the pots, but do not let it lie near the stem of the trees; then place them at wider distances in the house, that the air may circulate round their heads; giving them air discretionally, as the weather grows warm, but do not remove them into the open air until the middle or latter end of *May*, that the weather is settled; for many times, when they are removed out too soon, the mornings often proving cold, give them at least a great check, which will change the colour of their leaves, and many times kill the extreme weak part of the shoots. Let the situation for your Orange trees, during the summer season, be as much defended from the sun in the heat of the day, and strong winds, as possible, by tall trees or hedges; both of which, if they are exposed thereto, are very hurtful to them.

As these trees advance, it will be necessary in the summer to stop strong shoots when they grow irregular, to force out lateral branches to fill the head; but do not pinch off the tops of all the shoots (as is the practice of some), which

will fill the tree with small shoots, too weak to support fruit; but endeavour to form a regular head, and obtain strong shoots, taking away weak trifling branches where they are too close.

During the summer season, your Orange trees will require frequent waterings in dry weather, especially if they are large; therefore you should endeavour to have the water as near the trees as possible, to save the trouble of carrying it, which in a large quantity of trees, takes up much time. Your water should be soft, and exposed to the air, but never add dung of any sort thereto; which, although by many frequently recommended, yet has always been found destructive to these trees, if much used; it being like hot liquors to human bodies, which, at first taking, seem to add vigour, yet certainly leave the body weaker after some time, than before.

Your Orange trees will require to be shifted and new potted every other year, therefore you must prepare a quantity of good earth, at least a year before you intend to use it, that it may be well mixed and perfectly rotten. The best season for this work is about the end of *April*, that they may have taken fresh root before they are removed out of the green-house; and when this work is performed, it will be necessary to let them remain in the house a fortnight longer than usual, to be well settled.

When you first set these trees abroad after shifting, you should place them near the shelter of hedges, and fasten their stems to strong stakes, to prevent their being disturbed by winds; which sometimes will blow fresh planted trees out of the pots, if too much exposed thereto, and thereby greatly injure their new roots.

If old Orange trees have been ill managed, and their heads become ragged and decayed, the best method to restore them, is to cut off the greatest part of their heads early in *March*, and prune their roots; then soak and clean their stems and branches, planting them into good earth, and setting them into a hot-bed of tanners bark, as was directed for such trees as came from abroad, managing them in the same manner: by this method they will produce new heads, and in two years time, become good trees again. But if these are large trees, and have grown in tubs for several years, your best way will be to prepare a parcel of rough baskets (such as are used for basketting Ever-greens, when sent to a distant place): let these be somewhat less than the tubs you design to plant your trees into; then plant your trees herein, plunging them into the hot-bed, and about the beginning of *July*, when your trees have made good shoots, you may remove them into the tubs, with their baskets about them, filling the empty space with the same good earth: this will preserve your tubs from rotting in the bark, and the trees will do equally well as if planted into the tubs at first, provided you are careful in removing the baskets, not to disturb their roots; and also let them remain in the green-house a fortnight or three weeks after planting, before you set them abroad.

In the management of Orange trees which are in good health, the chief care should be to supply them with water duly, and not (as is sometimes practised) starve them in winter, whereby their fibres are dried, and become mouldy, to the great prejudice of the trees; nor to give them water in too great abundance; but rather let their waterings be frequent, and given in moderate quantities. You must also observe, that the water has free passage to drain off, for if it be detained in the tubs or pots, it will rot the tender fibres of the trees; nor should they be placed too near each other in the green-house, but set them at such a distance, that their branches may be clear of each other, and that the air may circulate freely round their heads. In summer they should be placed where the winds are not violent, and to have the morning and evening sun; for if they are too much exposed

to the mid-day sun, they will not thrive. The best situation for them is near some large plantation of trees, which will break the force of the winds, and screen them from the violent heat of the sun. In such a situation they may remain until the beginning of *October*, or later, according as the season proves favourable; for if they are carried into the green-house early, and the autumn should prove warm, it will occasion the trees to make fresh shoots, which will be weak and tender, and so liable to perish in winter; nor should they remain so long abroad as to be injured by morning frosts.

The best compost for Orange trees is two-thirds of fresh earth from a good pasture, which should not be too light, nor over stiff, but rather a Hazel loam; this should be taken about ten inches deep with the sward, which should be mixed with the earth to rot, and one third part of neats dung; these should be mixed together, at least twelve months before it is used, observing to turn it over every month, to mix it well, and to rot the sward; this will also break the clods, and cause the mould to be finer.

Of late years there have been many of these trees planted against walls, and frames of glass made to fix over them in winter; and some few curious persons have planted these trees in the full ground, and have erected moveable covers to put over them in winter, which are so contrived as to be all taken away in summer: where these have been well executed, the trees have made great progress in their growth, and produced a much larger quantity of fruit, which have ripened so well, as to be extremely good for eating. If these are planted either against walls with design of training the branches to the walls, or in borders at a small distance, so as to train them up as standards, there should be a contrivance of a fire-place or two, in proportion to the length of the wall, and flues carried the whole length of the wall, to warm the air in very cold weather, otherwise it will be very difficult to preserve the trees in very hard winters alive. The manner of making these flues is fully explained under the article of *HOT WALLS*. Where this contrivance is made, there will be no hazard of losing the trees, be the winter ever so severe, with a little proper care; whereas, if this is wanting, there will require great care and trouble to cover and uncover the glasses every day, when there is any sun; and if the wall is not thicker than they are usually built, the frost will penetrate through the walls in severe winters; so that covering and securing the glasses of the front will not be sufficient to preserve the trees, be it done with ever so much care: therefore the first expence of the walls will save great trouble and charge, and be the securest method.

If the ground is wet, or of a strong clay, so as to detain the moisture, the borders should be raised above the level of the ground, in proportion to the situation of the place; for where the wet lies in winter near the surface, it will greatly prejudice, if not totally destroy the trees; so that lime rubbish should be laid at least two feet thick, in the bottom of the border, to drain off the wet; and the earth should be laid two and an half or three feet thick thereon, which will be a sufficient depth for the roots of the trees. In these borders there may be a few roots of the *Guernsey* and *Belladonna* Lilies planted, or any other exotick bulbous-rooted flowers, which do not grow high, or draw too much nourishment from the borders; and these, producing their flowers in autumn or winter, will make a good appearance, and thrive much better than if kept in pots.

AURICULA MURIS, Mouse Ear.

This is a sort of Hawkweed with small hairy leaves, which are white underneath: the plant trails upon the ground, taking root at the joints, by which means it will soon spread over a large compass of ground.

This is very common in *England*; it grows chiefly on dry barren places, or upon old walls, and is too often a troublesome weed in grass plats in gardens.

AURICULA URSI, Bear's Ear, or Auricula.

To enumerate the varieties of this plant, would be almost endless and impossible; for every year produces vast quantities of new flowers, differing in shape, size, or colour of the flowers; and also in the leaves of these plants there is as great a variety, so that the skilful florist is often capable of distinguishing the particular sorts thereby.

But as it seldom happens, that such of these flowers as are at one time in great esteem, continue to be regarded a few years after, (there being still finer or larger flowers produced from seeds, which are what the florists chiefly seek after), it would be needless to mention any of them; wherefore I shall proceed to give the characters of a good Auricula.

1. *The stem of the flower should be lofty and strong.*
2. *The foot-stalk of the single flower should be short, that the umbel may be regular and close.*
3. *The pipe or neck of each flower should be short, and the flowers large, and regularly spread, being no ways inclinable to cup.*
4. *That the colours are very bright, and well mixed.*
5. *That the eye of the flower be large, round, and of a good white, or yellow; and that the tube or neck be not too wide.*

All the flowers of this kind, that want any of the above mentioned properties, are now rejected by every good florist; for as the varieties every year increase from seeds, so the bad ones are turned out to make room for their betters; but in some people the passion for new flowers so much prevails, that, supposing the old flower greatly preferable to a new one, if it is of their own raising, the latter must take place of the old one.

In order to obtain good flowers from seeds, you must make choice of the best flowers you have; which should be exposed to the open air, that they may have the benefit of showers, without which they seldom produce good seeds: the time of their ripening is in *June* and *July*, which you will easily know, by their seed-vessel turning to a brown colour, and opening; you must therefore be careful lest the seeds be scattered out of the vessel, for it will not be all fit to gather at the same time.

The time for sowing this seed is commonly in *August*; but if it be sown before *Christmas*, it will be time enough.

The best soil for this seed is good fresh light sandy mould, mixed with very rotten neats dung, or very rotten dung from the bottom of an old hot-bed: with this you should fill your pots, or boxes, in which you intend to sow your seeds; and having levelled the surface of the earth very smooth, sow your seeds thereon, covering it very lightly with rotten Willow mould taken out of the stems of decayed hollow Willow trees; then cover the box, &c. with a net or wire, to prevent the cats, fowls, &c. from scratching out, or burying your seeds too deep; for whenever this happens, the seeds will remain a year in the ground before the plants appear, if it should grow at last; therefore many persons never cover these seeds, but sow them upon the surface of the earth, in the boxes uncovered with earth, for the rain to wash them into the ground, which is often the best method: let these boxes, &c. be placed so as to receive only the morning sun, during the winter season; but in the beginning of *March*, remove them where they may have scarce any sun, for your young plants will now soon begin to appear, which, if exposed to one whole day's sun only, will be all destroyed.

During the summer season, in dry weather, often refresh them with water, but never give them too great quantities at once. In the *July* following, your plants will be large enough to transplant, at which time you must prepare a bed, or boxes, filled with the above mentioned soil, in which you

may plant them about three inches square, and (if in beds) you must shade them every day, till they are thoroughly rooted, as also in very hot dry weather; but if they are in baskets, or boxes, they may be removed to a shady place.

When the seedling Auriculas are planted in beds, there should be some rotten neats dung laid about ten inches under the surface, and beaten down close and smooth: this will prevent the worms from drawing the young plants out of the earth, which they generally do where this is not practised. This dung should be laid about a foot thick, which will entirely prevent the worms getting through it until the plants are well established in the beds; and the roots of the Auriculas will strike down into the dung by the spring, which will make their flowers stronger than usual: these beds should be exposed to the east, and screened from the south sun.

When you have taken all your plants which are come up, out of the boxes or pots, level the earth gently again; for it often happens, that some of the seeds will lie in the ground two years before they appear, especially if they were covered too deep when sown, as was before observed.

The spring following many of these flowers will shew; when you may select such of them as have good properties, which should be removed each of them into a pot of the same prepared earth, and preserved until the next season, at which time you will be capable to form a judgment of the goodness of the flower; but those that produce plain coloured or small flowers, should be taken out, and planted in borders in the out-parts of the garden, to make a shew, or gather for nosegays, &c. the others, which do not produce their flowers the same year, may be taken up, and transplanted into a fresh bed, to remain till you see how they will prove.

The manner of propagating these flowers when obtained, is from offsets, or slips, taken from the old roots in *April*, when the flowers are in bloom: these offsets must be planted into small pots filled with the same sort of earth, as was before directed for the seedlings; and, during the summer season, should be set in a shady place, and must be often (but very gently) refreshed with water: but in the autumn and winter, should be sheltered from violent rains. The spring following, these young plants will produce flowers, though but weak; soon after they are past flowering, you must put them into larger pots, and the second year they will blow in perfection.

But, in order to obtain a fine bloom of these flowers, you must observe the following directions.

First, Preserve your plants from too much wet in winter, which often rots and spoils them, but let them have as much free open air as possible; nor should they be too much exposed to the sun, which is apt to forward the budding for flower too soon; and the frosty mornings, which often happen in *March*, thereby destroy their buds, if they are not protected therefrom. To prevent which, those who are very curious in these flowers, place their pots in the autumn, under a common hot-bed frame; where, in good weather, the plants may enjoy the full air, by drawing off the glasses; and in great rains, snow, or frost, the plants may be screened, by covering them. When this method is practised with judgment, the flowers will be much stronger, and the plants will increase faster, than when they are exposed abroad.

Secondly, In the beginning of *February*, if the weather is mild, you must take off the upper part of the earth in the Auricula pots, as low as you can without disturbing their roots, and fill up the pots with fresh rich earth, which will greatly strengthen them for bloom; as also prepare your offsets for transplanting in *April*, by causing them to push out new roots.

Those plants which have strong single heads always produce the largest cluster of flowers; therefore the curious florists pull off the offsets as soon as it can be done with safety to their growing, to encourage the mother plants to flower the stronger; they also pinch off the flowers in the autumn, where they are produced, and suffer them not to open, that the plants should not be weakened thereby.

Thirdly, You must cover your pots with mats in frosty weather, during this time of their budding for flower, lest the sharp mornings blight them, and prevent their blowing.

Fourthly, When your flower-stems begin to advance, and the blossom buds grow turgid, you must protect them from hasty rains, which would wash off their white mealy farina, and greatly deface the beauty of their flowers; but at the same time observe to keep them as much uncovered as possible, otherwise their stems will be drawn up too weak to support their flowers (which is often the case when their pots are placed under walls), and give them gentle waterings to strengthen them; but let none of the water fall into the center of the plant, or among the leaves.

Fifthly, When your flowers begin to open, you should remove their pots upon a stage (built with rows of shelves, one above another, and covered on the top, to preserve them from wet: this should be open to the morning sun, but sheltered from the heat of the sun in the middle of the day): in this position they will appear to much greater advantage, than when the pots stand upon the ground; for, their flowers being low, their beauty is hid from us; whereas, when they are advanced upon shelves, we see them in full view: in this situation they may remain until the beauty of their flowers is past; when they must be set abroad to receive the rains, and have open free air, in order to obtain seeds, which will fail, if they are kept too long under shelter. When your seed is ripe, observe to gather it when it is perfectly dry, and expose it to the sun in a window upon papers, to prevent its growing mouldy, and let it remain in the pods till the season for sowing it.

AURICULA URSI MYCONI. See Verbascum.

AZALEA. *Lin. Gen. Plant.* 195. American upright Honey-suckle.

The Characters are,

It hath a coloured empalement which is permanent, cut into five acute parts at the top. The flower is funnel-shaped, having a long naked tube, cut into five parts; the two upper segments are reflexed backward, the two sides are bent inward, and the lower one turns downward. It hath five slender stamina of unequal lengths, with

a round germen, which afterward becomes a roundish capsule, having five cells, filled with roundish small seeds.

The Species are,

1. AZALEA foliis margine scabris, corollis piloso-glutinosis. *Lin. Sp. Plant.* 151. This is the American upright Honey-suckle with a white flower.

2. AZALEA foliis ovatis corollis pilosis staminibus longissimis. *Lin. Sp. Pl.* 150. Commonly called red American upright Honey-suckle.

The first of these is a low shrub, rising with several stems two or three feet high. The leaves come out in clusters at the end of the shoots without order, and their edges are set with very short teeth, which are rough. The flowers come out in clusters between the leaves, at the extremity of the branches, which are white, with a mixture of dirty yellow on their outside. They have a tube an inch long, and at the top are pretty deeply cut into five segments; the two upper are reflexed, the two side ones are bent inward, and the lower is turned downward, with five stamina a little longer than the petals; the style is much longer than the stamina. These flowers have much the appearance of those of the Honey-suckle, and are as agreeably scented.

The second sort grows taller than the first, and in its native country, frequently rises the height of twelve feet, but in *England* is never more than half that height. This hath several stems with oblong smooth leaves. The flower-stalks arise from the division of the branches, which are long and naked, supporting a cluster of red flowers; they are divided at the top into five equal segments, which spread open. The five stamina, and the style, are much longer than the petals, and stand erect.

These plants grow naturally in shade, and upon moist ground, in most parts of *North America*, so they must have a moist soil, and a shady situation, otherwise they will not thrive. They can only be propagated by shoots from their roots, for they do not produce seeds here; and if good seeds are obtained, they are difficult to raise, and will be a long time before they would flower. But when they are in a proper situation, their roots extend, and put out shoots, which may be taken off with roots, and transplanted. The autumn is the best time to remove the plants, but the ground about their roots should be covered in winter to keep out the frost; and if this is every year practised to the old plants, it will preserve them in vigour, and cause them to flower well.

AZEDARACH. See Melia.

AZEROLE, or L'AZAROLE. See Mespilus.

B.

B A C

B A C

BACCHARIS, Ploughman's Spikenard.

The Characters are,

The flower is composed of many hermaphrodite and female florets, which are included in one common, cylindrical, scaly empalement. The hermaphrodite florets are funnel-shaped; and have five slender stamina with an oval germen, which afterward becomes a single short seed crowned with a long down. The female flowers have no stamina, but in other respects are the same.

The Species are,

1. BACCHARIS foliis lanceolatis longitudinaliter dentato-serratis. *Hort. Cliff.* African tree Groundsel with a sawed leaf.

2. BACCHARIS foliis obversè ovatis, superne emarginato-crenatis. *Lin. Hort. Cliff.* Virginia Groundsel tree, with an Orach leaf.

The first sort was brought from the *Cape of Good Hope*, but grows naturally in *Peru*, and in other parts of *America*. There

is little beauty in the flower; it grows to the height of five or six feet, and is a manageable shrub; it may be propagated by cuttings, which should be planted in a shady border during any of the summer months, or by seeds sown in a common border in the spring of the year, which ripen well in this country; and, if permitted to scatter on the ground, the plants will come up the following spring. It is pretty hardy, and will live abroad in mild winters, if planted in a warm situation; but it is usually kept in green-houses, and placed abroad in summer; it requires much water in warm weather.

The second sort is a native of *Virginia* and other parts of *North America*; it grows about seven or eight feet high, with a crooked shrubby stem, and flowers in *October*; the flowers are white, and not very beautiful; but the leaves continuing green through the year, has occasioned this shrub to be admitted into many curious gardens.

This sort may be propagated by cuttings, which should be planted in *April* or *May*, upon a shady border, and, at *Michaelmas*, they will be fit to transplant where they are to remain; this will live in the open air, and never is injured by the cold of our ordinary winters; but severe frost will sometimes destroy them.

BALAUSTIA. See *Punica*.

BALLOTE, Black Horehound.

This is a common weed, growing on the sides of banks in most parts of *England*, so is seldom allowed a place in gardens; there are two varieties of it, one with a white, and the other a purple flower.

BALM. See *Melissa*.

BALSAMINA, the female Balsamine or Balsamine. See *Impatiens*.

BALSAMITA. See *Tanacetum*.

BAMIA MOSCHATA. See *Hibiscus*.

BANANA. See *Musa*.

BANISTERIA. *Houft. Mss. Lin. Gen. 509.*

The Characters are,

The flower hath five petals, which are shaped like those of the papilionaceous tribe, but spread open, having in some species one, in others two, and in some, several nectarious glands, with ten short stamina. There are in some species three, and in others but one germen, which afterward become so many winged fruit, like those of the *Maple*, each containing a single seed.

The Species are,

1. BANISTERIA foliis ovato-oblongis rigidis racemis terminalibus caule fruticoso scandente. Banisteria with oblong oval stiff leaves, spikes of flowers terminating the branches, and a shrubby climbing stalk.

2. BANISTERIA foliis ovatis glabris, floribus corymbosis terminalibus, caule fruticoso scandente. Banisteria with oval smooth leaves, flowers growing in a corymbus at the extremity of the branches, and a shrubby climbing stalk.

3. BANISTERIA foliis ovatis acuminatis floribus laxè spicatis, ramis diffusis scandentibus. Banisteria with oval pointed leaves, flowers growing in loose spikes, and climbing diffused branches.

4. BANISTERIA foliis cordatis nervosis subtus incanis, floribus lateralibus, caule fruticoso scandente. Banisteria with nervous heart-shaped leaves, hoary on their under side, flowers growing from the side of the branches, and a shrubby climbing stalk.

5. BANISTERIA foliis ovato-oblongis acuminatis racemis lateralibus seminibus patentibus. *Flor. Zeyl. 176.* Banisteria with oblong oval pointed leaves, spikes of flowers growing from the side of the branches, and spreading seeds.

6. BANISTERIA foliis pinnatis foliolis ovatis spicis lateralibus seminibus erectis. Banisteria with winged leaves, whose small leaves are oval, spikes of flowers growing from the side of the branches, and erect seeds.

The first grows naturally in *Jamaica*. This hath a woody stalk, which twists itself round the neighbouring trees, and raises itself to their top. It is garnished with leaves as large as those of the *Bay tree*, and of the same thickness, growing opposite; the flowers are produced in long branching spikes at the end of the branches, which are yellow, and are succeeded by two or three winged seeds like those of the greater *Maple*.

The second sort grows naturally in *Jamaica*, at *Campeachy*, and several other parts of *America*. This hath slender winding stalks, which rise five or six feet high, with oval smooth leaves; the flowers grow in a round bunch at the extremity of the branches, which are of a brownish yellow colour, and are succeeded by winged seeds like the former, but smaller, and have narrower wings.

The third sort came from *Carthagera*, where it naturally grows. This sends out many branches, which divide again into others, growing without order, and become very bushy upward, sending out tendrils by which they fasten themselves to the neighbouring trees, and mount to a great height; these have oval stiff leaves, ending in a point. The flowers are produced in loose spikes at the ends of the branches, which are first of a gold colour, and fade to a scarlet, and are succeeded by seeds of the same shape with the former, but are slender, thin, and for the most part single.

The fourth sort was sent me from *Campeachy*; this hath many irregular climbing stalks, which fasten themselves to the neighbouring trees, and rise to a great height, with heart-shaped leaves, which are hairy on their under side, where they have many transverse ribs. The flowers come out thinly from the side of the branches, which are of a pale yellow colour, and are succeeded by large winged seeds, which are double.

The fifth sort hath strong woody stalks, which twine about the trees that grow near it, and rises twenty feet high, garnished with oblong pointed leaves, like those of the *Bay tree*, growing by pairs opposite; from the wings of the leaves, the flowers are produced in loose spikes, upon long foot stalks, which are blue, and are succeeded by slender winged seeds, which spread open from each other.

The sixth sort hath strong ligneous stalks, covered with an Ash-coloured bark, and divide into many branches, garnished with winged leaves, composed of five or six pair of oval small leaves, whitish on their under side; from the wings of the leaves are produced slender bunches of flowers, growing in a racemus like those of the *Currant bush*, and are of a purplish colour; these are succeeded by broad winged seeds, growing erect.

These plants are all of them natives of warm countries, so cannot be preserved in *England*, unless they are kept in a bark stove. They are propagated by seeds, which must be procured from the countries where they grow naturally. These seeds should be fully ripe when gathered, and put into sand, in which they should be sent to *England*, otherwise they will lose their vegetative quality; for these seeds are not only in shape like those of the *Maple*, but also are of the same quality, requiring to be sown as soon as possible, when they are ripe, or preserved in sand till they are sown, otherwise they rarely succeed. The seeds should be sown in pots, and plunged into a hot-bed of tanners bark, where the heat is very moderate, and if the plants should not appear the first year, the pots should be preserved till the next spring, to see if the seeds will grow. When the plants come up, they must be planted in separate pots, filled with light earth, and plunged into the bark bed, after which they must be treated like other tender plants from the same countries.

BAOBOB. See *Adanfonia*.

BARBA CAPRÆ. See *Spiræa*.

BARBA JOVIS. See Anthyllis.

BARBAREA. See Erysimum.

BARDANA. See Arctium.

BARLERIA. The inhabitants of the island of Jamaica call it Snap-dragon.

The Characters are,

The flower is nearly of the lip kind, of one leaf, funnel-shaped, and divided into five parts at the top. It hath four slender stamens, two short, and two longer. In the center is placed the oval germen, which after-ward becomes an oblong membranaceous vessel, with two cells, which is very elastic, containing two roundish compressed seeds.

The Species are,

1. BARLERIA foliis ovatis, pedunculis dichotomis paniculatis. Barleria with oval leaves, and flowers growing in panicles, arising at the division of the branches.

2. BARLERIA foliis ovatis petiolis longissimis, floribus lateralibus, pedunculis multifloris. Barleria with oval leaves, having very long foot-stalks, and flowers growing from the side of the branches, many upon each foot-stalk.

3. BARLERIA spinis axillaribus foliis lanceolatis integerrimis floribus verticillatis sessilibus. Barleria with spines on the side of the branches, spear-shaped leaves which are entire, and flowers growing in close whorls round the stalk.

4. BARLERIA spinis axillaribus quaternis foliis integerrimis. Lin. Sp. Pl. 636. Barleria with spines growing by fours from the side of the branches, and entire leaves.

The first sort rises with a hairy branching stalk, four or five feet high, garnished with two oval leaves at every joint; upon short foot-stalks, at every division of the branches, comes out a long foot-stalk, which divides into many smaller, and at each division of these, is placed a single flower, without foot-stalk, of a pale colour; the upper segment being broad, and shaped like the galea, or helmet, the two lateral segments are narrow, and the under one is bent downward, representing the under lip, and is cut into two parts. The germen becomes an oblong membranaceous capsule with two cells, each containing two compressed roundish seeds. This seed-vessel is very elastic, and throws out the seeds with violence on their being touched when ripe.

The second sort rises six or seven feet high, sending out many lateral branches, from the bottom upward, so as to form a sort of pyramid; the leaves are oval. The flowers grow upon branching foot-stalks, which come out from the wings of the leaves, each standing upon a short separate foot-stalk, and are succeeded by elastic seed-vessels, of the same shape with the former.

The third sort hath square stalks, three feet high, garnished with two oblong entire leaves at every joint, above which the flowers come out in whorls surrounding the stalks, and under each whorl there are six sharp spines, which are as long as the empalement of the flowers. The flowers are blue, and have more of the form of the labiated flowers, than any of the other species.

The fourth sort sends out many slender stems from the root, which rise seven or eight feet high, garnished with oval pointed leaves, two growing opposite at each joint, which are attended by four long spines standing cross-ways.

The three first sorts are propagated by seeds, which they annually produce in plenty; but if they are not carefully watched, to gather them as they ripen, their pods burst open and disperse the seeds, which falling upon the neighbouring pots, will come up and furnish young plants.

The roots of these will continue three or four years, but after the second year, they grow too rambling, and the lower parts of the branches naked, so are not so sightly as the young plants; therefore a succession of these should be preserved, and the old ones turned out. When the seeds are

received from abroad, they must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they must be each planted in a separate pot, and plunged into a hot-bed of tanners bark, where they must constantly remain, and managed in the same manner as other tender exoticks from the same countries, giving them water frequently in summer, and letting the fresh air to them every day in warm weather, but in winter they should have little water, and be kept warm. They flower in June, July, and August, and their seeds ripen soon after.

The fourth sort is only propagated by cuttings, which must be planted in pots, and plunged into a moderate hot-bed, where they will take root, and the plants should be kept constantly in the stove. This sort requires plenty of water in summer, and in winter they must be frequently refreshed, but they must not have it in too great quantity.

BASELLA, or climbing Nightshade from Malabar.

The Characters are,

The flower hath no empalement; it is shaped like a pitcher, closed toward the brim. It hath five stamens fastened to the petal. The globular germen, which is situated in the center, supports three slender styles, crowned by oblong stigma. The petal of the flower remains, and incloses a roundish fleshy berry, including one round seed.

The Species are,

1. BASELLA foliis rotundo-cordatis carnosis. Basella with round heart-shaped leaves.

2. BASELLA foliis oblongis flaccidis obtusis. Basella with oblong blunt flaccid fleshy leaves.

The first sort has thick strong succulent stalks and leaves, which are of a deep purple colour. The plant will climb to the height of ten or twelve feet, which will twist round stakes, provided the plants are preserved in the stove; for if they are exposed to the open air, they will not grow so large, nor will they perfect their seeds, except it be in very warm seasons; but if they are placed in the stove, they will often live till the following spring, and produce great quantities of flowers and seeds. The flowers of this plant have no great beauty, but the plant is preserved for the odd appearance of the stalks and leaves.

There is a variety of this with green stalks and leaves, and the flowers are of a whitish green colour, tipped with purple on their edges, but in all other respects the same, so is supposed to be only a feminal variation.

The second sort hath flaccid leaves, smaller flowers and fruit, in which it essentially differs from the first.

These plants are propagated by seeds, which should be sown in a hot-bed in the spring; and when the plants are fit to remove, they should be each planted into a separate pot, and plunged into the tan bed, where they must be treated in the same manner as other tender exoticks. They may also be propagated by cuttings, which should be planted in pots, and plunged into a moderate hot bed of tanners bark, where they will take root in a fortnight or three weeks time, when they should be treated in the same manner as the seedling plants. But as these rise so easily from seeds, so they are seldom propagated any other way, because they are plants of short duration.

These will climb to a considerable height, and send forth a great number of branches, so they should be trained up to a trellise, or fastened to the back of the stove, otherwise they will twist themselves about whatever plants stand near them, which will make a very disagreeable appearance in a stove; whereas, when they are regularly trained to a trellise, they will have a good effect.

From the berries of the first sort I have seen a beautiful colour drawn, but when used for painting, did not continue very long, but changed to a pale colour; though I believe there

there might be a method invented, whereby this beautiful colour might be fixed, so as to become very useful; for I have been assured, that the juice of these berries has been used for staining of calicoes in *India*.

BASILICUM, or BASIL. See *Ocymum*.

BASTERIA, All-spice.

As this plant has no proper title given to it, so I have given it this in honour of my worthy friend Dr. *Job Baster*, F. R. S. of *Zurick Zee*, in *Holland*, who is a gentleman well skilled in botany, and has a fine garden stored with rare plants, of which he is very communicative to his friends.

The Characters are,

The flower hath a double series of narrow petals, which spread open, and turn inward at their extremity. Under the receptacle is situated an oval germen, surrounded by many short stamina, crowned by obtuse summits. The germen afterward becomes a roundish fruit, compressed at both ends, having cells, containing oblong seeds.

We have but one Species of this genus, viz.

BASTERIA. Basteria with oval leaves placed opposite, and a branching shrubby stalk; commonly called in *Carolina* All-spice.

This shrub grows naturally in *America*; Mr. *Catesby*, who first introduced it into the *English* gardens, procured it from the continent, some hundred miles on the back of *Charles Town*, in *Carolina*.

It seldom rises more than four feet high in this country, dividing into many slender branches near the ground, with two oval leaves, placed opposite at every joint, which are entire; the flowers comes out from the wings of the leaves; they have two series of narrow thick petals, which spread open, and turn inward at the top, like those of the starry Anemone, or the Virgin's Bower: these are of a full purple colour, and have a disagreeable scent; they appear in *May*; the embryo sits beneath the flower, and supports five stigma; this afterward appears to have five cells, but it never comes to perfection in this country, therefore I can only give a description of it, from an imperfect rudiment. The bark of this shrub is brown, and has a very strong aromatick scent; from whence the inhabitants of *Carolina* gave it the title of All-spice, by which it is generally known in the nurseries near *London*.

This shrub will thrive in the open air in *England*, if it be planted in a warm situation, and a dry soil: it is propagated by laying down the young branches, which will take root in one year, and may then be taken from the mother plant, and planted where they are designed to remain, for they do not bear transplanting well, after they are grown to any size.

The best time for laying down the branches is in the autumn, but they should not be transplanted till the spring twelve months after; for the spring is the safest time to remove these plants. After the branches are laid down, there should be some old tanners bark laid upon the surface of the ground, to keep out the frost, which should also be done every winter, while the plants are young, which will prevent the frost from penetrating to their roots, and thereby secure them.

BAUHINIA, Mountain Ebony.

The Characters are,

The flower is composed of five petals. It hath ten stamina: the oblong germen sits upon the foot-stalk, which afterward becomes a long taper pod, inclosing a row of roundish compressed seeds.

The Species are,

1. BAUHINIA foliolis obliquis emarginatis caule aculeato, floribus spicatis terminalibus. Prickly Bauhinia with a round indented leaf.

2. BAUHINIA caule inermi foliis cordatis lobis acutis glabris, floribus spicatis terminalibus. Bauhinia with a smooth stalk, heart-shaped smooth leaves with pointed lobes, and spikes of flowers terminating the branches.

3. BAUHINIA foliis ovatis lobis acuminatis semi-ovatis. *Lin. Sp. Pl.* 375. Bauhinia with oval leaves, and pointed lobes which are half oval.

4. BAUHINIA foliis oblongo-cordatis, lobis acuminatis parallelis trinerviis, siliquis planis. Bauhinia with oblong heart-shaped leaves, with pointed parallel lobes, having three ribs, and plain flat pods.

5. BAUHINIA caule aculeato, foliis cordatis lobis orbiculatis subtus tomentosiss. Bauhinia with a prickly stalk, and heart-shaped leaves with round lobes, which are woolly on their under side.

6. BAUHINIA foliis cordatis lobis semi-orbiculatis, floribus paniculatis axillaribus. Bauhinia with heart-shaped leaves, having roundish lobes, and flowers growing in loose spikes from the side of the branches.

7. BAUHINIA foliis subcordatis bipartitis rotundatis caule aculeato, floribus sparsis. Bauhinia with heart-shaped bifid rounded leaves, a prickly stalk, and flowers growing at a distance.

8. BAUHINIA foliis cordatis lobis coadunatis obtusis. *Lin. Sp. Plant.* 375. Bauhinia with heart-shaped leaves, and obtuse lobes which join together.

9. BAUHINIA caule cirrhifero. *Lin. Sp. Pl.* 374. Bauhinia with a stalk having tendrils.

10. BAUHINIA foliis ovatis lobis divaricatis. *Lin. Sp. Pl.* 374. Bauhinia with oval leaves, whose lobes spread different ways, called in *Jamaica* Honeyfuckle.

The first sort grows plentifully in *Jamaica*, and the other islands in *America*, where it rises to the height of sixteen or eighteen feet, with a crooked stem, and divides into many irregular branches, armed with short strong spines, and garnished with compound winged leaves, each having two or three pair of lobes, ending with an odd one, which are oblique, blunt, and indented at the top. The stalks are terminated by several long spikes of yellow flowers, which are succeeded by pods, about three inches long, which have borders, and contain two or three swelling seeds. The pods are glutinous, and have a strong balsamick scent, as have also the leaves when bruised. It is called in *America*, the *Indian Savin tree*, from its strong odour, somewhat resembling the common *Savin*.

The second sort came from *Campeachy*, where it grows naturally. This rises to the height of twelve or fourteen feet, with a smooth stem, dividing into many branches, garnished with heart-shaped leaves, having two smooth pointed lobes; the extremity of every branch is terminated by a long spike of yellow flowers, so that when these trees are in flower, they make a fine appearance. The pods are swelling, and about five inches long, each containing five or six roundish compressed seeds.

The third sort grows naturally in both *Indies*, where it rises with several pretty strong, upright, smooth stems, which send out many slender branches on every side, garnished with leaves, deeply divided into two oval lobes. The leaves come out without order, and have long foot-stalks, but are much thinner than those of the species before-mentioned. The flowers come out at the extremity of the branches, three or four in a loose bunch; the petals are red, or striped with white, others are plain upon the same branch; the stamina and style are white, and stand out beyond the petals. These flowers are succeeded by long flat pods of a dark brown colour, each containing five or six roundish compressed seeds. The wood of this tree is very hard, and veined with black, from whence the inhabitants of *America* call it *Mountain Ebony*.

The fourth sort grows naturally at *Campeachy*. This rises to the height of twenty feet, with a smooth stem, which divides into many small branches, garnished with oblong heart-shaped leaves, having two pointed parallel lobes, which

which have each three longitudinal veins. The leaves are placed alternately on the branches, which are terminated by loose bunches of white flowers; these are succeeded by very long narrow compressed pods, which have eight or ten compressed roundish seeds in each.

The fifth sort seldom rises more than ten feet high, dividing into many irregular branches, which are armed with short crooked spines; the leaves grow alternate, are heart-shaped, and have two roundish lobes; they are woolly on their under side, and have short foot-stalks. The flowers grow at the extremity of the branches, two or three together; these are large, and of a dirty white colour, and are succeeded by short flat pods, each containing two or three seeds.

The sixth sort grows naturally at *La Vera Cruz*. It rises to the height of twenty-five, or thirty feet, with many irregular stems, garnished with heart-shaped leaves, having two roundish lobes. The flowers come out in loose spikes at every joint from the wings of the leaves, with naked foot-stalks, and are of a dry white colour. These are succeeded by oblong compressed pods, each containing three or four compressed seeds.

The seventh sort grows naturally at *Carthagena*, in *New Spain*. This rises twenty feet high, with a strong upright stem, which sends out many branches, which are armed with spines growing by pairs. The leaves grow alternately, and are heart-shaped, with two rounded lobes. The flowers are large and white, coming out thinly at the end of the branches. The petals of these are near two inches long, and spread open wide; these are succeeded by long flat pods, which are narrow, each containing five or six seeds.

The eighth sort grows naturally in both *Indies*. It rises with a strong stem, upward of twenty feet high, dividing into many strong branches, which are garnished with heart-shaped leaves, having obtuse lobes. The flowers grow in loose panicles at the extremity of the branches, which are large, and of a purplish red colour, marked with white, and have a yellow bottom. These have a very agreeable scent. The flowers are succeeded by compressed pods, about six inches long, and three quarters of an inch broad, containing three or four compressed seeds in each.

The ninth sort grows naturally in both *Indies*, where it rises with many slender stalks, which put out tendrils, and fasten themselves to the neighbouring trees, whereby they rise to a great height; the leaves are heart-shaped, standing upon long foot-stalks, and are deeply cut into two pointed lobes, each having three prominent ribs running longitudinally.

The tenth sort grows naturally in great plenty on the north side of the island of *Jamaica*, where it is called Upright Honeyfuckle. This is a low shrub, seldom rising more than five or six feet high, but divides into several branches, garnished with oval leaves, divided into two lobes, which spread from each other. The flowers grow in loose panicles at the end of the branches, which are white, and have a very agreeable scent. The flowers are succeeded by taper pods, about four inches long, each containing four or five roundish compressed seeds, of a dark colour.

All these plants are natives of the warm countries, so will not thrive in *England*, unless they are kept in a warm stove. They are propagated by seeds, which must be procured from the countries where they grow naturally, for they do not perfect their seeds in *England*.

The seeds should be sown in pots, and plunged into a moderate hot-bed of tanners bark; if they are good, the plants will come up in about six weeks, and in a month or six weeks after, will be fit to transplant, when they should be carefully shaken out of the seed pot, so as not to tear

off the roots, and each planted into a separate small pot, and plunged into the hot-bed again, being careful to shade them until they have taken fresh root, after which they should have fresh air admitted to them every day in warm weather. In the autumn they must be placed in the bark stove, and treated in the same way as other tender exoticks, giving them but little water in winter.

BAY. See *Laurus*.

BEANS. See *Faba*.

KIDNEY or FRENCH BEANS. See *Phaseolus*.

BEAN-TREFOIL. See *Cytisus*.

BEAR'S-EAR. See *Auricula*.

BEAR'S-EAR SANICLE. See *Verbascum*.

BEAR'S-FOOT. See *Helleborus*.

BECABUNGA, or Brook-lime.

This is a sort of *Veronica*, or Water Speedwell; of which there are two sorts, one with a long leaf, and the other round; they are both very common in ditches, and watery places, almost every-where in *England*; the second sort is used in medicine.

BEE, or GNAT-FLOWER. See *Orchis*.

BEECH-TREE. See *Fagus*.

BELL-FLOWER. See *Campanula*.

BELLADONA. See *Atropa*.

BELLIS, the Daisy.

The Characters are,

It hath a radiated discous flower, composed of many hermaphrodite flowers in the disk, and female florets which form the border, or rays, included in a common empalement. The hermaphrodite flowers have an oval germen, attended by five short stamina; the germen afterward becomes a single naked seed placed vertically.

The Species are,

1. *BELLIS scapo nudo uniflora. Hort. Cliff. 418.* Daisy with a naked stalk, having one flower.
2. *BELLIS caule subfolioso. Lin. Sp. Pl. 887.* Daisy with leaves on the lower part of the stalk.
3. *BELLIS hortensis flore pleno majore. C. B. P. 261.* Garden Daisy with a larger double flower.

The first sort is the common Daisy, which grows naturally in pasture land in most parts of *Europe*, and is often a troublesome weed in the grass of gardens, so is never cultivated.

The second sort is a low annual plant, which grows naturally on the *Alps*, and the hilly parts of *Italy*. This seldom rises more than three inches high, with an upright stalk, which is garnished with leaves on the lower part, but the upper part is naked, supporting a single flower like that of the common Daisy, but smaller.

The Garden Daisy is generally supposed to be only a variety of the wild sort, which was first obtained by culture. This may probably be true, but there has not been any instance of late years of the wild sort having been altered by culture; nor have I ever observed the Garden Daisy to degenerate to the wild sort, where they have been some years neglected, though they have altered greatly with regard to the size and beauty of their flowers; therefore I shall not consider them as distinct species, but shall only mention the varieties, which are cultivated in the gardens.

1. The red and white Garden Daisy, with double flowers.
2. The double variegated Garden Daisy.
3. The Childing, or Hen and Chicken Daisy.
4. The Cockscorn Daisy, with red and white flowers.

The Garden Daisies flower in *April* and *May*, when they make a pretty variety, being intermixed with plants of the same growth; they should be planted in a shady border, and a loamy soil without dung, in which they may be preserved without varying, provided the roots are transplanted and parted every autumn; which is all the culture they require, except the keeping them clear from weeds.

BELLIS MAJOR. See Chrysanthemum.

BELLONIA.

The Characters are,

The flower is wheel-shaped, of one leaf, with a short tube, but spread open above, and cut into five obtuse segments. It hath five stamina, which close together. The germen is situated under the receptacle of the flower, which afterward becomes an oval turbinated seed vessel, ending in a point, having one cell filled with small round seeds.

We have but one Species of this plant, viz.

BELLONIA. Lin. Sp. Plant. 172. Shrubby Bellonia with a rough Balm leaf.

This plant is very common in several of the warm islands in America.

It hath a woody stem, which rises ten or twelve feet high, sending out many lateral branches, garnished with oval rough leaves placed opposite; the flowers come out from the wings of the leaves, in loose panicles, which are of the wheel shape, of one leaf, divided into five parts; these are succeeded by oval capsules, ending in a point, which are full of small round seeds.

It is propagated by seeds, which should be sown in a pot, and plunged into a hot-bed of tanners bark. When the plants are come up half an inch high, they should be carefully transplanted into pots, and plunged into the hot-bed again, observing to water and shade them until they have taken root; after which time they should have air admitted to them every day, when the weather is warm, and frequently watered. In autumn they must be plunged into the bark stove, and treated in the same manner as other tender exotics. The second year these plants will sometimes flower; but they rarely produce good seeds in this climate; however, they may be propagated by cuttings in the summer months, provided they are planted in light earth on a moderate hot-bed, and carefully watered and shaded until they have taken root.

BELVEDERE. See Chenopodium.

BENZOIN, the Benjamin Tree. See Laurus.

BERBERIS, the Barberry, or Pipperidge Bush.

The Characters are,

The flower hath a coloured empalement, composed of six concave leaves; the flower is of six leaves, which are roundish and concave. It hath two coloured nectariums, fastened to the base of each petal, and six stamina, with two summits fastened on each side their apex. The germen is cylindrical, and afterward becomes an obtuse cylindrical umbilicated berry, having a puncture, and one cell, inclosing two cylindrical seeds.

The Species are,

1. BERBERIS pedunculis racemosis. Mat. Med. 290. The Common Barberry.

2. BERBERIS foliis obversè ovatis. Canada Barberry with very broad leaves.

3. BERBERIS pedunculis unifloris. Lin. Sp. Pl. 331. Barberry with a single flower on each foot-stalk.

The first sort grows naturally in the hedges in many parts of England, but is also cultivated in gardens for its fruit, which is pickled, and used for garnishing dishes. This shrub rises with many stalks from the root, to the height of eight or ten feet, which have a white bark, yellow on the inside; the stalks and branches are armed with sharp thorns, which commonly grow by threes; the leaves are oval, obtuse, and slightly sawed on their edges. The flowers come out from the wings of the leaves, in small ramose bunches, like those of the Currant bush, which are yellow; these are succeeded by oval fruit, which are first green, but when ripe turn to a fine red colour. The flowers appear in May, and the fruit ripens in September.

This sort is generally propagated by suckers, which are put out in great plenty from the root; but such plants are

very subject to send out suckers in greater plenty than those which are propagated by layers, therefore the latter method should be preferred. The best time for laying down the branches, is in the autumn, when their leaves begin to fall; the young shoots of the same year are the best for this purpose; these will be well rooted by the next autumn, when they may be taken off, and planted where they are designed to remain. Where this plant is cultivated for its fruit, it should be planted single, (not in hedges, as was the old practice) and the suckers every autumn taken away, and all the gross shoots pruned out: by this method the fruit will be much fairer, and in greater plenty, than upon those which are suffered to grow wild.

The Canada sort was more common in the English gardens, some years past, than at present. The leaves of this are much broader, and shorter than those of the common sort, and the fruit is black when ripe. This may be propagated in the same way as the common sort, and is equally hardy.

The Box-leaved sort is at present very rare in England, and while young, the plants are somewhat tender, so have frequently been killed by severe frost. This never rises more than three or four feet high in England, but sends out many stalks from the root, which are strongly armed with spines at every joint; the leaves are shaped like those of the narrow leaved Box tree; the flowers come out from between the leaves, each upon a slender foot-stalk; but these are not succeeded by fruit in England.

This sort may be propagated by laying down the branches in the same manner as the first; but when the young plants are taken off, they should be planted in pots, and sheltered under a frame in winter, till they have obtained strength, when they may be turned out of the pots, and planted in a warm situation.

BERMUDIANA. See Sisyrrinchium.

BERNARDIA. See Croton.

BESLERIA.

The Characters are,

The flower is of the lip kind, and of one leaf; it hath four stamina in the tube of the flower, two of which are longer than the other, with an oval germen, which afterward becomes an oval berry, with one cell filled with small seeds.

The Species are,

1. BESLERIA pedunculis ramosis, foliis ovatis. Lin. Sp. Pl. 619. Besleria with branching foot-stalks, and oval leaves.

2. BESLERIA pedunculis simplicibus confertis, foliis lanceolatis. Lin. Sp. Pl. 619. Besleria with simple foot-stalks, growing in clusters, and spear-shaped leaves.

3. BESLERIA pedunculis simplicibus solitariis, involucris pentaphyllis. Lin. Sp. Pl. 619. Besleria with stalks growing single, and a five leaved involucre.

The first sort hath a smooth woody jointed stalk; at each joint are placed two oval nervous leaves opposite; the flowers come out from the wings of the leaves, upon short branching foot-stalks, each sustaining six or eight flowers, which stand each upon a separate smaller foot stalk. They are of one leaf, of an anomalous figure, and quinquefid; after the flower is past, the germen becomes an oval soft berry, with one cell filled with small seeds.

The second sort rises with a lignous stem six or seven feet high, dividing toward the top into many irregular branches, garnished with spear-shaped leaves, which have many transverse veins; the flowers come out at the wings of the leaves, in large clusters, each having a separate foot-stalk: these are small, tubulous, of a pale yellow colour, and are succeeded by round soft berries, inclosing many small seeds.

The third sort hath a creeping stalk, which sends out roots at every joint, garnished with oval leaves placed opposite, which have many transverse ribs, and are sharply

sawed on their edges; from the wings of the leaves come out the foot-stalks of the flowers single, each sustaining one tubulous irregular hairy flower, divided at the top into five obtuse parts, with a large five leaved involucre, deeply sawed on the border.

These plants grow naturally in the warm parts of *America*, so are too tender to live in this country, without artificial heat. They are propagated by seeds which should be sown on a hot-bed, and when the plants are come up half an inch high, they should be each transplanted into a small pot, and plunged into a hot-bed of tanners bark, where they should have air and water in proportion to the warmth of the season. When the plants have filled these small pots with their roots, they should be shaken out of them, and put into larger pots, and plunged into the hot-bed again, giving them a large share fresh air in warm weather. In winter they must be removed into the stove, where they must be kept in a temperate warmth, and should be often, but sparingly, watered. The second year these plants will flower, and sometimes they will perfect their seeds in this country; but they must be constantly preserved in the stove.

BETA, the Beet.

The Characters are,

The flower hath a five leaved empalement, which is permanent, but no petal, and five stamina placed opposite to the leaves of the empalement. The germen is situated below the receptacle, which afterward becomes a capsule with one cell, having a single seed, wrapped up in the empalement.

The Species are,

1. BETA *caulibus decumbentibus, foliis triangularibus petiolatis*. Beet with declining stalks and triangular leaves, having foot-stalks.

2. BETA *foliis radicalibus petiolatis, caulibus sessilibus, spicis lateralibus longissimis*. The common white Beet, or Cicla of the shops.

3. BETA *foliis latissimis, radice pyramidato carneso*. Red Beet with a pyramidal root.

The first sort grows naturally on the banks of the sea, and in salt marshes in divers parts of *England*. This has been supposed by many, to be the same with the second species; but I have brought the seeds from the places where they grow naturally, many times, and have cultivated the plants with care, but could not find any of the plants vary from their parent plants in their characters, so that I can make no doubt of its being a distinct species.

The second sort is cultivated in gardens for its leaves, which are frequently used in soups; the root of this sort seldom grows larger than a man's thumb; the spikes of flowers come out from the wings of the leaves, which are long, and have narrow leaves placed between the flowers. The lower leaves of the plant are thick and succulent, and their foot stalks are broad. The varieties of this are, the white Beet, the green Beet, and the *Swiss* or chard Beet. These will vary from one to the other by culture, as I have often experienced, but never alter to the first or third sort.

The third sort hath large thick succulent leaves, which are for the most part of a dark green, or purple colour. The roots of this are large, and of a deep red colour, on which their goodness depends; for the larger these roots grow, the tenderer they will be; and the deeper their colour, the more they are esteemed. The varieties of this are, the common red Beet, the Turnep-rooted red Beet, and the green-leaved red Beet.

The second sort, which is cultivated in gardens for its leaves, which are used in the kitchen, is commonly sown by itself, and not mixed with other crops, the beginning of *March*, upon an open spot of ground, not too moist. When the plants have put out four leaves, the ground should be

hoed, as is practised for Carrots, carefully cutting up all the weeds, and also the plants where they are too near each other, leaving them at least six inches asunder. In three weeks or a month's time, the ground should be a second time hoed over, to cut up the weeds, and thin the plants to a greater distance; for by this time they will be past danger, so should not be left nearer than eight or ten inches, if regard is had to the goodness of the leaves: and if it is of the *Swiss* kind, with broad leaves, the plants must not be nearer than a foot: in six weeks after, the ground should be hoed over a third time; which, if properly done, will destroy all the weeds; so that after this, the plants will spread and prevent the weeds from growing, therefore will want but little cleaning for a considerable time, and the leaves will soon be fit for use, when the outer larger leaves should be first gathered, leaving the small inner leaves to grow larger; so that a small spot of ground will supply a moderate family, and furnish a new supply of leaves the whole year, provided the plants are not permitted to run up to seed, for after that their leaves will not be good.

The red Beet is frequently sown with Carrots, Parsneps, or Onions, by the kitchen gardeners near *London*, who draw up their Carrots or Onions when they are young, whereby the Beets will have room to grow, when the other crops are gathered; but where the crops are not timely removed from them, it will be a better method to sow them separately. This sort requires a deep light soil, for as their roots run deep in the ground, so in shallow ground, they will be short and stringy. The seeds should be sown in *March*, and must be treated in the same manner as the former sort; but the plants should not be left nearer than a foot distance, or in good land a foot and an half, for the leaves will cover the ground at that distance. The roots will be fit for use in the autumn, and continue good all the winter; but in the spring, when they begin to shoot, they will be hard and stringy.

BETONICA, Betony.

The Characters are,

The flower is of one leaf, of the lip kind, with a cylindrical incurved tube; the upper lip is roundish, plain, erect, and entire; the lower lip is cut into three parts. It hath four stamina, two long and two shorter, which incline to the upper lip. The germen is quadripartite, which afterward becomes four naked oval seeds, lodged in the empalement.

The Species are,

1. BETONICA *spicâ interraptâ, corollarum laciniâ labii intermediâ emarginatâ*. *Flor. Leyd. Prod.* 316. Betony with an interrupted spike, and the middle segment of the lower lip of the flower indented at the end. This is the *Betonica purpurea*. *C. B. P.* 235. Purple or Wood Betony.

2. BETONICA *foliis radicalibus ovato-cordatis, caulibus lanceolatis obtusis spicâ crassiore*. Greater Danish Betony.

3. BETONICA *foliis triangularibus obtusis spicâ brevior*. The least Alpine Betony.

4. BETONICA *spicâ integrâ, corollarum laciniâ labii intermediâ integerrimâ*. *Flor. Leyd. Prod.* 316. Eastern Betony with very long narrow leaves, and a thicker spike of flowers.

5. BETONICA *foliis lanceolatis obtusis incanis spicâ florum crassiori*. Hoary Italian Betony, with a fleshy flower.

6. BETONICA *verticillata calycibus spinosis*. *Hort. Upsal.* 165. Annual Field Betony with a yellowish white flower.

7. BETONICA *spicâ basi foliosâ*. *Lin. Sp. Plant.* 573. Yellow Mountain Betony.

The first sort grows naturally in woods, and on shady banks, in most parts of *England*, so is seldom cultivated in gardens. This is the sort which is used in medicine, and is greatly esteemed as a vulnerary herb. There is a variety of this with a white flower, which I have often found growing naturally in *Kent*.

The second sort grows naturally in *Denmark*. This differs greatly from our common sort, the lower leaves being much broader and heart-shaped; those upon the stalks are spear-shaped and rounded at the end, and the stalks are larger, stand upright, and are terminated by thicker spikes of flowers.

The third sort grows naturally upon the *Alps*, where it seldom rises more than four inches high; and when cultivated in a garden, not above seven or eight. The leaves of this are much broader at the base than those of the common sort, and are very different in their shape, being triangular and blunt at the end. The flowers grow in very short close spikes, on the top of the stalks.

The fourth sort hath very long, narrow, hairy leaves, neatly crenated on their edges. The flowers grow in very close thick spikes at the top of the stalks, which are larger, and of a lighter purple colour than those of the common sort.

The fifth sort grows naturally in *Italy*. The leaves of this are broader, and not so long as those of the common sort, and are hoary; the stalks are shorter and much thicker, as are also the spikes of flowers, which are larger and of a flesh colour.

The sixth sort is annual, and grows naturally on arable land in *France*, *Italy*, and *Germany*; and if brought into a garden, the seeds will scatter, and produce plenty of the plants without farther care.

The other sorts are perennial plants, which may be propagated by seeds, or parting of their roots. They are all very hardy, but require a shady situation and moist stiff soil, in which they will thrive better than in rich ground.

BETONICA AQUATICA. See Scrophularia.

BETONICA PAULI. See Veronica.

BETULA, the Birch Tree.

The Characters are,

It hath male and female flowers, at separate distances on the same tree; the male flowers are collected in a cylindrical katkin. The flower is composed of three equal florets, fixed to the empalement by a single scale, and have four small stamina. The female flowers grow in a katkin, in the same manner as the male, which are heart-shaped. They have no visible petals, but a short oval germen. It hath no pericarpium, but the seeds are included in the scales of the katkin, which are oval and winged.

The Species are,

1. BETULA foliis ovatis acuminatis serratis. Hort. Cliff. 442. The common Birch tree.

2. BETULA foliis orbiculatis crenatis. Flor. Lap. 266. Dwarf Birch with roundish leaves.

3. BETULA foliis cordatis oblongis acuminatis serratis. Lin. Sp. Plant. 983. Birch tree, with oblong pointed heart-shaped sawed leaves.

4. BETULA foliis rhombico-ovatis acuminatis duplicato-serratis. Lin. Sp. Pl. 982. Black Virginia Birch tree.

The first is the common Birch tree, which is so well known as to need no description. This is not much esteemed for its wood, but however it may be cultivated to advantage upon barren land, where better trees will not thrive; for there is no ground so bad, but this tree will thrive in it; for it will grow in moist springy land, or in dry gravel or sand, where there is little surface: so that upon ground which produced nothing but moss, these trees have succeeded so well, as to be fit to cut in ten years after planting, when they have been sold for near 10 l. per acre standing, and the after produce has been considerably increased. And as many of the woods near *London*, which were chiefly stocked with these trees, have been of late years grubbed up, so the value of these plantations have advanced in proportion. Therefore those persons who are possessed of such poor land, cannot employ it better, than by planting it with these trees, especially as the expence of doing it is not great.

The best method to cultivate this tree, is to furnish yourself with young plants from the woods, where they naturally grow, and are generally found there in great plenty; but in places where there are no young plants to be procured near, they may be raised from seeds, which should be carefully gathered in the autumn, as soon as the scales under which they are lodged begin to open, otherwise they will soon fall out and be lost: the seeds are small, so should not be buried deep in the ground. The autumn is the best season to sow them, and in a shady situation, the plants will thrive better than when they are exposed to the full sun; for in all places where there are any large trees, their seeds fall, and the plants come up well without care; so that if the young plants are not destroyed by cattle, there is generally plenty of them, in all the woods where there are any of these trees. These wild plants should be carefully taken up, not to injure their roots. The ground where they are to be planted, will require no preparation; all that is necessary to be done, is to loosen the ground with a spade or mattock, in the places where the plants are to stand, making holes to receive their roots, covering them again when the plants are placed, closing the earth hard to their roots. If the plants are young, and have not much top, they will require no pruning; but where they have bushy heads, they should be shortened to prevent their being shaken and displaced by the wind. When the plants have taken root, they will require no other care, but to cut down the great weeds which would over-hang the plants, being careful not to cut or injure the young trees. This need not be repeated oftener than twice in a summer the two first years, after which time the plants will be strong enough to keep down the weeds, or at least be out of danger from them.

These may be planted any time from the middle of *October* till the middle of *March*, when the ground is not frozen; but in dry land the autumn is the best season, and the spring for moist. The distance which they should be planted, is four feet square, that they may soon cover the ground, and by standing close they will draw each other up; for in situations where they are much exposed, if they are not pretty close, they will not thrive so well.

If the plants take kindly to the ground, they will be fit to cut in about ten years; and afterward they may be cut every seventh or eighth year, if they are designed for the broom-makers only; but where they are intended for hoops, they should not be cut oftener than every twelfth year.

The broom-makers are constant customers for Birch, in all places within twenty miles of *London*, or where it is near water carriage: in other parts the hoop-benders are the purchasers; but the larger trees are often bought by the turners, and the wood is used for making ox-yokes, and other instruments of husbandry.

In some of the northern parts of *Europe*, the wood of this tree is greatly used for making of carriages and wheels, being hard and of long duration. In *France* it is generally used for making wooden shoes. It makes very good fuel.

In some places these trees are tapped in the spring, and the sap drawn out to make Birch wine, which has been recommended for the stone and gravel, as is also the sap unfermented. The bark of the Birch tree is almost incorruptible. In *Sweden* the houses are covered with it, where it lasts many years. It frequently happens, that the wood is entirely rotten, and the bark perfectly sound and good.

The second sort grows naturally in the northern parts of *Europe*, and upon the *Alps*; this seldom rises above two or three feet high, having slender branches, garnished with round leaves, but seldom produces either male or female flowers here. It is preserved in some curious gardens for the sake of variety, but is a plant of no use.

The third and fourth sorts grow naturally in *North America*. In *Canada* these trees grow to a large size, where the third sort is called *Merisier*. The natives of that country make canoes of the bark of these trees, which are very light, and of long duration.

Both these sorts may be propagated by seeds, in the same manner as the first, and are equally hardy.

BIDENS. *Tourn. Inst. R. H.* 362. Water Hemp Agrimony.

The Characters are,

It hath a compound flower, the middle or disk is composed of hermaphrodite flowers; these have five stamina, with an oblong germen. The female flowers which compose the border are naked; these are all succeeded by a single angular obtuse seed, having two or more bristles or teeth.

There are several species of this plant, which are seldom admitted into gardens, some of which are common weeds in *England*, therefore I shall only mention those which are frequently preserved in the gardens of the curious.

1. BIDENS foliis pinnatis serratis semiuibus erecto-constantibus calycibus frondosis corollis radiatis. *Lin. Sp. Plant.* 832. Broad-leaved *Canada Hemp Agrimony*, with a yellow flower.

2. BIDENS foliis oblongis integerrimis caule dichotomo floribus solitariis sessilibus. *Lin. Sp. Pl.* 832. *Hemp Agrimony* with oblong entire leaves, a stalk divided into two parts, and a single flower growing close to the stalk.

3. BIDENS foliis simplicibus serratis petiolatis, floribus globosis, pedunculis elongatis seminibus levibus. *Lin. Sp. Plant.* 833. *Hemp Agrimony* with single sawed leaves having foot-stalks, globular flowers with longer foot-stalks, and smooth seeds.

4. BIDENS calyce oblongo squamoso seminibus radii corolla non decidua coronatis. *Juss.* *Hemp Agrimony* with an oblong scaly empalement, and the seeds crowned by the rays of the florets, which are permanent. This plant is now titled *Zinnia* by *Linnaeus*.

5. BIDENS foliis ovatis serratis petiolatis, caule fruticoso. *Hort. Cliff.* 399. *Hemp Agrimony* with oval sawed leaves having foot-stalks, and a shrubby stalk.

The first sort grows naturally in *Virginia*, *Maryland*, and *Canada*, where it is often a troublesome weed. It rises from three to four feet high, sending out many horizontal branches garnished with trifoliate leaves, deeply sawed on their edges; the flowers are produced at the end of the branches, in small clusters, which are yellow, and succeeded by oblong square seeds, having two crooked horns, by which they fasten themselves to the clothes of those who pass near them. This is an annual plant, which decays soon after the seeds are ripe.

The second sort grows naturally in warm countries. It is an annual plant, which rises near three feet high, dividing into several branches, which are garnished with oblong entire leaves; the flowers come out single at the divisions of the branches, sitting close; these are white, and succeeded by smooth seeds.

This sort must be sown upon a moderate hot-bed in the spring, and afterward treated like other hardy annual plants, planting them into the full ground the latter end of *May*. They will flower in *June*, and their seeds ripen in autumn, soon after which the plants will decay.

The third sort grows naturally in *South Carolina*, and also at *Campacky*. This is also an annual plant, which rises three feet high; the leaves come out by pairs at each joint, upon long slender foot-stalks. The flowers grow at the extremity of the branches, in small globular heads, which are very white, and are succeeded by smooth seeds. This must be sown upon a hot-bed, and treated as the former. It flowers and seeds about the same time.

The fourth sort grows naturally in *Peru*. It rises to the height of four feet; the stalks are ligneous, and divide into many branches, garnished with oblong smooth leaves, by

pairs: at the extremity of the branches the flowers are produced, each standing single. This empalement is composed of many scales, placed *imbricatim*, like the tiles on a house, and closely embrace the flower. The whole flower continues, and never falls off; so that when the seeds are ripe, the rays of the flower are remaining firm, and adhere so closely to the seeds, as to render it difficult to part them.

The seeds of this plant must be sown upon a hot bed in the spring, and the plants must be transplanted to another hot-bed, to bring the plants forward, but must not be drawn too weak; therefore when the weather is favourable, they should have a large share of air admitted to them. By the beginning of *June* they should be inured to the open air, and about the middle of that month, they should be transplanted, with balls of earth to their roots, some of them into pots, and others into warm borders, shading them until they have taken root. In *July* the plants will flower, and the seeds are ripe in *October*; but in wet cold seasons the seeds will not ripen in *England*, unless the plants are sheltered under glasses.

The fifth sort rises with a shrubby stalk, to the height of six or seven feet. The flowers are produced at the end of the branches in small clusters, each standing upon a long naked foot-stalk; and are succeeded by flat seeds, having two short teeth at their extremity. This sort grows naturally in *Carthagena* in *New Spain*. It is propagated by seeds, which should be sown on a hot-bed in the spring; and the plants must be each planted into a separate small pot, and plunged into a fresh hot-bed, and treated as other tender plants from the same countries, and in autumn placed in the stove: the following summer they will flower and produce seeds, but the plants will abide some years with proper management.

BIFOLIUM, Twyblade. See *Ophrys*.

BIGNONIA. *Tourn. Inst.* 164. Trumpet Flower, or Scarlet Jasmine.

The Characters are,

The flower is of the ringent, or grinning kind, tubulous, with long chaps, which are swelling, and bell shaped; it hath four stamina shorter than the petal, two longer than the other. In the center is an oblong germen, which afterward becomes a bivalve pod, with two cells, filled with compressed winged seeds, lying over each other *imbricatim*.

The Species are,

1. BIGNONIA foliis pinnatis, foliolis incis, geniculis radicatis. *Lin. Hort. Cliff.* 217. *Bignonia* with winged leaves, which are cut on their edges, and roots coming out at their joints, commonly called *Trumpet Flower*.

2. BIGNONIA foliis pinnatis minoribus, foliolis mucronatis, marginibus serratis geniculis radicatis. *Bignonia* with smaller winged leaves, ending in a sharp point, sawed on their edges, and roots coming from the joints.

3. BIGNONIA foliis simplicibus cordatis, caule erecto, floribus diandris. *Lin. Sp. Pl.* 622. Commonly called *Catalpa*.

4. BIGNONIA foliis pinnatis, foliolis lanceolatis acutis serratis, caule erecto, floribus paniculatis erectis. *Bignonia* with winged leaves, having acute sawed lobes, an upright stalk, and flowers growing in panicles erect.

5. BIGNONIA foliis conjugatis cirrhosis foliolis cordato-lanceolatis foliis imis simplicibus. *Vir. Cliff.* 59. *Bignonia* with conjugated leaves, having tendrils and a short pod.

6. BIGNONIA foliis conjugatis, cirrho brevissimo arcuato tripartito. *Lin. Sp. Plant.* 623. *Bignonia* with leaves by pairs, and short arched tendrils, divided into three parts, and a very long pod.

7. BIGNONIA foliis conjugatis cirrhosis, foliolis ovatis acuminatis undatis perennantibus. *Bignonia* with jointed leaves, having tendrils, whose lobes are oval, pointed, waved, and ever-green.

8. *BIGNONIA foliis simplicibus lanceolatis caule volubili.* *Lin. Sp. Plant.* 623. Bignonia with single spear-shaped leaves, and a twining stalk, called sweet-scented Jasmine in *Carolina*.

9. *BIGNONIA foliis digitatis integerrimis.* *Hort. Cliff.* 497. Bignonia with fingered leaves, which are entire.

10. *BIGNONIA foliis conjugatis cirrhosis, foliolis cordato-ovatis, floribus racemoso-paniculatis.* *Lin. Sp. Pl.* 623. Bignonia with jointed leaves, having tendrils, the lobes oval and heart-shaped, and flowers in branching panicles.

11. *BIGNONIA foliis bipinnatis foliolis lanceolatis integris.* *Lin. Sp. Plant.* 625. Bignonia with double winged leaves, which are entire and spear-shaped, commonly called Bastard Guajacum.

12. *BIGNONIA foliis conjugatis cirrhosis foliolis cordatis foliis imis ternatis.* *Vir. Cliff.* 60. Bignonia with jointed heart-shaped leaves, having tendrils, and the under leaves trifoliate.

The first sort grows naturally in *Virginia* and *Canada*. The second grows naturally in *Carolina*, but have both been old inhabitants in some of the *English* gardens, but the first is the most common in *Europe*.

These plants when old have large rough stems, which send out many weak trailing branches, putting out roots at their joints, which fasten themselves to the trees in their natural places of growth, whereby they climb to a great height; and in *Europe*, where they are generally planted against walls, they fasten themselves thereto by their roots, which strike into the mortar of their joint so strongly, as to support their branches, and will rise to the height of forty or fifty feet. The branches are garnished with winged leaves placed opposite, which are composed of four pair of small leaves, terminated by an odd one. The flowers are produced at the ends of the shoots of the same year, in large bunches; they have long swelling tubes, shaped somewhat like a trumpet, from whence they had the appellation of Trumpet Flower; they are of an Orange colour, and appear the beginning of *August*.

The second sort is like the first, but the leaves are smaller; the lobes are placed closer, and the flowers are not so large, and of a paler red colour.

Both these sorts are very hardy, so will thrive in the open air; but as they have trailing branches, so they must be supported; therefore they are usually planted against walls, or buildings, where, if they have room, they will rise very high, so are very proper for covering of buildings, which are unsightly.

They are propagated by seeds, but the young plants so raised do not flower in less than seven or eight years; therefore those which are propagated by cuttings or layers, from flowering plants, are most esteemed, because they will flower in two or three years after planting. The old plants also send out many suckers from their roots, which may be taken off, and transplanted where they are to remain, for these plants will not transplant safely if they are old.

The third sort was brought into *England* by Mr. *Catesby*, who found it growing naturally on the back of *South Carolina*, at a great distance from the *English* settlements, and brought the seeds to *Charles Town*, where the inhabitants have propagated it, and dispersed it through most of the *English* settlements in *North America*, and is now very plenty in the *English* gardens near *London*.

This sort rises with a strong stem, covered with a smooth brown bark, dividing into many branches, which are garnished with very large heart shaped leaves, placed opposite at every joint. The flowers are produced in large branching panicles at the end of the branches, of a dirty white colour, with a few purple spots, and faint stripes of yellow on their inside, and waved on their edges. The flowers are in *America* succeeded by very long taper pods, filled with flat

winged seeds, lying over each other like the scales of fish. These plants, when young, are frequently injured by frost, for as they shoot pretty late in the autumn, so the early frosts often kill the extremity of their branches; but as the plants advance in strength, so they become more hardy, and are seldom injured but in very severe winters. It is late in the spring before these trees come out, which has often caused persons to believe they were dead, and some have been so imprudent, as to cut them down on that supposition, before the tree was so well known.

It may be propagated by cuttings, which should be planted in pots in the spring before the trees begin to push out their shoots, and plunged into a moderate hot-bed. In about six weeks these will have taken root, and made shoots above, therefore should have air admitted to them constantly, and hardened by degrees to bear the open air, into which they should be removed for the summer, but in winter will require some shelter, and the spring following planted out into a nursery bed, where they may stay two years to get strength, and then may be removed to the place where they are to remain.

As these trees have very large leaves, so they require a sheltered situation, for where they are much exposed to strong winds, their leaves are often torn and rendered unsightly, and many times their branches are split and broken by the winds, their leaves being so large, that the wind has great force against them. They delight in a light moist soil, where they make great progress, and in a few years will produce flowers.

The fourth sort is a native of the warmer parts of *America*. This rises with an upright stem, to the height of twelve or fourteen feet, sending out many branches, garnished at every joint, by two long winged leaves placed opposite; the small leaves which compose these, are long and spear-shaped, ending in a point. The flowers are produced in loose panicles at the end of the branches, and are shaped like those of the other species, but spread open more at the top. They are yellow, and are succeeded by compressed pods about six inches long, having two rows of flat winged seeds, like those of the other species.

This sort is propagated by seeds; which must be sown on a hot-bed; and the plants afterward transplanted into separate small pots, and plunged into a fresh hot bed, to bring the plants forward, that they may obtain strength before winter; in the autumn they must be removed into the bark stove, and during the winter should have but little water. The plants should constantly remain in the bark stove, and be treated in the same manner as other tender plants from those countries. The third year from seed they will flower, but they do not produce seeds in *England*.

The fifth sort grows naturally in several parts of *North America*; this hath very slender trailing stalks, which must be supported; so they require the assistance of a wall, and to have a good aspect, for they are impatient of much cold: the branches are clothed with oblong leaves, which remain green all the year; these are often single at bottom, but upward are placed by pairs opposite at each joint; the flowers are produced at the wings of the leaves, which are shaped like those of the Foxglove, and are yellow. This is propagated either by seeds, or layers; the seeds should be sown on a moderate hot-bed, and the plants, when they have obtained strength, should be removed into the open air to harden them; but the first winter they will require a little shelter, and the following spring may be planted where they are to remain.

The sixth sort hath slender stalks like the former, which require the same support; these are garnished with small oval leaves, which are entire, placed opposite by pairs at every joint; at the same places come out the tendrils, by which

which they fasten themselves to the plants which grow near them; the flowers come out from the wings of the leaves, which are shaped like those of the former sort, but are smaller. This grows naturally in *Carolina*, and the *Bahama Islands*, but will live in the open air, if it is planted against a wall to a south aspect, and sheltered in very severe frost. It is propagated in the same manner as the former sort.

The seventh sort hath very weak slender branches, which put out tendrils at the joints: at each joint there are four leaves, two on each side; these are oval pointed, and waved on their edges, of a bright green; the branches ramble very far where they have room.

The eighth sort grows naturally in *South Carolina*, where it spreads over the hedges, and at the season of flowering, perfumes the air to a great distance; it also grows in some parts of *Virginia*, but not in so great plenty as at *Carolina*; the inhabitants there call it Yellow Jasmine, I suppose from the sweet odour of its flowers.

This rises with slender stalks, which twist themselves round the neighbouring plants, and mount to a considerable height; the branches are garnished with oblong pointed leaves, which come out single and opposite to each other at every joint. The flowers come out from the wings of the leaves sometimes by two, at other times four, at each joint; these stand erect, are trumpet-shaped, yellow, and have a very sweet scent, and in the countries where they naturally grow, they are succeeded by short taper pods, filled with small winged seeds.

The plants of this sort, when young, are impatient of cold, so must be sheltered in the winter until they have obtained strength, when they should be planted against a warm wall, and in winter protected from frost by coverings of mats, and the ground about their roots covered with tan. It is propagated by seeds, in the same manner as the former sorts.

The ninth sort grows naturally in *Jamaica*. This rises with an upright stem, near twenty feet high, sending out many lateral branches, which are covered with a white bark. The leaves come out opposite at the joints, upon long foot-stalks; these are composed of five oval stiff leaves, which are joined in one center at their base. They are of a pale green, inclining to white on their under side; the flowers are produced at the ends of the branches, four or five together, on very short foot-stalks; they are narrow at bottom, but the tube enlarges upward, and at the top spreads open wide, and are of a pale bluish colour, and smell sweet, and are in *America* succeeded by taper crooked pods about four inches long, which are filled with oval compressed seeds, with wings of a silver colour.

This sort is a native of the warmer parts of *America*, therefore will not thrive in this country, but in a stove. It is propagated by seeds, which must be sown on a hot-bed, and the plants treated in the same manner as the fourth sort.

The tenth sort rises with lignous stalks, which put out tendrils at the joints, whereby they fasten themselves to the neighbouring plants; the leaves come out on each side the branches, upon pretty long foot-stalks, two at each joint, which are heart-shaped and entire, having a fine hairy down on their under side. The flowers grow in loose spikes at the ends of the branches, which are tubulous, and do not spread much at the top; they are of a Violet colour, and smell very sweet. These in their native country are succeeded by oval, hard, lignous seed vessels, which open in four parts, and are full of compressed winged seeds.

This sort is propagated by seeds, which must be sown on a hot-bed, and the plants must be treated in the same manner as the fourth sort, for they will not thrive in this country unless they are placed in the bark stove.

The eleventh sort grows naturally in the *Bahama Islands*.

This, in the country where it grows naturally, rises to the height of twenty feet, sending out many lateral branches, which are garnished with compound winged leaves, each having eleven alternate wings, with spear-shaped small lobes, which grow alternate, and are entire; at the ends of the branches the flowers are produced in very loose panicles; the foot-stalks branching into three or four, each sustaining a single blue flower; with a long swelling tube, cut into five unequal segments at the top, where it spreads open. The flowers are succeeded by oval seed vessels, which open in two parts, and are filled with flat winged seeds.

The twelfth sort hath a woody stem, which sends out many branches, which have four narrow borders or wings running longitudinally, so as to resemble a square stalk; the leaves are produced by pairs, on each side the branches opposite; they are heart-shaped, smooth, and have short foot-stalks; these have tendrils coming out by their foot-stalks, which fasten themselves to the plants which grow near them, and thereby rise to a great height. The flowers are produced in small clusters from the wings of the leaves, which have pretty long tubes, spread open at the top; they are of a pale yellow colour, and are succeeded by flat pods a foot in length, which have two rows of flat winged seeds, joined to the intermediate partition.

This plant is tender, so must be constantly kept in the bark stove, and treated in the same manner as the fourth sort. It is propagated by seeds, which must be obtained from the country where it grows naturally, for it doth not produce any in *England*.

BIHAI. See *Musa*.

BINDWEED. See *Convolvulus*.

BIRCH TREE. See *Betula*.

BISCUTELLA. *Lin. Gen. Plant.* 724. Buckler Mustard, or Bastard Mithridate Mustard.

The Characters are,

The flower hath four petals, placed in form of a cross; it hath six stamina, four long and two short. In the center is situated an orbicular compressed germen, which afterward becomes a plain compressed erect capsule, with two convex lobes, having two cells, terminated by the rigid style, which is joined to the side of the partition.

The Species are,

1. BISCUTELLA *calycibus nectario utrinque gibbis, filiculis in stylum coeuntibus.* *Lin. Hort. Cliff.* 329. Buckler Mustard, with the cup of the nectarium swelling on each side, and small pods joined to the style.

2. BISCUTELLA *filiculis orbiculato-didymis à stylo divergentibus.* *Hort. Cliff.* 329. Buckler Mustard, with a double orbicular pod, diverging from the style.

3. BISCUTELLA *hirsuta foliis oblongis dentatis semiamplexicaulibus floribus spicatis stylo brevior.* Hairy Buckler Mustard, with oblong indented leaves which half embrace the stalk, flowers growing in spikes, and a shorter style.

4. BISCUTELLA *foliis lanceolato-linearibus hispida, floribus corymbosis terminalibus.* Buckler Mustard, with linear spear-shaped rough leaves, and flowers growing in a corymbus, terminating the stalk.

The first sort grows naturally in the south of *France* and *Italy*, where it rises about a foot high; but in a garden generally grows two feet high, dividing into several branches, having oblong entire leaves a little indented; those on the lower part of the stalk being broader and more obtuse than those on the upper. The flowers are produced at the ends of the branches in loose panicles, of a pale yellow colour; these are succeeded by double round compressed seed vessels, swelling in the middle, where is lodged a single round flat seed.

The second sort grows naturally in the south of *France*, *Italy*, and *Germany*. This hath many long narrow leaves, spreading

spreading near the ground, which are deeply indented on each side, resembling those of Hawkweed, and are hairy; from the center arises the stalk, which divides upward into many branches, having no leaves on them, and are terminated by loose panicles of yellow flowers. These are succeeded by round compressed seed vessels like the former, but are smaller, and the style of the flowers bends from them.

The third sort sends out many oblong hairy leaves, which are slightly indented on their edges; from among these there arises a hairy branching stalk, which grows two feet high, and at each joint is placed one oblong indented leaf, which half embraces the stalk at its base; each branch is terminated by a close spike of pale yellow flowers, which are succeeded by round compressed seed vessels like the other sorts, but the style of the flower, which is joined to them, is shorter than those of the other species.

The fourth sort grows naturally in *Spain* and *Sicily*. This seldom rises more than a foot high; the leaves at the bottom grow upright, they are near four inches long, narrow, stiff, and set on every side with rough prickly hairs. The stalk is single, seldom putting out any side branches, and naked. The flowers are produced in compact clusters at the end of the branches, which are of a deep yellow colour, and shaped like those of the other species.

All these sorts are annual plants, which perish soon after they have perfected their seeds. These should be sown either in spring, or in the autumn, upon a border of light earth, in an open situation, where they are to remain for good. Those which are sown in autumn, the plants will live through the winter without any protection, so will flower earlier the following summer, whereby good seeds may always be obtained; whereas those which are sown in the spring, do, in bad seasons, decay before their seeds are ripe. If their seeds are permitted to scatter, there will be plenty of young plants produced without any care.

BISERRULA. *Lin. Gen. Plant.* 800.

The Characters are,

The flower is papilionaceous, having a large roundish standard, whose edges are reflexed. The wings are oblong, and the keel is of the same length with the wings. It hath ten stamina, nine of which are joined, and the other single. In the center is situated an oblong compressed germen, which afterward becomes a flat narrow pod, indented on both edges like the saw of the sword fish, having two cells, filled with kidney-shaped seeds.

We have but one Species of this genus, which is,

BISSERULA. *Hort. Cliff.* 361. We have no *English* name for this plant.

This is an annual plant, which grows naturally in *Italy*, *Sicily*, *Spain*, and the south of *France*. It sends out many angular stalks, which trail on the ground, and are subdivided into many branches, garnished with long winged leaves, composed of many pairs of lobes, and terminated with an odd one; toward the upper part of the branches come out the pedicle of the flowers, which sustains several small butterfly flowers, of a purplish colour, collected together, which are succeeded by plain pods, indented on both sides the whole length, containing two rows of kidney-shaped seeds.

It is propagated by seeds, which in this country should be sown in the autumn, on a bed of light earth, where the plants are to remain, for they will live in the open air very well. When the plants are come up, they will require no other care, but where they are too near, they should be thinned to about a foot distance from each other. It flowers in *June*, and the seeds ripen in *September*.

BISLINGUA. See *Rufcus*.

BISTORTA, Bistort, or Snakeweed.

There are three different species of this plant, which are found wild in *England*; but as they are seldom planted in gardens, I shall pass them over with only mentioning the common sort, which is used in medicine.

BISTORTA major, radice minus intortá. *C. B.* The common great Bistort, or Snakeweed.

This plant flowers in *May*, and if the season proves moist, will continue to produce new spikes of flowers till *August*: it may be propagated by planting the roots in a moist shady border, either in spring or autumn, which will soon furnish the garden with plants, for it greatly increases by its creeping roots.

BIXA. *Lin. Gen. Plant.* 581. Anotta, by the *French*, Roucou.

The Characters are,

The flower hath a double series of petals, the outer consisting of five, which are large, the inner of the same number and shape, but narrower. It hath a great number of bristly stamina. In the center is situated an oval germen, which afterward becomes an oval heart-shaped capsule, covered with sharp bristles, opening with two valves, with one cell, and filled with angular seeds.

We have but one Species of this genus, viz.

BIXA. *Hort. Cliff.* 211. The Anotta, or Arnotta, by the *French*, Roucou.

This shrub grows naturally in the warm parts of *America*, where it rises with an upright stem, to the height of eight or ten feet, sending out many branches at the top, forming a regular head, garnished with heart-shaped leaves ending in a point, which have long foot-stalks. The flowers are produced in loose panicles at the end of the branches; these are of a pale Peach colour, having large petals, and a great number of bristly stamina of the same colour, in the center. After the flower is past, the germen becomes a heart-shaped, or rather a mitre-shaped seed vessel, covered on the outside with bristles, opening with two valves, and filled with angular seeds, covered with a red pulp or paste, which colours the hands of those who touch it, and is collected for the use of dyers and painters.

This plant is propagated by seeds, which should be sown in a small pot, and plunged into a hot-bed of tanners bark. When the plants are about an inch high, they should be shaken out of the pot and carefully separated, so as not to tear off their tender roots, and each planted in a small pot, and plunged into a fresh hot-bed of tanners bark, observing to shade them until they have taken new root; after which they must be treated as other tender plants from the same country, by admitting fresh air to them in proportion to the warmth of the season; when the heat of the tan declines, it should be turned up from the bottom, and, if necessary, some fresh tan added to renew the heat. If the plants are raised early in the spring, and properly managed, they will be a foot and an half high by the autumn, when they should be removed into the bark stove, and plunged into the tan bed. During the winter, they must have but little water, and while the plants are young, they must have a good share of warmth, otherwise they are very subject to cast their leaves, and frequently lose their tops, which renders them unsightly. They must be constantly kept in the bark stove, otherwise they will not thrive well in *England*.

BLADDER NUT. See *Staphylea*.

BLATTARIA. See *Verbasum*.

BLITUM. *Lin. Gen. Plant.* 14. Strawberry Elite.

The Characters are,

The flower hath no petals, but one bristly stamina the length of the empalement. In the center is situated an oval pointed germen; the empalement afterward becomes an oval compressed capsule, including one globular compressed seed, the size of the capsule.

The Species are,

1. **BLITUM capitellis spicatis terminalibus.** *Hort. Upsal.* 3. Blite with spikes terminated by little heads, commonly called Strawberry Blite, or Strawberry Spinage.

2. **BLITUM capitellis sparsis lateralibus.** *Hort. Upsal.* 3. Blite with small heads growing scatteringly from the sides of the stalks.

The

The first sort grows naturally in *Spain* and *Portugal*, but hath been long preserved in the *Englysh* gardens. This is an annual plant which hath leaves somewhat like those of Spinage; the stalk rises two feet and an half high, the upper part of the stalk hath flowers coming out in small heads, at every joint, and is terminated by a small cluster of the same: after the flowers are past, the little heads swell to the size of Wood Strawberries, and when ripe have the same appearance, being very succulent, and full of a purple juice, which stains the hands of those who bruise them of a deep purple colour.

The second sort grows naturally in the south of *France* and *Italy*. This seldom grows more than one foot high, with smaller leaves than the first, but of the same shape; the flowers are produced at the wings of the leaves, almost the length of the stalk, which are small, and collected in little heads, which are shaped like those of the first, but smaller, and not so deeply coloured.

These are annual plants, which will drop their seeds if permitted, and the plants will come up in plenty the following spring: or if the seeds of either of the sorts are sown in *March* or *April*, upon a bed of common earth, in an open situation, the plants will come up; and, if they are to remain in the place where they are sown, will require no other care but to thin them out, so as to leave them eight or ten inches apart: in *July* the plants will begin to shew their berries, when they will make a pretty appearance: but many people transplant these plants into the borders of their flower gardens, and others plant them in pots, to have them ready for removing to court yards, or to place them upon low walls, among other annual flowers to adorn those places.

When these plants are designed to be removed, they should be transplanted before they shoot up their flower stems, for they will not bear transplanting well afterward. They will require to be duly watered in dry weather, otherwise the plants will stint, and not grow to any size: and, as the flower stems advance, they should be supported by sticks; for if they are not, the branches will fall to the ground, when the berries are grown pretty large and weighty.

BLOODWORT. See *Lapathum*.

BOCCONIA.

The Characters are,

The flower hath four narrow petals, with a great number of very short stamina: in the center is situated a roundish germen, contracted at both ends, which afterward becomes an oval fruit, contracted at both ends, having one cell, full of pulp, including a single round seed.

There is but one Species of this genus at present known, which is,

BOCCONIA. *Lin. Sp. Plant.* 505. Branching Bocconia, with a woolly Cow Parsnep leaf.

It is very common in *Jamaica*, and several other parts of *America*, where it grows to the height of ten or twelve feet; having a fruit trunk, as large as a man's arm, which is covered with a white smooth bark. At the top it divides into several branches, on which the leaves are placed alternately. These leaves are eight or nine inches long, and five or six broad; are deeply sinuated, sometimes almost to the mid-rib, and are of a fine glaucous colour. The whole plant abounds with a yellow juice, like the greater Celandine, which is of an acrid nature; so that it is used by the inhabitants of *America*, to take off warts, and spots from the eyes.

It is propagated by seeds, which should be sown in a pot filled with light fresh earth, early in the spring, and plunged into a hot-bed of tanners bark. When the plants are come up, they should be each transplanted into separate small pots, and plunged into the hot bed again; observing to shade the glasses in the heat of the day, until the plants

have taken root, then they should have a large share of air, by raising the glasses of the hot-bed. When the plants have filled these small pots with their roots, they should be shaken out of them, and planted into pots one size larger, and plunged into the bark stove, where they should have a good share of fresh air in warm weather. These plants must be constantly kept in the stove, being too tender to thrive in this country, in any other situation. The singular beauty of this plant renders it worthy of a place in every curious collection; and it seems the *Indians* were very fond of it, for *Hernandez* tells us, the *Indian* kings planted it in their gardens.

BOERHAAVIA. Hogweed.

The Characters are,

The flower hath one bell-shaped petal, which is pentangular and entire. It hath in some species one, and in others two short stamina. The germen is situated below the receptacle, which afterward becomes a single oblong seed, having no cover.

The Species are,

1. BOERHAAVIA caule recto. *Lin. Sp. Pl.* 3. Boerhaavia with an erect stalk.

2. BOERHAAVIA caule diffuso. *Lin. Sp. Pl.* 3. Boerhaavia with a diffused stalk.

3. BOERHAAVIA caule scandente. *Lin. Sp. Plant.* 3. Boerhaavia with a climbing stalk.

4. BOERHAAVIA foliis ovatis, foribus lateralibus compactis, caule hirsuto procumbente. Boerhaavia with oval leaves, flowers coming from the wings of the leaves in close heads, and a hairy trailing stalk.

The first sort was discovered by the late Dr. *Houfston*, at *La Vera Cruz*, in 1731. This rises with an upright smooth stalk, two feet high, at each joint it hath two oval pointed leaves growing opposite, upon foot-stalks, an inch long. At the joints, which are far asunder, come out small side branches, growing erect; these, as also the large stalk, are terminated by loose panicles of flesh-coloured flowers, which are succeeded by oblong glutinous seeds.

The second sort grows naturally in *Jamaica*. This sends out many diffused stalks, a foot and an half long, garnished with small roundish leaves at each joint. The flowers grow very scatteringly upon long branching foot-stalks from the wings of the leaves, as also at the end of the branches, which are of a pale red colour, and are succeeded by seeds like the former.

The third sort sends out several stalks from the root, which divide into many branches, and trail over whatever plants grow near them, and rise to the height of five or six feet; are garnished with heart-shaped leaves, growing by pairs opposite at each joint upon long foot-stalks, which are of the colour and consistence of those of the greater Chickweed. The flowers grow in loose umbels at the extremity of the branches, which are yellow, and are succeeded by small oblong viscous seeds.

The fourth sort sends out many trailing hairy stalks, which divide into smaller branches, which are garnished with oval leaves at every joint; and at the wings of the leaves come out the naked foot-stalks, sustaining a small close head of scarlet flowers, which are very fugaceous, seldom standing more than half a day before their petals drop; these are succeeded by short oblong seeds.

The first, second, and fourth sorts are annual plants, which decay in autumn, but the third sort is perennial. They are all tender plants, so will not thrive in the open air in *England*; they are propagated by seeds, which must be sown on a hot-bed in the spring; and when the plants are fit to remove, they should be each planted in a small pot, and plunged into the hot-bed, and treated as other tender exotics. When they are grown too tall to remain under the common frame, a plant or two of each sort should be placed in the stove, the other may be turned out of the pots,

pots, and planted in a warm border, where, if the season proves warm, they will perfect their seeds; but as these are subject to fail in cold seasons, so those in the stove will always ripen their seeds in autumn; the third sort may be preserved in a warm stove two or three years.

BOMBAX. *Lin. Gen. Pl.* 580. Silk Cotton Tree.

The Characters are,

The flower is quinquefid and spreading. It hath many stamina, which are the length of the petal: in the center is situated the round germen. The empalement afterward becomes a large oblong turbinated capsule, having five cells, which are lignous, containing many roundish seeds, wrapped in a soft down.

The Species are,

1. **BOMBAX foliis digitatis caule aculeato.** *Lin. Sp. Pl.* 511. Silk Cotton with fingered leaves, and a prickly stalk.

2. **BOMBAX foliis digitatis caule inermi.** *Lin. Sp. Plant.* 511. Silk Cotton with fingered leaves, and a smooth stalk.

3. **BOMBAX foliis quinque-angularibus villosis, caule geniculato herbaceo.** Silk Cotton with five cornered hairy leaves, and a jointed herbaceous stalk.

The first and second sorts grow naturally in both Indies, where they arrive to a great magnitude, being some of the tallest trees in those countries; but the wood is very light; and not much valued, except for making of canoes, which is the chief use made of them. Their trunks are so large, as when hollowed, to make very large ones.

These trees generally grow with very strait stems; those of the first sort are closely armed with short strong spines; but the second hath very smooth stems, which in the young plants are of a bright green, but after a few years, they are covered with a gray, or Ash-coloured bark, which turns to a brown as the trees grow older. The branches toward the top are garnished with leaves composed of five, seven, or nine oblong smooth little leaves, which are spear-shaped, and join to one center at their base, where they adhere to the long foot-stalk. The flower buds appear at the end of the branches, and soon after the flowers expand, which are composed of five oblong purple petals, with a great number of stamina in the center; when these fall off, they are succeeded by oval fruit, as large as a swan's egg, having a thick lignous cover, which, when ripe, opens in five parts, and is full of a dark short Cotton, inclosing many roundish seeds, as large as small Pease.

The third sort was sent me from the Spanish West-Indies, where it grows naturally, but I do not know to what size; the plants which have been raised here, have soft herbaceous stalks very full of joints, and do not appear as if they would become woody, for the plants of several years growth have soft pithy stems. The leaves come out on long hairy foot-stalks at the top of the plants; these have the appearance of those of the Mallow tree, but are larger, and of a thicker consistence, and on their under side are covered with a short, brown, hairy down, and are cut on their edges into five angles. These plants have not as yet flowered in England, nor have I received any information what flowers they produce, but by the pods and seeds, it appears evidently to be of this genus. The down inclosed in these pods is of a fine purple colour, and I have been informed that the inhabitants of the countries where the trees grow naturally, spin it, and work it into garments, which they wear without dying of any other colour.

The plants of all these sorts are propagated by seeds, which must be sown on a hot-bed in the spring; those of the two first sorts will be strong enough to transplant in a short time after they are up, when they should be each planted in a small pot, and plunged into a moderate hot-bed of tanners bark, being careful to shade them from the sun, till they have taken fresh root, after which they should have a large share of air admitted to them when the weather is

warm, to prevent their being drawn up weak. In this bed they may remain till autumn (provided there is room for the plants under the glasses;) when the heat of the bed declines, the tan should be stirred up, and fresh added to it, and if the plants have filled the pots with their roots, they should be shifted into pots a little larger; but there must be care taken not to over-pot them, for nothing is more injurious to these plants, than to be put into large pots, in which they will never thrive. In the autumn they must be removed into the bark stove, where they must constantly remain, being too tender to thrive in this country, in any other situation. In winter they must have but little wet, especially if they cast their leaves; but in the summer they should be frequently refreshed with water, and in warm weather must have plenty of fresh air admitted to them.

These plants require a large stove where they may have room to grow, but as they are several years old before they flower, in the countries where they grow naturally, so there is little hopes of their producing any in England.

BONDUC. See Guilandina.

BONTIA. *Lin. Gen. Plant.* 709. Barbadoes Wild Olive.

The Characters are,

The flower is of the ringent kind, gaping at the brim; the upper lip is erect, the lower lip is trifid and turns backward. It hath four stamina, two of them being longer than the other. In the center is situated the oval germen, which afterward becomes an oval berry with one cell, including a nut of the same form.

We have but one Species of this genus, viz.

BONTIA. *Lin. Sp. Pl.* Barbadoes Wild Olive.

This plant is greatly cultivated in the gardens at Barbadoes, for making of hedges; than which there is not a more proper plant to thrive in those hot countries, it being an ever-green, and of quick growth. I have been informed, that from cuttings (planted in the rainy season, when they have immediately taken root) there has been a complete hedge, four or five feet high, in eighteen months. In England it is preserved in stoves. It may be raised from seeds, which should be sown on a hot-bed early in the spring, that the plants may acquire strength before winter. When the plants are come up, they must be transplanted out each into a separate small pot, and plunged into a moderate hot-bed of tanners bark, observing to shade them until they have taken root; after which, they must have a large share of air in warm weather, and be often refreshed with water. In winter they must be placed in the stove, where they should have a moderate degree of warmth, and but little water during that season. In summer they may be exposed abroad, in very hot weather, in a sheltered situation. With this management, these plants will produce flowers and fruit in three years from seed. They may also be propagated by cuttings, which should be planted in the spring, before the plants have begun to shoot. These must be put into pots, and plunged into a moderate hot-bed, observing to shade them until they have taken root; after which they must be treated as hath been directed for the seedling plants. These plants being ever-green, and growing in a pyramidal form, make a pretty variety in the stove, amongst other exotic plants.

BONUS HENRICUS. See Chenopodium.

BORBONIA. *Lin. Gen. Plant.* 764.

The Characters are,

The flower hath five leaves, and is of the butterfly shape. The standard is obtuse and reflexed, the wings are heart shaped and shorter than the standard; the keel hath two obtuse lunulated leaves. It hath nine stamina joined in a cylinder, and one upper standing single. In the center is situated a germen, which afterward becomes a round pointed pod terminated with a spine, having one cell inclosing a kidney-shaped seed.

The Species are,

1. *BORBONIA foliis lanceolatis multinerviis integerrimis*. Lin. Sp. Plant. 707. Borbonia with entire spear-shaped leaves having many nerves.

2. *BORBONIA foliis cordatis multinerviis integerrimis*. Lin. Sp. Plant. 707. Borbonia with entire heart-shaped leaves having many nerves.

3. *BORBONIA foliis lanceolatis trinerviis integerrimis*. Lin. Sp. Pl. 707. Borbonia with entire spear-shaped leaves having three veins.

The plants grow naturally at the *Cape of Good Hope*, where they rise to the height of ten or twelve feet; but in *Europe*, they are seldom more than four or five; having slender stems dividing into several branches, garnished with stiff leaves, placed alternately; those of the first sort are narrow, long, and end in a sharp point. The flowers come out from between the leaves at the end of the branches in small clusters, these are yellow, and shaped like those of the Broom.

The second sort hath broader leaves than the first; the stalks of this are slender, covered with white bark. The leaves embrace these at their base. The flowers are produced in small clusters at the end of the branches, which are the of same shape and colour as those of the former, but are larger.

The third sort hath stronger stalks than either of the former, which are garnished almost their whole length, as are also the branches with stiff spear-shaped leaves, having three longitudinal nerves in each. The flowers are produced at the extremity of the branches, each standing on a separate foot-stalk. They are of the same shape and colour with the former, but are larger.

As these plants do not perfect their seeds in this country, so they are with difficulty propagated here. The only method by which I have yet succeeded, hath been by laying down their young shoots; but these are commonly two years laid before they put out roots fit to be separated from the old plant. In laying these down, the joint which is laid in the ground should be slit upward, as is practised in laying Carnations, and the bark of the tongue at bottom taken off. The best time to lay these down is in the beginning of *September*, and the shoots most proper for this purpose, are those which come out immediately from the root, and of the same year's growth, not only from their situation being near the ground, and thereby better adapted for laying; but these are also more apt to put out roots, than any of the upper branches.

But where good seeds can be procured, that is the more eligible method of propagating the plants; for those raised from the seeds make the straightest plants, and are quicker of growth. When good seeds are obtained, they should be sown in pots as soon as they are received; which if it happens in the autumn, the pots should be plunged into an old bed of tanners bark, under a frame, where they may remain all the winter, being careful that they have not much wet; and in the spring, the pots should be plunged into a hot-bed, which will bring up the plants in five or six weeks. When these are fit to remove, they should be each planted into a separate small pot, and plunged into a moderate hot-bed, observing to shade them until they have taken fresh root. After this they must by degrees be inured to the open air, into which they should be removed in *June*, and placed in a sheltered situation; where they may remain till autumn, when they must be removed into the green-house, and placed where they may enjoy the air and sun; during the winter season, these plants must be sparingly watered; but in summer, when they are placed abroad, they will require to be frequently refreshed, but must not have too much water given them each time.

BORRAGO, Borage.

The Characters are,

The flower is of one leaf, having a short tube, and spread wide open above. The chaps of the flower are crowned by five prominences. It hath five stamina which are joined together. It hath four germen situated in the center, which after-ward becomes so many roundish rough seeds, inserted in the cavities of the receptacle.

The Species are,

1. *BORRAGO foliis omnibus alternis, calycibus patentibus*. Hort. Upsal. 34. Borage with all the leaves growing alternate, and a spreading flower cup.

2. *BORRAGO calycibus tubo corollæ brevioribus, foliis cordatis*. Hort. Cliff. 45. Borage of *Constantinople* with a blue reflexed flower, and a swelling flower cup.

3. *BORRAGO calycinis foliolis ovatis acutis erectis*. Hort. Cliff. 45. Borage with the leaves of the empalement oval, pointed and erect.

4. *BORRAGO foliis ramificationum oppositis calycinis foliolis sagittatis*. Lin. Sp. Pl. 137. Borage with opposite leaves on the branches, and spear-shaped leaves to the flower cup.

The first is the common Borage, whose flowers are used in medicine, and the herb for cool tankards in summer. Of this, there are three varieties which generally retain their difference from seeds; one hath a white, and another a red flower: the third hath variegated leaves.

This common Borage is an annual plant, which, if permitted to scatter its seeds, the plants will come up in plenty without care; or if the seeds are sown either in spring or autumn, on a spot of open ground where the plants are designed to remain, and the ground hoed, to destroy the weeds, and also to cut up the plants where they are too near each other; after this they will require no farther care, unless the weeds should come up again, then the ground should be a second time hoed over to destroy them, which if well performed, and in dry weather, will clear the ground from weeds, so it will require no more cleaning till the Borage is decayed.

The second sort grows near *Constantinople*. This is a perennial plant, with a thick fleshy root, which spreads under the surface of the ground, and is thereby propagated with great facility. It sends out many oblong heart-shaped leaves from the root, having long hairy foot-stalks; from the root arises the flower stem, which is more than two feet high when fully grown, having at the joints a single small leaf without a foot-stalk. The upper part of the stalk branches out into several small foot-stalks, which are terminated by loose panicles of flowers; these are of a pale blue colour, and the petal is reflexed backward, so that the connected stamina and style are left naked. It flowers in *March*, and the seeds ripen in *May*.

The third and fourth sorts grow naturally in *Africa*; these are both annual plants, which rarely rise a foot high, having rough stalks; those of the third sort are set on by pairs, with short foot-stalks, but the leaves of the fourth closely embrace the stalks at their base; the flowers come out on short foot-stalks from the wings of the leaves, and also at the top of the stalks. Those of the third sort are white, and those of the fourth a pale yellow, but neither of them make any great appearance, so are seldom cultivated, but in botanick gardens for variety.

If the seeds of these plants are sown in the autumn, in a warm border, the plants will live through the winter, and flower early the following summer, so will produce good seeds; for when they are sown in the spring, if the season is not very favourable, they do not perfect their seeds in *England*. The seeds should be sown where the plants are to remain, for they seldom succeed when they are transplanted.

BOSIA.

The Characters are,

The flower hath no petals, but five stamina which are as long as the empalement; in the center is situated an oval oblong pointed germen, which afterward becomes a globular berry with one cell including one pointed seed.

We have but one sort of this plant, viz.

BOSIA. *Lin. Hort. Cliff.* 84. Commonly called Golden-rod Tree.

This plant is a native of the islands of the *Canaries*; and it hath also been since found in some of the *British* islands in *America*: it was first brought into *England* from the *Canaries*, and has been long an inhabitant of the *English* gardens; but I have not as yet seen any of these plants in flower, though I have had many old plants under my care more than forty years: it makes a pretty strong woody shrub, growing with a stem as large as a middling person's leg; the branches come out very irregular, and make considerable shoots in summer, which should be shortened every spring. These branches retain their leaves till toward the spring, when they fall away, and new leaves are produced soon after: it may be propagated by cuttings planted in the spring, and the plants must be housed in the winter, being too tender to live through the winter, in the open air, in this country.

BOTRYS. See *Chenopodium*.

BOX-TREE. See *Buxus*.

BRABEJUM, *African Almond*, vulgò.

The Characters are,

The flower is composed of four narrow obtuse petals which are erect; it hath four slender stamina. In the center is a small hairy germen, which afterward becomes an oval, hairy, dry berry, inclosing an oval nut.

We have but one sort of this plant, viz.

BRABEJUM. *Hort. Cliff.* *African*, or *Ethiopian Almond*, with a silky fruit.

This tree is a native of the country about the *Cape of Good Hope*.

In *Europe* it seldom grows above eight or nine feet high, but in its native soil it is a tree of middling growth; as it is too tender to live through the winter in the open air, so we cannot expect to see it grow to a great size.

It rises with an upright stem, which is soft, and full of pith within, and covered with a brown bark. The leaves come out all round the branches at each joint, they are indented on their edges, standing on very short foot-stalks. The flowers are produced toward the end of their shoots, which are of a pale colour, inclining to white.

This plant is, with difficulty, propagated by layers, which are often two years before they make roots strong enough to be taken from the plants; when the branches are laid down, it will be a good method to slit them at a joint (as is practised in laying *Carnations*) which will promote their taking root.

The best time to make the layers is in *April*, just as the plants are beginning to shoot, and the layers must always be made of the former year's shoots. As this plant is very difficult to propagate, so it is very scarce in *Europe*, there being but few in the *Dutch* gardens at present.

The plants must have a good green-house in winter, but in summer should be set abroad in a sheltered situation, where, when they arrive to a proper age, they will thrive, and annually produce flowers in the spring, so will make a pretty variety among other exotick plants in the green-house.

BRANCA URSINA. See *Acanthus*.

BRASSICA, the Cabbage.

The Characters are,

The flower is cross-shaped, having four petals, and four oval

nectarious glands. It hath six stamina, which are erect, two of which are opposite, and the other four are longer. It hath a taper germen the length of the stamina, which afterward becomes a long taper pod, depressed on each side, and is terminated by the apex of the intermediate partition, which divides it into two cells, filled with round seeds.

I shall first enumerate the species, which are distinct, and afterward mention the varieties, which are cultivated for the table.

The Species are,

1. BRASSICA radice caulescente tereti carnosâ. *Hort. Cliff.* 338. The common white Cabbage.

2. BRASSICA radice caulescente orbiculari carnosâ, foliis sessilibus. Turnep-rooted Cabbage.

3. BRASSICA radice caulescente tereti carnosâ, floralibus multicaulis. The Cauliflower.

4. BRASSICA radice cauleque tenui ramofo perenni foliis alternis marginibus incis. Taller shrubby branching Sea Cabbage.

5. BRASSICA foliis lanceolato-ovatis glabris indivisis dentatis. *Hort. Upsal.* 191. Cabbage with entire oval spear-shaped smooth leaves, which are indented.

6. BRASSICA foliis oblongo cordatis amplexicaulibus, integerrimis. *Champaign* Colewort with a thorough wax leaf, and a purple flower.

7. BRASSICA foliis cordatis semiamplexicaulibus, marginibus dentatis, siliquis tetragonis longissimis. Eastern perfoliated Colewort with a white flower and a quadrangular pod.

8. BRASSICA radice caulescente tereti, foliis inferioribus petiolatis superioribus semiamplexicaulibus. The wild Navew, or Cole Seed.

The Varieties of the first sort are,

1. Brassica sabauda hyberna. *Lob. Icon.* The Savoy Cabbage, commonly called Savoy.

2. Brassica capitata rubra. *C. B. P.* 111. The red Cabbage.

3. Brassica capitata alba pyramidalis. The sugar loaf Cabbage.

4. Brassica capitata alba præcox. The early Cabbage.

5. Brassica peregrina moschum olens. *H. R. Par.* Foreign Musk Cabbage.

6. Brassica capitata alba minor Muscovitica. *H. A.* Small *Russia* Cabbage.

7. Brassica capitata alba compressa. *Boerb. Ind. Alt.* 11. The large sided Cabbage.

8. Brassica capitata viridis Sabauda. *Boerb. Ind.* 11. The green Savoy.

9. Brassica fimbriata. *C. B. P.* 111. The Borecole.

10. Brassica fimbriata virescens. *Boerb. Ind.* 2. 12. Green Borecole.

11. Brassica fimbriata Siberica. *Boerb. Ind.* 2. 12. *Siberian* Borecole, called by some *Scotch Kale*.

The Varieties of the third sort are,

1. Brassica Italica purpurea Broccoli dicta. *Juss.* Purple Broccoli.

2. Brassica Italica alba Broccoli dicta. *Juss.* White Broccoli.

The second sort, I believe, never varies, for I have cultivated it many years, and have not found it to alter. This grows naturally on the sea shore, near *Dover*. It hath a perennial branching stalk, in which it differs from all the other species. In very severe winters, when the other sorts are destroyed, this is a necessary plant, for the most severe frosts do not injure it. The flower-stalks grow from the end of the branches, and spread out horizontally; but those which arise from the center of the plants, grow erect, and seldom put out branches.

The two sorts of Broccoli I take to be only varieties of the Cauliflower, for although these may with care be kept distinct,

distinct, yet I doubt, if they were to stand near each other for seeds, if they would not intermix; and I am rather inclined to believe this, from the various changes which I have observed in all these sorts, for I have frequently had Cauliflowers of a green colour, with flower buds regularly formed at the ends of the shoots, as those of Broccoli, though the colour was different, and the white Broccoli approaches so near to the Cauliflower, as to be with difficulty distinguished from it; yet when these are cultivated with care, and never suffered to stand near each other, when left to produce seeds, they may be kept very distinct, in the same garden; for the variations of these plants is not occasioned from the soil, but the mixing of the farina of the flowers with each other, where they are planted near together; therefore those persons who are curious to preserve the several varieties distinct, should never suffer the different kinds to stand near each other for seed.

The Cauliflower has been much more improved in *England*, than in any other part of *Europe*. In *France* they rarely have Cauliflowers till *Michaelmas*; and *Holland* is generally supplied with them from *England*. In many parts of *Germany* there was none of them cultivated till within a few years past; and most parts of *Europe* are supplied with seeds from hence.

The eighth sort, which is generally known by the title of Rape or Cole Seed, is much cultivated in the isle of *Ely*, and some other parts of *England* for its seed, from which the Rape oil is drawn; and it hath also been cultivated of late years, in other places, for feeding of cattle, to great advantage.

The Cole Seed, when cultivated for feeding of cattle, should be sown about the middle of *June*. The ground for this should be prepared for it in the same manner as for Turneps. The quantity of seeds for an acre of land, is from six to eight pounds, and as the price of the seed is not great, so it is better to allow eight pounds; for if the plants are too close in any part, they may be easily thinned, when the ground is hoed, which must be performed in the same manner as is practised for Turneps, with this difference only, of leaving these much nearer together; for as they have fibrous roots, and slender stalks, so they do not require near so much room. These plants should have a second hoeing, about five or six weeks after the first, which, if well performed in dry weather, will entirely destroy the weeds, so they will require no farther culture. Where there is not an immediate want of food, these plants had better be kept as a reserve for hard weather, or spring seed, when there may be a scarcity of other green food. If the heads are cut off, and the stalks left in the ground, they will shoot again early in the spring, and produce a good second crop in *April*, which may be either fed off, or permitted to run to seeds, as is the practice, where this is cultivated for the seeds: but if the first is fed down, there should be care taken that the cattle do not destroy their stems, or pull them out of the ground. As this plant is so hardy, as not to be destroyed by frost, so it is of great service in hard winters for feeding of ewes; for when the ground is so hard frozen, as that Turneps cannot be taken up, these plants may be cut off, for a constant supply. This will afford late food after the Turneps are run to seed; and if it is afterward permitted to stand for seed, one acre will produce as much as, at a moderate computation, will sell for five pounds, clear of charges.

Partridges, pheasants, turkeys, and most other fowl, are very fond of this plant; so that wherever it is cultivated, if there are any birds in the neighbourhood, they will constantly lie among these plants.

The seeds of this plant are sown in gardens, for winter and spring sallots, this being one of the small sallot herbs.

The common white, red, flat, and long-sided Cabbages are chiefly cultivated for winter use: the seeds of these sorts must be sown the beginning or middle of *April*, in beds of good fresh earth; and when the young plants have about eight leaves, they should be pricked out into shady borders, about three or four inches square, that they may acquire strength, and to prevent their growing long shanked.

About the middle of *June*, you must transplant them out, where they are to remain for good (which in the kitchen gardens near *London*, is commonly between Cauliflowers, Artichokes, &c. at about two feet and an half distance in the rows); but if they are planted for a full crop in a clear spot of ground, the distance from row to row should be three feet and an half, and in the rows two feet and an half asunder: if the season should prove dry when they are transplanted out, you must water them every other evening, until they have taken fresh root; and afterwards, as the plants advance in height, you should draw the earth about their stems with a hoe, which will keep the earth moist about their roots, and greatly strengthen the plants.

These Cabbages will some of them be fit for use soon after *Michaelmas*, and will continue until the end of *February*, if they are not destroyed by bad weather; to prevent which, the gardeners near *London* pull up their Cabbages in *November*, and trench their ground up in ridges, laying their Cabbages against their ridges as close as possible on one side, burying their stems in the ground: in this manner they let them remain till after *Christmas*, when they cut them for the market; and although the outer part of the Cabbage be decayed (as is often the case in very wet or hard winters), yet, if the Cabbages were large and hard when laid, the inside will remain sound.

The *Russian* Cabbage was formerly in much greater esteem than at present, it being now only to be found in particular gentlemen's gardens, who cultivate it for their own use. This must be sown late in the spring of the year, and managed as those before directed, with this difference only, that these must be sooner planted out for good, and must have an open clear spot of ground, and require much less distance every way, for it is but a very small hard Cabbage. This sort will not continue long before they will break, and run up to seed.

The early and sugar loaf Cabbages are commonly sown for summer use, and are what the gardeners about *London* commonly call *Michaelmas* Cabbages. The season for sowing of these is about the end of *July*, or beginning of *August*, in an open spot of ground; and when the plants have got eight leaves, you must prick them into beds at about three or four inches distance every way, that the plants may grow strong and short shanked; and toward the end of *October*, you should plant them out for good: the distance that these require is, three feet row from row, and two feet and an half asunder in the rows. The ground must be kept clean from weeds, and the earth drawn up about your Cabbage plants.

In *May*, if your plants were of the early kind, they will turn in their leaves for cabbaging; at which time, the gardeners near *London*, in order to obtain them a little sooner, tie in their leaves close with a slender Osier-twig to blanch their middle; by which means, they have them at least a fortnight sooner than they could have if they were left untied.

The early Cabbage being the first, we should choose (if for a gentleman's use) to plant the fewer of them, and a greater quantity of the sugar-loaf kind, which comes after them; for the early kind will not supply the kitchen long, generally cabbaging apace when they begin, and as soon grow hard, and burst open; but the sugar-loaf kind is longer before it comes, and is as slow in its cabbaging; and being of an hollow kind, will continue good for a long time.

Although

Although I before have advised the planting out of Cabbages for good in *October*, yet the sugar-loaf kind may be planted out in *February*, and will succeed as well as if planted earlier, with this difference only, that they will be later before they cabbage. You should also reserve some plants of the early kind in some well-sheltered spot of ground, to supply your plantation, in case of a defect; for in mild winters many of the plants are apt to run to seed, especially when their seeds are sown too early, and in severe winters they are often destroyed.

The *Savoy* Cabbages are propagated for winter use, as being generally esteemed the better when pinched by the frost: these must be sown about the end of *April*, and treated after the manner as was directed for the common white Cabbage; with this difference, that these may be planted at a closer distance than those; two feet and an half square will be sufficient. These are always much better when planted in an open situation, which is clear from trees and hedges; for in close places they are very subject to be eaten almost up by caterpillars, and other vermin, especially if the autumn prove dry.

The Borecole may be also treated in the same manner, but need not be planted above one foot asunder in the rows, and the rows two feet distance: these are never eaten till the frost hath rendered them tender, for otherwise they are tough and bitter.

The seeds of the Broccoli, (of which there are several kinds, *viz.* the *Roman*, or purple, and the *Neapolitan*, or white, and the black Broccoli, with some others; but the *Roman* is chiefly preferred to them all) should be sown about the latter end of *May*, or beginning of *June*, and when the plants are grown to have eight leaves, transplant them into beds (as was directed for the common Cabbage); and toward the latter end of *July* they will be fit to plant out for good, which should be into some well sheltered spot of ground, but not under the drip of trees: the distance these require is about a foot and an half in the rows, and two feet row from row. The soil in which they should be planted, ought to be rather light than heavy, such as are the kitchen gardens near *London*: if your plants succeed well (as there will be little reason to doubt, unless the winter prove extreme hard), they will begin to shew their small heads, which are somewhat like a Cauliflower, but of a purple colour about the end of *December*, and will continue eatable till the middle of *April*.

The brown or black Broccoli is by many persons greatly esteemed, though it doth not deserve a place in the kitchen-garden, where the *Roman* Broccoli can be obtained, which is much sweeter, and will continue longer in season: indeed, the brown sort is much hardier, so that it will thrive in the coldest situations, where the *Roman* Broccoli is sometimes destroyed in very hard winters. The brown sort should be sown in the middle of *May*, and managed as hath been directed for the common Cabbage, and should be planted at the same distance, which is about two feet and an half asunder. This will grow very tall, so should have the earth drawn up to their stems as they advance in height. This doth not form heads so perfect as the *Roman* Broccoli; the stems and hearts of the plants are the parts which are eaten.

The *Roman* Broccoli (if well managed) will have large heads, which appear in the center of the plants, like clusters of buds. These heads should be cut before they run up to seed, with about four or five inches of the stem; the skin of these stems should be stripped off, before they are boiled. After the first heads are cut off, there will be a great number of side shoots produced from the stems, which will have small heads to them, but are full as well flavoured as the large.

The *Naples* Broccoli hath white heads, very like those of the Cauliflower, and eats so like it, as not be distinguished from it.

Besides this first crop of Broccoli (which is usually sown in the end of *May*), it will be proper to sow another crop the beginning of *July*, which will come in to supply the table the latter end of *March*, and the beginning of *April*; and being very young, will be extremely tender and sweet.

In order to save good seeds of this kind of Broccoli in *England*, you should reserve a few of the largest heads of the first crop, which should be let remain to run up to seed, and all the under shoots should be constantly stripped off, leaving only the main stem to flower and seed. If this be duly observed, and no other sort of Cabbage permitted to seed near them, the seeds will be as good as those procured from abroad, and the sort may be preserved in perfection many years.

The Turnep-rooted Cabbage was formerly more cultivated in *England*, than at present; for since other sorts have been introduced which are much better flavoured, this sort has been neglected. There are some persons who esteem this kind for soups; but it is generally too strong for most *English* palates, and is seldom good but in hard winters, which will render it tender, and less strong.

At the end of *June*, the plants should be transplanted out where they are to remain, allowing them two feet distance every way, observing to water them until they have taken root; and as their stems advance, the earth should be drawn up to them with a hoe, which will preserve a moisture about their roots, and prevent their stems from drying, and growing woody, so that the plants will grow more freely; but it should not be drawn very high, for as it is the globular part of the stalk which is eaten, so that should not be covered. In winter they will be fit for use, when they should be cut off, and the stalks pulled out of the ground, and thrown away, as being good for nothing after the stems are cut off.

The curled Colewort or *Siberian* Borecole is now more generally esteemed than the former. Being extreme hardy, so is never injured by cold, but is always sweeter in severe winters, than in mild seasons. This may be propagated by sowing of the seeds the beginning of *July*; and when the plants are strong enough for transplanting, they should be planted in rows about a foot and a half asunder, and ten inches distance in the rows. These will be fit for use after *Christmas*, and continue good until *April*, so that they are very useful in a family.

The Musk Cabbage. This may be propagated in the same manner as the common Cabbage, and should be allowed the same distance: it will be fit for use in *October*, *November*, and *December*; but, if the winter proves hard, these will be destroyed much sooner than the common sort.

The common Colewort or *Dorsetshire* Kale, is now almost lost near *London*, where their markets are usually supplied with Cabbage plants, instead of them. Indeed, where farmers sow Coleworts to feed their milch-cattle in the spring, when there is a scarcity of herbage, the common Colewort is to be preferred, as being so very hardy, that no frost will destroy it. The best method to cultivate this plant in the fields is, to sow the seeds about the beginning of *July*, choosing a moist season, which will bring up the plants in about ten days or a fortnight: the quantity of seed for an acre of land is nine pounds; when the plants have got five or six leaves, they should be hoed, as is practised for Turneps, cutting down all the weeds from amongst the plants, and also thinning the plants where they are too thick; but they should be kept thicker than Turneps, because they are more in danger of being destroyed by the fly: this work should

should be performed in dry weather, that the weeds may be killed. About six weeks after, the plants should have a second hoeing, which, if carefully performed in dry weather, will entirely destroy the weeds, and make the ground clean, so that they will require no farther culture: in the spring they may either be drawn up and carried out to feed the cattle, or they may be turned in to feed upon them as they stand; but the former method is to be preferred, because there will be little waste; whereas, when the cattle are turned in amongst the plants, they will tread down and destroy more than they eat, especially if they are not fenced off by hurdles.

The two last sorts of Cabbage are varieties fit for a botanick garden, but are plants of no use. They are annual plants, and perish when they have perfected their seeds.

The best method to save the seeds of all the best sorts of Cabbages is: about the end of *November* you should make choice of some of your best Cabbages, which you should pull up, and carry to some shed, or other covered place, where you should hang them up for three or four days by their stalks, that the water may drain from between their leaves; then plant them in some border, under a hedge or pale, quite down to the middle of the Cabbage, leaving only the upper part of the Cabbage above ground, observing to raise the earth about it, so that it may stand a little above the level of the ground; especially if the ground is wet, they will require to be raised pretty much above the surface.

If the winter should prove very hard, you must lay a little straw or Pease-haulm lightly upon them, to secure them from the frost; taking it off as often as the weather proves mild, lest by keeping them too close they should rot. In the spring of the year these Cabbages will shoot out strongly, and divide into a great number of small branches: you must therefore support their stems, to prevent their being broken off by the wind; and if the weather should be very hot and dry when they are in flower, you should refresh them with water once a week all over the branches, which will greatly promote their feeding, and preserve them from mildew.

When the pods begin to change brown, you will do well to cut off the extreme part of every shoot with the pods, which will strengthen your seeds; for it is generally observed, that those seeds which grow near the top of the shoots, are very subject to run to seed before they cabbage; so that by this there will be no loss, but a great advantage.

When your seeds begin to ripen, you must be particularly careful, that the birds do not destroy it, for they are very fond of these seeds. The best method I know to prevent this, is to get a quantity of birdlime, and dawb over a parcel of slender twigs, which should be fastened at each end to stronger sticks, and placed near the upper part of the seed, in different places, so that the birds may alight upon them, by which means they will be fastened thereto; where you must let them remain, if they cannot get off themselves: and although there should not above two or three birds be caught, yet it will sufficiently terrify the rest, that they will not come to that place again for a considerable time after, as I have experienced.

When your seeds are fully ripe, you must cut it off; and, after drying, thresh it out, and preserve it in bags for use.

But in planting of Cabbages for seed, I would advise never to plant more than one sort in a place, or near one another: as for example, never plant red and white Cabbages near each other, nor Savoy with white or red Cabbages; for I am very certain they will, by the commixture of their effluvia, produce a mixture of kinds; and it is wholly owing to this neglect, that the gardeners rarely save any good red

Cabbage seed in *England*, but are obliged to procure fresh seeds from abroad, as supposing the soil or climate of *England* alters them from red to white, and of a mixed kind between both; whereas, if they would plant red Cabbages by themselves for seeds, and not suffer any other to be near them, they might continue the kind as good in *England*, as in any other part of the world.

Cauliflowers have of late years been so far improved in *England*, as to exceed in goodness and magnitude what are produced in most parts of *Europe*, and by the skill of the gardener, are continued for several months together; but the most common season for the great crop, is in *May*, *June*, and *July*. I shall therefore begin with directions for obtaining them in this season.

Having procured a parcel of good seed, you must sow it about the twenty-first of *August*, upon an old Cucumber or Melon bed, sifting a little earth over the seeds, about a quarter of an inch thick; and if the weather should prove extreme hot and dry, you should shade the bed with mats, to prevent the earth from drying too fast, and give it gentle waterings, as you may see occasion. In about a month's time after sowing, your plants will be fit to prick out; you should therefore put some fresh earth upon your Cucumber or Melon beds, or where these are not to be had, some beds should be made with a little new dung, which should be trodden down close, to prevent the worms from getting through it; but it should not be hot dung, which would be hurtful to the plants at this season, especially if it proves hot; into this bed you should prick your young plants, at about two inches square, observing to shade and water them at first planting; but do not water them too much after they are growing, nor suffer them to receive too much rain, if the season should prove wet, which would be apt to make them black shanked (as the gardeners term it, which is no less than a rottenness in their stems), and is the destruction of the plants so affected.

In this bed they should continue till about the thirtieth of *October*, when they must be removed into the place where they are to remain during the winter season, which, for the first sowing, is commonly under bell or hand glasses, to have early Cauliflowers, and these should be of an early kind; but in order to have a succession during the season, you should be provided with another more late kind, which should be sown four or five days after the other, and managed as was directed for them.

In order to have very early Cauliflowers, you should make choice of a good rich spot of ground, that is well defended from the north, east, and west winds, with hedges, pales, or walls; but the first is to be preferred, if made with reeds, because the winds will fall dead in these, and not reverberate as by pales, or walls. This ground should be well trenched, burying therein a good quantity of rotten dung; then level your ground; and if it be naturally a wet soil, you should raise it up in beds about two feet and a half, or three feet broad, and four inches above the level of the ground: but if your ground is moderately dry, you need not raise it at all: then plant your plants, allowing about two feet six inches distance from glass to glass, in the rows, always putting two good plants under each glass, which may be at about four inches from each other; and if you design them for a full crop, they may be three feet and a half, row from row: but if you intend to make ridges for Cucumbers between the rows of Cauliflower plants (as is generally practised by the gardeners near *London*), you must then make your rows eight feet asunder.

When you have planted your plants, if the ground is very dry, you should give them a little water, and then set your glasses over them, which may remain close down over them, until they have taken root, which will be in about a week

week or ten days time, unless there should be a kindly shower of rain; in which case you may set off the glasses, that the plants may receive the benefit of it; and in about ten days after planting, you should be provided with a parcel of forked sticks or bricks, with which you should raise your glasses about three or four inches on the side toward the south, that your plants may have free air: in this manner your glasses should remain over the plants, night and day, unless in frosty weather, when you should set them down as close as possible: or if the weather should prove very warm, which many times happens in *November*, and sometimes in *December*; in this case, you should keep your glasses off in the day time, and put them on only in the night, lest, by keeping the glasses over them too much, you should draw them into flower at that season; which is many times the case in mild winters, especially if unskilfully managed.

Toward the latter end of *February*, if the weather proves mild, you should prepare another good spot of ground, to remove some of the plants into, from under the glasses, which should be well dunged and trenched (as before); then set off your glasses, and, after making choice of one of the most promising plants under each glass, which should remain for good, take away the other plant, by raising it up with a trowel, &c. so as to preserve as much earth to the root as possible; but have a great regard to the plant that is to remain, not to disturb or prejudice its roots: then plant the plants which you have taken out, at the distance before directed, *viz.* If for a full crop, three feet and an half, row from row; but if for ridges of Cucumbers between them, eight feet, and two feet four inches distance in the rows: then, with a small hoe, draw the earth up to the stems of the plants which were left under the glasses, taking great care not to let the earth fall into their hearts; and set your glasses over them again, raising your props an inch or two higher than before, to give them more air, observing to take them off whenever there may be some gentle showers, which will greatly refresh the plants.

In a little time after, if you find your plants grow so fast as to fill the glasses with their leaves, you should then slightly dig about the plants, and raise the ground about them in a bed broad enough for the glasses to stand, about four inches high, which will give your plants a great deal of room by raising the glasses so much higher, when they are set over them; and by this means they may be kept covered until *April*, which otherwise they could not, without prejudice to the leaves of the plants: and this is a great advantage to them; for many times we have returns of severe frosts at the latter end of *March*, which prove very hurtful to these plants, if exposed thereto, especially after having been nursed up under glasses.

After you have finished your beds, you may set your glasses over your plants again, observing to raise your props pretty high, especially if the weather be mild, that they may have free air to strengthen them; and in mild soft weather set off your glasses, as also in gentle showers of rain: and now you must begin to harden them by degrees to endure the open air; however, it is advisable to let your glasses remain over them as long as possible, if the nights should be frosty, which will greatly forward your plants: but be sure do not let your glasses remain upon them in very hot sun-shine, especially if their leaves press against the sides of the glasses; for I have often observed, in such cases, that the moisture which hath risen from the ground, together with the perspiration of the plants, which, by the glasses remaining over them, hath been detained upon the leaves of the plants, and when the sun hath shone hot upon the sides of the glasses, hath acquired such a powerful heat from the beams thereof, as to scald all their larger leaves, to the no small prejudice of the plants: nay, sometimes I have

seen large quantities of plants so affected therewith, as never to be worth any thing after.

If your plants have succeeded well, toward the end of *April* some of them will begin to fruit: you must therefore look over them carefully every other day, and when you see the flower plainly appear, you must break down some of the inner leaves over it to guard it from the sun, which would make the flower yellow and unsightly, if exposed thereto; and when you find your flower at its full bigness (which you may know by its outside parting, as if it would run), you must then draw it out of the ground, and not cut them off, leaving the stalk in the ground, as is by some practised; and if they are designed for present use, you may cut them out of their leaves; but if designed to keep, you should preserve their leaves about them, and put them into a cool place: the best time for pulling of them is in a morning, before the sun hath exhales the moisture; for Cauliflowers, pulled in the heat of the day, lose that firmness which they naturally have, and become tough.

But to return to our second crop (the plants being raised and managed as was directed for the early crop, until the end of *October*); you must then prepare some beds, either to be covered with glass frames, or arched over with hoops, to be covered with mats, &c. These beds should have some dung laid at the bottom, about six inches or a foot thick, according to the size of your plants; for if they are small, the bed should be thicker of dung, to bring them forward, and so *vice versa*: this dung should be beat down close with a fork, in order to prevent the worms from finding their way through it; then lay some good fresh earth about four or five inches thick thereon, in which you should plant your plants about two inches and an half square, observing to shade and water them until they have taken new root; but be sure do not keep your coverings close, for the warmth of the dung will occasion a large damp in the bed, which, if pent in, will greatly injure the plants.

When your plants have taken root, you must give them as much free open air as possible; by keeping the glasses off in the day-time, as much as the weather will permit; and in the night, or at such times as the glasses require to be kept on, raise them up with props to let in fresh air, unless in frosty weather; at which time the glasses should be covered with mats, straw, or Pease-haulm, &c. but this is not to be done but in very hard frosts: you must also observe to guard them against great rain, which in winter time is very hurtful to them, but in mild weather, if the glasses are kept on, they should be propped to admit fresh air; and if the under leaves grow yellow and decay, be sure to pick them off; for if the weather should prove very bad in winter, so that you should be obliged to keep them close covered for two or three days together, as it sometimes happens, these decayed leaves will render the inclosed air very noxious; and the plants, perspiring pretty much at that time, are often destroyed in vast quantities.

In the beginning of *February*, if the weather be mild, you must begin to harden your plants by degrees, that they may be prepared for transplantation; the ground where you intend to plant your Cauliflowers out for good (which should be quite open from trees, &c. and rather moist than dry), having been well dunged and dug, should be sown with Radishes a week or fortnight before you intend to plant out your Cauliflowers: the reason why I mention the sowing of Radishes particularly, is this; *viz.* that if there are not some Radishes amongst them, and the month of *May* should prove hot and dry, as it sometimes happens, the fly will seize your Cauliflowers, and eat their leaves full of holes, to their prejudice, and sometimes their destruction; whereas, if there are Radishes upon the spot, the flies will take to them, and never meddle with the Cauliflowers so long;

long as they last: indeed, the gardeners near *London* mix Spinage with their Radish seed, and so have a double crop; which is an advantage where ground is dear, or where persons are streightened for room; otherwise it is very well to have only one crop amongst the Cauliflowers, that the ground may be cleared in time.

Your ground being ready, and the season good, about the middle of *February*, you may begin to plant out your Cauliflowers: the distance which is generally allowed by the gardeners near *London* (who plant other crops between their Cauliflowers to succeed them, as Cucumbers for pickling, and winter Cabbages) is every other row four feet and an half apart, and the intermediate rows two feet and an half, and two feet two inches distance in the rows; so that in the latter end of *May*, or beginning of *June* (when the Radishes and Spinage are cleared off), they put in seeds of Cucumbers for pickling, in the middle of the wide rows, at three feet and an half apart; and in the narrow rows, plant Cabbages for winter use, at two feet two inches distance, so that these stand each of them exactly in the middle of the square between four Cauliflower plants; and these, after the Cauliflowers are gone off, will have full room to grow, and the crop be hereby continued in a succession through the whole season.

There are many people, who are very fond of watering Cauliflower plants in summer; but the gardeners near *London* have almost wholly laid aside this practice, as finding a deal of trouble and charge to little purpose; for if the ground be so very dry as not to produce tolerable good Cauliflowers without water, it seldom happens, that watering of them renders them much better; and when once they have been watered, if it is not constantly continued, it had been much better for them if they never had any; as also, if it be given them in the middle of the day, it rather helps to scald them: so that, upon the whole, if care be taken to keep the earth drawn up to their stems, and clear them from every thing that grows near them, that they may have free open air, you will find that they will succeed better without than with water, where any of these cautions are not strictly observed.

But in order to have a third crop of Cauliflowers, you should make a slender hot-bed in *February*, in which you should sow the seeds, covering them a quarter of an inch thick with light mould, and covering the bed with glass frames. When the plants are come up, and have gotten four or five leaves, you should prepare another hot-bed to prick them into, which may be about two inches square; and in the beginning of *April* harden them by degrees, to fit them for transplanting, which should be done the middle of that month, at the distance directed for the second crop, and must be managed accordingly: these (if the soil is moist where they are planted, or the season cool and moist) will produce good Cauliflowers about a month after the second crop is gone, whereby their season will be greatly prolonged.

There is also a fourth crop of Cauliflowers, which is raised by sowing the seed about the twenty-third of *May*; and being transplanted, as hath been before directed, will produce good Cauliflowers in a kindly season, and good soil, after *Michaelmas*, and continue through *October* and *November*, and, if the season permit, often a great part of *December*.

The reason why I fix particular days for the sowing of this seed, is because two or three days often make a great difference in their plants; and because these are the days usually fixed by the gardeners near *London*, who have found their crops to succeed best when sown at those times, although one day, more or less, will make no great odds. I have also, in this edition, altered the days to the new style.

BREYNIA. *Plum. N. Gen.* 40. *Lin. Gen.* 566.

The Characters are,

The flower hath four oval petals, which are a little longer than the empalement. It hath a great number of slender stamina. In the center is situated a slender oblong obtuse germen, which afterward becomes a long soft fleshy pod opening in two valves, with one cell, inclosing a row of fleshy kidney-shaped seeds.

The Species are,

1. BREYNIA *foliis oblongo-ovalibus*. *Prod. Leyd.* 476. Breynia with oblong oval leaves.

2. BREYNIA *foliis lanceolatis serratis, petiolatis*. Breynia with sawed spear-shaped leaves, which have long foot-stalks.

The first sort grows naturally in most of the sugar islands in *America*.

This, in the countries where it naturally grows, rises with an upright stem, to the height of twenty-five or thirty feet, dividing into many branches at the top, which are covered with an Ash-coloured bark, and closely garnished with oblong leaves, ending in a point; which are of the consistence with those of the Bay tree, white on their under side, but of an Olive colour on their upper side, and are very smooth and shining.

The flowers are produced in loose panicles at the extremity of the branches, each standing on a separate foot-stalk. In the center arises the long germen, attended by a great number of slender purple stamina, which are stretched out a great length beyond the petals. After the flowers decay, the germen becomes a long, cylindrical, fleshy pod, containing three or four seeds; situated at a distance; where each seed is lodged, the pod has a large swelling, but is contracted between them.

The second sort grows at *Campeachy*. This grows to a larger size than the former, and sends out many lateral branches at the top, which are garnished with oblong serrated leaves, standing on pretty long foot-stalks; these are of a much thinner consistence than those of the other sort, and are green on both sides. As this sort hath not as yet flowered in *England*, so I can give no account of their shape or colour.

These plants are both very impatient of cold; therefore must be preserved in stoves, otherwise they will not live through the winter in this climate. They may be propagated by seeds, which should be sown on a hot-bed early in the spring, and when the plants are come up two inches high, they should be carefully transplanted, each into a separate small pot, and then plunged into a moderate hot-bed of tanners bark, observing to water and shade them until they have taken new root. If the plants have thriven so well as to fill the pots with their roots by the middle of *August*, they may be then shaken out carefully, so as to preserve the earth to their roots; and after trimming the fibres on the outside of the ball of earth, they should be put into pots of a size larger, then plunge them again into the hot-bed, to promote their taking good root before the autumn is cold. In this bed they may remain until the end of *September*, when they must be placed in the bark stove, where, during the winter season, they should be kept in a temperate heat, and must be often refreshed with water; but it must not be given them in large quantities at this season.

BROMELIA. *Plum. Nov. Gen.* 46. *Tab.* 8. *Lin. Gen. Plant.* 356.

The Characters are,

The flower hath three long narrow petals, each having a nectarium joined to it above the base: it hath six stamina. The germen is situated below the receptacle, which afterward becomes an oblong capsule, divided by a partition in the middle, to which the seeds are fixed quite round; these are smooth and almost cylindrical.

Dr. Dillenius has supposed this to be same with Plumier's Karatas, which mistake he was led into by Plumier's Drawings, where the flower of his Caraguata is joined to the fruit of his Karatas, and *vice versa*.

The Species are,

1. BROMELIA *foliis radicalibus dentato-spinosis caulinis integerrimis*. Lin. Sp. Pl. 286. Bromelia with lower leaves indented, and prickly, and those of the stalks entire.

2. BROMELIA *foliis serrato-spinosis obtusis, spicis alternis*. Lin. Sp. Plant. 285. Bromelia with sawed prickly leaves, which are obtuse, and spikes of flowers growing alternate.

The first sort hath leaves very like some of the sorts of Aloes, but not so thick and succulent, which are sharply indented on their edges, where they are armed with strong black spines; from the center of the plant arises the flower stalk, which is near three feet high, the lower part of which is garnished with entire leaves, placed alternately at every joint. The upper part of the stalk is garnished with flowers, set in a loose spike, or thyse, quite round; these have three narrow herbaceous petals, fitting upon the germen, and within are six slender stamina, with the style, which are shorter than the petals. These are succeeded by oval seed-vessels, having a longitudinal partition, in the center of which are fastened cylindrical seeds on every side, which are smooth.

The second sort hath shorter leaves than the first, which are narrow at the base, increasing in width gradually to the top, where they are broadest; they are sharply sawed on their edges, and are of a deep green colour. The flower stem arises from the center of the plant, which divides upward into several branches; the upper part of these are garnished with spikes of flowers, which come out alternately from the side of the branches, each having a narrow entire leaf just below it, which is longer than the spike. The flowers are placed very close on the spikes, each having three short petals, situated upon the globular empalement; when these decay, the empalement turns to an oval pointed seed-vessel, inclosing seeds of the same shape with the former.

Both these plants grow naturally in very warm countries. The first sort grows also on the coast of Guinea.

These plants are propagated by seeds, which must be sown in small pots, and plunged into a moderate hot-bed of tanners bark. If the seeds are good, the plants will appear in about five or six weeks, and in a month or six weeks after will be fit to transplant, when they should be carefully shaken out of the pots, and each planted in a separate small pot; then they must be plunged again into a moderate hot-bed, observing frequently to sprinkle them over with water, but be cautious of giving them too much, lest the roots should be thereby rotted. During the summer season the plants should have a moderate share of air, in proportion to the heat of the weather; and, in autumn they must be removed into the bark stove, and treated in the same manner as the Ananas, or Pine Apple, with which management they will make good progress.

These plants make a pretty variety in the hot house, so those who have room, may allow a plant or two of each sort to have a place in their collection of exotic plants.

BROOM, the common. See Spartium.

BROOM, the Spanish. See Spartium and Genista.

BROWALLIA. Lin. Gen. Pl. 691. Hort. Cliff.

The Characters are,

The flower is funnel-shaped, of one leaf, having a cylindrical tube, twice the length of the empalement; the upper part is spread open, and divided into five parts. It hath four stamina included in the chaps of the petal, the two upper being very short, and the two under broad, and longer. In the center is situated an oval germen. The empalement afterward becomes an oval obtuse vessel

with one cell, opening at the top in four parts, and filled with small compressed seeds.

We have but one Species of this genus, viz.

BROWALLIA. Hort. Cliff. 138. This is the Dalea. Hort. Cbell. Ind. 67. We have no English name for this plant.

The seeds of this plant, were sent me by Mr. Robert Millar, from Panama, in the year 1735. The plants are annual, so perish in autumn; the seeds must be sown upon a hot bed in the spring, and the plants brought forward on another, otherwise they will not perfect their seeds in England. Some of these plants may be transplanted in June, into the borders of the flower garden, where, if the season proves warm, they will flower and perfect seeds; but lest these should fail, there should be a plant or two kept in the stove. They usually grow about two feet high, and spread out into lateral branches on every side the stalk, garnished with oval leaves which are entire, and have short foot-stalks. Toward the end of the branches the flowers are produced singly, upon pretty long foot-stalks, arising from the wing of the leaf. These have a short empalement of one leaf, which is cut into five parts; out of the center of the empalement the flower arises, which is crooked and bent downward; the top of the tube is spread open, and the brim, or open part of the flower, has some resemblance to a lip flower, being irregular; it is of a light blue colour, sometimes inclining to a purple or red, and often there are flowers of three colours on the same plant. When these fail away, the germen in the center becomes an oval capsule of one cell, filled with small brown angular seeds. It flowers in July, August, and September, and the seeds are ripe in five or six weeks after.

BRUNELLA, Self-heal. See Prunella.

BRUNSFELSIA. Plum. Nov. Gen. 12. Lin. Gen. Pl. 230.

The Characters are,

The flower is of one leaf, and funnel-shaped, having a long tube, but spreads open at the top; it hath five stamina the length of the tube, which are inserted in the petal. In the center is placed a small round germen. The empalement afterward becomes a globular berry with one cell, inclosing a great number of small seeds, which adhere to the skin of the fruit.

We know but one Species of this genus, viz.

BRUNSFELSIA. Lin. Sp. Pl. 191. Brunfelsia with a white flower, and a soft Saffron coloured fruit.

This plant rises with a woody stem, to the height of eight or ten feet, sending out many side branches, which are covered with a rough bark, and are garnished with oblong oval leaves. At the extremity of the branches, the flowers are produced, generally three or four together. These are almost as large as those of the greater Bindweed, but have very long narrow tubes, which are hairy. After the flower is past, the empalement turns to a round soft fruit, inclosing many oval seeds, which are situated close to the cover or skin, to which they adhere.

This plant grows naturally in most of the sugar islands in America, but in the English gardens, it is at present very rare; it may be propagated from seeds, which should be sown early in the spring in pots, and plunged into a hot-bed of tanners bark. When the plants are come up, they should be transplanted each in a separate small pot, and plunged into the hot-bed again, observing to water and shade the plants until they have taken root. When the plants have advanced so high as not to be contained in the frames, they should be removed into the bark stove, where, during the summer months, they should have a large share of free air, but in the winter they must be kept very close. These plants may also be increased by planting their cuttings in the spring, before they shoot, in pots filled with fresh light earth, and plunged into a hot-bed of tanners bark.

BRUSCUS. See Ruscus.

BRYONIA, Bryony.

The Characters are,

It hath male and female flowers on the same plant. The male flowers are bell shaped, adhering to the empalment, and cut into five segments. They have three short stamina. The female flowers sit upon the germen; the petal is the same with those of the male. The germen, which is under the flower, afterward becomes a smooth globular berry, containing oval seeds adhering to the skin.

The Species are,

1. BRYONIA foliis palmatis utrinque calloso scabris. Hort. Cliff. 453. Rough or white Bryony with red berries.

2. BRYONIA foliis palmatis quinquepartitis utrinque lævibus, laciniis pinnatifidis. Lin. Sp. Plant. 1013. African tuberous rooted Bryony, with indented leaves and an herbaceous flower.

3. BRYONIA foliis palmatis supra calloso-punctatis. Hort. Cliff. 453. Spotted Bryony of Crete.

4. BRYONIA foliis trilobis supra calloso punctatis, fructu racemoso ovali. Bryony with a red Olive-shaped fruit.

5. BRYONIA foliis palmatis, laciniis lanceolatis, supra punctatis infernè lævibus, fructu ovato sparsis. American Bryony with a variegated fruit.

6. BRYONIA foliis palmatis quinquepartitis hirsutis, laciniis obtusis. Bryony with hairy palmated leaves divided into five parts, and obtuse segments.

The first sort grows upon dry banks, under hedges, in many parts of *England*. The roots of this plant have been formerly, by impostors, brought into a human shape, and carried about the country, and shewn for Mandrakes to the common people, who were easily imposed on by their credulity, and these got good livings thereby. The method which these people practised, was to find a young thriving Bryony plant, then they opened the earth all round the plant, being careful not to disturb the lower fibres; and (being prepared with such a mould, as is used by the people who make plaster figures) they fixed the mould close to the root, fastening it with wire, to keep it in its proper situation; then they filled the earth about the root, leaving it to grow to the shape of the mould, which in one summer it will do; so that if this be done in *March*, by *September* it will have the shape. The leaves of this plant are also often imposed on the people in the market for Mandrake leaves, although there is no resemblance between them, nor any agreement in quality.

The second and fourth sorts are perennial plants, but their branches decay every winter. These roots must be planted in pots filled with fresh light earth, and in winter must be placed in the green-house, to protect them from frost, and great rains; which would destroy them, if they were exposed thereto. In summer, they may be exposed to the open air, and must be frequently refreshed with water in dry weather. These plants will flower in *July*, and in warm summers will perfect their seeds.

The third, fifth, and sixth sorts, are annual plants; these must be raised on a hot-bed early in the spring, and when the plants are about three inches high, they should be each transplanted into a small pot, and plunged into a hot-bed of tanners bark. When the plants are grown so large, as to ramble about on the surface of the bed, and begin to entangle with other plants, they should be shifted into larger pots, and placed in the bark stove, where their branches may be trained to the wall, or against an espalier, that they may have sun and air, which is absolutely necessary for their producing fruit. When these plants are full of fruit, they make a pretty variety in the stove amongst other exotick plants.

BRYONIA NIGRA. See Tamnus.

BUBON. Lin. Gen. Plant. 312. Macedonian Parsley.

The Characters are,

It hath an umbelliferous flower; the small umbels have twenty rays. The empalment of the flower is permanent; the flower is composed of five spear-shaped petals, which turn inward; it hath five stamina. The oval germen is situated below the flower, which afterward becomes an oval channelled hairy fruit, dividing in two parts, each having an oval seed, plain on one side, but convex on the other.

The Species are,

1. BUBON foliolis rhombeo ovatis crenatis, umbellis numerosissimis. Hort. Cliff. 95. Macedonian Parsley.

2. BUBON foliolis linearibus. Hort. Cliff. 95. Hard or rigid Ferula, with very short leaves.

3. BUBON foliolis rhombeis serratis glabris, umbellis paucis. Hort. Cliff. 96. African Ferula bearing Galbanum, with a leaf and appearance of Lovage.

4. BUBON foliolis glabris inferioribus rhombeis serratis, superioribus pinnatifidis tridentatis. Prod. Leyd. 100. Galbanum-bearing African Ferula, with the Mock Chervil leaf.

The first sends out many leaves from the root, the lower growing almost horizontally, spreading near the surface of the ground, which are garnished with smooth rhomb-shaped leaves, which are of a bright pale green colour, and sawed on their edges. In the center of the plant arises the flower stem, which is little more than a foot high, dividing into many branches, each being terminated by an umbel of white flowers, which are succeeded by oblong hairy seeds.

This plant in warm countries is biennial, the plants which rise from seeds one year, produce flowers and seeds the next, and then perish: but in *England*, they seldom flower till the third or fourth year from seed; but whenever the plant flowers, it always dies.

It is propagated by seeds, which should be sown on a bed of light sandy earth in *April*. When the plants come up, they will require no other care but to be kept clean from weeds, till the beginning of *October*, when they should be carefully taken up, and planted in a warm border of dry ground; and a few of them should be put into pots, that they may be sheltered under a frame in winter; for in severe frost, those which are exposed to the open air, are frequently killed; though, in moderate winters, they will live abroad without covering. The seeds of this plant is one of the ingredients in *Venice treacle*.

The second sort grows naturally in *Sicily*. This is a low perennial plant, having short stiff leaves, which are very narrow: the flower stalk rises near a foot high, which is terminated by an umbel of small white flowers, which are succeeded by small oblong channelled seeds. It is propagated by seeds, and should have a dry soil and a warm situation, where the plants will continue several years. It is a plant of little beauty or use, so is only preserved for the sake of variety.

The third sort rises with an upright stalk, to the height of eight or ten feet, which at bottom is woody, having a purplish bark, covered with a whitish powder, which comes off when handled; the upper part of the stalk is garnished with leaves at every joint, the foot-stalks half embracing them at their base, and are set with leaves like those of Lovage, but smaller, and of a gray colour; the top of the stalk is terminated by an umbel of yellow flowers, which are succeeded by oblong channelled seeds, which have a thin membrane or wing on their border. When any part of the plant is broken, there issues out a little thin milk of a cream colour, which hath a strong scent of Galbanum.

The fourth sort, like the third, rises with a lignous stalk, about the same height, and is garnished with leaves at each joint, which branch-out like the former; but the small leaves or lobes are narrow and indented, like those of Ballard Hemlock. The stalk is terminated by an umbel of small yellow

yellow flowers, which are succeeded by seeds like of those of the former sort.

They are propagated by seeds, which should be sown in pots filled with light loamy earth, as soon as they arrive; which, if it happens toward autumn, should be plunged into an old bed of tanners bark, where the heat is gone, and screened from frost in winter. In the spring the plants will come up, and by the middle of *April* will be fit to remove, when they should be carefully shaken out of the pots, and planted each into separate small pots: then plunge the pots into the tan again, and water them to settle the earth to the roots of the plants, and shade them from the sun in the day time, until they have taken new root; after this they must be inured gradually to bear the open air, into which they should be removed in *June*, and placed with other exotick plants in a sheltered situation, where they may remain till autumn, when they must be removed into the green-house, and placed where they may enjoy as much of the sun and air as possible, but defended from frost.

These plants make a pretty variety in the green-house in winter, and when they are placed abroad in the summer with other green-house plants, they have a good effect, especially when they are grown to a large size. In warm summers, the plants will perfect their seeds in *England*, if they stand in a warm sheltered situation.

The Galbanum of the shops is supposed to be procured from both these sorts indifferently; and upon breaking of their leaves, the juice which flows out from the wound, hath a strong odour of the Galbanum, which is a confirmation of it.

BUCKSHORN, or HARTSHORN. See *Plantago*.

BUDDING. See *Inoculating*.

BUDDLEJA. *Houft. Mss. Lin. Gen. Plant.* 131.

The Characters are,

The flower is of one leaf, bell-shaped, and quadrifid; it hath four short stamina, which are placed at the divisions of the petal. The oblong germen is situated in the center, which afterward becomes an oblong capsule, having two cells filled with small seeds.

The Species are,

1. BUDDLEJA *foliis ovatis serratis oppositis subtus pilosis, floribus spicatis racemosis, caule fruticoso*. Shrubby Buddleja with leaves growing by pairs, sawed at their edges, and yellow flowers growing in spikes.

2. BUDDLEJA *foliis lanceolatis acuminatis integerrimis oppositis, spicis interruptis, caule fruticoso ramoso*. Buddleja with pointed spear-shaped leaves which are entire, and placed opposite, divided spikes, and a branching shrubby stalk.

The first sort grows naturally in *Jamaica*, and most of the other islands in *America*, where it rises to the height of ten or twelve feet, with a thick woody stem, covered with a gray bark; and sends out many branches toward the top, which come out opposite; as are also the leaves so placed, which are oval, and covered on their under side with a brown hairy down. At the end of the branches the flowers are produced in long close spikes, branching out in clusters, which are yellow, consisting of one leaf, cut into four segments; these are succeeded by oblong capsules, filled with small seeds.

The second sort grows at *Carthagena*. This rises much taller than the first, and divides into a great number of slender branches, which are covered with a russet hairy bark, garnished with long spear-shaped leaves, ending in sharp points: at the end of the branches are produced branching spikes of white flowers, growing in whorls round the stalks, with small spaces between each. The leaves of this are much thinner than those of the first sort, and have scarce any down on their under side; the spikes of flowers grow more erect, so form a large loose spike at the end of every branch.

These plants grow naturally in gullies or other low sheltered spots, in the *West-Indies*, their branches being too

tender to resist the force of strong winds, so are rarely seen in open situations.

They are propagated by seeds, which should be brought over in their capsules or pods, for those which are taken out before they are sent seldom grow. They should be sown in pots, and very lightly covered; for as the seeds are very small, so if they are buried deep in the ground, they will perish. The pots should be plunged into a moderate hot-bed. If the seeds are fresh and good, the plants will come up in about six weeks; and if they grow kindly, will be large enough to transplant in about a month after. Then they should be carefully separated, and each planted into a separate small pot, and plunged into the hot-bed again, observing to shade them from the sun until they have taken new root. After the plants have taken fresh root in the pots, there should be fresh air admitted to them every day, in proportion to the warmth of the season; they must also be frequently, but moderately, refreshed with water. When the plants have filled these small pots with their roots, it will be proper to shift them into pots one size larger, that they may have time to take good root again, before the cold weather comes on. When these are new potted, the tan should be turned over, to renew the heat, and if it is wanted, some fresh tan must be added to the bed, to encourage the roots of the plants. In this bed they may remain till autumn, when they must be removed into the stove, and plunged into the tan bed; where they must constantly remain, for they are too tender to thrive in this country, if they are not so treated. During the winter they must have but little water, and should be kept warm; but in summer they should have fresh air admitted to them constantly when the weather is warm, and frequently sprinkled all over with water. With this management, the plants will flower the fourth year from seeds, and continue so to do every year after, and will make a good appearance in the stove.

BUGLOSSUM. See *Anchusa*, and *Lycopsis*.

BUGULA. *Tourn. Inst. R. H.* 208. *Tab.* 98. Bugle.

The Characters are,

The flower is of one leaf, of the lip kind, having an incurved cylindrical tube; the upper lip is very small; erect, and bifid; the under lip is large, open, and divided into three segments; it hath four erect stamina, two of which are longer than the upper lip, and two shorter. In the center is situated the four germen, which afterward become four naked seeds inclosed in the empalement.

The Species are,

1. BUGULA *foliis caulinis semiamplexicaulibus, stolonibus reptatricibus*. Common Bugle.

2. BUGULA *foliis oblongo-ovatis, caulibus decumbentibus, verticillis distantibus*. Bugle with a large leaf, and pale blue flower.

3. BUGULA *foliis obtuso dentatis, caule simplici*. Bugle with blunt indented leaves, and a single stalk.

4. BUGULA *foliis oblongis tomentosiss, calycibus hirsutis*. Bugle with a flesh coloured flower.

5. BUGULA *villosa, foliis ovato-dentatis sessilibus, floribus resupinatis*. Hairy Eastern Bugle with an inverted white flower having a purple rim.

The first sort grows naturally in woods, and shady moist places, in most parts of *England*. There are two varieties of this, one with a white, and the other a pale purple flower; but these do not differ in any other respect than the colour of their flowers from the common, therefore I have only mentioned them as varieties.

The common Bugle is greatly esteemed as a vulnerary herb, and is used both internally and externally; it enters as an ingredient into the vulnerary decoctions of the surgeons, and is commended externally, applied to ulcers. As this grows naturally wild in great plenty, so it is seldom admitted into gardens.

The second sort grows naturally on the *Alps*, the leaves of this are much longer than those of the common Bugle, the stalks are weaker, and decline on every side, and the whorls of flowers are much smaller, and are ranged at a greater distance.

The third sort grows naturally in *France*, *Germany*, and other countries. It grows about four or five inches high, with a single stalk, which is garnished with leaves placed opposite. The flowers grow in whorls round the stalks, and toward the top form a close thick spike, and are of a fine blue colour.

The fourth sort grows naturally in many parts of *Europe*. This approaches near to the common Bugle, but the leaves of this are woolly, and the flower cups are very hairy. There are two varieties of this, one with a white, and the other a red flower.

The fifth sort was brought from the *Levant* by Dr. *Tournefort*, and is preserved by those who are curious in collecting rare plants.

This sort requires a little protection in winter, therefore the plants should be planted in pots filled with a loamy soil, and placed in a shady situation in summer; but in the winter they must be removed under a common frame, where they may enjoy as much free air as possible in mild weather.

This may be propagated by seeds, which should be sown soon after it is ripe, in a pot, and placed in a shady situation till autumn, when it should be removed under a frame, where it may be screened from hard frost. In the spring the plants will come up, which should be transplanted into separate pots as soon as they are strong enough to remove, and, in summer, placed in the shade, and treated as the old plants.

All the other sorts are hardy enough, and are easily multiplied by their side shoots; these delight in a moist shady situation, where they are apt to spread too much, especially the two first sorts.

BULBINE. See Anthericum.

BULBOCASTANUM. See Bunium.

BULBOCODIUM. *Tourn. Cor.* 50.

The Characters are,

The flower hath no empalement, it is funnel-shaped, and composed of six petals, which are concave. It hath six stamina, inserted in their middle. It hath an oval, blunt, three-cornered germen, which afterward becomes a triangular pointed capsule, having three cells, which are filled with angular seeds.

The Species are,

1. BULBOCODIUM *foliis subulato-linearibus. Prod. Leyd.* 41. Bulbocodium with narrow awl-shaped leaves.

2. BULBOCODIUM *foliis lanceolatis. Prod. Leyd.* 41. Bulbocodium with spear-shaped leaves; or, *Spanish Spring Meadow Saffron*.

The first sort grows naturally upon the *Alps*, and also upon *Snowdon*, in *Wales*. It hath a small bulbous root, which sends out a few long narrow leaves, somewhat like those of the Saffron, but are narrower; in the middle of these the flower comes out, which stands on the top of the foot-stalk, growing erect, and is shaped like those of the Crocus, but smaller; the foot-stalk rises about three inches high, and hath four or five short narrow leaves placed alternately upon it below the flower. This flowers in *March*, and the seeds are ripe in *May*.

The second sort grows naturally in *Spain*. It hath a bulbous root, shaped like those of the Snowdrop, which sends out three or four spear-shaped concave leaves, between which comes out the flower, standing on a very short foot-stalk; these, when they first appear, are of a pale colour, but afterward change to a white purple. It produces the flowers about the same time with the first.

These plants are propagated by offsets, in the same manner as other bulbous rooted flowers. The time to remove them, is soon after their leaves decay, but the roots may be kept out of the ground two months without prejudice at that season. They should not be removed oftener than every third year, for their roots do not multiply very fast, so by suffering them to remain, they will flower much stronger, and make a greater increase than if they are often taken up.

BUNIAS. *Lin. Gen. Plant.* 737.

The Characters are,

The flower hath four petals, placed in form of a cross, joined at their base, and erect. It hath six stamina, two of which are opposite, and shorter than the other. In the center is situated an oblong germen, which afterward becomes an irregular short oval pod, with four angles, one or other of which is prominent and pointed, inclosing one or two roundish seeds.

The Species are,

1. BUNIAS *filiculis ovatis gibbis verrucosis. Lin. Sp. Plant.* 670. Bunias with oval convex pods, having protuberances; or, *Eastern Sea Kale*.

2. BUNIAS *filiculis tetragonis angulis bicristatis. Lin. Sp. Pl.* Bunias with short four-cornered pods, whose angles are doubly crested.

3. BUNIAS *filiculis ovatis levibus ancipitibus. Lin. Sp. Pl.* 670. Bunias with smooth oval pods, standing two ways on the stalk.

The first sort grows naturally in the *Levant*. This hath a perennial root, and an annual stalk. It sends out many oblong leaves, which spread on every side, and are deeply jagged on their edges, like those of the Dandelion; from between these arise the stalks, which grow upwards of two feet high, sending out branches on every side, which are garnished at each joint by one oblong sharp pointed leaf, eared at the base. The branches are terminated by long loose spikes of yellow flowers, composed of four leaves, shaped like those of the Cabbage; these are succeeded by short oval rough pods, ending in a point, inclosing one round seed.

The second sort grows naturally in the south of *France* and *Italy*. This is an annual plant, which branches on every side, and incline toward the ground. These are garnished with glaucous leaves, which are deeply divided into many parts, almost like those of Swines Cress. The flowers are produced singly from the wings of the leaves; these are very small, of a pale yellowish colour, which are succeeded by short pods, crested on each side, containing one or two roundish seeds.

The third sort grows naturally about *Montpelier*; this is an annual plant, which sends out many oblong leaves near the root, deeply cut on each side, and spread on the ground; between these arise two or three stalks, which grow a foot and an half high, sending out several side branches, which are garnished with oblong rough leaves, indented on their edges; the upper part of the branches are destitute of leaves, but have flowers placed alternately on each side the branches, standing on short foot-stalks, which are purple; these are succeeded by oval pointed pods, containing one or two roundish seeds.

These plants are all propagated by seed; the first sort may be sown where the plants are designed to remain in the beginning of *April*; and when the plants come up, they should be thinned, leaving them two feet asunder, after which they will require no other care but to keep them clean from weeds.

The other two sorts must be sown where they are to remain, but the best time is in autumn, because those which are sown in the spring often fail, or do not come up time enough to perfect their seeds. These require no other culture

ture but to keep them clean from weeds, and thin the plants to one foot distance.

BUNIUM. *Lin. Gen. Plant.* 298. Pig Nut or Earth Nut.

The Characters are,

The involucre of the great umbel, is composed of many short narrow leaves. The proper empalement of the flower is scarce discernable. The flowers have five heart shaped petals which are equal, and turn inward; they have five stamina; the oblong germen is situated below the receptacle, which afterward becomes an oval fruit dividing in two parts, containing two oval seeds.

The Species are,

1. **BUNIUM bulbo globofo.** *Sauv. Monsp.* 256. Earth Nut with a globular root.

2. **BUNIUM radice turbinato.** Earth Nut with a turbinated root.

3. **BUNIUM foliis tripartitis filiformibus linearibus.** Earth Nut with very narrow tripartite leaves.

The first sort grows naturally in moist pastures, and in woods in many parts of *England*; of this there is a variety, supposed to be larger than that which grows commonly here. This hath a tuberous solid root, which lies deep in the ground. The leaves are finely cut, and lie near the ground. The stalk rises a foot and an half high, which is round, channelled, and solid; the lower part being naked, but above, where it branches out, there is one leaf placed below every branch. The flowers are white, and shaped like those of other umbelliferous plants; the seeds are small, oblong, and when ripe are channelled.

The roots of this sort are frequently dug up, and by the poorer sort of people are eaten raw, having much resemblance in taste to the Chestnut, from whence it had the title of *Bulbocastanum*.

The second sort was discovered by *Dr. Tournefort* in the island of *Crete*, but it grows naturally in many other parts of, the *Lewant*.

The third sort I received from the *Alps*. This is a very low plant, seldom rising above six inches high.

These plants delight to grow among grass, so cannot without difficulty be made to thrive long in a garden.

BUPHTHALMUM. *Lin. Gen. Pl.* 876. Ox-eye.

The Characters are,

It hath a compound radiated flower, composed of hermaphrodite and female florets. The hermaphrodite flowers compose the disk, and are funnel-shaped. In the center is situated an oval compressed germen, which afterward becomes an oblong seed. The female flowers which compose the rays are stretched out on one side like a tongue, and are indented at the top in three parts; these have no stamina, but a double headed germen, which becomes a single compressed seed, cut on each side.

The Species are,

1. **BUPHTHALMUM calycibus foliosis, foliis cordatis serratis trinerviis basi hinc brevioribus.** *Hort. Upsal.* 264. Ox eye with a leafy empalement, heart shaped sawed leaves, having three veins, and the base on one side shorter than the other.

2. **BUPHTHALMUM foliis lanceolatis subdenticulatis glabris, calycibus nudis.** *Hort. Cliff.* 415. Ox-eye with smooth spear-shaped leaves (indented below) and naked empalements.

3. **BUPHTHALMUM foliis lanceolatis subserratis viliosis calycibus nudis.** *Hort. Cliff.* 414. Ox eye with spear-shaped leaves, sawed below and hairy, and naked empalements.

4. **BUPHTHALMUM calycibus acutè foliosis, ramis alternis, foliis lanceolatis amplexicaulis integerrimis.** *Hort. Cliff.* 414. Ox-eye with acute leafy empalements, branches placed alternate, and entire leaves embracing the stalks.

5. **BUPHTHALMUM calycibus obtusè foliosis pedunculatis, ramis alternis, foliis cuneiformibus.** *Hort. Cliff.* 414. Ox-eye with blunt leafy empalements, having foot stalks, alternate branches, and wedge-shaped leaves.

6. **BUPHTHALMUM calycibus obtusè foliosis sessilibus, axil-**

laribus, foliis oblongis obtusis. *Hort. Cliff.* 414. Ox-eye with blunt leafy empalements, sitting close to the side of the stalks, and oblong blunt leaves.

7. **BUPHTHALMUM foliis oppositis lanceolatis petiolatis bidentatis.** *Hort. Cliff.* 415. Ox eye with spear-shaped leaves growing opposite, with foot stalks having two teeth.

8. **BUPHTHALMUM foliis oppositis linear lanceolatis crassis, glabris, floribus pedunculatis.** Ox-eye with thick, smooth, narrow, spear-shaped leaves growing opposite, and flowers having foot-stalks.

9. **BUPHTHALMUM foliis oppositis linear lanceolatis crassis incanis, floribus sessilibus.** Ox-eye with thick, hoary, narrow, spear-shaped leaves placed opposite, and flowers growing close to the branches.

The first sort grows naturally in *North America*; this hath a perennial root, and an annual stalk, which rises upward of six feet high, garnished at each joint with two oblong heart-shaped leaves, which have three longitudinal veins, and the base on one side shorter than the other. The flowers come out at the extremity of the branches, having a leafy empalement; these are of a bright yellow colour, resembling a small Sun flower, from whence the inhabitants of *America* have given it that appellation. It propagates easily by parting of the roots. The best time to transplant and part the roots, is toward the end of *October*, when the stalks begin to decay. These should be removed every other year, to prevent their spreading too far; they are very hardy, so will thrive in any situation, and are proper for large borders on the sides of rural walks, or in spaces between shrubs.

The second sort grows naturally on the *Alps*, as also in *Austria, Italy*, and the south of *France*. This hath also a perennial root, and an annual stalk; it grows near two feet high, with slender branching stalks, garnished with oblong smooth leaves; the flowers grow at the extremity of the branches, of a bright yellow colour, like those of *Starwort*. There are two or three varieties of this, differing in the breadth of their leaves and size of their flowers, but from the same seeds all these have been produced.

This sort may be propagated by parting of the roots, at the same time, and in the same manner as is directed for the second sort.

The third sort is somewhat like the second, but the leaves are broader and obtuse; the stalks and leaves are also hairy, in which consists their difference.

The fourth sort is an annual plant, which grows naturally in the south of *France, Italy, Spain*, and *Sicily*. The stalks rise two feet and an half high, and divide into many branches upward, and the side branches rise above the middle stalk. They are garnished with spear-shaped hairy leaves, placed alternately; the flowers are produced at the end of the branches, on short foot-stalks; the empalement consists of seven long stiff spear-shaped leaves, ending in a sharp point. The flower sits close upon the empalement, the border or rays being composed of many female florets. The middle or disk of the flower, is composed of hermaphrodite flowers, which are tubulous and funnel-shaped. They are of a bright yellow colour, and are succeeded by oblong compressed seeds.

The seeds of these should be sown in *April*, on open borders, where they are to remain, and will require no other care, but to keep them clear of weeds, and thin them to the distance of a foot and an half, that their branches may have room to spread.

The fifth and sixth sorts are also annual plants, which grow naturally in the same countries with the two last. These seldom grow more than one foot high in gardens, but send out many spreading branches near the root; the leaves are oblong, blunt, and hairy. The flowers of these have much the appearance of those of the last, but are smaller,

smaller, and those of the sixth sort have an agreeable odour.

The fifth sort is a low perennial plant, with a shrubby stalk, which rarely rises a foot high, sending out many spreading branches from the stem, garnished with hairy leaves, which are very narrow at their base, but broad and roundish at their extremity; the flowers are produced at the end of the branches, which are yellow, and shaped like those of the former sorts, but the leaves of the empalement are soft and obtuse. These are rarely succeeded by seeds in *England*, but the plant is easily propagated by slips during the summer season, which will take root in about six weeks, when they should be carefully taken up, and each planted in a separate small pot, and placed in a shady situation till they have taken fresh root, after which they may be removed to an open situation, where they may remain till the end of *October*, when they must be removed to a frame for the winter season, being too tender to live abroad in this country; but as they only require protection from hard frosts, so they will thrive better when they have a great share of air in mild weather, than if confined in a green-house; therefore the best method is to place them in a common frame, where they may be fully exposed in mild weather, but screened from the frost.

The seventh sort rises with several woody stems, which grow to the height of eight or ten feet, garnished with leaves very unequal in size; some are narrow and long, others are broad and obtuse; these are intermixed at the same joint, and often at the intermediate one; they are soft, hoary, and placed opposite: the foot-stalks of the larger leaves have on their upper side, near their base, two sharp teeth standing upward. The flowers are produced at the ends of the branches; they are of a pale yellow colour, and have scaly empalements. This sort has been long preserved in the *English* gardens, and was originally brought from *Virginia*.

The eighth sort grows naturally in the *Bahama Islands*. This seldom grows much more than three feet high. It has succulent spear-shaped leaves placed opposite; the flowers are produced at the end of the branches, which are larger than those of the seventh sort, and are of a bright yellow colour. I received this also from the *Hawannah*, where it grows plentifully on the borders of the sea.

The ninth sort grows in the *Bahama Islands*. This sends out many slender stalks from the root, which rise near three feet high, with long narrow thick succulent leaves, which are very hoary, growing opposite, embracing the stalk at their base; the flowers are yellow, and are produced at the ends of the shoots, having very short foot-stalks.

As the three last sorts do not perfect their seeds in this country, so they are propagated by cuttings, which should be planted in *July*, when the plants have been for some time exposed to the open air, whereby their shoots will be hardened and better prepared to take root, than when they first come abroad. They should be planted in small pots filled with light loamy earth, and plunged into a very gentle warmth, observing to shade them from the sun in the heat of the day. In about six weeks these will have taken root, when they must be gradually inured to bear the open air, and soon after they should be each planted in a separate small pot, filled with light loamy earth, and placed in the shade until they have taken fresh root; after which they may be removed to a sheltered situation, where they may remain till the middle of *October*, when they must be removed into the green-house. During the winter, they should have but little moisture, and in very mild weather they should have fresh air admitted to them. In the summer they must be placed abroad in a sheltered situation, and treated in the same manner as other exotic plants.

BUPLEUROIDES. See Phyllis.

BUPLEURUM, Hare's-ear.

The Characters are,

It is a plant with an umbellated flower; the rays of the principal umbel are thin; the involucre of the great umbel is composed of many leaves, those of the small have five. The flower hath five small heart-shaped petals, which are inflexed; it hath five slender stamina. The germen is situated below the flower, which afterward becomes a roundish compressed fruit which is channelled, dividing in two parts, containing two oblong channelled seeds.

The Species are,

1. BUPLEURUM *involucris universalibus nullis, foliis perfoliatis*. Hort. Upsal. 64. The most common or Field Thorough Wax.

2. BUPLEURUM *involucellis pentaphyllis orbiculatis, universalis triphylo ovato, foliis amplexicaulibus cordato-lanceolatis*. Lin. Sp. Pl. 236. Greater narrow-leaved Thorough Wax of the Alps, with an angular leaf.

3. BUPLEURUM *involucellis pentaphyllis acutis, universalis triphylo, flosculo centrali altiore, ramis divaricatis*. Lin. Sp. Plant. 237. Smaller narrow-leaved Thorough Wax with a Hare's-ear leaf.

4. BUPLEURUM *caule dichotomo subnudo, involucris minimis acutis*. Lin. Sp. Pl. 238. Hare's ear with a stiff leaf.

5. BUPLEURUM *umbellis simplicibus alternis pentaphyllis subtrifloris*. Lin. Sp. Plant. 238. Hare's-ear with a very narrow leaf.

6. BUPLEURUM *frutescens, foliis obovatis integerrimis*. Lin. Sp. Pl. 238. Shrubby Hartwort of *Ethiopia*.

7. BUPLEURUM *frutescens, foliis vernalibus decompositis planis incis, aestivalibus filiformibus angulatis trifidis*. Lin. Sp. Plant. 238. Shrubby Hare's-ear, whose spring leaves are decomposed, plain and cut, and the summer leaves are narrow, angular, and trifid.

The first sort grows naturally upon chalky land amongst Wheat, in several parts of *England*, so is seldom admitted into gardens. The leaves and seeds of this plant are used in medicine; the herb is esteemed good for dissolving scrophulous tumours, and is by some used for internal ailments, ruptures, and bruises from a fall. This is an annual plant.

The second, third, fourth, and fifth sorts, are also annual. The fifth sort grows naturally in several parts of *England*, the others are natives of the Alps and Pyrenees; these are seldom cultivated but in botanick gardens for the sake of variety. Their seeds should be sown in autumn, where the plants are designed to remain, and keep the plants clean from weeds, which is all the culture they require.

The sixth sort hath a woody stem, which sends out many branches on every side, so as to form a large head or bush, with oblong oval stiff leaves, which are very smooth, and of a sea-green colour; the ends of the branches are terminated by umbels of yellow flowers, somewhat like those of Fennel.

It is commonly known among gardeners by the title of shrubby *Ethiopian* Hartwort, and is now propagated in the nursery gardens for sale. It grows five or six feet high, forming a large regular bush, and the leaves continuing green through the year render it more valuable. It is hardy, so will live in the open air, and may be intermixed with other ever-green shrubs of the same growth, where they will make an agreeable variety. It is propagated by cuttings, which should be planted in pots, and in winter sheltered under a hot bed frame; in the spring the cuttings will put out roots, but they will not be fit to transplant till the autumn following; so the pots should be placed in a shady situation in summer. The young plants may be planted in a nursery bed at two feet distance, for a year or two to get strength, and then transplanted where they are to remain.

The seventh sort grows naturally at the *Cape of Good Hope*. This rises with a shrubby stalk to the height of five or six feet, sending out some side branches, which in the spring have their lower parts garnished with leaves composed of many small plain lobes, which are finely cut like those of Coriander, and of a sea green colour; these leaves soon fall off, and the upper part of the branches are closely covered with long Rush like leaves having four angles, which come out in clusters from each joint. The flowers grow in spreading umbels at the extremity of the branches, which are small and of an herbaceous colour, and are succeeded by oblong channelled seeds.

This sort is propagated by cuttings, which do readily take root, if they are planted in *April* in pots, and plunged into a moderate hot-bed. When they have taken root, they should be inured to the open air by degrees, and after having obtained strength, they may be planted each into a separate pot, placing them in the shade, till they have taken fresh root, when they may be placed with other exotic plants in a sheltered situation, where they may remain till the autumn, when they must be removed into the greenhouse, and placed with such hardy plants as require a large share of air in mild weather, and only require protection from frost.

BURNET. See *Poterium* and *Sanguisorba*.

BURSA PASTORIS, Shepherds pouch

This is a common weed in most parts of *England*, which propagates so fast by seeds, as not to be easily cleared when they are permitted to shed; for there are commonly four or five generations of this plant from seeds in a year, so fast does the seed ripen, and the plants come up; therefore it cannot be too soon rooted out of a garden.

BUTOMUS, the Flowering-rush, or Water-gladiole.

The Characters are,

The flowers grow in a single umbel; they have six roundish concave petals, which are alternately smaller, and nine awl-shaped stamina, six of which surround the other. It hath six oblong pointed germen, which afterward become six oblong pointed capsules, having one cell filled with oblong seeds.

We know but one Species of this genus, viz.

BUTOMUS. *Fl. Lap.* 159. The Flowering-rush, or Water-gladiole.

There are two varieties of this plant, one with a Rose-coloured flower, and the other with a white flower; but these are only accidental variations, therefore not to be enumerated as distinct species.

The Rose-coloured sort is pretty common in standing waters, in many parts of *England*; the other is a variety of this, though less common with us near *London*. These plants may be propagated in boggy places, or by planting them in cisterns, which should be kept filled with water, that should have about a foot thickness of earth in the bottom, into which the roots should be planted, or the seed sown as soon as they are ripe; these, though common plants, yet produce very pretty flowers, and are worth propagating for variety's sake, especially if in any part of the garden there should be conveniency for an artificial bog, or where there are ponds of

standing water, as is many times the case, and persons are at a loss what to plant in such places, that may appear beautiful.

BUXUS, the Box Tree.

The Characters are,

It hath male and female flowers on the same plant; the male flowers have a three leaved, and the female a four leaved empalement. The male flowers have two, and the female three concave petals. The male flowers have four upright stamina, with a rudiment of a germen, but no style or stigma. The female flowers have roundish, blunt, three-cornered germen. The empalement afterward becomes a roundish capsule, shaped like an inverted portage pot, opening in three cells, each having two oblong seeds.

The Species are,

1. *Buxus arborescens, foliis ovatis*. Box Tree with oval leaves.

2. *Buxus arborescens foliis lanceolatis*. Narrow-leaved Box.

3. *Buxus humilis foliis orbiculatis*. Dwarf or Dutch Box.

The two sorts of Tree Box have been frequently raised from seeds, and constantly produced plants of the same kind from those the seeds were taken from; and the Dwarf Box will never rise to any considerable height with any culture, nor have I ever seen this sort flower, where the plants have been encouraged to grow many years in the greatest luxury. There are two or three varieties of the first sort, which are propagated in the gardens, one with yellow, and the other white striped leaves. The other hath the tops of the leaves only marked with yellow, which is called Tipped Box.

The first and second sorts grow in great plenty upon *Box-hill* near *Dorking* in *Surry*, where were formerly large trees of these kinds, but of late they have been pretty much destroyed; yet there are great numbers of the trees remaining, which are of a considerable bigness.

The tree or large Box are proper to intermix in clumps of Ever-greens, &c. where they add to the variety of such plantations; these may be propagated by planting the cuttings in autumn in a shady border. When they are well rooted, they may be transplanted into nurseries, till they are fit for the purposes intended. The best season for removing these trees is in *October*, though indeed, if care be used to take them up with a good ball of earth, they may be transplanted almost at any time, except in the middle of summer: these trees are a very great ornament to cold and barren soils, where few other things will grow.

The dwarf kind of Box is used for bordering of flower beds, or borders; for which purpose it far exceeds any other plant, it being subject to no injuries from cold or heat, and is of long duration; is very easily kept handsome, and, by the firmness of its rooting, keeps the mould in the borders from washing into the gravel-walks, more effectually than any plant whatever. This is increased by parting the roots, or planting the slips; but as it makes so great an increase of itself, and so easily parts, it is hardly worth while to plant the slips that have no roots.

C.

C A C

CAAPEBA. See Cissampelus.
CABBAGE. See Brassica.
CACALIANTHEMUM. See Cacalia.
CACALIA, Foreign Coltsfoot.

The Characters are,

It hath compound flowers, which are included in one common cylindrical empalement: the flowers are tubulous and funnel-shaped; these have each five short slender stamina. The germen is crowned with down, which afterward becomes a single oblong seed, crowned with long down.

The Species are,

1. *CACALIA foliis reniformibus acutis denticulatis*. Lin. Sp. Plant. 836. Cacalia with kidney-shaped leaves, which are sharply indented.

2. *CACALIA foliis cordatis serratis glabris*. Cacalia with smooth heart-shaped leaves, sawed on their edges.

3. *CACALIA caule herbaceo foliis hastato-sagittatis denticulatis, petiolis supernè dilatatis*. Hort. Upsal. 254. Taller American Cacalia with a triangular leaf eared at the base, and white flowers.

4. *CACALIA caule herbaceo, foliis subcordatis, dentato-sinuatis, calycibus quinquesloris*. Lin. Sp. Plant. 835. Cacalia with an herbaceous stalk, heart-shaped sinuated leaves, and five florets in each empalement.

5. *CACALIA caule fruticoso, foliis compressis carnosis*. Lin. Sp. Plant. 834. African Tree Groundsel with the leaf and appearance of Fig Marigold.

6. *CACALIA caule fruticoso composito, foliis lanceolatis planis, petiolorum cicatricibus obsolete*. Lin. Sp. Pl. 834. Cacalia with a compound shrubby stalk, and plain spear-shaped leaves, and the foot-stalks leaving scars.

7. *CACALIA caule fruticoso obvallato spinis petiolaribus truncatis*. Lin. Sp. Plant. 834. Cacalia with a shrubby stalk, guarded on every side with broken rough foot-stalks.

8. *CACALIA caule fruticoso, foliis ovato-oblongis, petiolis basi linea triplici deductis*. Lin. Sp. Pl. 834. Cacalia with a shrubby stalk, oblong oval leaves, and three lines connected to the base of the foot-stalk.

The first sort grows naturally in *Austria*, and the *Helvetian* mountains, but is frequently preserved in curious gardens for the sake of variety. It hath a fleshy root which spreads in the ground, from which springs up many leaves, standing on single foot-stalks, shaped like those of Ground Ivy, but are of a thicker texture, of a shining green on their upper side, but white on their under side; between these arise the stalk, which is round, branching toward the top, and grows a foot and an half high; the branches are terminated by purplish flowers, growing in a sort of umbel. These are succeeded by oblong seeds, crowned with down.

The second sort hath the appearance of the first, but the leaves are heart-shaped, pointed, and sharply sawed on their edges, and on both sides very green; the stalks rise higher, and the leaves upon the stalks have much longer foot-stalks than those of the first. The flowers of this are of a deeper purple colour.

The third sort grows naturally in *North America*. This

C A C

hath a perennial creeping root, which sends out many stalks, garnished with triangular spear-shaped leaves, sharply sawed on their edges. The stalks rise to the height of seven or eight feet, and are terminated by umbels of white flowers, which are succeeded by oblong seeds crowned with down. This plant multiplies greatly by its spreading roots, and also by the seeds, which are spread to a great distance by the wind, the down which adheres to them being greatly assisting to their conveyance.

The fourth sort is a native of *America*. This hath a perennial root, and an annual stalk, which rises four or five feet high, garnished with roundish heart-shaped leaves, greatly indented on their edges, of a sea-green on the under side, but darker above; the stalks are terminated by umbels of yellowish herbaceous flowers.

The first and second sorts are propagated by parting of their roots, for they seldom produce good seeds in *England*. The best time to transplant and part their roots is in the autumn. They require a loamy soil, and a shady situation.

The third and fourth sorts propagate in great plenty, both by their spreading roots, and also their seeds. The roots should be transplanted in autumn, and require a moist soil and an open situation.

The fifth sort grows naturally at the *Cape of Good Hope*. This rises with strong round stalks, to the height of seven or eight feet, which are woody at bottom, but soft and succulent upward, sending out many irregular branches, which are garnished with thick taper succulent leaves, a little compressed on two sides, ending in points, and are covered with a whitish glaucous farina, which comes off when handled. At the extremity of the branches the flowers are produced in small umbels; they are white, tubulous, and cut into five parts at the top. Some of the noblemen in *France* have the leaves of this plant pickled, in the doing of which, they have a contrivance to preserve the white farina, with which they are covered, and thereby render them very beautiful.

This sort is easily propagated by cuttings, during the summer months: these should be cut from the plants, and laid to dry a fortnight, that the wound may be healed over before they are planted. If they are planted in *June*, or *July*, they will take root in the open air. I have frequently had the branches broken off by accident, and fallen on the ground, which have put out roots without any care. The plants should have a light sandy earth, and in winter be placed in an airy glass case, where they may enjoy the sun and air in mild weather, but must be protected from frost, and have but little water; they must be treated like the *Ficoides*, and other succulent plants from the same country.

The sixth sort grows naturally in the *Canary Islands*. This rises with a thick fleshy stem, divided at certain distances, as it were in so many joints; each of these divisions swell much larger in the middle, than they do at each end; toward their extremities they are garnished with long narrow spear-shaped leaves, of a glaucous colour. As these fall off, they leave a scar at the place, which always remains on the branches. The flowers are produced in large clusters,

at the extremity of the branches, which are tubulous, and of a faint Carnation colour.

This plant hath been called Cabbage tree, by the gardeners, I suppose from the resemblance which the stalks of it have to that of the Cabbage: others have titled it Carnation tree, from the shape of the leaves, and colour of the flowers.

It is propagated by cuttings, in the same manner as the former sort, and the plants require the same culture.

The seventh sort resembles the sixth in its form and manner of growth, but the leaves are narrower and more succulent. These do not fall off entire like the other, but break off at the beginning of the foot-stalk, which are very strong and thick. This sort hath not as yet produced any flowers in *England*. It is propagated in the same manner as the two former sorts, from cuttings, and the plants must be treated in the same way, as hath been directed for the fifth sort, but requires to be kept drier, both in winter and summer: This sort grows naturally at the *Cape of Good Hope*.

The eighth sort has been long preserved in the *English* gardens, and was generally titled Ante-uphorbium, supposing it to have a contrary quality to the Euphorbium. This rises with many succulent stalks from the root, as large as a man's finger, which branch out upward, into many irregular stalks of the same form, but smaller, and are garnished with flat oblong succulent leaves, placed alternately round the branches; under each foot-stalk there are three lines or ribs, which run longitudinally through the branches joined together. This sort very rarely flowers in *Europe*, but is propagated by cuttings in the same manner as the fifth, and is equally hardy.

CACAO. *Tourn. Inst. R. H.* 660. The Chocolate Nut.

The Characters are,

The flower hath five petals, which are irregularly indented; it hath five erect stamina. In the center is placed the oval germen, which afterward becomes an oblong pod, ending in a point, which is divided into five cells, filled with oval, compressed, fleshy seeds.

We have but one Species of this plant, viz.

CACAO. *Clus. Exot.* The Chocolate Nut Tree.

This tree is a native of *America*, and is found in great plenty in several places between the tropicks, but particularly at *Carracca* and *Carthogena*, on the river *Amazons*, in the isthmus of *Darien*, at *Honduras*, *Guatemala*, and *Nicaragua*. At all these places it grows naturally without culture; but it is cultivated in many of the islands which are possessed by the *French* and *Spaniards*, and was formerly planted in some of the islands which are in possession of the *English*.

In the making a plantation of Chocolate trees, you must first be very careful in the choice of the situation and the soil, otherwise there will be small hopes of success. As to the situation, it should be in a place where the trees may be protected from strong winds, to which if they are exposed, they will soon be destroyed: so that in such places where terrents of water have washed away the earth so as to leave broad and deep furrows (which the inhabitants of those islands call gullies), these trees will thrive exceedingly. The soil in these gullies is generally rich and moist, which is what these trees require, so that they will make great progress in these places; but where there are not a sufficient number of these gullies, choice should be made of a situation which is well sheltered by large trees; or, if there are not trees already grown, there should be three or four rows planted round the spot which is designed for the Chocolate trees, of such sorts which are of quickest growth; and within these rows there should be some Plantain trees planted at proper distances, which being very quick of growth, and the leaves being very large, will afford a kindly shelter to the young Chocolate trees placed between them.

The Chocolate trees which are cultivated, seldom grow

to be more than fourteen or fifteen feet in height, nor do they spread their branches very wide; so that if the Plantain trees are placed in rows, about twenty-four feet asunder, there will be room enough for two rows of Chocolate trees between each row of Plantains; and if they are planted at ten feet distance in the rows, it will be sufficient room for them.

The soil upon which these trees thrive to most advantage, is a moist, rich, deep earth; for they generally send forth one tap root, which runs very deep into the ground, so that wherever they meet with a rocky bottom near the surface, they seldom thrive, nor are of long continuance; but in a rich, deep, moist soil, they will produce fruit in pretty good plenty the third year from seed, and will continue fruitful for several years after.

Before the plantation is begun, the ground should be well prepared by digging it deep, and clearing it from the roots of the trees, and noxious plants, which, if suffered to remain in the ground, will shoot up again after the first rain, and greatly obstruct the growth of the plants; so that it will be almost impossible to clear the ground from those roots, after the Chocolate plants are come up, without greatly injuring them.

When the ground is thus prepared, the rows should be marked out by a line where the nuts are to be planted, so as that they may be placed in a quincunx order, at equal distances every way, or at least that the Plantain trees between them may form a quincunx, with the two rows of Chocolate trees, which are placed between each row of them.

In making a plantation of Chocolate nut trees, the nuts must be planted where the trees are to remain; for if the plants are transplanted, they seldom live; and those which survive it, will never make thriving trees; for, as I before observed, these trees have a tender tap root, which, if broken, or any way injured, the tree commonly decays.

The nuts should always be planted in a rainy season, or at least when it is cloudy weather, and some hopes of rain falling soon after. As the fruit ripens at two different seasons, viz. at *Midsummer*, and at *Christmas*, the plantation may be made at either of those; but the chief care must be to chuse such nuts as are perfectly ripe and sound, otherwise the whole trouble and expence will be lost. The manner of planting the nuts is, to make three holes in the ground, within two or three inches of each other, at the place where every tree is to stand; and into each of these holes should be one sound nut planted about two inches deep, covering them gently with earth. The reason for putting in three nuts at every place is, because they seldom all succeed; or, if most of them grow, the plants will not be all equally vigorous; so that when the plants have had one year's growth, it is very easy to draw up the weak unpromising plants, and leave the most vigorous; but in doing this, great care should be had to the remaining plants, so as not to injure or disturb their roots in drawing the other out.

It is very proper to observe, that the Chocolate nuts will not retain their growing faculty long after they are taken from the trees, so that there is no possibility of transporting them to any great distance for planting; nor should they be kept long out of the ground, in the natural places of their growth.

When the Chocolate trees first appear above ground, they are very tender, and subject to great injuries from the strong winds, the scorching sun, or great droughts, for which reason the planters are obliged to guard against all these enemies, first, by making choice of a sheltered situation, or at least by planting trees to form a shelter; and, if possible, to have the plantation near a river, for the conveniency of watering the plants the first season, until they have made strong roots, and are capable of drawing their nourishment from some depth in the earth, where they meet with moisture.

The Plantains, which will be fit to cut in about twelve months after planting, will defray the whole expence of preparing the ground, so that the produce of the Chocolate trees will be neat profit; for as the Plantains produce fruit and decay, they will be succeeded by suckers, which will produce fruit in eight months after; whereby there will be a continual supply of food for the negroes, which will more than pay for keeping the ground wrought, and clear from weeds, until the Chocolate trees begin to produce fruit, which is generally the third year after planting.

The planters usually set the Plantain trees two or three months before the Chocolate nuts are ripe, that they may be large enough to afford shelter to the young plants when they come up. Some people plant Potatoes, others Cucumbers and Melons, or Water Melons, between the rows of Chocolate plants; which, they say, will prevent the weeds from rising to injure the young plants; for as all these trail on the ground, they occupy the whole surface, and prevent the weeds from growing: but where this is practised, it should be done with great caution, lest, by being over covetous, you injure the young Chocolate nuts so much, as that they may never recover it.

In about seven or eight days after the Chocolate nuts are planted, the young plants will begin to appear above ground; when they should be carefully looked over, to see if any of them are attacked by insects; in which case, if the insects are not timely destroyed, they will soon devour all the young plants; or if there should be any weeds produced near the plants, they should be carefully cut down with a hoe; in doing which, great care should be taken that the tender shoot, nor the rind of the bark are injured. About twenty days after the plants have appeared, they will be five or six inches high, and have four or six leaves, according to the strength of the plants. In ten or twelve months they will be two feet and an half high, and have fourteen or sixteen leaves.

In two years time the plants will have grown to the height of three feet and an half, and sometimes four feet, many of which will begin to flower; but the careful planters always pull off all these blossoms, for if they are permitted to remain to produce fruit, they will so much weaken the trees, that they seldom recover their strength again, so as to become vigorous. When these plants are two years and an half old, they will produce flowers again, some of which are often left to bear fruit; but the most curious planters pull off all these, and never leave any to produce fruit until the third year; and then but a few, in proportion to the strength of the trees; by which method their trees always produce larger and better nourished fruit, than those which are suffered to bear a larger quantity, and will continue much longer in vigour. The fourth year they suffer their trees to bear a moderate crop; but they generally pull off some flowers from those trees which are weak, that they may recover strength before they are too old.

From the time when the flowers fall off, to the maturity of the fruit, is about four months. It is easy to know when the fruit is ripe, by the colour of the pods, which become yellow on the side next the sun. In gathering of the fruit, they generally place a negroe to each row of trees; who, being furnished with a basket, goes from tree to tree, and cuts off all those which are ripe, leaving the others for a longer time to ripen. When the basket is full, he carries the fruit, and lays it in an heap at one end of the plantation; where, after they have gathered the whole plantation, they cut the pods lengthways, and take out all the nuts, being careful to divest them of the pulp which closely adheres to them; and then they carry them to the house, where they lay them in large casks, or other vessels of wood, raised above ground, and cover them with leaves of the *Indian Reed*

and mats, upon which they lay some boards, putting some stones thereon to keep them down close, in order to press the nuts. In these vessels the nuts are kept four or five days; during which time, they must be stirred and turned every morning, otherwise they will be in danger of perishing from the great fermentation they are usually in. In this time they change from being white to a dark red or brown colour. Without this fermentation, they say the nuts will not keep; but will sprout, if they are in a damp place, or shrivel and dry too much, if they are exposed to heat.

After the nuts have been thus fermented, they should be taken out of the vessels and spread on coarse cloths, where they may be exposed to the sun and wind; but at night, or in rainy weather, they must be taken under shelter, otherwise the damp will spoil them. If the weather proves fair, three days time will be long enough to dry them, provided they are carefully turned from time to time, that they may dry equally on every side. When they are perfectly dry, they may be put up in boxes or sacks, and preserved in a dry place until they are shipped off, or otherwise disposed of. The fresher these nuts are, the more oil is contained in them; so that the older they are, the less they are esteemed.

When the trees are full grown and vigorous, they will sometimes produce two hundred, or two hundred and forty pods, at one season; which will make ten or twelve pounds of Chocolate, when dried; so that it is a very profitable commodity, and can be managed with very little charge, when compared with sugar.

The Chocolate trees, if planted on a good soil, and properly taken care of, will continue vigorous and fruitful twenty-five or thirty years: therefore the charge of cultivating a plantation of these trees, must be much less than that of sugar; for although the ground between the rows of plants will require to be often hoed and wrought, yet the first working of a ground to make a new plantation of Sugar, Indigo, Cassada, &c. is a larger expence than the after-workings are. Besides, Sugar canes require as much labour in their cultivation as any plant whatever.

The leaves of these trees being large, make a great litter upon the ground when they fall; but is not injurious, but rather of service to the trees; for the surface of the ground being covered with them, they preserve the moisture in the ground, and prevent its evaporating; which is of great use to the young tender roots, which are just under the surface; and when the leaves are rotten, they may be buried in digging the ground, and it will serve as good manure. Some planters let the pods, in which the Chocolate is inclosed, lie and rot in a heap (after they have taken the nuts out) which they also spread on the ground instead of dung.

Besides the ordinary care of digging, hoeing, and manuring the plantations of Chocolate trees, there is also another thing requisite in order to their doing well; which is, to prune the decayed branches off, and to take away small ill placed branches, wherever they are produced. But you should be cautious how this work is performed; for there should be no vigorous branches shortened, nor any large amputations made on these trees, because they abound with a soft glutinous milky juice, which will flow out for many days whenever they are wounded, which greatly weakens the trees.

In order to cultivate this plant in *Europe*, by way of curiosity, it will be necessary to have the nuts planted into boxes of earth (in the countries where they grow) soon after they are ripe; because, if the nuts are sent over, they will lose their growing quality before they arrive. These boxes should be placed in a shady situation, and must be frequently watered, in order to forward the vegetation of the

the nuts. In about a fortnight after the nuts are planted, the plants will appear above-ground; when they should be carefully watered in dry weather, and protected from the violent heat of the sun. When the plants are grown strong enough to transport, they should be shipped and placed where they may be screened from strong winds, salt water, and the violent heat of the sun. During their passage they must be frequently refreshed with water; but it must not be given them in great quantities, lest it rot the tender fibres of their roots; and when they come into a cool latitude, they must be carefully protected from the cold, when they will not require so frequently to be watered: for in a moderate degree of heat, if they have gentle waterings once a week, it will be sufficient.

When the plants arrive in *England*, they should be carefully taken out of the boxes, and each transplanted into a separate pot filled with light rich earth, and plunged into a moderate hot-bed of tanners bark. In this hot-bed the plants may remain till *Michaelmas*, when they must be removed into the bark stove, and plunged into the tan, in the warmest part of the stove. During the winter season the plants must be frequently refreshed with water, but it must be given to them in small quantities; yet in summer they will require a more plentiful share. These plants are too tender to live in the open air in this country, even in the hottest season of the year; therefore must constantly remain in the bark stove, observing in very warm weather, to let in a large share of fresh air to them, and in winter to keep them very warm. The leaves of these plants must be frequently washed, to clear them from filth, which they are subject to contract by remaining constantly in the house; and this becomes an harbour for small insects, which will infest the plants, and destroy them, if they are not timely washed off. If these rules are duly observed, the plants will thrive very well, and may produce flowers in this climate: but it will be very difficult to obtain fruit from them; for, being of a very tender nature, they are subject to many accidents in a cold country.

CACHRYS. *Tourn. Inst.* 325. *Lin. Gen. Plant.* 304.

The Characters are,

It hath an umbellated flower; the involucre is composed of many narrow spear-shaped leaves: the flower hath five spear-shaped erect petals. It hath five single stamina. The turbinated germen is situated under the receptacle; the empalement afterward becomes a large oval blunt fruit dividing in two parts, each having one large fungous seed.

The Species are,

1. CACHRYS *foliis pinnatis, foliolis linearibus trifidis, fructu levi.* Cachrys with very narrow pinnated trifid leaves and a smooth fruit.
2. CACHRYS *foliis pinnatis, foliolis linearibus planis acutis, fructu rugoso.* Cachrys with narrow, plain, pinnated, acute leaves, and a rough fruit.
3. CACHRYS *foliis pinnatis foliolis acutis multifidis.* *Lin. Sp. Plant.* 246. Cachrys with pinnated, multifid leaves, which are acute.
4. CACHRYS *foliis pinnatis foliolis linearibus multifidis fructu sulcato plano.* Cachrys with very narrow, multifid, pinnated leaves, and a plain channelled fruit.
5. CACHRYS *foliorum impari lobato, hirsuto, semine fungoso sulcato plano.* Cachrys with hairy leaves, terminated with an odd lobe, and a plain channelled seed.

The first sort hath a thick fleshy root which strikes deep in the ground, from which springs out many narrow winged leaves resembling those of Giant-fennel; from between these arise a hollow fungous stalk about two feet high, terminated by a large umbel of yellow flowers, which are succeeded by oval smooth fungous fruit, dividing into two parts, each inclosing an oblong seed.

The second sort hath a large firm sweet smelling root which sends out several pinnated leaves like those of Hog's-fennel, but shorter. The stalk is smooth jointed, and rises four or five feet high, which is terminated by large umbels of yellow flowers, like those of Dill.

The third sort hath a thick fleshy root like the Fennel, which runs deep into the ground, sending out several narrow pinnated leaves, ending in many parts; between these arises a smooth jointed stalk, about three feet high, which is terminated by large umbels of flowers.

The fourth sort hath very thick roots, which strike deep in the ground, sending out very narrow pinnated leaves, like those of Hog's-fennel. The stalk rises five or six feet high, and is jointed like those of Fennel, terminated by large umbels of yellow flowers.

The first sort grows naturally in the south of *France* and *Spain*; the second and third in *Italy*; the fourth in *Sicily*, and the fifth in *Hungary*.

These plants are all propagated by seeds, which should be sown soon after they are ripe; for if they are kept out of the ground until the following spring, they often miscarry; and when they succeed, they never come up until the spring after; so that by sowing them in autumn, a whole year is saved, and the seeds seldom miscarry. These seeds should be sown on a shady border, where the plants are to remain; for the plants having long tap roots, will not bear transplanting so well as many other kinds. The distance to be observed for the sowing of their seeds should be three feet apart; so that if each kind is sown in a drill, when the plants are come up, they may be thinned, leaving two of the most promising plants of each kind to remain. These plants will begin to appear early in *April*, when they must be carefully cleared from weeds; and in dry weather they should be gently watered, which greatly promotes their growth the first year; after which time, they will require no farther care but to keep them clean from weeds, and every spring to dig the ground carefully between them, so as not to injure the roots.

These plants decay to the ground every autumn, and come up again in the spring: they commonly flower in the beginning of *June*, and their seeds are ripe in *September*: their roots sometimes run down three or four feet deep in the earth, provided the soil be light, and are often as large as Parsneps: they will continue many years, and if the soil is moist and rich, they will annually produce good seeds; but when they grow on a dry soil, the flowers commonly fall away, and are not succeeded by seeds.

CACTUS. *Lin. Gen. Plant.* 539.

The Characters are,

The flower is composed of six petals, which rests upon the embryo; it hath six long slender stamina. The oval germen, which is situated below the petals, afterward becomes a pyramidal fleshy fruit with one cell, filled with small angular seeds surrounded with pulp.

The Species are,

1. CACTUS *subrotundus quatuordecem angularis.* *Hort. Cliff.* 181. Roundish Cactus with fourteen angles; or, the Hedgehog Melon-thistle, commonly called Great Melon-thistle.
2. CACTUS *subrotundus quinquedecem angularis, angulis in spiram intortis, spinis erectis.* Roundish Cactus or Melon-thistle, with fifteen angles spirally twisted, and erect spines.
3. CACTUS *subrotundus quinquedecem angularis, spinis latis recurvis creberrimis.* Roundish Melon-thistle with fifteen angles, having broad recurved spines set very close.
4. CACTUS *subrotundus quatuordecem angularis, spinis longis recurvis albidis.* Roundish Melon-thistle with fourteen angles, and long white recurved spines.

5. *CACTUS subrotundus testus tuberculis ovatis barbatis.* Hort. Cliff. 181. Roundish Cactus closely covered with bearded tubercles; or, Smaller American Melon-thistle.

6. *CACTUS proliferus subrotundus, testus tuberculis ovatis, barbatis longis albidis.* Roundish prolifick Cactus with oval tubercles closely joined, having long white beards, commonly called Small Childing Melon-thistle.

These strange plants commonly grow upon the steep sides of rocks in the warmest parts of *America*, where they seem to be thrust out of the apertures, having little or no earth to support them, their roots shooting down into the fissures of the rock to a considerable depth, so that it is troublesome to get the plants up, especially as they are so strongly armed with thorns as to render it very dangerous to handle them.

The great sorts were some years since brought over to *England* in much greater plenty than of late; but then many of them were destroyed by the unskilfulness of those persons who had the care of them in the voyage; for, by giving them water, they generally caused them to rot before they were taken out of the ships; and some of those which have appeared to be sound, have been so replete with moisture, as to rot soon after they have been placed in the stoves; therefore whoever proposes to bring these plants from abroad, should be very careful to take up their roots as entire as possible, and to plant them in tubs filled with stones and rubbish, mixing very little earth with it, and to plant three or four plants in each tub, in proportion to their sizes; for if they are placed close together, it will save room; and as they do not increase in their growth during their passage, so there need not be any room allowed them for that purpose. There should be several pretty large holes bored through the bottom of these tubs, to let the moisture pass off; and if the plants are planted in the tubs, a month or more before they are put on board the ship, they will in that time have made new roots, which will be the most secure method to have them succeed; but, during their continuance in the country, they should have no water given them, unless the season should prove very hot and dry; and, in that case, it should be given to them sparingly; but after they are put on board the ship, they must not have any moisture whatever; therefore it will be a good method to cover the plants with tarpaulin, to keep off the spray of the sea in bad weather, and expose them at all times to the open air, when the sea is calm. By observing these directions, the plants may be brought to *England* in good health, provided they are brought in summer.

The third sort was brought into *England* by the late Dr. *William Housloun*, who procured the plants from *Mexico*; but as they were long in their passage, and had received wet, they were decayed before they arrived in *England*; but from the remains of them which were left, they appeared to be the most singular of all the species yet known. This has two order of thorns; one of which is strait, and set on at the joints in clusters, spreading out from the center each way like a star; and in the middle of each cluster is produced one broad flat thorn, near two inches in length, which stands erect, and is recurved at the point, and is of a brownish red colour. These thorns are, by the inhabitants of *Mexico*, set in gold or silver, and made use of for picking their teeth; and the plant is by them called *Visnaga*, *i. e.* Toothpick.

The sort with spiral ribs, as also that with white spines, I received from *Antigua*, with the common sort; but whether these are only accidental varieties, arising from the same seeds, or real different species, I cannot take upon me to determine, since, in this country, they are very rarely propagated by seeds; nor could I observe, in the several years that I have had these plants under my care, there was the least disposition in either of them to produce fruit; when, at the same time, the common large sort produced plenty of

fruit out of their caps every year, from the seeds of which I have raised some young plants; but although some of these have grown to a considerable size, yet none of them have as yet produced caps, therefore no fruit can be yet expected from them.

The fifth sort produces quantities of fruit annually; and as the seeds grow very readily, it is now very common in those gardens where there are stoves to keep them; for if the fruit is permitted to drop upon the earth of the pots, and that is not disturbed, there will plenty of plants come up without any farther trouble; and these seedling plants may be taken up as soon as they are of a proper size to remove, and planted six or seven of them into a small halfpenny pot, where they may stand one year; by which time they will be large enough to be each planted into a separate pot, and afterward they will make great progress. This sort is much more hardy than the large kind, so may be preserved in a moderate stove, or in a warm room, but the plants will not make near the progress as those which are kept in a greater degree of heat. It will continue many years with proper care, and the plants will grow to be a foot high, or more; but when they are so tall, the lower part of them is not so slightly, their green being decayed, and the spines changed to a dark dirty colour, they appear as if dead, so that the upper part of these old plants only seem to have life; whereas the plants of middling size appear healthy from top to bottom. The fruit are of a fine scarlet colour, and continue fresh upon the plants through the winter, which renders them very beautiful at that season. In the spring, when the fruit shrivels, and becomes dry, the seeds will be ripe, and may then be rubbed out, and sown upon the surface of the earth in small pots.

The sixth sort is but little larger than the fifth, growing nearly in the same form; but this produces a great number of young plants from the sides, by which it is increased. It produces tufts of a soft white down upon the knobs, and also between them at every joint, which makes the whole plant appear as if it was covered with fine Cotton. The flowers of this sort are produced from between the knobs, round the sides of the plants; which are in shape and colour very much like those of the fifth sort, but larger. These flowers are not succeeded by any fruit, at least all those which I have under my care, have not produced any, although they have produced plenty of flowers for some years; but from the same places where the flowers have appeared, there have been young plants thrust out the following season.

All the species of this genus are plants of a singular structure; but especially the larger kinds of them, which appear like a large fleshy green Melon, with deep ribs, set all over with strong sharp thorns, and when the plants are cut through the middle, their inside is a soft, pale, green, fleshy substance, very full of moisture. And I have been assured by persons of credit, who have lived in the *West-Indies*, that in times of great drought, the cattle repair to the barren rocks, which are covered with these plants, and after having ripped up the large plants with their horns, so as to tear off the outside skin with the thorns, they have greedily devoured all the fleshy moist parts of the plants, which has afforded them both meat and drink.

The fruit of all the sorts of Melon-thistles, are frequently eaten by the inhabitants of the *West-Indies*; there is scarce any difference in the fruits of all the kinds I have yet seen, either in size, shape, colour, or taste. They are about three quarters of an inch in length, of a taper form, drawing to a point at the bottom toward the plant, but blunt at the top, where the empalement of the flower was situated. The taste is an agreeable acid, which, in a hot country, must render the fruit more grateful.

All the larger sorts of these plants require a very good stove

stove to preserve them through the winter in *England*; nor should they be exposed to the open air in summer, for although they may continue fair to outward appearance, when they have been some time exposed abroad, yet they will imbibe moisture, which will cause them to rot soon after they are removed into the stove again. And this is frequently the case of those plants which are brought from abroad, which have a fair healthy appearance many times at their first arrival, but soon after decay, and this will happen very suddenly; scarce any appearance of disorder will be seen, till the whole plant is killed; which, in a few hours time, has often been the fate of the plants, when they have been placed in the stove.

If these plants are plunged into a hot-bed of tanners bark in summer, it will greatly forward them in their growth; but when this is practised, there should be scarce any water given to the plants, for the moisture which they will imbibe from the fermentation of the tan, will be sufficient for them, and more would cause them to rot. The best method to preserve all the large kinds is, in winter, to place the pots, either upon the top of the fires, or, at least, very near them, that they may have the warmest place of the stove; and during that season never to give them any water. The soil in which these should be planted, must be of a sandy nature, and if mixed with some dry lime rubbish, it will be still better. In the bottom of the pots should be placed some stones, in order to drain off any moisture which may be in the earth; for as these plants naturally grow upon the hot dry burning rocks, which have no earth, and, were it not for these plants, would be absolutely barren, we must imitate their natural soil as near as possible, making some allowance for the difference of the climates.

The great sorts may be propagated by seeds, which must be sown and managed as hath been directed for the smaller sort; but as the plants which are raised from seeds in *England*, will be some years in arriving to any considerable size, it will be much the best way to procure some plants from the *West-Indies*.

The two small sorts propagate so fast in *England*, as to render it unnecessary to send for plants of these kinds from abroad; for whoever hath a mind to be plentifully stocked with them, may be soon supplied; the fifth sort from seeds, and the sixth from the young plants which are thrust out from the side of the old.

CÆSALPINA. *Plum. Nov. Gen.* 9. Brasiletto.

The Characters are,

The flower hath five petals, which are situated like those of the butterfly flowers. It hath ten declining stamina which are distinct. It hath an oblong germen. The empalement afterward becomes an oblong compressed pod, with one cell inclosing three or four compressed seeds.

The Species are,

1. CÆSALPINA foliis duplicato-pinnatis foliolis emarginatis, floribus decandris. Cæsalpina with doubly winged leaves, whose small leaves are indented at the end, and flowers with ten stamina; commonly called Brasiletto.

2. CÆSALPINA foliis duplicato-pinnatis foliolis ovatis integerrimis floribus pentandriis. Cæsalpina with doubly winged leaves, whose small leaves are oval and entire, and flowers with five stamina.

The first sort is the tree which affords the Brasiletto wood which is much used in dying. It grows naturally in the warmest parts of *America*, from whence the wood is imported for the dyers; and the demand for it has been so great, that there are no large trees left in any of the *British* colonies, the biggest scarce exceeding eight inches in diameter, and fifteen feet in height. It hath very slender branches, which are armed with recurved thorns. The leaves are winged, branching out into many divisions, garnished with small oval lobes which are indented at the top. The foot-

stalks of the flowers come out from the side of the branch, and are terminated by a loose pyramidal spike of white flowers, which are shaped somewhat like those of the butterfly kind.

The second sort grows naturally in the same countries with the first, but is of larger size: it sends out many weak irregular branches, armed with short strong upright thorns. The leaves branch out in the same manner as the first, but the lobes (or small leaves) are oval and entire. The flowers are produced in long spikes like those of the former, but are variegated with red.

These plants are propagated by seeds, which should be sown in small pots filled with light rich earth early in the spring, and plunged into a hot-bed of tanners bark. In about six weeks after, the plants will begin to appear, when they must be carefully cleared from weeds, and frequently refreshed with water; in warm weather the glasses of the hot-bed should be raised in the middle of the day, to admit fresh air to the plants. When the plants are two or three inches high, they should be carefully taken out of the pots, and each transplanted into a separate small pot, and plunged into the hot-bed again, observing to water them, and screen them from the heat of the sun, until they have taken new root; after which time, the glasses of the hot-bed should be raised every day, in proportion to the heat of the weather, to admit fresh air to the plants. In this hot-bed the plants may remain till autumn, when they should be removed into the stove, and plunged into the bark bed, where they may have room to grow. These plants being tender, should always be kept in the bark stove, and have a moderate share of heat in the winter; and being placed among other tender exotick plants of the same country, will afford an agreeable variety.

CAINITO. See *Chrysophyllum*.

CAKILE. See *Rocket and Bunias*.

CALAMINTHA. See *Melissa*.

CALCEOLUS, Ladies Slipper. See *Cypripedium*.

CALENDULA. *Lin. Gen. Plant.* 885. Marigold.

The Characters are,

It hath a compound radiated flower, the border or rays being composed of female florets, which are stretched out on one side like a tongue. The hermaphrodite flowers, which compose the disk, are tubulous and quinquesfid. The germen is situated under the petal. These flowers are barren; but the female flowers are each succeeded by one oblong incurved seed, with angular membranes.

The Species are,

1. CALENDULA foliis lineari-lanceolatis semiamplexicaulibus, seminibus echinatis. Marigold with narrow spear-shaped leaves, half embracing the stalk, and prickly seeds; or, the least Marigold.

2. CALENDULA seminibus radii cymbiformibus echinatis, disci bicornibus. *Hort. Cliff.* 425. Marigold with boat-shaped prickly seeds in the border, and those in the center bicorned; or, Common Marigold.

3. CALENDULA foliis lanceolatis denticulatis, pedunculis filiformibus. *Hort. Upsal.* 274. Marigold with spear-shaped indented leaves, and slender foot-stalks.

4. CALENDULA foliis lanceolatis sinuato dentatis caule nudo. *Lin. Sp. Plant.* 922. Marigold with sinuated indented spear-shaped leaves, and a naked stalk.

5. CALENDULA foliis lanceolatis dentatis pedunculis superre incrassatis. *Hort. Cliff.* 274. Marigold with indented spear-shaped leaves, and the upper part of the foot-stalk swelling.

6. CALENDULA foliis linearibus subintegerrimis caule subnudo. *Lin. Sp. Plant.* 922. Marigold with narrow entire leaves, and a naked stalk.

7. CALENDULA foliis obversè ovatis denticulatis, caule fruticoso perenni. *Prod. Leyd.* 531. Marigold with obverse oval leaves which are indented, and a perennial shrubby stalk.

The

The first sort grows naturally in the south of *France, Spain, and Italy*; it rises with a slender branching stalk, which spreads near the ground, and is garnished with narrow, spear-shaped, hairy leaves, which half surround the stalk at their base; the flowers are produced at the extremity of the branches, upon long naked foot-stalks. These are very small, and of a pale yellow colour; the seeds are long, narrow, and on their outside armed with prickles. The root is annual, and perishes soon after the seeds are ripe. If the seeds of this plant are permitted to scatter, there will be a fresh supply of young plants.

The second sort is the common Marigold, which is cultivated for use in the gardens; this is so well known, as to require no description. Of this there are the following varieties; *the common single; the double flowering; the largest very double flower; the double Lemon coloured flower; the greater and smaller childing Marigold.*

These varieties are supposed to have been originally obtained from the seeds of the common Marigold; but these differences continue, if the seeds are properly saved; nor have I observed the common sort approaching to either of these, where they have been long cultivated in the greatest plenty; but as the two childing Marigolds, and the largest double, are subject to degenerate, where care is not taken in saving of their seeds, so I conclude they are not distinct species. The best way to preserve these varieties, is to pull up all those plants, whose flowers are less double, as soon as they appear, that they may not impregnate the others with their farina, and save the seeds from the largest and most double flowers; and the childing sort should be sown by itself, in a separate part of the garden, and the seeds saved from the large center flowers only.

The seeds of these may be sown in *March* or *April*, where the plants are to remain, and will require no other culture, but to keep them clean from weeds, and to thin the plants where they are too close, leaving them ten inches asunder, that their branches may have room to spread.

The third grows naturally at the *Cape of Good Hope*. This plant is annual, and perishes soon after the seeds are perfected.

The lower leaves are oblong, spear-shaped, and deeply indented on their edges. The stalks are produced on every side the root, which decline toward the ground, and are garnished with leaves from the bottom, to within two inches of the top. The upper part of the stalk is very slender, upon which rests one flower, shaped like those of the common Marigold, having a purple bottom; and the rays (or border) of the flower are of a Violet colour on their outside, and of a pure white within; these open when the sun shines, but shut up in the evening, and remain so in cloudy weather.

The fourth sort is a native of the *Cape of Good Hope*. This is also an annual plant, and has much the appearance of the former, but the leaves are more deeply indented on their edges; the stalks grow about the same length as the former; the flower is a little smaller, and the outside of the rays are of a fainter purple colour. The seeds of this are flat and heart-shaped, but those of the former are long and narrow.

The fifth sort was brought from the same country as the two former, and is also an annual plant; the leaves of this are much longer than those of either the former sorts, and broader at the end; they are regularly indented near the root, but those on the stalks have but few and shallow indentures. The stalks of this sort are much longer and thicker than those of the former; and at the top, just below the flower, swell larger than it is at bottom; the flower is smaller than those of the other sorts, but is of the same colour.

The seeds of these plants should be sown in the spring, in the borders of the garden, where the plants are designed to remain, for they do not bear transplanting well; therefore they may be treated in the same manner, and sown at the same time, with Candy Tuft, Venus Looking-glass, and other hardy annual plants, putting four or five seeds in each patch; if they all grow, there should not be more than two or three plants left; after this they require no farther care, but to keep them clean from weeds. If the seeds of these plants are permitted to scatter, the plants will come up the following spring without care, and these will flower earlier than those which are sown in the spring.

The sixth sort is also a native of the same country. This is a perennial plant, which divides near the root, into several tufted heads, which are closely covered with long grassy leaves, coming out on every side without order, and are for the most part entire. From between the leaves arise naked foot-stalks, about nine inches long, sustaining one flower at the top, which is about the size of the common Marigold, having a purple bottom; the rays are also purple without, but of a pure white within. These expand when the sun shines, but always close in the evening, and in cloudy weather. This sort doth not often produce good seeds in *Europe*, but it is easily propagated by slips taken off from the heads, in the same manner as is practised for Thrift. They may be planted any time in summer, in a shady border, covering them close with a Melon glass. After they have got strong roots, they should be each planted into separate small pots, filled with fresh light earth, and placed in a shady situation, till they have taken fresh root, when they may be placed in the open air, in a sheltered situation, where they may remain till autumn, and then should be placed in a dry airy glass case, for the winter season, or under a common hot-bed frame; for they only require protection from frost and wet, and should enjoy the air at all times when the weather is mild.

The seventh sort hath been of late years introduced from the *Cape of Good Hope*. It hath a slender, shrubby, perennial stalk, which rises to the height of seven or eight feet, but requires support; this sends out a great number of weak branches, from the bottom to the top, which hang downward, unless they are supported; they are garnished with oval leaves, having short flat foot-stalks; they are of a shining green colour on their upper side, but paler underneath; the flowers come out at the end of the branches, on short naked foot-stalks, and are in size and colour like those of the fifth sort.

This is easily propagated by cuttings, which may be planted any time in summer in a shady border, or otherwise shaded with mats in the heat of the day: in five or six weeks, these will have taken root, when they should be carefully taken up, and each put into a separate pot, and placed in the shade till they have taken fresh root; then they may be placed with other hardy exotick plants in a sheltered situation, where they may remain till the frost begins, when they must be removed into the green-house, placing them near the windows that they may enjoy the free air, for this plant only requires protection from frost.

CALF'S-SNOUT. See Antirrhinum.

CALLA. *Lin. Gen. Plant.* 917. Wake Robin, or *Ethiopian Arum*.

The Characters are,

It hath a large open spathe of one leaf, coloured and permanent. It hath a single upright spadix, to which the flowers and fruit adhere. This hath male and female flowers, intermixed toward the upper part of the club, or spadix. The male flowers consist of many very short stamina; the female flowers have a compressed style, resting upon an obtuse germen, which after-ward becomes a globular pulpy fruit, compressed on two sides, inclosing two or three obtuse seeds.

We have but one *Species* of this genus in the gardens, viz.

CALLA foliis sagitato-cordatis, spathâ cucullatâ, spadice superne masculo. Hort. Cliff. 436. Calla with arrow-headed heart-shaped leaves, a hooded spatha or sheath, and male flowers situated on the upper part of the spadix.

This plant hath thick fleshy tuberous roots, which are covered with a thin brown skin, and strike down many strong fleshy fibres into the ground. The leaves have foot-stalks more than a foot long, which are green and succulent. The leaves are shaped like the point of an arrow, they are eight or nine inches in length, ending in a sharp point, which turns backward; between the leaves arises the foot-stalk of the flower, which is thick, smooth, of the same colour as the leaves, and rises above them, and is terminated by a single flower, shaped like those of the Arum, the hood or spatha being twisted at the bottom, but spreads open at the top, and is of a pure white colour. When these fade, part of those which are situated at the top of the club, are succeeded by roundish fleshy berries compressed on two sides, each containing two or three seeds.

This plant grows naturally at the *Cape of Good Hope*. It propagates very fast by offsets, which should be taken off the latter end of *August*, at which time the old leaves decay; for at this season the roots are in their most inactive state. These roots have generally a great number of offsets about them, so that unless there is a want of them, the largest only should be chosen, which should be separated from all the smaller, and each planted in a separate pot, and placed with other hardy exotick plants in the open air till autumn, when they must be removed into shelter for the winter season. This plant is so hardy as to live in the open air in mild winters, without any cover, if they are planted in warm borders, and have a dry soil; but with a litter shelter in hard frost, they may be preserved in full growth very well.

CALLACARPA. See *Johnsonia*.

CALTHA. Lin. Gen. Plant. 623. Marsh Marigold.

The Characters are,

The flower is composed of five large oval petals which are concave; it hath a great number of slender stamina. In the center there are several oblong compressed germen situated, which afterward become so many short pointed capsules, containing many roundish seeds.

We have but one *Species* of this genus, viz.

CALTHA foliis orbiculatis crenatis, flore majore. Marsh Marigold with round crenated leaves, and a larger flower.

This plant grows upon moist boggy land, in many parts of *England*; of this there is a variety, with very double flowers, which for its beauty is preserved in gardens, and is propagated by parting of the roots in autumn. It should be planted in a moist soil, and a shady situation; and as there are often such places in gardens, where few other plants will thrive, so these may be allowed to have room, and during their season of flowering, will afford an agreeable variety.

CAMARA. See *Lantana*.

CAMERARIA. Plum. Nov. Gen. 18.

The Characters are,

The flower is of one leaf, salver-shaped, and divided at the top into five acute segments; it hath five short inflexed stamina. In the bottom of the tube are situated two roundish germen, which afterward become two long, taper, leafy capsules, filled with oblong cylindrical seeds.

The Species are,

1. *CAMERARIA foliis subrotundis, utrinque acutis.* Hort. Cliff. 76. Cameraria with roundish leaves ending in points.

2. *CAMERARIA foliis linearibus.* Lin. Sp. Pl. 210. Cameraria with very long narrow leaves.

The first sort was sent me from the *Havanna*, where it grows naturally in great plenty. This rises with a shrubby

stalk, to the height of ten or twelve feet, dividing into several branches, which are garnished with roundish pointed leaves placed opposite. The flowers are produced at the end of the branches in loose clusters, which have long tubes enlarging gradually upward, and at the top are cut into five segments, broad at their base, but end in sharp points: the flower is of a yellowish white colour.

The second sort hath an irregular shrubby stalk, which rises about eight feet high, sending out many branches, which are garnished with very narrow, thin leaves placed opposite at each joint. The flowers are produced scatteringly at the end of the branches, which are shaped like those of the former sort, but smaller. Both these plants abound with an acrid milky juice like the Spurge. The second sort grows naturally in *Jamaica*.

These plants are propagated by seeds, which must be procured from the places of their growth. They may also be propagated by cuttings planted in a hot-bed during the summer months: they must have a bark stove, for they are very tender plants; but in warm weather must have plenty of air.

CAMPANULA. Tourn. Inst. R. H. 108. Tab. 38. Bell-flower.

The Characters are,

The flower is of one leaf shaped like a bell, spreading at the base. In the bottom is situated the five-cornered nectarium, which is joined to the top of the receptacle; it hath five short stamina. Below the receptacle is situated the angular germen; the empalement afterward becomes a roundish angular capsule, which in some species have three, and in others five cells, each having a hole toward the top, through which the seeds are scattered when ripe.

The Species are,

1. *CAMPANULA foliis ovatis glabris subserratis, - caule erecto paniculato, ramulis brevibus.* Bell-flower with oval, smooth leaves sawed below, an upright paniculated stalk, and short branches.

2. *CAMPANULA foliis radicalibus obovatis, caulibus lanceolato-linearibus subserratis sessilibus remotis.* Lin. Sp. Plant. 164. Peach-leaved Bell-flower.

3. *CAMPANULA capsulis quinquelocularibus testis, calycis sinibus reflexis.* Vir. Cliff. 16. Garden Bell-flower with an oblong leaf and flower, commonly called *Canterbury Bell-flower*.

4. *CAMPANULA caule angulato, foliis petiolatis, calycibus ciliatis, pedunculis trifidis.* Vir. Cliff. 16. Greater and rougher Bell-flower with Nettle leaves.

5. *CAMPANULA foliis ovato-lanceolatis, caule simplicissimo tereti, floribus solitariis pedunculatis fructibus cernuis.* Vir. Cliff. 17. Greatest Bell-flower with broadest leaves.

6. *CAMPANULA foliis undulatis radicalibus lanceolato-ovalibus, paniculâ coarctatâ.* Hort. Upsal. 40. Bell-flower with an esculent root, commonly called *Rampion*.

7. *CAMPANULA caule angulato simplici, floribus sessilibus capitulo terminali.* Vir. Cliff. 16. Meadow Bell-flower with flowers gathered in bunches.

8. *CAMPANULA caule ramosissimo diffuso foliis oblongis subcrenatis, calycibus solitariis corollâ longioribus, capsulis prismaticis.* Hort. Upsal. 41. Upright Field Bell-flower with yellow Eye-bright leaves.

9. *CAMPANULA caule ramoso foliis ovatis sessilibus, floribus pedunculatis terminatricibus.* Upright Field Bell-flower, or *Venus Looking-glass*.

10. *CAMPANULA caule basi subramoso stricto, foliis oblongis crenatis, calycibus aggregatis corollâ longioribus, capsulis prismaticis.* Lin. Sp. Pl. 168. Least upright Field Bell-flower, or small *Venus Looking-glass*.

11. *CAMPANULA caule dichotomo, foliis sessilibus utrinque dentatis.* Hort. Cliff. 65. Smaller annual Bell-flower with cut leaves.

12. *CAMPANULA caule subdiviso ramosissimo, foliis linearibus acuminatis. Hort. Cliff. 66.* Five-cornered Bell-flower of *Thrace*, with a very large flower.

13. *CAMPANULA caule simplici, foliis cordatis dentatis amplexicaulibus, floribus sessilibus aggregatis. Hort. Upsal. 40.* Five-cornered perfoliate Bell-flower.

14. *CAMPANULA caule ramoso, foliis linguiformibus crenulatis margine cartilagineo. Prod. Leyd. 246.* Smaller *American* Bell-flower with stiff leaves, and a blue spreading flower.

15. *CAMPANULA foliis hastatis dentatis oppositis petiolatis, capsulis quinquelocularibus. Lin. Sp. Plant. 168.* Canary Bell-flower, with an Orach leaf and a tuberous root.

There are several other species of this genus, some of which grow naturally in *England*, and others in the northern parts of *Europe*, which have but little beauty, therefore are seldom cultivated in gardens, so I shall not enumerate them here. There are also several varieties of some of the sorts here mentioned, which I shall take notice of in their proper place; but as they are not distinct species, so I have omitted them in the above list.

The first sort hath thick tuberous roots which are milky; this sends out strong, smooth, upright stalks, which rise four feet high, garnished with smooth oblong leaves, whose edges are a little indented. The flowers are produced from the side of the stalks, and are regularly set on for more than half their length, forming a sort of pyramid; these are large, open, and shaped like a bell. The most common colour of the flowers is a light blue; but there have been some with white flowers, which make a variety when intermixed with the blue, but the latter is most esteemed.

This plant is cultivated to adorn halls, and to place before chimnies in the summer, when it is in flower, for which purpose there is no plant more proper; for when the roots are strong, they will send out four or five stalks, which will rise as many feet high, and are garnished with flowers great part of their length. When the flowers begin to open, the pots are removed into the rooms, where, being shaded from the sun, and kept from the rain, the flowers will continue long in beauty; and if the pots are every night removed into a more airy situation, but not exposed to heavy rains, the flowers will be fairer, and continue much longer in beauty.

Those plants which are thus treated, are seldom fit for the purpose the following season, therefore a supply of young plants should be annually raised. The common method of propagating this plant, is by dividing the roots. The best time for doing this is in *September*, that the offsets may have time to get strong roots before winter.

This method of propagating by the offsets is the quickest, therefore generally practised; but the plants which are raised from seeds are always stronger, and the stalks will rise higher, and produce a greater number of flowers, therefore I recommend it to the practice of the curious; but in order to obtain good seeds, there should be some strong plants placed in a warm situation, near a pale, or wall, in autumn; and, if the following winter should prove severe, they should be covered either with hand glasses or mats, to prevent their being injured by the frost; and, in the summer, when the flowers are fully open, if the season should prove very wet, the flowers must be screened from great rains, otherwise there will be no good seeds produced: the not observing this, has occasioned many to believe that the plants do not bear seeds in *England*, which is a great mistake, for I have raised great numbers of the plants from the seeds of my own sowing; but I have always found that the plants which have been long propagated by offsets, do seldom produce seeds, which is the same with many other plants which are propagated by slips or cuttings, which in a few years become barren.

When the seeds are obtained, they must be sown in autumn in pots, or boxes, filled with light undunged earth, and placed in the open air till the frost, or hard rains come on, when they should be placed under a hot-bed frame, where they may be sheltered from both; but in mild weather the glasses should be drawn off every day, that they may enjoy the free air; with this management the plants will come up early in the spring, and then they must be removed out of the frame, placing them first in a warm situation; but when the season becomes warm, they should be removed where they may have the morning sun only. In *September* the leaves of the plants will begin to decay, at which time they should be transplanted; therefore there must be one or two beds prepared, in proportion to the number of plants. These beds must be in a warm situation, and the earth light, sandy, and without any mixture of dung, which last is an enemy to this plant. If the situation of the place is low, or the natural soil moist, the beds must be raised five or six inches above the surface of the ground, and the natural soil removed a foot and an half deep, putting lime rubbish or stones, eight or nine inches thick in the bottom of the trench, to drain off the moisture. When the beds are prepared, the plants must be taken out of the pots or cases, very carefully, so as not to break or bruise their roots, for they are very tender, and, on being broken, the milky juice will flow out plentifully, which will greatly weaken them. These should be planted at about six inches distance each way, with the head, or crown of the root, half an inch below the surface; if there happens a gentle shower of rain soon after they are planted, it will be of great service to the plants, but as the season sometimes proves very dry at this time of the year, so, in that case, it will be proper to give them a gentle watering three or four days after they are planted, and to cover the beds with mats every day, to prevent the sun from drying the earth, but these must be taken off in the evening, that the dew may fall on the ground. Towards the end of *November* the beds should be covered over with some old tanners bark to keep out the frost, and where there is not conveniency of covering them with frames, they should be arched over with hoops, that in severe frosts they may be covered with mats, for these plants, when young, are often destroyed in winter, where this care is wanting. In the spring the coverings must be removed, and the following summer the plants must be kept clean from weeds. The following autumn the surface of the ground should be stirred between the plants, and some fresh earth spread over the beds, and in the winter covered as before. In these beds the plants may remain two years, during which time they must be treated in the manner before directed, by which time the roots will be strong enough to flower, so in *September* they should be carefully taken up, and some of the most promising planted in pots; the others may be planted into warm borders, or in a fresh bed, at a greater distance than before, to allow them room to grow. Those plants which are potted should be sheltered in winter from great rains and hard frosts, otherwise they will be in danger of rotting, or at least will be so weakened, as not to flower with any strength the following summer; and those which are planted in the full ground, should have some old tanners bark laid round them, to prevent the frost from entering deep to the roots; with this management these plants may be brought to the utmost perfection, and a constant succession of good roots raised, which will be much preferable to those which are propagated by offsets.

The second sort grows naturally in the northern parts of *Europe*. Of this there are the following varieties, *viz.* the single blue, and white flower, which have been long here; and the double flower of both colours, which have not been more than thirty years in *England*, but have been propagated in such plenty, as to have almost banished those with single flowers from

from the gardens. All these varieties are easily propagated by parting of their roots in autumn, every head which is then slipped off will take root; they are extreme hardy, so will thrive in any soil or situation, therefore are very proper furniture for the common borders of the flower garden.

The third sort is a biennial plant, which perishes soon after it hath ripened seeds. It grows naturally in the woods of *Italy* and *Austria*, but is cultivated in the *English* gardens for the beauty of its flowers. Of this sort there are the following varieties, the blue, the purple, the white, the striped, and double flowering.

This hath oblong, rough, hairy leaves, which are serrated on their edges: from the center of these a stiff, hairy, furrowed stalk, arises about two feet high, sending out several lateral branches, which are garnished with long, narrow, hairy leaves, sawed on their edges: from the setting on of these leaves, come out the foot-stalks of the flower; those which are on the lower part of the stalk and branches, being four or five inches long, diminishing gradually in their length upward, and thereby form a sort of pyramid. The flowers of this kind are very large, so make a fine appearance. The seeds ripen in *September*, and the plants decay soon after.

It is propagated by seeds, which must be sown in the spring, on an open bed of common earth, and when the plants are fit to remove, they should be transplanted into the flower nursery, in beds six inches asunder; and the following autumn, they should be transplanted into the borders of the flower garden. As these plants decay the second year, so there should be annually young ones raised to succeed them.

The fourth sort hath a perennial root, which sends up several stiff hairy stalks, having two ribs, or angles. These put out a few short side branches, garnished with oblong pointed leaves, which are hairy, and deeply sawed on their edges. Toward the upper part of the stalks, the flowers come out alternately, upon short trifid foot stalks, having hairy empalements.

The varieties of this are, the deep and pale blue; the white with single flowers, and the same colours with double flowers. The double sorts are propagated by parting of their roots in autumn, which should be annually performed, otherwise the flowers are apt to degenerate to single. The soil should not be too light or rich in which they are planted, for in either of these they will not produce double flowers. The plants are extreme hardy, and may be planted in any situation; those with single flowers do not merit a place in gardens.

The fifth sort grows naturally in the northern parts of *England*; this hath a perennial root, composed of many fleshy fibres, that abound with a milky juice, from which arise several strong, round, single stalks, which never put out branches, but are garnished with oval spear-shaped leaves, slightly indented on their edges. Toward the upper part of the stalk, the flowers come out singly upon short foot-stalks. After the flowers are past, the empalement becomes a five-cornered seed vessel, which turns downward till the seeds are ripe, when it rises upward again.

The varieties of this are the blue, purple, and white flowering. This sort is easily propagated by seeds, which it furnishes in great plenty, and, if suffered to scatter, the plants will come up in as great plenty the following spring, when they may be transplanted into the nursery till autumn, at which time they should be transplanted where they are designed to remain.

The sixth sort hath roundish fleshy roots, which are eatable, and are much cultivated in *France* for sallets; and some years past it was cultivated in the *English* gardens, but is now generally neglected. It grows naturally in several parts of *England*, but those roots never grow to half the size of those

which are cultivated. This is propagated by seeds, which should be sown in a shady border, and when the plants are about an inch high, the ground should be hoed, as is practised for Onions, to cut up the weeds, and thin the plants to the distance of three or four inches; and when the weeds come up again, they must be hoed over to destroy them; this, if well performed in dry weather, will make the ground clean for a considerable time, so that being three times repeated, it will keep the plants clean till the winter, which is the season for eating the roots, when they may be taken up for use as they are wanted. These will continue good till *April*, at which time they will send out their stalks, when they will become hard and unfit for use.

The seventh sort grows naturally upon chalky pastures in many parts of *England*, where the stalks do not rise many times a foot high, and in other places it grows to double that height, which has occasioned their being taken for two distinct plants. This hath a perennial root, which sends up several round hairy stalks, which rise upward of two feet high; the bottom leaves are broad, and stand upon long foot-stalks. Those which are upon the stalks are long, narrow, have no foot-stalks, and are placed alternately at considerable distances. From the wings of the leaves, towards the upper part of the stalk, come out long naked foot-stalks, supporting two or three bell-shaped flowers, closely joined together in a head, and the main stalk is terminated by a large cluster of the same flowers, which are succeeded by roundish capsules filled with small seeds. This plant is easily propagated, either by seeds or parting of the roots, and will thrive in any soil or situation.

The eighth sort is an annual plant, which rises with slender stalks a foot high, branching out on every side, garnished with oblong leaves, a little curled on their edges; from the wings of the leaves come out the flowers, sitting close to the stalks, which are of a beautiful purple, inclining to a Violet colour. In the evening they contract and fold into a pentagonal figure, from whence it is by some titled *Viola Pentagonia*, or five-cornered Violet. If this plant is sown in autumn, it will grow much taller, and flower a month earlier than when the seeds are sown in the spring. The autumnal plants will flower in *May*, and the spring plants in *June* and *July*.

The ninth sort is the common Venus Looking-glass. This sort seldom rises more than six inches high, with a stalk branching from the bottom upward, and garnished with oval leaves, sitting close to the stalks, from the base of which the branches are produced, which are terminated by flowers, very like those of the former sort.

The tenth sort grows naturally in *England*, in arable land; this sends out an upright stalk, about six or seven inches high, and near the root there are a few lateral branches, which are weak, and spread out on every side. These are garnished with oval obtuse leaves, which are slightly indented on their edges, placed alternately. At the extremity of the branches the flowers are produced in clusters, which are small, but of the same shape with the former, having a five leaved empalement, much longer than the petal; the seed-vessel is shaped like those of the two former, but are smaller.

The eleventh sort grows naturally in the south of *France* and *Italy*. This is also a low annual plant, which seldom rises six inches high, but divides into many branches, which are garnished with short oval leaves, sitting close to the branches. The flowers are produced at the ends of the branches, which are shaped like those of the other three sorts last mentioned, but they are small, and their colour less beautiful, and the leaves of the empalement are broader.

The twelfth sort grows naturally in *Thrace*. This is also a low annual plant, which rises little more than six
P inches

inches high; the stalks divide by pairs, and frequently there arises a branch from the middle of the divisions; the lower leaves are oblong and obtuse, but those which come out toward the end of the branches are much narrower, and pointed. The flowers come out single at the end of the branches, having a long five-leaved empalement, and are larger than those of the three last sorts, and of a fine blue colour.

The ninth sort is the old Venus Looking-glass, which was formerly cultivated in the gardens, but since the eighth sort hath been introduced, it hath almost supplanted the other; for the eighth is a much taller plant, and the flowers are larger, but their colour is less beautiful; however it produces a greater quantity of seeds, so is to be had in plenty, and there are few persons that are curious enough to distinguish them.

If these, and the Venus Navelwort, Dwarf Lychnis, Candy Tuft, and other low annual flowers, are properly mixed in the border of the flower garden, and sown at two or three different seasons, to have a succession of them in flower, they will afford an agreeable variety. If these seeds are sown in autumn, the plants will flower early in spring, but those which are sown in the spring, will not flower till the middle of *June*; and if a third sowing is performed about the middle of *May*, the plants will flower in *August*, but from the last sowing, good seeds must not be expected.

The thirteenth sort is an annual plant, which in good ground will rise a foot and an half, but in poor land, or where it grows wild among Corn, scarcely rises to the height of six inches. The stalk is single, rarely putting out any branches, unless near the root. The leaves are roundish, and embrace the stalk at their base; their edges are sharply sawed, and from their base comes out a close tuft of flowers, surrounded by the leaf, as in an empalement. The flowers are five-cornered, shaped like those of the Venus Looking-glass, but are much smaller; these are produced the whole length of the stalk. The seeds are inclosed in short capsules, which are shaped like those of the former sorts. If the seeds of this sort are permitted to scatter, the plants will come up without care; or the seeds may be sown in the spring, in the same manner as those of the last sorts, and treated in the same way.

The fourteenth sort is a native of *America*. This hath many rigid oblong leaves coming out from the root on every side, which form a sort of head like those of House-leek, and are crenated, having a strong rib running on their border longitudinally. From the center of the plant proceeds the stalk, which rises about a foot high, and is thinly garnished with very narrow stiff leaves, of a shining green. From the wings of the leaves come out the foot-stalks of the flower, which are from two to four inches long, each being terminated by one spreading bell-shaped flower, whose empalement is short, and cut into five acute segments. There is a white and a blue flower of this sort in the gardens, and in *Holland* they have it with a double flower. This sort doth not produce seeds in *England*, so is only propagated by offsets; which may be taken off from the old plants in *August*, that they may get good root before the cold weather begins; they must be planted in small pots, and placed in the shade until they have taken root, then they may be placed with other hardy exotick plants, and in autumn some of them should be removed into shelter; for in severe frosts, those in the open air are often killed.

The fifteenth sort is a native of the *Canary Islands*. This hath a thick fleshy root, which is of an irregular form, sometimes running downward like a Parsnep, at other times dividing into several knobs near the top, and when any part of the root is broken, there issues out a milky juice at the

wound. From the head, or crown of the root, arises one, two, three, or more stalks, in proportion to the size of the root; but that in the center is generally larger, and rises higher than the others. These stalks are very tender, round, and of a pale green; their joints are far distant from each other, and when the roots are strong, the stalks will rise ten feet high, sending out several smaller side branches. At each joint they are garnished with two, three, or four spear-shaped leaves, with a sharp pointed beard on each side. These are of a sea-green, and, when they first come out, are covered slightly with an Ash-coloured pounce. From the joints of the stalk the flowers are produced, which are of the perfect bell-shape, and hang downward; they are of a flame colour, marked with stripes of a brownish red; the flower is divided into five parts, at the bottom of each is situated a nectarium, covered with a white transparent skin, much resembling those of the Crown Imperial, but are smaller. In the center of the flower is situated the style, which is longer than the stamina, and is crowned by a trifid stigma, which is reflexed. The flowers begin to open in the beginning of *October*, and there is often a succession of them till *March*. The stalks decay to the root in *June*, and new ones spring up in *August*.

It is propagated by parting of the roots, which must be done with caution; for if they are broken or wounded, the milky juice will flow out plentifully, so that if these are planted before the wounds are skinned over, it occasions their rotting; therefore whenever any of them are broken, they should be laid in the green-house a few days to heal. These roots must not be too often parted, especially if they are expected to flower well; for by frequent parting, the roots are weakened. The best time for transplanting and parting of their roots, is in *July*, soon after the stalks are decayed. The earth in which these should be planted, must not be rich, for that will cause them to be luxuriant in branches, and but thinly garnished with flowers. The soil in which they have succeeded best, is a light sandy loam, mixed with a fourth part of screened lime rubbish; when the roots are first planted, the pots should be placed in the shade; and, unless the season is very dry, should not be watered, for during the time they are inactive, wet is very injurious to them. About the middle of *August* the roots will begin to put out fibres, at which time, if the pots are placed under a hot-bed frame, and as the nights grow cool, covered with the glasses, but opened every day to enjoy the free air, it will greatly forward them for flowering, and increase their strength; when the stalks appear, the plants must be now and then refreshed with water, which must not be given too often, nor in great quantity. The plants thus managed, by the middle of *September* will have grown so tall, as not to be kept longer under the frame, so they should be removed into a dry airy glass case, where they may enjoy the free air in mild weather, but screened from cold. During the winter season, they must be frequently refreshed with water, and guarded from frost; and in the spring, when the stalks begin to decay, the pots should be set abroad in the shade, and not watered.

CAMPHORA. See *Laurus*.

CAMPION. See *Lychnis*.

CANDLE-BERRY-TREE. See *Myrica*.

CANDY-TUFT. See *Iberis*.

CANNA. *Lin. Gen. Pl.* 1. *Indian Cane*.

The Characters are,

The flower hath one petal, which is divided into six parts: the three upper segments are erect, and broader than the lower, two of which are erect, and the other turns back and is twisted. It hath one spear-shaped stamina rising as high as the petal, having the appearance of a segment. Below the empalement is situated a roundish, rough germen, which becomes an oblong, roundish, membranaceous

branaceous capsule, having three longitudinal furrows, crowned by the empalement, which hath three cells filled with round smooth seeds.

The Species are,

1. *CANNA foliis ovatis utrinque acuminatis nervosis. Prod. Leyd.* 11. Common broad-leaved flowering Cane.

2. *CANNA foliis ovatis obtusis nervosis, spicis florum longioribus. Indian* flowering Cane, with a pale red flower.

3. *CANNA foliis lanceolatis petiolatis nervosis. Prod. Leyd.* 11. *Indian* Cane with glaucous leaves, a very large flower, and the appearance of the Marsh Iris.

The first grows naturally in both *Indies*: the inhabitants of the *British* islands in *America* call it *Indian Shot*, from the roundness and hardness of the seeds.

This plant hath a thick, fleshy, tuberous root, which divides into many irregular knobs, it sends out many large oval leaves without any order; these, at their first appearance, are twisted like a horn, but afterwards expand and are near a foot long, and five inches broad in the middle, lessening gradually to both ends, and terminated in a point. The stalks are herbaceous, rising four feet high, and are encompassed by the broad leafy foot-stalks of the leaves; at the upper part of the stalk, the flowers are produced in loose spikes, each being at first covered by a leafy hood, which afterward stands below the flower, and turns to a brown colour. The flower is encompassed by a three-leaved empalement, which sits upon a small, roundish, rough germen, which, after the flower is fallen, swells to a large fruit or capsule, oblong, rough, and is crowned by the three-leaved empalement of the flower which remains. When the fruit is ripe, the capsule opens lengthways into three cells, which are filled with round, hard, black, shining seeds.

As this sort is a native of the warmest parts of *America*, so it requires to be placed in a moderate stove in winter, where they always flower in that season, at which time they make a fine appearance; and in the summer, place them abroad in a sheltered situation with other tender exotick plants, where they flower again, and produce ripe seeds annually.

The second sort grows naturally in *Carolina*, and some of the other northern provinces of *America*. The leaves of this sort are longer than those of the former, and terminate in sharper points. The stalks grow taller, and the segments of the flower are much narrower; the colour is a pale red, so it makes no great appearance. The seeds are like those of the former sort. If the roots of this sort are planted in warm borders and a dry soil, they will live through the winter in the open air without cover, and flower well every year.

The seeds of the third sort I received from *Carthage* in *New Spain*, in the year 1733, which produced very strong plants the first year, some of which flowered the same autumn. The roots of this are much larger than either of the former sorts, and strike down strong fleshy fibres deep in the ground. The stalks rise seven or eight feet high. The leaves are near two feet long, narrow, smooth, and of a sea-green colour. The flowers are produced in short thick spikes at the extremity, which are large, and of a pale yellow colour; the segments of the petal are broad, but their shape like those of the other sorts. The seed vessels are larger, and much longer than those of the other sorts, but contain fewer seeds, which are very large.

All the sorts are propagated by seeds, which should be sown on a hot-bed in the spring, and when the plants are fit to remove, they should be transplanted into separate small pots, and plunged into a moderate hot-bed of tanners bark, observing to shade them till they have taken root; after which, they should have a large share of free air admitted to them every day, in warm weather. As these plants will make great progress in their growth, so they must be shifted into larger pots, and part of them plunged into the hot-

bed again; the others may be placed abroad in *June*, with other exotick plants, in a warm situation. Those which are placed in the hot-bed, will be strong enough to flower well in the stove the following winter; but those in the open air, will not flower before the following summer: these may remain abroad till the beginning of *October*, when they must be removed into the stove, and treated in the same manner as the old plants. These plants will continue many years with proper management, but as young plants always flower better than the old roots, so it is scarce worth while to continue them after they have borne good seeds.

The second sort which is much hardier than either of the other, should have a different treatment. The young plants of this must be earlier inured to the open air, where they may remain till the frost begins; then they must be placed in the green-house, and should have but little wet in winter; and the beginning of *May*, these should be turned out of the pots, and planted in a warm south border, in a dry soil, where they will thrive and produce flowers annually. There is a variety of this with variegated leaves, which is preserved in some gardens, and is propagated by parting of the roots; but this hath little beauty, so is scarce worth cultivating.

CANNABINA. See *Datisca*.

CANNABIS, Hemp.

The Characters are,

It is male and female in different plants. The male flowers have no petals; they have five short hairy stamina, terminated by oblong square summits. The female flowers have no petals but a small germen, which afterward becomes a globular depressed seed, inclosed in the empalement.

We have but one Species of this plant, viz.

CANNABIS. *Lin. Sp. Plant.* 1027. Hemp.

This plant is propagated in the rich fenny parts of *Lincolnshire*, in great quantities, for its bark, which is useful for cordage, cloth, &c. and the seeds afford an oil, which is used in medicine.

Hemp is always sown on a deep moist rich soil, such as is found in *Holland*, in *Lincolnshire*, and the fens in the isle of *Ely*, where it is cultivated to great advantage; as it might in many other parts of *England*, where there is the like soil; but it will not thrive on clay, or stiff cold land: it is esteemed very good to destroy weeds, which is no other way effected, but by robbing them of their nourishment, for it will greatly impoverish the land, so that this crop must not be repeated on the same ground.

The land on which Hemp is designed to be sown, should be well ploughed, and made very fine by harrowing; about the middle of *April* is a good season for sowing of the seed: three bushels is the usual allowance for an acre, but two is fully sufficient: in the choice of the seed, the heaviest and brightest coloured should be preferred, and particular care should be had to the kernel of the seed, so that some of them should be cracked to see if they have the germ or future plant perfect; for in some places the male plants are drawn out too soon from the female, *i. e.* before they have impregnated the female plants with the farina; in which case, though the seeds produced by these female plants may seem fair to the eye, yet they will not grow, as is well known to the inhabitants of *Bickar*, *Swineshead*, and *Dunnington*, three parishes in the fens of *Lincolnshire*, where Hemp is cultivated in great abundance, who have dearly bought their experience.

When the plants are come up, they should be hoed out in the same manner as is practised for Turneps, leaving them two feet apart; observe also to cut down all the weeds, which if well performed, and in dry weather, will destroy them. This crop will require a second hoeing about six weeks after the first, in order to destroy the weeds: if this

be well performed, it will require no farther care; for the Hemp will soon after cover the ground, and prevent the growth of weeds.

The first season for pulling the Hemp is usually about the middle of *August*, when they begin to pull what they call the Fimble Hemp, which is the male plants; but it would be much the better method to defer this a fortnight or three weeks longer, until these male plants have fully shed their dust, without which, the seeds will prove abortive, produce nothing if sown the next year, nor will those concerned in the oil mills give any thing for them, there being only empty husks, without any kernels to produce the oil. These male plants decay soon after they have shed their farina.

The second pulling is a little after *Michaelmas*, when the seeds are ripe: this is usually called Karle Hemp, it is the female plants, which were left at the time when the male were pulled. This Karle Hemp is bound in bundles of a yard compass, according to statute measure, which are laid in the sun for a few days to dry; and then it is stacked up, or housed to keep it dry, till the seed can be threshed out. An acre of Hemp on a rich soil, will produce near three quarters of seed, which, together with the unwrought Hemp, is worth from six to eight pounds.

CANNACORUS. See *Canna*.

CAPERS. See *Capparis*.

CAPNOIDES. See *Fumaria*.

CAPNORCHIS. See *Fumaria*.

CAPPARIS. *Lin. Gen. Plant.* 567. The Caper Bush.

The Characters are,

The flower hath four large roundish petals; it hath a great number of slender stamina. In the midst of these arise a single style longer than the stamina, with an oval germen, which afterward becomes a fleshy turbinated capsule with one cell, filled with kidney-shaped seeds.

The Species are,

1. CAPPARIS *aculeata*. *Hort. Cliff.* 203. Prickly Caper.
2. CAPPARIS *inermis foliis ovatis perennantibus*. Smooth Caper with oval leaves, which remain all the year.
3. CAPPARIS *inermis foliis ovato-oblongis determinatè confertis perennantibus*. *Hort. Cliff.* 201. Smooth Caper with oval oblong leaves, growing in clusters, which continue through the year.
4. CAPPARIS *foliis lanceolato-ovatis perennantibus caule arborescenti*. Caper with oval spear-shaped leaves, which continue through the year, and a tree-like stalk.
5. CAPPARIS *foliis lanceolatis venosis perennantibus, floribus racemosis*. Caper with spear-shaped veined leaves which continue through the year, and flowers growing in bunches.
6. CAPPARIS *foliis ovatis oppositis perennantibus floribus racemosis*. Caper with oval leaves placed opposite, which continue through the year, and flowers growing in bunches.
7. CAPPARIS *foliis oblongo ovatis alternis sessilibus perennantibus, floribus solitariis axillaribus*. Caper with oblong oval leaves, placed alternate close to the stalks, which continue through the year, and flowers growing singly from the sides of the branches.
8. CAPPARIS *foliis lanceolatis acutis confertis perennantibus, caule fruticoso*. Caper with pointed spear shaped leaves, growing in clusters, which continue through the year, and a shrubby stalk.
9. CAPPARIS *foliis lanceolatis alternis, petiolis longissimis floribus confertis*. Caper with spear-shaped leaves placed alternate, on very long foot-stalks, and flowers growing in clusters.
10. CAPPARIS *foliis lanceolatis nervosis perennantibus, pedunculis trifloris*. Caper with nervous spear-shaped leaves, which continue through the year, and three flowers upon each foot-stalk.

The first is the common Caper, whose full grown flower bud is pickled, and brought to *England* annually from *Italy*,

and the *Mediterranean*. This is a low shrub, which generally grows out of the joints of old walls, the fissures of rocks, and amongst rubbish, in most of the warm parts of *Europe*: it hath woody stalks, which send out many lateral slender branches; under each of these are placed two short crooked spines, between which and the branches come out the foot-stalk of the leaves, which are single, short, and sustain a round smooth entire leaf; at the intermediate joints between the branches, come out the flowers upon long foot-stalks; before these expand, the bud, with the empalement, is gathered for pickling; but those which are left expand in form of a single Rose, having five large white petals, which are roundish and concave; in the middle is placed a great number of long stamina, surrounding a style, which rises above them, and is crowned with an oval germen, which afterward becomes a capsule, filled with kidney-shaped seeds.

This sort is cultivated upon old walls about *Toulon*, and in several parts of *Italy*. Mr. Ray observed it growing naturally on the walls and ruins at *Rome*, *Sicenna*, and *Florence*.

The second sort hath weaker stalks than the first, which are smooth, having no spines on them; the leaves are oval, smooth, and in their natural place of growth, continue through the year; but in *England* the young shoots are generally killed in winter. From the foot-stalk of the leaves come out the flowers, which stand upon very long foot-stalks, and are produced singly; these flowers are like those of the former, but are much larger, as are also the buds; but these are not esteemed so good as those of the first for pickling.

These plants are with difficulty preserved in *England*, for they delight to grow in crevices of rocks, and the joints of old walls or ruins, and always thrive best in an horizontal position, so that when they are planted either in pots or the full ground, they rarely thrive, though they may be kept alive for some years. They are propagated by seeds in the warm parts of *Europe*, but it is very difficult to get them to grow in *England*. There is an old plant growing out of a wall in the gardens at *Cambden House*, near *Kensington*, which has resisted the cold for many years, and annually produces many flowers, but the young shoots of it are generally killed to the stump every winter.

The roots of these plants are annually brought from *Italy*, by the persons who import Orange trees, some of which have been planted in walls, where they have lived a few years, but have not continued long.

The third sort I received from *Carthagena* in *New Spain*, near which place it grows naturally. This rises with a woody stem, to the height of twelve or fourteen feet, sending out many lateral branches, covered with a russet bark, and garnished with oblong oval leaves; the flowers are produced from the side of the branches singly, which are like those of the last sort.

The fourth sort was also sent me from *Carthagena*. This grows with a strong upright trunk near twenty feet high, sending out many lateral branches, which are covered with a very white bark, and are closely garnished with large oblong stiff leaves, of a thicker consistence than those of the common Laurel, of a splendid green; the flowers come out from the side of the branches, which are large, and the summits of the stamina are purple.

The fifth sort was sent me from the same country. This rises with a trunk about twenty feet high, sending out many long slender branches, covered with a brown bark, and garnished with leaves like those of the Bay tree, but longer, and deeply ribbed on their under side. The flowers are produced upon long foot-stalks, which terminate the branches, each sustaining two or three flowers, which are large, white, and are succeeded by pods two or three inches long, and the thickness of a man's little finger, which are filled with large kidney-shaped seeds.

The sixth sort was sent me from *Tolu* in *America*. This rises with a shrubby stalk to the height of eight or ten feet, sending out many ligneous branches, garnished with oval stiff leaves, which are placed opposite, upon short red foot-stalks; from the wings of the leaves are produced the foot-stalks of the flowers, which are long, slender, and branch out into many smaller, each of which sustains a small white flower, which is succeeded by an oval pod containing many small kidney-shaped seeds.

The seventh sort rises with a shrubby stem, to the height of twelve or fourteen feet, sending out many strong lateral branches, garnished with oblong oval leaves, placed alternately; the leaves are of a thicker consistence than those of the Bay tree; at the foot-stalk of each leaf comes out a single flower, almost the whole length of the branches, which are small, and stand upon short foot-stalks; the summits of these flowers are of a purplish colour, but the stamina are white.

The eighth sort rises with a shrubby stalk, to the height of ten or twelve feet, sending out slender horizontal branches on every side, which are covered with a reddish bark; the joints of these branches are far distant; at each of these come out several leaves in clusters, without order, standing upon pretty long foot-stalks, smooth on their upper side, but have many transverse ribs on their under side, which are prominent.

The ninth sort I received from *Carthageria*, where it grows naturally; this hath many shrubby stalks arising from the root, which send out many lateral branches on every side, closely garnished with large spear-shaped leaves, standing upon very long foot-stalks; the flowers are produced in clusters at the end of the branches, upon very short foot-stalks; they are small, white, with yellowish stamina, and a very long style, which is incurved, terminated by an oblong germen, which afterwards becomes an oblong fruit.

The tenth sort hath slender shrubby stalks, which rise seven or eight feet high, sending out many ligneous branches, garnished with very long nervous spear-shaped leaves. The flowers come out at the end of the branches, three standing upon each foot-stalk; these are small, white, and are succeeded by oval fruit.

These last eight sorts are natives of warm countries, so will not live through the winter in *England*, without the assistance of a stove. They are propagated by seeds, which must be procured from the countries where they grow naturally. These must be sown in small pots, and plunged into a hot-bed of tanners bark. In about two months the plants will appear, provided the seeds are good, then they must have but little wet, and a good share of air in warm weather; when they are large enough to remove, they must be each transplanted into a separate small pot, and plunged into the hot-bed again, observing to shade them until they have taken fresh root, after which they should have fresh air admitted to them every day, in proportion to the warmth of the season. In autumn they must be removed into the stove, and plunged into the bark bed, where they should constantly remain, and will require the same treatment as other tender exotick plants from the same countries, with this difference only, that they require but little water, especially during the winter, for the roots of these plants are very subject to rot with wet.

BEAN CAPER. See *Zygophyllum*.

CAPRARIA. *Lin. Gen. Pl.* 686. Sweet Weed.

The Characters are,

The flower is bell-shaped, of one leaf, divided at the top into five equal parts; it hath four stamina, which are inserted in the base of the petal, and but little more than half so long, two of the under being shorter than the other. It hath a conical germen, which afterwards becomes an oblong conical capsule, com-

pressed at the point, having two cells, divided by a partition filled with roundish seeds.

We have but one Species of this genus, viz.

CAPRARIA *foliis alternis corollis quinquesidis. Hort. Cliff.* 320. Capraria with alternate leaves, and the petal divided into five parts.

This plant grows naturally in the warm parts of *America*, where it is often a troublesome weed in the plantations; it rises with an angular green stalk, about a foot and an half high, sending out branches at every joint, which sometimes come out by pairs opposite, but generally there are three at a joint standing round the stalk; the leaves are also placed round the branches by threes; these stand upon short foot-stalks, are oval, hairy, and a little indented on their edges. The flowers are produced at the wings of the leaves, coming out on each side the stalk, each foot-stalk sustaining three flowers; they are white, and succeeded by conical capsules, compressed at the top, opening in two parts, and filled with small seeds.

This plant is preserved in botanick gardens for the sake of variety; but as it hath no great beauty, it is seldom admitted into other gardens.

It is propagated by seeds, which must be sown upon a hot-bed in the spring of the year, and the plants must be brought forward by planting them upon a second hot-bed; and about the middle or latter end of *June* they may be transplanted into a warm border, and may then be exposed to the open air, where they will perfect their seeds in autumn.

CAPRIFOLIUM. See *Periclymenum*.

CAPSICUM. *Lin. Gen. Plant.* 225. Guinea Pepper.

The Characters are,

The flower hath but one petal, which is wheel-shaped; it hath five small stamina. It hath an oval germen, which afterwards becomes a soft fruit, or capsule, of an indeterminate figure, having two or more cells, divided by intermediate partitions, to which adhere many compressed kidney-shaped seeds.

The Species are,

1. CAPSICUM *caule herbaceo, fructu oblongo propendente.* Capsicum with an herbaceous stalk, and an oblong fruit hanging downward.

2. CAPSICUM *caule herbaceo, fructu cordiformi.* Capsicum with an herbaceous stalk, and a heart-shaped fruit.

3. CAPSICUM *caule herbaceo, fructu maximo anguloso obtuso.* Capsicum with an herbaceous stalk, and a large angular obtuse fruit, commonly called Bell Pepper.

4. CAPSICUM *caule herbaceo, fructu cordiformi anguloso.* Capsicum with an herbaceous stalk, and an angular heart-shaped fruit.

5. CAPSICUM *caule herbaceo, fructu rotundo glabro.* Capsicum with an herbaceous stalk, and a round smooth fruit.

6. CAPSICUM *caule herbaceo, fructu ovato.* Capsicum with an herbaceous stalk, and an oval fruit.

7. CAPSICUM *caule fruticoso foliis lineari-lanceolatis, fructu pyramidali erecto luteo.* Capsicum with a shrubby stalk, narrow spear-shaped leaves, and yellow pyramidal fruit growing upright.

8. CAPSICUM *caule fruticoso fructu conico erecto rubro.* Capsicum with a shrubby stalk, and a conical red fruit growing erect, commonly called Hen Pepper.

9. CAPSICUM *caule fruticoso, fructu parvo pyramidali erecto.* Capsicum with a shrubby stalk, and a small pyramidal fruit growing erect, commonly called Barberry Pepper.

10. CAPSICUM *caule fruticoso, fructu parvo ovato erecto.* Capsicum with a shrubby stalk, and a small oval fruit growing erect, commonly called Bird Pepper.

The first is the common long poded Capsicum, which is frequently cultivated in the gardens. Of this there is one with red, and another with yellow fruit, which only differ

differ in the colour of the fruit, which difference is permanent.

The *Varieties* of yellow *Capficum* are,

Capficum fructu surrecto oblongo. Tourn. *Capficum* with oblong fruit growing erect.

Capficum fructu bifido. Tourn. *Capficum* with a divided fruit.

Capficum siliquis surrectis & oblongis brevibus. Tourn. *Capficum* with oblong and short pods growing erect.

Capficum fructu tereti spithameo. Tourn. *Capficum* with a taper fruit a span long.

Of these different forms I have had both the red and yellow, but neither of them have changed their colours, though they have frequently varied in their shape.

The second sort with heart-shaped fruit is undoubtedly a different species from the first, and never alters toward it, though there are several varieties of this, which sprout from feeds. Of this there are red and yellow fruit, which do not alter in colour, though they produce the following varieties:

Capficum siliqua propendente rotunda & cordiformi. Tourn. *Capficum* with round, heart-shaped, hanging pods.

Capficum siliqua latiore & rotundiore. Tourn. *Capficum* with a larger and rounder pod.

Capficum rotundo maximo. Tourn. *Capficum* with the largest round fruit.

Capficum siliquis surrectis cordiformibus. Tourn. *Capficum* with upright heart-shaped pods.

Capficum siliquis surrectis rotundis. Tourn. *Capficum* with round upright pods.

The third sort I have cultivated many years, and have not found it alter, nor have I seen any other but the red fruit of this. It is the only sort which is proper for pickling; the skin of the fruit being fleshy and tender, whereas those of the other sorts are thin and tough. The pods of this sort are from one inch and an half, to two inches long, are very large, swelling, and wrinkled; flatted at the top, where they are angular, and sometimes stand erect, at others grow downward. When the fruit of this are designed for pickling, they should be gathered before they arrive to their full size, while their rind is tender; then they must be slit down on one side to get out the feeds, after which, they should be soaked two or three days in salt and water; when they are taken out of this and drained, boiling vinegar must be poured on them, in a sufficient quantity to cover them, and closely stopped down for two months; then they should be boiled in the vinegar to make them green; but they want no addition of any sort of spice, and are the wholesomest and best pickle in the world.

The fourth sort is also a distinct species from all the other: this hath broad wrinkled leaves, the fruit is also furrowed and wrinkled, generally growing upright, and of a beautiful scarlet colour: some of the fruit will have their tops compressed like a bonnet, from whence it had the name.

The fifth sort was sent me from the *Spanish West Indies*: this doth not grow so tall as the other sorts, but spreads near the ground. The leaves come out in clusters, which are of a shining green, and stand on long foot-stalks. The fruit is round, smooth, of a beautiful red, and the size of a common Cherry.

The sixth sort I received from *Barbadoes*: this is like the common in its stalk and leaves, but the fruit is oval, and about the size of a *French Olive*.

These six sorts are annual with us, whatever they may be in their native countries, for their stalks decay soon after the fruit is ripe. They are propagated by feeds, which must be sown upon a hot-bed in the spring; and when the plants have six leaves, they should be transplanted on another hot-bed, at four or five inches distance, shading them in the day time from the sun, until they have taken root, after which,

they must have a large share of air admitted to them in warm weather, to prevent their drawing up weak. Toward the end of *May*, the plants must be hardened by degrees to bear the open air, and in *June* they should be carefully taken up, preserving as much earth about their roots as possible, and planted into borders of rich earth, observing to water them well, as also to shade them until they have taken root, after which time, they will require no other management, but to keep them clean from weeds, and in very dry seasons, to refresh them two or three times a week with water. These directions are for the culture of the common sorts of *Capficum*, which are generally planted by way of ornament. But the plants of the third sort, which are propagated for pickling, should be planted in a rich spot of ground, in a warm situation, about a foot and an half asunder, and shaded till they have taken root, and afterward duly watered in dry weather; which will greatly promote their growth, and cause them to be more fruitful, as also enlarge the size of the fruit. By this management, there may be three or four crops of fruit for pickling obtained the same year, provided the season proves not too cold.

The fourth, fifth, and sixth sorts being tender, the plants should be put into pots, and placed in an old hot-bed under a deep frame, where they may have room to grow; or if they are planted in the full ground, the plants should be each covered with a bell glass, to screen them from cold. These glasses may be set off every day in warm weather, and placed over them in the evening again; and at such times as the weather is not favourable, the glasses should be raised on the contrary side to the wind, to admit the fresh air. With this care, the fruit of these sorts will ripen in *England*, which without it rarely come to maturity, but in very warm seasons.

The four last sorts have perennial shrubby stalks, which rise four or five feet high; these are not so hardy as the other, therefore when the plants have been brought forward in the hot-bed, as was directed for the common sorts, they should be planted in pots filled with rich earth, and plunged into a very moderate hot-bed, under a deep frame, where they may have room to advance; in warm weather, they should have a large share of air admitted to them, but must be covered with glasses every night, or in cold weather, and frequently watered. With this management, they will produce plenty of fruit in autumn, which ripen in winter; but they must be removed into the stove, on the first approach of frost, and placed where they may have a temperate warmth, in which they will thrive better than in a greater heat; and the fruit will continue in beauty most part of winter, making a pretty appearance in the stove, during that season.

The seeds of the seventh sort I received from *Egypt*: the leaves of this are much narrower than those of any other sort I have yet seen; the pods always grow erect, and are produced in great plenty, so that the plants make a good appearance for three months in the winter.

The eighth sort I received from *Antigua*, by the title of *Hen Pepper*. This rises with a shrubby stalk three or four feet high, sending out many branches toward the top: the fruit is about half an inch long, shaped in form of an obtuse cone, and of a bright red, growing erect.

The ninth sort grows about the same height as the eighth, but differs from it in the shape and size of the fruit: those of this sort being about the bigness of a *Barberry*, and nearly of the same shape. This I have long cultivated, and have not observed it to alter.

The tenth sort is commonly known by the title of *Bird Pepper* in *America*. This rises with a shrubby stalk four or five feet high: the leaves are of a lucid green: the fruit grows at the divisions of the branches, standing erect: these are small, oval, and of a bright red; they are much more sharp and biting than those of the other sorts. From the fruit

of this sort, is made the *Cayan* butter or what the inhabitants of *America* call Pepper pots, which they esteem as the best of all the spices.

CARACALLA. See *Phaseolus*.

CARAGANA. See *Robinia*.

CARDAMINDUM. See *Tropæolum*.

CARDAMINE. *Lin. Sp. Plant.* 727. In *English*, Ladies-smock.

The Characters are,

The flower hath four oblong petals, placed in form of a cross; it hath six stamina, four of which are the length of the empalement; the other two, which are opposite, are much longer. It hath a cylindrical germen, which after-ward turns to a long compressed cylindrical pod, with two cells, opening in two valves, which twist spirally, and cast out the seeds when ripe, by their elasticity.

The Species are,

1. CARDAMINE *foliis pinnatis, foliolis radicalibus subrotundis, caulinis lanceolatis. Lin. Sp. Plant.* 656. Meadow Ladies-smock with a large purplish flower.

2. CARDAMINE *foliis pinnatis, foliolis incisiss, floribus exiguis, caule erecto ramoso.* Annual impatient Cress, with a very small flower.

3. CARDAMINE *foliis pinnatis, floribus tetrandis. Hort. Cliff.* 336. Ladies-smock, or impatient Cress with winged leaves, and flowers with four stamina.

4. CARDAMINE *foliis pinnatis foliolis radicalibus subrotundis, caulinis angulatis.* Impatient Cress with winged leaves, whose lower small leaves are roundish, and those on the stalks angular.

5. CARDAMINE *foliis pinnatis foliolis palmatis equalibus petiolatis. Prod. Leyd.* 345. Sicilian impatient Cress with Fumitory leaves.

6. CARDAMINE *foliis pinnatis, foliolis subrotundis angulosis. Hall. Helv.* 558. Greater bitter Water Cress.

7. CARDAMINE *foliis ternatis obtusis, caule subnudo. Lin. Sp. Pl.* 654. Alpine three-leaved Cress.

8. CARDAMINE *foliis simplicibus ovatis integerrimis petiolis longis. Flor. Lap.* 206. Smaller Alpine Cress with a Daisy leaf.

9. CARDAMINE *foliis simplicibus oblongis dentatis. Lin. Sp. Pl.* 654. Rock Cress.

10. CARDAMINE *foliis pinnatis foliolis quinis incisiss. Lin. Sp. Plant.* 655. Smooth impatient Cress, with a Celandine leaf.

The first sort grows naturally in the meadows, in many parts of *England*; it is called Cuckow-flower, and Ladies-smock. Of this there are four varieties, viz. the single with purple and white flowers, which are frequently intermixed in the meadows, and the double flower of both colours. The single sorts are seldom admitted into gardens; but as the first sort stands in the list of medicinal plants, so I have enumerated it. The young leaves of this plant have been gathered in the spring, by some persons, and put into sallats instead of Cress: it is supposed to be an antiscorbutick.

The two varieties with double flowers, were accidentally found growing in the meadows, and were transplanted into gardens, where they have been propagated. These deserve a place in shady moist borders of the flower garden, where they will thrive, and make a pretty appearance during their continuance in flower. They are propagated by parting their roots; the best time for this is the autumn, at which time they should be transplanted. They delight in a soft loamy soil, not too stiff, and must have a shady situation.

The seventh, eighth, and tenth sorts grow naturally on the *Alps*, and other mountainous places. These are low perennial plants, which may be propagated by parting of their roots in the autumn, and require a strong soil and shady situation: they may also be propagated by seeds, which should

be sown in the autumn, on a shady border, where they will come up soon after, and are never hurt by frost.

The ninth sort is a low biennial plant, which grows naturally in several parts of *England* and *Wales*; and is preserved in some gardens, for the sake of variety.

The sixth sort grows naturally by the sides of rivers, and in ditches, in most parts of *England*, so is not admitted into gardens.

The other sorts are low annual plants, which grow naturally in several parts of *England*. These have the title of Impatient Cress, from the elasticity of their pods, which, if touched when they are ripe, spring open, and cast out their seeds with violence, to a considerable distance. These sorts when young, are by the country people eaten in sallats, and have the flavour of the common Cress, but milder.

CARDIACA. *Tourn. Inst. R. H.* 186. Motherwort.

The Characters are,

The flower is of the lip kind, of one leaf, with a narrow tube spreading at the brim; it hath four stamina fastened to the upper lip, two of which are longer than the other. It hath four germen, which after-ward becomes four naked oblong seeds, inclosed in the empalement.

The Species are,

1. CARDIACA *foliis radicalibus quinquelobatis, caulinis trilobis acutis.* Common Motherwort.

2. CARDIACA *foliis tripartito multifidis linearibus obtusiusculis.* Motherwort with leaves divided into three parts, which terminate with many very narrow blunt segments.

3. CARDIACA *foliis tripartitis laciniatis, calycibus villosis.* Motherwort with leaves divided into three parts, which are cut on their edges, and hairy empalements.

The first sort is the common Motherwort which is used in medicine. It grows naturally on the side of banks, and in lanes, in many parts of *England*, so is seldom cultivated in gardens.

The lower leaves of this sort are large, and divided into five lobes; the stalks are square, and rise from four to five feet high, garnished with two leaves standing opposite at each joint upon long foot-stalks; these are divided into three lobes, which end in long acute points. The flowers come out at every joint in whorls, just above the leaves, surrounding the stalk, included in prickly empalements; when these decay, they are succeeded by four naked seeds inclosed in the empalement. If the seeds are permitted to scatter, they will fill the ground near them with young plants.

The seeds of the second sort were sent me from *Petersburgh*, by the late Dr. *Amman*, who received them from *Siberia*. This plant hath the appearance of the first sort, and the stalks grow about the same height, but the leaves are deeply cut into three parts, which are again divided toward their extremity into many narrow blunt segments.

The seeds of the third sort were sent me from *Isiria*. This hath a weaker stalk than either of the former, but rises near the same height. The lower leaves of this are divided into five acute parts, and those upon the stalks into three, which are deeply jagged. The empalement of the flower is hairy, but the flower is like that of the common Motherwort.

These two sorts are preserved in botanick gardens for the sake of variety, but are rarely cultivated in other places; they rise easily from seeds sown in the spring upon a bed of common earth, and require no other care but to keep them clean from weeds, and thin them where they are too close.

CARDINALS FLOWER. See *Rapuntium*.

CARDIOSPERMUM. *Lin. Gen. Pl.* 447. Heart Pea.

The Characters are,

The flower hath four obtuse petals, which are alternately larger, and a small four-leaved nectarium encompassing the germen, with eight stamina, three and three standing opposite, the other

two on each side. The germen is three-cornered, which afterward becomes a roundish swollen capsule with three lobes, divided into three cells, opening at the top, each having one or two globular seeds, marked with a heart.

The Species are,

1. *CARDIOSPERMUM foliis ternato-ternatis acuminatis incisif, petiolis longissimis.* Heart Pea with a smaller leaf and fruit, called in America Wild Parsley.

2. *CARDIOSPERMUM foliis quinato-ternatis acuminatis incisif glabris.* Heart Pea with a larger leaf and fruit.

3. *CARDIOSPERMUM villosum foliis quinato-ternatis, incisif obtusif, petiolis brevibus.* Hairy Heart Seed with leaves divided by fives, and those divided again into three parts, which are bluntly cut, and have short foot-stalks.

The first sort rises with a slender channelled climbing stalk, to the height of four or five feet, sending out many side branches, garnished with leaves, upon very long foot-stalks, coming out opposite at the lower part of the stalk; but upward the leaves come out on one side, and the foot-stalk of the flower on the other, opposite. The foot-stalk of the flowers are long, naked, and toward the top, divided into three short ones, each sustaining a single flower. Immediately under these divisions, come out a tendril, or clasper, like those of the Vine, but smaller; these fasten themselves to whatever grows near them, and thereby are supported. The flowers are small, white, and composed of four small concave petals, two of which standing opposite, are larger than the other; when these fall away, the germen becomes a large inflated bladder, having three lobes, in each of which is contained one, two, and sometimes three seeds, which are round, hard, and the size of small Peas, each being marked with a black spot in shape of a heart.

The second sort differs from the first in having taller stalks, the leaves being first divided into five, and again into three parts. The foot-stalks are shorter, and the seeds and bladders in which they are contained are much larger, and the whole plant is smoother, in other respects they agree.

The third sort hath stronger stalks than either of the former; the leaves have very short foot-stalks; they have each five parts, which are again divided into three obtuse lobes, which are bluntly indented on their edges, and the whole plant is covered with a yellowish hairy down.

These plants grow naturally in both Indies, where they climb upon whatever shrubs are near them, and there they rise to the height of eight or ten feet, but in England they seldom are above half so high; they send out many side branches, which spread to a considerable distance every way.

They are annual, and perish soon after they have perfected their seeds, and being natives of hot countries, they will not thrive in England in the open air. They are propagated by seeds, which should be sown upon a hot-bed in the spring, and when the plants are two inches high, they should be transplanted into pots, then plunged into a very moderate hot-bed, where they must be carefully shaded until they have taken fresh root; after which they must have a large share of air admitted to them every day, to prevent their being drawn up weak: then they may be removed into a glass case, where they may have room to grow and be screened from the cold of the nights, but in warm weather they will require a large share of air; with this management they will flower in July, and their seeds will ripen in autumn.

CARDUUS. Lin. Gen. Plant. 832. Thistle.

The Characters are,

It hath a compound flower, made up of many hermaphrodite florets which are fruitful; these are included in one common scaly empalement; the florets are funnel shaped, and of one leaf; each of these florets have five short hairy stamina. In the center is situated an oval germen, crowned with down, which afterward

becomes an oblong four-cornered seed, crowned with down, and inclosed by the prickly empalement.

The Species are,

1. *CARDUUS foliis integris subtus tomentosis, spinis ramosis lateralibus.* Prod. Leyd. 133. Low prickly Thistle with leaves like the Eternal flower.

2. *CARDUUS foliis sessilibus bifariam pinnatifidis laciniis alternis erectis, calycibus globosis villosis.* Hort. Upsal. 249. Woolly-headed Thistle, called by some Friars Cowl.

3. *CARDUUS foliis lanceolatis dentatis ciliatis decurrentibus, spinis marginalibus duplicibus.* Greater Fish Thistle.

4. *CARDUUS squamis calycinis margine apiceque spinosis.* Hort. Cliff. 393. Our Ladies Thistle, or Milk Thistle.

5. *CARDUUS foliis lanceolatis decurrentibus denticulis inermibus, calyce spinoso.* Hort. Cliff. 392. English soft or gentle Thistle.

6. *CARDUUS foliis lanceolatis sessilibus integerrimis margine spinis ternatis.* Hort. Cliff. 393. The supposed true Fish Thistle of Theophrastus.

There are a great number of species more than are here enumerated; some of which are very troublesome weeds in the gardens and fields, therefore are better to be kept out of both; so I thought it needless to mention them here.

The first sort grows naturally in Sicily. This is an annual plant, which rises with a channelled stalk about two feet high, sending out several side branches toward the top, garnished with long narrow leaves, like those of Austrian Parmica, which are of a deep green above, but white on their under side; just below the foot-stalk of the leaf, come out several unequal yellow spines; at the end of the branches the flowers are produced; these have very prickly empalements, under which are placed two long leaves; the flowers are purple, and shaped like those of the common Thistle, but are smaller; these are succeeded by oblong smooth seeds, which have a long woolly down sitting on their top. It is propagated by seeds, which should be sown on a bed of light earth in the spring, where the plants are to remain. The only care they will require, is to keep them clean from weeds, and thin the plants where they are too close.

The second sort grows naturally in several of the midland counties of England. This is a biennial plant, which sends out many long leaves near the ground, placed by pairs, and are joined to a winged border running on each side the midrib the whole length; these segments are alternately pointing upward, armed with long sharp spines, standing every way. The following spring, there arises from the center of the plant one strong channelled stalk, four or five feet high, branching every way toward the top; each branch is terminated by a single head of purple flowers, having a woolly empalement. One or two of these plants may be allowed a place in some abject part of the garden, for its singularity.

The third sort grows naturally in Spain and Portugal. This rises near three feet high, branching toward the top; the leaves are long, narrow, and the edges are set closely with small hairs; at every indenture of the leaves there comes out two long yellowish spines; at the end of the branches the flowers are produced from the side of the stalk, which have woolly oval empalements, closely armed with slender spines. The flowers are yellow, but make no great appearance. This plant may be propagated by seeds, in the same manner as the former sort. It is called Fish Thistle, from the resemblance which the spines have to the bones of fish.

The fourth sort grows very common on the side of banks, and in waste land in many parts of England, and is by some persons blanched and dressed, as a curious dish. This is a biennial plant, which should be sown very thin, and when the plants are come up so as to be well distinguished, the ground should be hoed, to cut down all the young weeds, and the plants left about two feet and an half distance; in

the autumn the leaves of the plants should be tied up, and the earth drawn up close to blanch them; when they are properly whitened, they will be fit for use. This is a biennial plant, which perishes soon after the seeds are ripe.

The fifth sort is a perennial plant, which is by some cultivated for medicinal use, and has been supposed a remedy for some sort of madness. This may be propagated by seeds, in the same manner as the second sort. It grows naturally in the northern parts of *England*, and flowers in *June*.

The sixth sort is supposed to be the true Fish Thistle of *Theophrastus*. This is a biennial plant, which rises with an upright stalk six or seven feet high; is garnished with long spear-shaped leaves, armed with triple spines at every indenture: on the side of the stalks the flowers come out in clusters, which are of a purple colour, and are succeeded by smooth, oval, black seeds. It grows naturally in *Sicily* and the *Levant*. It is propagated by seeds, as the second sort, which should be sown on a warm border, otherwise the plants will not live through the winter.

CARDUUS BENEDICTUS. See Cnicus.

CARDUUS FULLONUM. See Dipsacus.

CARICA. *Lin. Gen. Plant.* 1000. Papaw.

The Characters are,

It is male and female in different plants; the flowers of the male are funnel-shaped, and of one leaf, having a long slender tube, which expands at the top, where it is divided into five narrow obtuse parts; it hath ten stamina, five of which are alternately longer than the other. The female flowers have a small permanent empalement, indented in five parts, with five long spear-shaped petals; the oval germen afterward becomes a large oblong fleshy fruit, having five longitudinal cells, which are full of small oval furrowed seeds, inclosed in a glutinous pulp.

The Species are,

1. CARICA foliorum lobis sinuatis. *Hort. Cliff.* 461. Papaw with the fruit shaped like the Squash.

2. CARICA foliorum lobis integris. *Hort. Cliff.* 461. Papaw with the lobes of the leaves entire.

There are several varieties of the first sort, which differ in the size and shape of their fruit. *Plumier* mentions three of the female or fruitful Papaw, beside the male, one of which he titles Melon-shaped, and the other shaped like the fruit of the Gourd; and I have seen another variety in *England*, with a large smooth pyramidal fruit: but these are supposed to be accidental varieties, which arise from the same seeds.

The first sort rises with a thick, soft, herbaceous stem, to the height of eighteen or twenty feet, which is naked till within two or three feet of the top, and hath marks of the vestiges of the fallen leaves on the stem; the leaves come out on every side upon very long foot-stalks; those which are situated undermost are almost horizontal, but those on the top are erect: these leaves (in full grown plants) are very large, and divided into many parts (or lobes) which are deeply sinuated, or cut into irregular divisions. The whole plant abounds with a milky acrid juice, which is esteemed good for the ringworm: the stem of the plant, and also the foot-stalks of the leaves, are hollow in the middle. The flowers of the male plant are produced from between the leaves, on the upper part of the plant, which have foot-stalks near two feet long, at the ends of which the flowers stand in loose clusters, each having a separate short foot-stalk; these are of a pure white, and have an agreeable odour; sometimes these are succeeded by small fruit, about the size and shape of a Catherine Pear. The flowers of the female Papaw also come out between the leaves, toward the upper part of the plant, upon very short foot-stalks, sitting close to the stem; they are large, and bell-shaped, composed of six petals, and are commonly yellow; when these fall away, the germen swells to a large fleshy fruit, the size of a small Melon, which are of different forms; some are an-

gular, and compressed at both ends, others are oval or globular, and some pyramidal; the fruit also abounds with the same acrid milky juice as the plants. This fruit, when ripe, is by the inhabitants of the *Caribbee Islands* eaten with pepper and sugar as Melons, but are much inferior to a common Melon in flavour, in its native country; but those which have ripened in *England* were detestable; the only use I have known made of this fruit, was, when they were about half grown, to soak them in salt water, to get out the milky juice, and pickle them for Mangos, for which they have been a good substitute.

The second sort was found growing in a garden at *Lima*, by Father *Feuillee*, and was the only plant he saw of that sort in his travels. This differs from the other, in having a branching stalk, the lobes or divisions of the leaves being entire, and the fruit being shaped like a Pear, which he says were of different sizes; that which he designed was about eight inches long, and three and an half thick, yellow within and without, and of a sweet flavour. The flower, he says, was of a Rose colour, and divided into five parts.

These plants being natives of hot countries will not thrive in *England*, unless they are preserved in a warm stove, which should be of a proper height to contain the plants. When they are grown to a large size, they make a noble appearance, with their strong upright stems, which are garnished on every side near the top, with large shining leaves, spreading out near three feet all round the stem: the flowers of the male sort come out in clusters on every side; and the fruit of the female growing round the stalks, between the leaves, being so different from any thing of *European* production, may intitle them to the care of the curious.

They are easily propagated by seeds, which are annually brought in plenty from the *West Indies*. These should be sown in a hot-bed, early in the spring: when the plants are near two inches high, they should be each transplanted into a separate small pot, and plunged into a hot-bed of tanners bark, carefully shading them from the sun till they have taken root; after which they must be treated in the same manner as other tender plants from the same country; but as these plants have soft herbaceous stalks, and abound with a milky juice, so they must not have much water, for they are frequently killed with moisture. When these plants are shifted from small pots into larger, care must be taken to preserve the ball of earth to the roots, for whenever their roots are left bare, they rarely survive it.

CARLINA. *Lin. Gen. Plant.* 836. The Carline Thistle.

The Characters are,

It hath a compound flower, made up of many hermaphrodite florets which are fruitful, included in a common swollen scaly empalement. The florets are funnel shaped, and cut into five parts at the brim; these have each five short hairy stamina. In the center is situated a short germen crowned with down, which afterward becomes a single taper seed, crowned with a branching plumose down.

The Species are,

1. CARLINA caule multifloro corymboso, floribus terminalibus. *Hort. Cliff.* 395. Common wild Carline Thistle.

2. CARLINA floribus sessilibus, lateralibus paucissimis. *Sauv. Meth.* 293. Small wild Spanish Carline Thistle.

3. CARLINA caule unifloro flore brevior. *Hort. Cliff.* 395. Low Carline Thistle with a large white flower.

4. CARLINA caule trifloro dichotomo intermedio sessili. *Sauv. Monsp.* 293. Fish Thistle with a reddish purple spreading flower.

5. CARLINA caule multifloro subdiviso, floribus sessilibus. *Prod. Leyd.* 135. Umbellated Fish Thistle of *Apulia*.

The first sort grows naturally upon sterile ground, in most parts of *England*, so is rarely admitted into gardens, but the others are preserved in botanick gardens for the sake of variety.

riety. They grow naturally in the south of *France, Spain,* and *Italy*.

They may all be propagated by sowing of their seeds in the spring on a bed of fresh undunged earth, where they are designed to remain; for, as they send forth tap roots, they will not bear transplanting so well as most other plants. When the plants appear above ground, they should be carefully weeded; and, as they grow in size, they should be thinned where they are too close, leaving them about ten inches or a foot asunder. The second year most of these plants will flower; but, unless the summer proves dry, they rarely produce good seeds in *England*; and most of them decay soon after they have flowered; therefore it is pretty difficult to maintain these plants in this country.

CARNATION. See *Dianthus*.

CARPINUS. *Lin. Gen. Plant.* 952. The Hornbeam, or Hardbeam.

The Characters are,

It hath male and female flowers, growing separate on the same plant. The male flowers are disposed in a cylindrical rope or katkin; the flowers have ten small stamina. The female flowers are disposed in the same form; these have one petal, which is shaped like a cup, cut into six parts, with two short germen. The katkin afterward grows large, and at the base of each scale is lodged an oval angular nut.

The Species are,

1. CARPINUS *squamis strobilorum planis.* *Hort. Cliff.* 447. Common Hornbeam.

2. CARPINUS *squamis strobilorum inflatis.* *Hort. Cliff.* 447. The Hop Hornbeam.

3. CARPINUS *foliis ovato-lanceolatis serratis strobilis brevibus.* Eastern Hornbeam, with a smaller leaf and shorter fruit.

4. CARPINUS *foliis lanceolatis acuminatis, strobilis longissimis.* *Virginia* flowering Hornbeam.

The first sort is very common in many parts of *England*, but is rarely suffered to grow as a timber tree, being generally reduced to pollards by the country people; yet where the young trees have been properly treated, they have grown to a large size. Of late years, this has been only considered as a shrub, and never cultivated but for under-wood in the country, and in the nurseries to form hedges, after the *Freuch* taste; but since these sort of ornaments have been almost banished from the *English* gardens, there has been little demand for these trees in the nurseries.

As this tree will thrive upon cold, barren, exposed hills, and in such situations where few other sorts will grow, so it may be cultivated to great advantage by the proprietors of such lands. But where these are propagated for timber, they should be raised from seeds, upon the same soil, and in the same situation, where they are designed to grow. Nor should they be propagated by layers, which is the common method where they are intended for hedges or under-wood; for which those so raised will answer the purpose full as well as those raised from seeds, but the latter must always be preferred for timber trees.

The seeds of this tree should be sown in the autumn, soon after they are ripe; for if they are kept out of the ground till spring, the plants will not come up till the following year. When the plants appear, they must be kept very clean from weeds, and treated as other forest trees; in two years time they will be fit to transplant, for the sooner all trees which are designed for timber are planted where they are to remain, the larger they will grow, and the wood will be firmer and more durable. If they are kept clean from weeds three or four years, it will greatly promote their growth, after which the plants will have obtained sufficient strength to keep down the weeds.

As the trees advance in their growth, so they must be thinned, which should be done with caution, cutting away

the most unpromising plants gradually, so as not to let too much cold air at once to those which are left, especially on the borders of the plantation.

The timber of this tree is very tough and flexible, so might be converted to many useful purposes, when suffered to grow to a proper size; but as they have been generally treated otherwise, so the principal uses it has been applied to, was for turnery ware, for which it is an excellent wood, and also for making mill cogs, heads of beetles, &c. It is also excellent fuel.

The Hop Hornbeam sheds its leaves in the winter, with the Elm, and other deciduous trees. It is said to grow plentifully in many parts of *North America*, but it is doubtful whether that is not a different sort from this. The Hop Hornbeam is of quicker growth than the common sort, but what the wood of that will be I do not know; for there are but few of the trees in *England* growing upon their own roots, most of them having been grafted upon the common Hornbeam, which is the usual method of propagating them in the nurseries; but the trees so raised are of short duration, for the graft generally grows much faster than the stock, so that in a few years there is a great disproportion in their size; and where they happen to stand exposed to strong winds, the graft is frequently broken from the stock, after many years growth; for which reason, I would caution every person not to purchase any of these trees which have been so propagated.

The *Virginia* flowering Hornbeam is less common than the last, and only to be seen in curious gardens; it is equally hardy as the other, and may be increased by layers.

The Eastern Hornbeam is a tree of humble growth, rarely rising above ten or twelve feet high in this country, shooting out many horizontal irregular branches, so cannot easily be trained up to a stem. The leaves of this sort are much smaller than those of the common Hornbeam, and the branches grow closer together: it may be kept in less compass than almost any other deciduous tree. It is as hardy as any of the sorts, and may be propagated in the same manner; but at present it is rare in the *English* nurseries.

CARROTS. See *Daucus*.

CARTHAMUS. *Lin. Gen. Plant.* 838. Bastard Saffron, or Safflower.

The Characters are,

It hath a flower composed of several hermaphrodite florets, included in one common scaly empalement. The florets are funnel-shaped, cut into five equal segments at the top; these have five short hairy stamina. In the center is situated a short germen, which afterward becomes a single, oblong, angular seed, inclosed in the empalement.

The Species are,

1. CARTHAMUS *foliis ovatis integris serrato aculeatis.* *Hort. Cliff.* 394. Bastard Saffron of the shops, with a Saffron-coloured flower.

2. CARTHAMUS *caule piloso supernè lanato, foliis inferioribus pinnatifidis, summis amplexicaulibus dentatis.* *Hort. Upsal.* 251. Yellow Distaff Thistle.

3. CARTHAMUS *caule glabro, foliis caulinis aculeatis, profundè dentatis, semiamplexicaulibus, capitulis ovatis.* Cnicus of *Crete* with a leaf and appearance of Distaff Thistle, and a whitish flower.

4. CARTHAMUS *foliis lanceolatis, acuminato-serratis.* *Hort. Cliff.* 135. Blue perennial Cnicus of *Tangier*.

5. CARTHAMUS *foliis caulinis linearibus pinnatis longitudine plantæ.* *Lin. Sp. Plant.* 831. Dwarf Cnicus of mount *Lufus* with a blue flower.

6. CARTHAMUS *caule erecto piloso, foliis lanceolatis hirsutis, capite maximo.* Rougher blue Cnicus.

7. CARTHAMUS *foliis ensiformibus sinuato-dentatis.* *Prod. Leyd.* 136. Stinking shrubby Cnicus of *Spain*.

8. CARTHAMUS

8. *CARTHAMUS foliis lineari-lanceolatis spinis marginalibus duplicibus, floribus solitariis terminalibus.* The least stalky Spanish Carline Thistle.

The first sort grows naturally in *Egypt*, and in some of the warm parts of *Asia*. It is at present cultivated in many parts of *Europe*, and also in the *Levant*, from whence great quantities of Safflower are annually imported to *England*, for dying and painting.

This is an annual plant, which rises with a stiff ligneous stalk, two feet and an half, or three feet high, dividing upward into many branches, garnished with oval pointed leaves, sitting close to the branches, which are entire, and are slightly sawed on their edges, each tooth being terminated by a short spine. The flowers grow single at the extremity of each branch: the heads of flowers are large, inclosed in a scaly empalement; each scale is broad at the base, flat, and formed like a leaf of the plant, terminating in a sharp spine. The lower part of the empalement spreads open, but the scales above closely embrace the florets, which stand out near an inch above the empalement; these are of a fine Saffron colour, and this is the part which is gathered for the uses above mentioned. If the season proves cold and moist when the plants are in flower, there will be no good seeds produced; so that there are few seasons, wherein the seeds of this plant come to perfection in *England*.

When this plant is propagated for use, the seeds should be sown in drills, drawn at two feet and an half distance from each other, in which the seeds should be scattered thinly, for the plants must not be left nearer each other, than a foot in the rows; but as some of the seeds will fail, so a greater quantity should be sown, as it will be easy to thin the plants, at the time when the ground is hoed. If the seeds are good, the plants will appear in less than a month; and in three weeks or a month after, it will be proper to hoe the ground, to destroy the weeds, and at the same time, the plants should be thinned where they are too close; but at this time they should not be separated to their full distance, lest some of them should afterward fail; so that if they are now left six inches asunder, there will be room enough for the plants to grow, till the next time of hoeing, when they must be thinned to the distance they are to remain for good: after this they should have a third hoeing, which, if carefully performed in dry weather, will destroy the weeds and make the ground clean, so that the plants will require no farther care till they come to flower; when, if the Safflower is intended for use, the florets should be cut off from the flowers as they come to perfection; but this must be performed when they are perfectly dry, and then they should be dried in a kiln, with a moderate fire, in the same manner as the true Saffron, which will prepare the commodity for use.

But those plants which are designed for seed, the flowers must not be gathered; for if the florets are cut off, it will render the seeds abortive, though they may swell and grow to their usual size, as I have frequently experienced; yet when they are broken, there will be found nothing more than a shell without any kernel. And this frequently happens to be the case with the seeds, in wet cold seasons; though in very wet years the germen will rot, and never come so forward as to form a shell.

The quantity of Safflower which is annually consumed in *England* is so great, as to make a very considerable article in trade, therefore might be very well worthy of the publick attention. If this plant was introduced to *Carolina*, it might be there cultivated to as great advantage, as in any part of the world, for there the seeds will constantly ripen; and, as this country is furnished with it from the *Mediterranean*, where there is great danger of our navigation being interrupted, so it should excite the inhabitants of our *American* colonies, to make trial of as many of the vegetables,

as there is a probability of succeeding there, as can be procured, which are of real use in any of the manufactures of this country. The seeds of this plant I sent to *Carolina* in the year 1758, which have succeeded there; and more seeds may be easily procured from the *American* islands, and in one season may be multiplied in so great quantity, as to furnish a whole province.

The good quality of this commodity is chiefly in the colour, which should be of a bright Saffron colour, and herein that which is cultivated in *England* often fails; for if there happens much rain, during the time the plants are in flower, it will cause the florets to change to a dark or dirty yellow, which will also befall that which is gathered when there is any moisture remaining upon it; therefore great care must be taken not to gather it till the dew is quite dried off, nor should it be pressed together till it has been dried on the kiln. The manner of doing this being the same as for the true Saffron, I shall not mention it here.

This plant may be admitted to have a place in the borders of large gardens, where it will add to the variety, during the time of its continuance in flower, which is commonly two months, or ten weeks; for if the seed be sown in the beginning of *April*, the first flowers will appear in the middle of *July* at farthest, and there will be a succession of flowers on the side branches till the end of *September*, or in mild warm weather till the middle of *October*.

When they are cultivated for this purpose, the seeds should be sown in the places where the plants are designed to remain, because they do not bear transplanting well; therefore three or four seeds should be sown in each patch, lest any of them should fail, and when the plants are grown so strong as to be out of danger, the most promising in each patch should be left, and the others pulled up, that they may not draw or injure those which are to stand.

The second sort grows naturally in the south of *France*, *Spain*, and *Italy*, where the women use the stalks of this plant for distaffs, from whence it had the title of Distaff Thistle.

The third sort was also discovered by *Tournefort* in the island of *Crete*. This differs from the former in having a smooth stalk, the leaves are very stiff, deeply indented, smooth, and are armed with very strong spines; the heads of flowers are oval, the florets white, and the plant grows near four feet high. This is an annual plant, which may be sown and treated in the same way as the former, and flowers about the same time.

The fourth sort hath a perennial root. This grows naturally in *Spain*, and was first brought to *England* from *Tangier*. It is propagated by parting of the roots. The best time for transplanting and parting them, is about the beginning of *March*; this should have a dry soil and a warm situation, otherwise the plants are liable to be destroyed in severe winters.

The fifth sort grows naturally in the south of *France*, *Spain*, and *Italy*. This hath a perennial root, the stalk rises about six inches high, is channelled, hairy, and garnished with long narrow leaves, ending in several sharp spines. Each stalk is terminated by one large head of blue flowers, having a leafy empalement, composed of very broad scales, each ending in a sharp spine.

This sort is difficult to propagate in *England*, for the roots do not put out offsets like the former, so is only to be raised from seeds, which do not come to perfection here, unless the season proves warm and dry. The plants should have a dry soil and a warm situation.

The sixth sort rises with a single stalk about two feet high, which is of a purplish colour, hairy, and channelled, pretty closely garnished with broad spear-shaped leaves, which are sharply sawed on their edges, and covered with a short hair-

ry down. The stalk is terminated by a single large head of blue flowers, having a scaly empalement. This sort may be propagated by parting of their roots, which should be performed in autumn, when the leaves decay. It should have a light dry soil, in which it will endure the cold of our winters, and continue many years.

The seventh sort I received from *Andalusia*, where it grows naturally in great plenty. This rises with a shrubby perennial stalk, to the height of eight or ten feet, which divides into many branches; these are garnished with pretty long sword-shaped leaves, which are indented, and armed with spines on their edges; they embrace the stalks with their base. The branches are terminated by large, scaly, prickly heads of yellow flowers, which come out in *July*, but are never succeeded by seeds in this country, so can only be propagated by side shoots, slipped from the branches in the spring, and planted in pots, and plunged into a moderate hot-bed, till they have taken root; then they must be gradually hardened, and removed into the open air, and when they have obtained strength, they may be separated, and some of them planted in a warm dry border, where they will endure the cold of our ordinary winters; but, in severe frost, they are frequently destroyed, therefore a plant or two should be kept in pots, and sheltered in the winter to preserve the species.

CARUM. *Lin. Gen. Plant.* 327. Carui, or Caraway.

The Characters are,

It hath an umbellated flower, composed of several small umbels, which are formed as rays to the general umbel, neither of which have any involucre; the flower hath five heart-shaped petals, and five hairy stamina. The germen is situated under the flower, which afterward becomes an oblong channelled fruit, dividing into two parts, each having an oblong furrowed seed.

The Species are,

1. CARUM foliis pinnatifidis planis, umbellulis inaequalibus confertis. Meadow Cumin, or Caraway of the shops.

2. CARUM foliis capillaribus multifidis, umbellis laxis. Caraway with capillary multifid leaves, and loose umbels.

The first sort is the common Caraway, whose seeds are greatly used, not only in medicine, but also in the kitchen, &c. This grows naturally in some rich meadows in *Lincolnshire* and *Yorkshire*, and is sometimes found growing in the pastures near *London*. It is also cultivated for use in *Essex*, and some other counties.

It is a biennial plant, which rises from seeds one year, flowers the next, and perishes soon after the seeds are ripe. It hath a taper root like a Parsnep, but much smaller, which runs deep into the ground, and hath a strong aromatick taste, sending out many small fibres; from the root arises one or two smooth, solid, channelled stalks, about two feet high, garnished with winged leaves, having long naked foot-stalks. The stalks divide upward into several smaller branches, each of which is terminated by an umbel, composed of six or eight small separate umbels, sustaining single white flowers, with heart-shaped petals; the flowers of these small umbels are closely joined together. After the flowers are decayed, the germen becomes an oblong channelled fruit, composed of two oblong channelled seeds.

The best season for sowing the seeds of this plant, is in autumn, soon after they are ripe, when they will more certainly grow, than those sown in the spring; and the plants which rise in the autumn, generally flower the following season, so that a summer's growth is hereby saved.

The second sort grows naturally in *Spain*. This plant rises with a stronger stalk than the former, which seldom grows more than a foot and an half high, but is closely garnished with fine narrow leaves, like those of *Dill*; the stalks divide upward into many branches, each being terminated by loose umbels, of white flowers, which are succeeded by long

furrowed seeds, having the same aromatick flavour as the common sort. This is a biennial plant, and may be treated in the same manner as the former.

CARYOPHYLLATA. See Geum.

CARYOPHYLLUS. *Lin. Gen. Plant.* 594. The Clove Tree, or All-spice.

The Characters are,

It hath a double empalement; the flower is of one leaf, cut into four obtuse parts, upon which the germen is situated; the fruit hath another empalement, which is small, and slightly divided into four parts, which are permanent. The flower hath four blunt petals; it has many stamina. The germen is situated under the flower, which afterward becomes a soft berry with two cells, each containing a single kidney-shaped seed.

The Species are,

1. CARYOPHYLLUS foliis ovato-lanceolatis oppositis, floribus terminalibus, staminibus corollâ longioribus. The Clove tree with oval spear-shaped leaves growing opposite, and flowers terminating the stalks, whose stamina are longer than the petals.

2. CARYOPHYLLUS foliis lanceolatis oppositis, floribus racemosis terminalibus, & axillaribus. The Pimento, or All-spice.

3. CARYOPHYLLUS foliis lanceolatis oppositis, floribus geminatis alaribus. *Brown. Hist. Jam.* 248. Clove tree with spear-shaped leaves placed opposite, and flowers growing by pairs from the sides of the stalks.

4. CARYOPHYLLUS foliis ovatis obtusis oppositis, floribus sparsis alaribus. Clove tree with oval blunt leaves placed opposite, and flowers growing thinly from the sides of the branches.

5. CARYOPHYLLUS foliis oblongo-ovatis, emarginatis, rigidis, glabris, floribus racemosis terminalibus. Clove tree with oblong oval leaves, which are stiff, smooth, and indented at the edges, and flowers growing in bunches terminating the stalk.

The first sort grows naturally in the *Moluccas*, and the hottest parts of the world, where it rises to the height of a common Apple tree; but the trunk generally divides at about four or five feet from the ground, into three or four large limbs, which grow erect, and are covered with a thin smooth bark, which adheres closely to the wood. These limbs divide into many small branches, which form a sort of conical figure; the leaves are like those of the Bay tree, and are placed opposite on the branches. The flowers are produced in loose bunches at the end of the branches, which are small, white, and have a great number of stamina, which are much longer than the petals. The flowers are succeeded by oval berries, which are crowned with the empalement, divided into four parts, which spread flat on the top of the fruit, in which form they are brought to *Europe*, for it is the young fruit beaten from the trees before they are half grown, which are the Cloves used all over *Europe*.

I have not heard of any plants of this kind being in the gardens, either in *England* or *Holland*, but I chose to mention it here, to introduce the other.

The second sort grows naturally in *Jamaica*, but particularly on the north side of that island, where it is found in great plenty, and is a considerable branch of their trade. The unripe fruit dried, being the All-spice so well known in *Europe*. It is now cultivated with care, in many of the plantations, for the trees will thrive upon shallow rocky land, which is unfit for the Sugar cane, so that a great advantage arises to the planters, from those lands which would otherwise be of small account to them.

This tree grows to the height of thirty feet or more, with a strait trunk, covered with a smooth brown bark, and divides upward into many branches which come out opposite; these are garnished with oblong leaves, resembling those of the Bay tree, both in form, colour, and texture,

and are also placed opposite; when these are bruised, or broken, they have a very fine aromattick odour, like that of the fruit. The branches grow very regular, so that the trees make a fine appearance, and as they retain their leaves through the year, so they are worthy of being propagated for ornament and shade about the habitations of the planters. The flowers are produced in large loose bunches from the side of the branches, toward their ends; the flowers are small, and of an herbaceous colour, they are male and female upon distinct trees. The male flowers have very small petals, and a great number of stamina in each, which are of the same colour with the petals, and are terminated by oval bifid summits; the female flowers have no stamina, but an oval germen, situated below the flower, supporting a slender style, with a blunt stigma at the top. The germen afterward becomes a globular pulpy berry, including two kidney-shaped seeds.

When the fruit of these trees are designed for use, they are gathered, or beaten down from the trees, a little before they arrive to their full size, and are separated from leaves, stalks, or any rubbish which may have accidentally mixed with them; then the fruit is exposed every day to the sun, spread on cloths, for ten or twelve days to dry, but removed under cover every evening to screen it from the dews; when the fruit is perfectly dry, it is packed up for exportation. If the fruit is permitted to grow to maturity, the pulp which surrounds the seeds is so full of moisture and glutinous, as to stick to the fingers of those who bruise them, therefore are unfit for those uses, to which the dried fruit are applied.

This tree is propagated by seeds, which in the natural place of its growth is conveyed and sown by birds, to a great distance; and, it is very probable, the seeds passing through them, are rendered fitter for vegetation, than those which are immediately gathered from the tree; for I have received great quantities of the berries, which were perfectly ripe and fresh, great part of which I sowed in different ways, and communicated some of them to several other curious persons, who did the same, but none of them have yet succeeded.

The plants cannot be preserved in *England*, unless they are placed in a stove during the winter season, but they will thrive in a moderate degree of warmth; they should be planted in a soft loamy soil, and, in winter, must have but little water; in the summer they should have a large share of air, and in *July*, if the season proves warm, they may be placed in the open air, in a warm sheltered situation, but upon the approach of cold nights, they must be removed into the stove again. The exposing of these plants to the open air, for one month only, will be of great service to clean their leaves from insects or filth, which they are subject to contract, by remaining long in the stove; but if the season should prove very wet or cold, it will not be safe to trust these plants long abroad; therefore their leaves should be now and then washed with a sponge to clean them, which will not only render them more sightly, but also promote their growth. This plant, being an ever-green, makes a fine appearance in the stove at all seasons of the year; and their leaves having such an agreeable fragrantcy when rubbed, render them as worthy of a place in the stove, as any other exotick plant which is preserved for ornament.

The third sort grows naturally in *Jamaica*. This rises with a divided trunk to the height of eighteen or twenty feet, sending out many branches, which are placed opposite, and are covered with a gray bark: the leaves come out by pairs, which are shorter and rounder at their points, than those of the last species; they are also smoother, and of a firmer texture. The flowers come out from the side of the branches, between the leaves, upon

slender foot-stalks, about an inch in length, two generally arising from the same point: these are succeeded by round berries, of a brighter colour than those of the former, having the empalement on their crowns. The leaves and fruit of this sort have no aromattick flavour, so are not of use, but the characters of the flower and fruit are the same as in the other sort.

The fourth sort was sent me from *Carthage* in *New Spain*. This rises with many irregular stems, about twelve or fourteen feet high, which are covered with an Ash-coloured bark, and divide into many branches upward: these are garnished with stiff oval leaves, placed opposite. The flowers are produced from the side of the branches, sometimes four, five, or six foot-stalks arise from the same point; at other times they come out single, or perhaps by pairs: these are white, and of the same shape with those of the second sort, and are succeeded by berries which are rounder, and, for the most part, contain but one kidney-shaped seed.

This sort agrees with the second in its general characters, but not in the virtues, for it hath none of the aromattick flavour with which that abounds; but as it retains its leaves through the year, may merit a place in the stove, better than many other plants which are preserved by the curious. This is propagated by seeds, in the same way as the second sort, and the plants must be treated in the same manner as those.

The fifth sort was sent me from the island of *Barbuda*, where it rises to the height of twenty feet: the trunk and branches are covered with a smooth brown bark. The branches come out opposite; these grow erect, and are garnished with very smooth lucid leaves, which are placed by pairs, and have very short foot-stalks. The leaves vary much in their form, some of them are oval, others are oblong, and some are indented so deeply at their ends, as to be almost heart-shaped. Their consistence is much thicker than those of the common *Laurel*, and their colour is a splendid green, with one deep midrib running through their middle, and many small veins going from thence transversely to their border. The flowers are produced in small loose bunches at the extremity of the branches, which have several narrow leaves intermixed with the bunches. The flowers are succeeded by berries of the same shape with those of the second sort, but are larger.

This tree is propagated by seeds as the other species, and deserves a place in the stove for the beauty of its ever-green leaves, which being of a thick consistence, and of a shining green colour, make a fine appearance at all seasons of the year; but this hath no aromattick flavour to recommend it, as hath the second sort, for which reason it is seldom noticed. I take this to be the Bay tree, mentioned by *Hughes* in the history of *Barbadoes*, which he describes to have no flavour; for I have seen plants of this sort which were brought from *Barbadoes*, so that I suppose it grows naturally there.

CASIA. See *Osyris*.

CASSIA. *Lin. Gen. Pl.* 461. Wild Senna.

The Characters are,

The flower hath five roundish concave petals, which spread open; it hath ten declining stamina, three of the lower are long, the three upper are shorter; the summits of the three lower are large, arched, beaked, and separated at their points. In the center is situated a long taper germen, which afterward becomes a long pod, divided by transverse partitions, each containing one or two roundish seeds, fastened to the margin of the upper valve.

The Species are,

1. *CASSIA foliolis quinquejugatis, ovato-lanceolatis, margine scabris, exterioribus majoribus, glandulâ baseos petiolorum.* *Lin. Sp. Plant.* 377. Cassia with leaves composed of five pair of

oval

oval spear-shaped lobes with rough borders, the upper lobes being the largest, and a small gland at the base of the foot-stalk.

2. *CASSIA foliolis quinquejugatis ovatis glabris, exterioribus longioribus, caule fruticoso.* Cassia with leaves composed of five pair of smooth, oval lobes, the upper being the longest, and a shrubby stalk.

3. *CASSIA foliolis octojugatis, ovali-oblongis, interioribus minoribus, petiolis eglandulosis stipulis patulis, Hort. Cliff. 158.* Cassia with eight pair of oblong, oval, little leaves, the inner being the least, foot-stalks without glands, and a spreading stipula.

4. *CASSIA foliolis trijugatis, oblongo ovatis æqualibus villosis, siliquis articulatis, caule erecto arboreo.* Cassia with three pair of oblong, oval, hairy leaves, which are equal, jointed pods, and an upright woody stem.

5. *CASSIA foliolis trijugatis, ovato-acuminatis, villosis, floribus solitariis axillaribus, siliquis erectis.* Cassia with three pair of lobes in each leaf, which are oval, pointed, and hairy, and single flowers proceeding from the sides of the stalks, with upright pods.

6. *CASSIA foliolis novemjugatis oblongis, glabris, æqualibus, floribus axillaribus.* Cassia with small leaves, composed of nine pair of lobes, which are oblong, smooth, and equal, and flowers proceeding from the sides of the stalks.

7. *CASSIA foliolis trijugatis obovatis glabris, interioribus rotundioribus minoribus, glandulâ interjectâ globosâ. Hort. Cliff. 159.* Cassia with three pair of oval smooth leaves, the inner one being rounder and smaller, and a globular gland placed between the leaves.

8. *CASSIA foliolis quinquejugatis, ovato-lanceolatis glabris, petiolis eglandulosis. Flor. Zeyl. 149.* Cassia with five pair of leaves, which are oval, spear-shaped, and smooth, and foot-stalks having no glands, or, the purging Cassia of *Alexandria*.

9. *CASSIA foliolis sexjugatis, lanceolatis, glabris, interioribus minoribus, floribus terminatricibus.* Cassia with six pair of leaves, which are smooth and spear-shaped, the inner ones being smaller, and flowers terminating the stalk.

10. *CASSIA foliolis bijugatis, ovato-lanceolatis, glabris, floribus terminalibus, siliquis longis teretibus, caule fruticoso.* Cassia with two pair of leaves which are oval, spear-shaped, and smooth, flowers terminating the stalks, long taper pods, and a shrubby stalk.

11. *CASSIA foliolis duodecjugatis, oblongis, obtusis, glabris, glandula nulla. Lin. Sp. Plant. 379.* Cassia with twelve pair of leaves, which are oblong, blunt, and smooth, and have no glands; commonly called Horse Cassia.

12. *CASSIA foliolis septemjugatis, oblongo-ovatis, obtusis, floribus spicatis axillaribus, siliquis recurvis.* Cassia with seven pair of leaves, which are oblong, oval and blunt, spikes of flowers proceeding from the sides of the stalks, and recurved pods.

13. *CASSIA foliolis trijugatis, obtusis, emarginatis, caulibus pilosis, floribus solitariis axillaribus petiolis longioribus.* Cassia with three pair of obtuse leaves, indented at the top, hairy stalks, flowers growing singly from the sides of the stalks, and a long foot-stalk.

14. *CASSIA foliolis quadrijugatis oblongo-ovatis, caulibus procumbentibus, floribus axillaribus pedunculis bifloris.* Cassia with four pair of oval, oblong leaves, trailing stalks, and flowers proceeding from the sides of the stalks, two growing upon each foot-stalk.

15. *CASSIA foliolis bijugatis oblongo ovatis, subtus villosis, floribus corymbosis, caule erecto arboreo.* Cassia with two pair of oblong, oval leaves, hairy on their under side, flowers growing in round bunches, and an erect tree like stem.

16. *CASSIA foliolis multijugatis, glandulâ petioli pedicellatâ, stipulis ensiformibus. Hort. Upsal. 101.* Cassia with many pair

of leaves, and the gland on the foot-stalk resembling an insect, and sword-shaped stipulæ.

The first sort grows naturally in most of the islands of the *West Indies*, where it is called Stinking Weed, from its unfavourable odour. This rises with a channelled stalk three or four feet high, dividing into several branches, garnished with winged leaves placed alternately; each of these is composed of five pair of lobes, which are oval, spear-shaped, sitting close to the midrib, and have rough edges. The flowers come out from the side of the stalks, two growing upon each foot-stalk, but the branches are terminated by loose spikes of flowers, which are composed of five concave yellow petals, with ten declining stamina. It hath a flat pod, having a border on each side, and is indented between each seed.

This is a biennial plant, which propagates by seed in plenty, in the countries where it grows naturally; but in *England*, the seeds must be sown on a hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a separate pot, filled with light earth, and plunged into a moderate hot-bed, to bring them forward; and toward the end of *June*; some of them may be planted into a warm border, where, if the autumn proves favourable, they will flower very well; but these will not perfect their seeds, therefore a plant or two should be put into pots that they may be removed into the stove in autumn to ripen seeds.

The second sort grows in *Jamaica*. This rises with a shrubby stalk five or six feet high, sending out many branches toward the top, with winged leaves, composed of five pair of small oval leaves, the upper ones being longest. The flowers come out from the side of the stalks, and also terminate the branches in loose spikes; they are yellow, and shaped like those of the former, but are smaller; the pods are long, taper, and contain two rows of seed.

This plant may be preserved three or four years in the stove, and will annually flower and perfect the seeds. It is propagated by seeds, which should be sown on a hot-bed in the spring; and the plants must be treated in the same manner as the former sort, with only this difference, that these when they are too tall to remain longer under the frames on the hot-bed, must be removed into the stove.

The third sort hath an herbaceous stalk, which rises five or six feet high, with long winged leaves, composed of eight or ten pair of large oval lobes, rounded at the end, where they are slightly indented. The flowers are produced in loose spikes at the top of the stalk, which are large, yellow, and of the same shape with those of the other species; the pods are long, taper, and have four borders or wings running longitudinally.

This sort seldom continues more than two years; it must be raised from seeds as the former sorts, and placed in the tan bed in the stove, being very tender, and should have but little water in winter.

The fourth sort grows naturally at *Campeachy*. This rises with a woody stem, to the height of fourteen or sixteen feet, sending out many lateral branches, garnished with winged leaves, composed of three pair of oblong, oval, hairy lobes, which are of equal size; the flowers come out in loose bunches at the end of the branches, which are of a pale straw colour and small, but shaped like the others.

This may be propagated by seeds, which must be sown upon a hot-bed, and the plants afterward treated as the former sorts.

The fifth sort is a low herbaceous plant, seldom rising a foot high; the stalk is single, and garnished with winged leaves, composed of three pair of oval, pointed lobes, which are hairy; the flowers come out single from the side of the stalks, they are of a pale yellow, and small; these are succeeded by narrow taper pods two inches long, which grow upright. This plant is annual; the seeds must be sown

sown on a hot-bed, and the plants treated as the first fort.

The sixth fort grows naturally in *Maryland*. It hath a perennial root, composed of a great number of black fibres, and sends out several upright stalks in the spring, which rise six feet high, garnished with winged leaves, composed of nine pair of oblong smooth lobes, which are equal; toward the upper part of the stalks the flowers come out from the wings of the leaves, two or three together. The stalks decay in autumn, and rise again in the spring. The roots of this fort continue many years, and will live abroad in a warm border and a dry soil.

The seventh fort is an annual plant, which rises a foot and half high, with an erect herbaceous stalk, which is garnished with winged leaves, composed of three pair of oval lobes; the flowers come out singly from the wings of the leaves, which are small, yellow, and of the same shape with those of the other species.

This is propagated by seeds, which must be sown on a hot-bed in the spring, and the plants afterward treated in the same manner as hath been directed for the first fort.

The eighth fort is the tree which produces the purging Cassia, which is used in medicine. It grows naturally in *Alexandria*, and in both *Indies*, where it rises to the height of forty or fifty feet, with a larger trunk, dividing into many branches, garnished with winged leaves, composed of five pair of spear-shaped lobes, which are smooth; the flowers are produced in long spikes at the end of the branches, each standing upon a pretty long foot-stalk; they are composed of five large concave petals, of a deep yellow colour, and are succeeded by round pods, which are from one to two feet long, with a dark brown woody shell, having a longitudinal seam on one side, and divided into many cells by transverse partitions, each containing one or two oval, smooth, compressed seeds, lodged in a sweetish black pulp, which is the part used in medicine.

This tree is propagated by seeds, which may be easily procured from the druggists who import the pods for use; which must be sown on a hot-bed in the spring, and when the plants come up, they must be treated in the same manner as the other forts, during the first summer, and in autumn they must be removed into a stove; during the winter they should have very little water, for as these trees grow naturally in dry sandy land, so moisture is a great enemy to them, but especially during that season. The plants may be exposed to the open air, in a sheltered situation, in the summer, in the warmest time of the year.

The ninth fort grows naturally in the *Bahama Islands*. This is an annual plant, which rises with an upright stalk, three feet and a half high, garnished with winged leaves, composed of six pair of lobes, which are smooth, narrow, and spear-shaped, standing at wide distances: the flowers are collected into loose bunches at the top of the stalks, which are of a pale yellow, and are succeeded by long compressed pods. This must be treated as the first fort.

The tenth fort grows at *La Vera Cruz* in *New Spain*. This rises upward of twenty feet high, with several trunks covered with brown bark, which divide into many branches upward, garnished with winged leaves, composed of two pair of lobes, which in the lower leaves are oval, and those of the upper are five inches long, and two and a half broad in the middle, smooth, and of a light green. The flowers are produced in loose spikes at the extremity of the branches, which are large, and of a gold colour.

This fort is propagated by seeds, which must be sown upon a hot-bed, and the plants afterward treated in the same manner as the eighth fort.

The eleventh fort grows in great plenty in most of the islands of the *West-Indies*. This rises to a great magnitude,

with a large trunk, dividing into many branches, garnished with very long winged leaves, composed of twelve or fourteen pair of oblong blunt lobes, which are smooth, of a light green, and placed near together. The flowers come out in loose spikes at the end of the branches, which are of a pale Carnation colour, shaped like those of the other species. This is called Horse Cassia, because it is generally given to horses, and seldom taken by any persons on account of its griping quality.

It is propagated by seeds, which should be sown, and the plants afterward treated in the same manner as the eighth fort.

The twelfth fort grows in the *Havannah*. This hath an herbaceous stalk, which divides into many branches, rising about three feet high, garnished with winged leaves, composed of seven pair of oblong oval lobes, which are rounded at the end. The flowers come out from the side of the branches, upon very long foot-stalks, and are disposed in loose spikes; these are of a pale yellow.

This is a biennial plant, which, if brought forward early in the spring, will sometimes perfect seeds the same year; but if they should fail, the plants may be kept through the winter in a stove, and good seeds may be obtained the following season.

The thirteenth fort rises with several weak shrubby stalks, about two feet high, closely garnished with winged leaves, composed of three pair of lobes, very narrow at their base, enlarging to the top, where they are rounded with a little indenture at the point. The flowers come out single from the side of the branches, standing upon very long foot-stalks; they are of a bright yellow, shaped like those of the other species, and are succeeded by narrow flat pods an inch and a half long. It is propagated by seeds, which must be sown on a hot-bed, and managed as the other tender forts; it will continue two or three years, if placed in a warm stove.

The fourteenth fort sends out from the root two or three slender stalks, which trail on the ground, garnished with winged leaves, having four pair of small roundish lobes, of a pale green; at the insertion of the foot-stalks arise those of the flower, which is jointed, dividing into two shorter at the top, sustaining two small yellow flowers. This is an annual plant, whose seeds must be sown early in the spring on a hot-bed, and treated like the other kinds.

The fifteenth fort grows at *La Vera Cruz* in *New Spain*. This rises with a strong upright trunk, to the height of twenty-five or thirty feet, dividing into many branches, covered with an Ash-coloured bark, garnished with winged leaves having long foot-stalks, each being composed of two pair of oblong oval lobes, which are smooth. The flowers are produced sometimes from the side of the stalks, where they are few and scattering, but the ends of the branches have large round bunches of flowers, which branch out from one center; they are of a deep yellow, inclining to an Orange colour.

The sixteenth fort grows common in all the islands of the *West Indies*. It rises with a slender stalk about two feet high, sending out a few side branches upward, garnished with winged leaves, composed of many pairs of narrow pinnæ, like those of the Sensitive Plant. The flowers come out upon short foot-stalks from the side of the branches, each foot-stalk sustaining two or three yellow flowers, of the same form with the other species of this genus; these are succeeded by short flat pods, containing three or four flat seeds in each.

This is an annual plant, and requires the same treatment as the first; but unless the plants are placed in a glass case, where they may have room to grow, and be screened from the cold, they will not perfect their seeds in *England*.

CASSIDA, Scull Cap. See Scutellaria.

CASSINE. *Lin. Gen. Plant.* 333. The Cassiberry bush, or *South Sea Thea*.

The Characters are,

The flower hath but one petal, which is cut into five obtuse segments; it hath five stamina, which spread from each other, and a conical germen, which after-ward becomes an umbilicated berry with three cells, each containing a single seed.

The Species are,

1. CASSINE *foliis ovato-lanceolatis, serratis, oppositis, floribus, corymbosis axillaribus.* *Fig. Pl. Plat.* 83. *fig.* 1. Cassine with oval spear-shaped leaves placed opposite, and flowers growing in round bunches from the sides of the branches; or, the Cassiberry bush.

2. CASSINE *foliis lanceolatis alternis semper-virentibus, floribus axillaribus.* *Fig. Pl. Plat.* 83. *fig.* 2. Cassine with ever-green spear-shaped leaves placed alternately, and flowers proceeding from the sides of the branches. *Yapon*, or *South-Sea Thea*.

The first sort rises with two or three stems, which send out many side branches, and become bushy; these seldom rise more than eight or nine feet high in *England*. The branches are garnished with oval spear-shaped leaves, sawed on their edges, which grow opposite. At the end of the branches, the flowers come out in roundish bunches; these are white, and divided into five parts almost to the bottom; in their center is placed the germen, attended by five stamina, which spread open, near as much as the segments of the petal. After the flower is past, the germen swells to a round berry, having three cells, each containing a single seed.

This sort is now become pretty common in the nurseries near *London*, where it is propagated by laying down the branches, which afford shoots in plenty for that purpose from the root, and lower part of the stem, so is easily increased. There are numbers of these shrubs which produce flowers in *England* every year, but none of them ripen their seeds.

The leaves of this plant are extremely bitter, so that if a single one is chewed, the bitterness cannot be gotten rid of in a long time.

It loves a light soil, not too dry, and should have a warm situation; for, in exposed places, the young shoots are frequently killed in the winter, whereby the shrubs are rendered unsightly, but where they are near the shelter of trees, or walls, they are very rarely hurt.

The second sort grows naturally in *Carolina*, and also in some parts of *Virginia*, but chiefly near the sea; this, in the natural places of its growth, rises to the height of ten or twelve feet, sending out branches from the ground upward, garnished with spear-shaped leaves, placed alternately, which continue green through the year. The flowers are produced in close whorls round the branches, at the foot-stalks of the leaves; they are white, and of the same shape with the former.

This plant was many years preserved in several curious gardens near *London*, till the severe winter in 1739; when most of them were destroyed, so that there was scarce any left; but of late years there have been many of the young plants raised from seeds, which came from *Carolina*. If this plant can be brought to thrive well in *England*, and to endure the winter in the open air, it will be a fine plant to make a variety in plantations of ever-green trees. The leaves of this sort are not so bitter as those of the first, especially when green.

The inhabitants of *North Carolina* and *Virginia*, where this shrub grows in plenty, give it the title of *Yapon*, which I suppose to be the *Indian* name. The leaves are about the size and shape of those of the small-leaved *Alaternus*, but are somewhat shorter, and a little broader at their base; they are a little notched about their edges, and are of a

thick substance and deep green colour; the flowers of this sort are produced at the joints near the foot-stalk of the leaves, but the Cassiberry bush produces its flowers in umbels at the extremity of the shoots.

These trees are propagated by sowing their seeds (which are obtained from *Carolina*, where they grow in great plenty near the sea coasts); they should be sown in pots, for the seeds do frequently remain in the ground until the second year; therefore the pots should be placed in a shady situation, where they may remain till *October*, when they must be removed into shelter during the winter season; and in *March* following put them upon a fresh hot-bed, which will forward the seeds in their vegetation.

When the plants are come up, they should, by degrees, be exposed to the open air, in order to inure them to our climate, placing them where they may be sheltered from cold winds; they should be sheltered during the two or three first winters under a frame, after which they may be planted abroad in a warm situation, where they will endure the cold of our common winters; but very severe frosts will kill them, if they have not some protection.

In *South Carolina* the plant is called *Cassena* or *South Sea Thea*: the inhabitants of that country do not make so great use of this Tea, as those of *Virginia* and *North Carolina*; in the last of which, the white people have it in as great esteem as the *Indians*, and make as constant use of it.

CASTANEA. *Tourn. Inst. R. H.* 584. The Chestnut tree.

The Characters are,

It hath male and female flowers on the same tree, sometimes at separate distances, and at other times near each other. The male flowers form a sort of katkin; they have no petals, but include about ten or twelve bristly stamina. The female flowers are of one leaf, divided into four parts, having no petals, but a germen fixed to the empalement, which becomes a roundish fruit armed with soft spines, including one or more nuts.

The Species are,

1. CASTANEA *foliis lanceolatis acuminato-serratis, subtus nudis.* The manured Chestnut.

2. CASTANEA *foliis lanceolato-ovatis acutè serratis, subtus tomentosis, amentis filiformibus nodosis.* Chestnut with oval spear-shaped leaves sharply sawed, which are woolly on their under side, and a slender knotted katkin.

3. CASTANEA *foliis oblongo-ovatis, serratis, fructu rotundo maximo echinato.* Chestnut with oblong, oval sawed leaves, and a very large, round, prickly fruit. This is the *Sloanea* of *Plumier*.

The Chestnut is a tree which deserves our care, as much as any of the trees which are propagated in this country, either for its use or beauty, being one of the best sort of timber, and affording a goodly shade. It will grow to a very great size, and spread its branches finely on every side where it has room. The leaves are large, of a lucid green, and continue late in the autumn; nor are they so liable to be eaten by insects, as are those of the Oak, which of late years having frequently happened to the latter, which has rendered them very unsightly great part of summer. There is no better food for deer, and many other animals, than their nuts, which most of them prefer to Acorns; but yet, there should not be many of these trees planted too near the habitation; because, when they are in flower, they emit a very disagreeable odour, which is very offensive to most people.

There are some varieties of this tree, which have accidentally arisen from seeds, that have been supposed distinct species; but the differences are only in the size of their fruit and leaves, which have been altered and improved by culture; so that the wild and manured Chestnut, are undoubtedly the same; for I have frequently found, that the nuts taken from the same tree, and cultivated in the

the same soil, with equal care, have produced trees with very small fruit; and among them have been others, whose fruit have been as large as those of the parent tree; therefore they can be only esteemed as varieties. But in many countries, where the trees are cultivated for their fruit, the people graft the largest and fairest fruit, upon stocks of Chestnut raised from the nut; and these grafted trees are by the *French* called *Maronnier*, but these grafted trees are unfit for timber.

There is also a Chestnut with variegated leaves, which is propagated in the nurseries by way of curiosity: this is maintained by budding, and inarching it upon common Chestnut stocks, in the same manner as other fruit trees; but these variegated trees and plants are not so much regarded at present, as they were some years past.

The third sort grows in *South Carolina*, from whence some of the fruit with their outer covers, were sent to his grace the duke of *Bedford*, a few years past: these were as large and round as a tennis-ball, and armed all over with strong spines like a hedge-hog: these capsulæ were divided regularly in four cells, each containing one small Chestnut. At that time I compared these with father *Plumier's* description and figure, which he exhibited under the title of *Sloanea*, and found them to agree exactly; and upon looking in the box in which they were sent, I found some of the leaves of the tree, which also tallied with his description, and confirmed my former opinion.

The first of these trees was formerly in greater plenty amongst us than at present, as may be proved by the old buildings in *London*, which were for the most part of this timber; and in a description of *London*, written by *Fitz-Stephens*, in *Henry the second's* time, he speaks of a very noble forest, which grew on the north part of it: *Proximè* (says he) *patet foresta ingens, saltus numerosi ferarum, latebræ cervorum, damarum, aprorum, & taurorum sylvestrium, &c.* And there are some remains of old decayed Chestnuts in *Enfield* chace, not far distant from *London*; which plainly proves, that this tree is not so great a stranger to our climate, as many people believe, and may be cultivated in *England*, to afford an equal profit with any of the larger timber trees, since the wood of this tree is equal in value to the best *Oak*, and, for many purposes, far exceeding it; as particularly for making vessels for all kinds of liquor, it having a property (when once thoroughly seasoned) of maintaining its bulk constantly; and is not subject to shrink or swell, as other timber is too apt to do; and I am certainly informed, that all the large casks, tuns, &c. for their wines in *Italy*, are made of this timber; and it is for that, and many more purposes, in greater esteem among the *Italians*, than any other timber whatever. It is also very valuable for pipes to convey water under ground, as enduring longer than the *Elm*, or any other wood. In *Italy* it is planted for coppice wood, and is very much cultivated in stools, to make stakes for their vines, which will endure seven years, which is longer than any other stakes will do, by near half the time. The usefulness of the timber, together with the beauty of the tree, renders it as well worth propagating as any tree whatever, especially in large plantations in parks.

The trees are propagated by planting the nuts in *February*, in beds of fresh undunged earth. The best nuts for sowing, are such as are brought from *Portugal* and *Spain*, which are commonly sold in winter for eating, provided they are not kiln-dried, which is generally the case of many of those brought from abroad, which is done to prevent their sprouting in their passage; therefore, if they cannot be procured fresh from the tree, it will be much better to use those of the growth of *England*, which are full as good to sow for timber or beauty, as any of the foreign nuts, though their fruit is much smaller: the nuts should be preserved, until the sea-

son for sowing, in sand, where mice, or other vermin cannot come to them, otherwise they will soon destroy them: before you set them, it will be proper to put them into water, to try their goodness, which is known by their ponderosity; such of them as swim upon the surface of the water should be rejected, as good for nothing; but such as sink to the bottom, you may be sure are good.

In setting these seeds or nuts, the best way is, to make a drill with a hoe (as is commonly practised in setting *Kidney Beans*) about four inches deep, in which you should place the nuts, at about four inches distance, with their eye uppermost; then draw the earth over them with a rake, and make a second drill at about a foot distance from the former, proceeding as before, allowing three or four rows in a bed, with an alley between, three feet broad, for a conveniency of clearing the beds, &c. When you have finished your plantation, you must be careful that it is not destroyed by mice, or other vermin; which is very often the case, if they are not prevented by traps, or other means.

In *April* these nuts will appear above ground; you must therefore observe to keep them clear from weeds, especially while young: in these beds they may remain for two years, when you should remove them into a nursery, at a wider distance. The best season for transplanting these trees, is either in *October* or the latter end of *February*; but *October* is the best season: the distance these should have in the nursery, is three feet row from row, and one foot in the rows. If these trees have a downright tap root, it should be cut off, especially if they are intended to be removed again; this will occasion their putting out lateral roots, and render them less subject to miscarry, when they are removed for good.

The time generally allowed them in the nursery, is three or four years, according to their growth; but the younger they are transplanted, the better they will succeed; young trees of this sort are very apt to have crooked stems; but when they are transplanted out, and have room to grow, as they increase in bulk, they will grow more upright, and their stems will become strait, as I have frequently observed, where there have been great plantations.

After they have remained three or four years in the nursery, they will be fit for transplanting where they are to remain; for the younger they are planted out for good, the better they will succeed. But if they are propagated for timber, it is by much the better method to sow them in furrows (as is practised for *Oaks*, &c.) and let them remain unremoved; for these trees are apt to have a downright tap root, which, being hurt by transplanting, is often a check to their upright growth, and causes them to shoot out into lateral branches, as is the case with the *Oak*, *Walnut*, &c.

If you design a large plantation of these trees for timber, after having two or three times ploughed the ground, the better to destroy the roots of weeds, you should make your furrows about six feet distance from each other, in which you should lay the nuts about ten inches apart, covering them with earth about two inches deep; and when they come up, you must carefully clear them from weeds: the distance allowed between each row, is for the use of the horse hoeing plough, which will dispatch a great deal of this work in a short time; but it should be performed with great care, so as not to injure the young plants; therefore the middle of the spaces only should be cleaned with this instrument, and a hand hoe must be used to clean between the plants in the rows, and also on each side, where it will be unsafe for the plough to be drawn; and in hand hoeing, there must be great care taken, not to cut the tender rind of the plant. But for the two first years after sowing, it will be advise-

able to dig the ground each winter, because the plants will be too small to admit the hoeing plough, and in summer to hand hoe the ground. When these have remained three or four years (if the nuts succeed well), you will have many of these trees to remove; which should be done at the seasons before directed, leaving the trees about three feet distance in the rows; at which distance they may remain for three or four years more, when you should remove every other tree, to make room for the remaining, which will reduce the whole plantation to six feet square; which will be distance enough for them to remain in, until they are large enough to cut for poles, when you may cut down every other of these trees (making choice of the least promising) within a foot of the ground, in order to make stools for poles, which, in eight or ten years time, will be strong enough to lop for hoops, hop poles, &c. for which purposes they are preferable to most other trees; so that every tenth year, here will be a fresh crop, which will pay the rent of the ground, and all other incumbent charges, and, at the same time, a full crop of growing timber left upon the ground.

The Chinquapin, or Dwarf *Virginian* Chestnut, is at present very rare in *England*; it is very common in the woods of *America*, where it seldom grows above twelve or fourteen feet high, and produces great plenty of nuts, which are, for the most part single, in each outer coat or capsule. This tree is very hardy, and will resist the severest of our winters in the open ground; but is very apt to decay in summer, especially if it is planted in very dry ground. The nuts of these trees, if brought from *America*, should be put up in sand as soon as they are ripe, and sent to *England* immediately; otherwise they lose their growing quality, which is the reason this tree is at present so scarce with us; for not one seed in five hundred sent over ever grew. Indeed, most of the nuts which have been brought over, have been kiln-dried, to preserve them from sprouting, which infallibly destroys the germen: when the nuts arrive, they should be put into the ground as soon as possible; for if they are long kept above ground, they lose their vegetative quality. This sort of Chestnut delights in a moist soil, but if the wet continues long upon the ground in the winter, it is apt to kill the trees.

CASTANEA EQUINA. See Esculus.

CASTOREA. See Durantia.

CATANANCHE. *Lin. Gen. Plant.* 824. *Candia* Lions Foot.

The Characters are,

The flower is composed of many hermaphrodite florets, included in one common scaly empalement, which is permanent and elegant. The florets are of one leaf, tongue-shaped, indented in five parts; they have each five short hairy stamina. The germen is situated below the flower, which afterward becomes a single oval seed, which is compressed, and crowned with bristles, inclosed in the empalement.

The Species are,

1. CATANANCHE *squamis calycinis inferioribus ovatis. Hort. Cliff.* 390. Catananche whose under scales of the empalement are oval.

2. CATANANCHE *squamis calycinis inferioribus lanceolatis. Hort. Cliff.* 390. Catananche whose under scales of the empalement are spear-shaped.

The first sort sends out many long, narrow, hairy leaves, which are jagged on their edges, like those of the Buckthorn Plantain, but broader; the jags are deeper, and at greater distances; these lie flat on the ground, turning their points upwards. Between the leaves come out the flower-stalks, which are in number proportionable to the size of the plant; for from an old thriving root, there is frequently eight or ten, and young plants do not send out more than two or

three. These stalks rise near two feet high, dividing into many small branches upward, garnished with leaves like those below, but are smaller, and have few or no jags on their edges: each of these smaller branches (or foot-stalks) are terminated with single heads of flowers, having a dry silvery scaly empalement, in which are included three or four florets, whose petals are broad, flat, and indented at their ends; these are of a fine blue colour, having a dark spot at bottom, and in each five stamina.

The second sort hath broader leaves than the first, and less jagged on their edges: from each root rise one or two stalks, which grow a foot and an half high, sending out two or three slender foot-stalks, each sustaining a single head of yellow flowers, inclosed in a dry scaly empalement, of a darker colour than those of the first.

The first of these plants is perennial, which is propagated by seeds, which may be sown in a bed of common earth in the spring. In the autumn following, the plants may be transplanted where they are to remain. It is a pretty ornament to a garden, and is easily kept within bounds. These plants should remain unremoved, which will cause them to flower better, and they will produce more seeds. The seeds ripen in *August*.

The other sort is an annual plant, and is propagated by seeds, which ripen very well in this country. The time for sowing them is early in *March*, in beds or borders of light earth where they are to remain, and will require no other care but to keep them clean from weeds, and thin the plants where they are too close. These flower in *June*, and perfect their seeds in *August* or *September*.

CATAPUTIA MAJOR. See Ricinus.

CATAPUTIA MINOR. See Euphorbia.

CATARIA. See Nepeta.

CATCH-FLY. See Lychnis.

CATESBÆA. *Lin. Gen. Plant.* 121. *Hist. Carolin.* vol. ii. p. 100. The Lily Thorn.

The Characters are,

The flower is of one leaf, funnel-shaped, having a very long tube, which gradually widens to the top, where it is four-cornered and spread open; it hath four stamina rising in the neck of the tube; the roundish germen is situated under the flower, which afterward becomes an oval berry with one cell, filled with angular seeds.

We know but one Species of this genus, viz.

CATESBÆA. *Lin. Sp. Plant.* 109. The Lily Thorn.

This shrub was discovered by Mr. *Catesby*, near *Nassau* town, in the island of *Providence*, where he saw two of them growing, which were all he ever saw; from these he gathered the seeds, and brought them to *England*.

It rises with a branching stem to the height of ten or twelve feet, covered with a pale russet bark; the branches come out alternately, which are garnished with small leaves, resembling those of the Box tree, coming out in clusters all round the branches, at certain distances; the flowers come out single from the side of the branches, hanging downward; they are tubulous, and near six inches long, very narrow at their base, but widening upward toward the top, where it is divided into four parts which spread open, and are reflexed backward: these are of a dull yellow colour.

This shrub is propagated by seeds, which must be procured from the country where it naturally grows. If the entire fruit are brought over in sand, the seeds will be better preserved; the seeds must be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanners bark. If the seeds are good, the plants will appear in about six weeks; these plants make little progress the first year. If the nights should prove cold, the glasses must be covered with mats every evening. As these plants grow slowly, so they will not require to be removed out of the seed

seed pots the first year, but in the autumn the pots should be removed into the stove, and plunged into the tan bed: in spring the plants should be carefully taken up, and each planted in a separate small pot, filled with light sandy earth, and plunged into a fresh hot-bed of tanners bark. In summer, when the weather is warm, they should have a good share of air admitted to them, but in autumn must be removed into the stove, where they should constantly remain, and must be treated afterward in the same manner as other tender exotick plants.

CAUCALIS, Bastard Parsley.

This is one of the umbelliferous plants with oblong seeds, which are a little furrowed and prickly: the petals of the flower are unequal, and heart-shaped.

There are several *Species* of this plant preserved in the botanick gardens; but as there is no great beauty or use in any of them, I shall pass them over with only observing, that if any person hath a mind to cultivate them, the best season to sow their seeds is in autumn, soon after they are ripe.

CEANOTHUS. *Lin. Gen. Plant.* 237. *Eunonymus. Com. Hort. New Jersey* Thea.

The Characters are,

The flower hath five roundish equal petals which spread open, and are less than the empalement; it hath five erect stamina placed opposite to the petals, and a three-cornered germen, which afterward becomes a dry capsule with three cells, in which are lodged three oval seeds.

1. CEANOTHUS *foliis trinerviis. Lin. Sp. Plant.* 195. Ceanothus with leaves having three nerves.

2. CEANOTHUS *foliis lanceolatis enerviis, stipulis subrotundis. Lin. Sp. Plant.* 196. Ceanothus with spear-shaped leaves without nerves, and roundish stipulæ.

3. CEANOTHUS *foliis ovatis venosis sessilibus, floribus singularibus alaribus.* Ceanothus with oval leaves set close to the branches, and single flowers proceeding from the wings of the leaves; commonly called Redwood.

The first sort grows naturally in most parts of *North America*, from whence great plenty of the seeds have been of late years brought to *Europe*, by the title of *New Jersey* Thea. The people of *Canada* use the root in venereal cases.

In *England* this shrub seldom rises more than four or five feet high, sending out branches on every side from the ground upward. These branches are garnished with oval pointed leaves, having three longitudinal veins running from the foot-stalk to the point, which diverge in the broad part of the leaves from each other: the leaves are placed opposite, and are of a light green colour. At the extremity of each shoot the flowers are produced in close thick spikes, which are composed of five small leaves, and are of a clear white; and every shoot is terminated by one of these spikes, so the whole shrub is covered over with flowers. When the autumn proves mild, these shrubs often flower again in *October*. In warm seasons the seeds will ripen pretty well in *England*. But this shrub is best propagated by laying down the young branches, which, in a light soil, will put out roots in a year's time, but these layers should not be much watered; for as the shoots are tender, so moisture will often occasion their rotting, when it is given in quantities, or too often repeated; therefore the best method is to cover the surface of the ground in dry weather, all round the layers with mulch, which will preserve a sufficient moisture in the ground, provided the season is not extremely dry, in which case they should have a little water once in eight or ten days, which will be sufficient.

The best time for laying down these branches is in autumn, and if after this is performed, the surface of the ground is covered over with some old tan, taken from a decayed hot-bed, it will prevent the frost from penetrating of the ground, which will secure them from injury, and

the same covering will prevent the winds from drying of the ground in the spring, and thereby promote their putting out roots. These layers, when rooted, may be taken up the following spring, and planted where they are to remain.

The second sort grows naturally at the *Cape of Good Hope*, from whence it was originally brought to *Holland*, where it has been long known by the title of *Alaternoides*, &c. and by some authors it is titled *Ricinoides Africana arborescens*, &c. but *Dr. Linnæus*, having examined the characters more exactly, has joined it to this genus.

This rises to the height of ten or twelve feet, with a woody stem, covered with a rough purple bark; it sends out many weak branches, which hang downward; they are garnished with oblong pointed leaves, of a lucid green, which are smooth, and slightly sawed on their edges. The flowers are small, of an herbaceous colour, coming out from the side of the branches.

It may be propagated either by layers or cuttings, the latter being a very sure and expeditious method, is generally preferred. The cuttings should be planted in the spring, in a shady border; in about two months, or less, they will have taken root, when they must be taken up, and each planted in a small pot filled with light earth, placing them in the shade till they have taken fresh root. In autumn they must be housed with *Myrtles*, and other more hardy exotick plants, and treated in the same manner.

The third sort grows naturally in the *American* islands; it rises with a shrubby stalk eighteen or twenty feet high, sending out several horizontal branches, which are garnished with oval veined leaves; the flowers come out at the wings of the leaves, with very short foot-stalks; they are of a white herbaceous colour, and are succeeded by dry capsules, shaped like those of the first sort.

This plant requires to be placed in a warm stove, otherwise it will not thrive in *England*; it is propagated by seeds, which must be sown upon a hot-bed in the spring, and when the plants are fit to remove, they should be each planted into a separate small pot filled with light sandy earth, and plunged into a hot-bed of tanners bark, observing to shade them till they have taken root; then they must be treated in the same manner as other tender exotick plants. In the autumn they must be placed in the bark stove, and during the winter, must be watered with great caution, for too much moisture at that season will destroy them.

CEDRUS, the Cedar tree of *Barbadoes*, and *Mahogany*, &c.

The Characters are,

The flower is of one leaf, divided at the top into five parts; it hath five short stamina, which adhere at bottom to the germen. In the center is situated the roundish germen, which afterward becomes an oval pod, having five cells, opening from the bottom upward with five valves, having a double cover, the outer being thick and woody, the inner very thin, which immediately surrounds the seeds; these are thick at their base, but upward are flat and thin, like the wings adhering to the seeds of *Firs* and *Pines*.

As the Cedar of *Libanus* is by *Tournefort* very properly referred to the genus of *Larix*, and all the berry bearing Cedars are joined to the *Junipers*, so I have given the title of *Cedrus* to this genus, as the plants were mentioned by imperfect titles by most of the authors who have treated of them; and as the first sort has been generally known by the appellation of Cedar, in the countries where it naturally grows, so the applying of the same name to those plants, which agree in their essential characters with it, will join them properly together.

The Species are,

1. CEDRUS *foliis pinnatis, foliolis multijugatis obtusis, fructu ovali*

ovali glabro. Cedar tree with winged leaves, composed of many pairs of small leaves (or lobes) which are obtuse, and an oval smooth fruit. This is the *Barbadoes* Cedar tree.

2. *CEDRUS foliis pinnatis, foliolis oppositis, glabris, floribus racemosis sparsis.* Cedar with winged leaves, whose lobes are smooth and stand opposite, and flowers growing in loose bunches. This is the Mahogany tree.

3. *CEDRUS foliis alternis simplicibus, cordato-ovatis acutis, fructu pentagono mucronato.* Cedar with single leaves placed alternately, which are oval, heart-shaped, and acute, and have a five-cornered pointed fruit.

The first sort is commonly known under the title of Cedar in the *British* islands of *America*, where this tree grows naturally, and is one of the largest trees of that country. The trunks of these trees are so large, that the inhabitants hollow them, and form them into the shape of boats and periaguas, for which purpose they are extremely well adapted; the wood being soft, it may be cut out with great facility, and being light, it will carry a great weight on the water. The wood has a fragrant odour, from whence the title of Cedar has been given to it. It is often used for wainscoting of rooms, and to make chests, because vermin do not so frequently breed in it, as in many other sorts of wood; this having a very bitter taste, which is communicated to whatever is put into the chests, especially when the wood is fresh, for which reason it is never made into casks, because spirituous liquors will dissolve part of the resin, and thereby acquire a very bitter taste.

This tree rises with a strait stem, to the height of seventy or eighty feet; while young the bark is smooth, and of an Ash colour, but as they advance, the bark becomes rough, and of a darker colour. Toward the top it shoots out many side branches, which are garnished with winged leaves, composed of sixteen or eighteen pair of lobes, (or small leaves) so that they are sometimes near three feet long; the lobes are broad at their base, and are near two inches long, blunt at their ends, and of a pale colour; these emit a rank odour in the summer season, so as to be very offensive. The fruit is oval, about the size of a partridge's egg, smooth, and of a very dark colour, and opens in five parts, having a five-cornered column standing in the middle, between the angles of which the winged seeds are closely placed, lapping over each other like the scales of fishes.

I have received plants of this kind from *Paris*, by the title of *Semiruba*, but whether the root of this tree is, what they use in medicine under that appellation, I cannot say. The seeds of this have also been sent me from the *French* islands in *America*, by the title of *Acajou Cedre*.

It is propagated by seeds, which may be easily procured from the *American* islands, which must be sown upon a hot-bed in the spring, and the plants treated in the same manner as the next.

The second sort is the Mahogany, whose wood is now well known in *England*.

This tree is a native in the warmest parts of *America*, growing plentifully in the islands of *Cuba*, *Jamaica*, and *Hispaniola*; there are also many of them on the *Babama* islands, but I have not heard of their being found in any of the *Leeward* islands. In *Cuba* and *Jamaica* there are trees of a very large size, so as to cut into planks of six feet breadth; but those on the *Babama* islands are not so large, though they are frequently four feet diameter, and rise to a great height, notwithstanding they are generally found growing upon the solid rocks, where there is scarce any earth for their nourishment. The wood which has been brought from the *Babama* islands has usually passed under the appellation of *Madeira* wood, but there is no doubt of its being the same as the Mahogany.

The excellency of this wood for all domestick uses, is

now sufficiently known in *England*; and it is a matter of surprise, that the tree should not have been taken notice of by any historian or traveller, to this time; the only author who has mentioned this tree, is Mr. *Catesby*, in his *Natural History of Carolina and the Bahama islands*, before whom I believe neither the tree or the wood was taken notice of by any writer on natural history, although the wood has been in many years brought to *England* in great quantities.

The leaves of this tree are winged like those of the Ash, having commonly six or eight pair of pinnæ (or lobes) which are shorter and broader at their base than those of the Ash, where they adhere to the midrib, by very short foot-stalks; these lobes are very smooth, having but one vein running through each, which is always on one side, so as to divide them unequally. We have no perfect account of the flower of this tree; those which are exhibited in Mr. *Catesby's Natural History*, were drawn from a withered imperfect fragment, which were the only remains of the flowers, which could be found at the time when he was there; but the fruit he has delineated very exactly, as I have had an opportunity of comparing it with some that have been brought to *England*. The entire fruit, before it opens, is of a brown colour; these fruit grow erect, upon long foot-stalks, which closely adhere to the five-cornered column, running through the middle of the fruit, and to which the seeds are fastened, lying *imbricatim*, like slates on a house, over each other; so that when the fruit is ripe, the outer cover divides at the bottom into five equal parts; and when these fall off, and the seeds are dispersed, the foot-stalk and the column remain some months after on the tree.

It is propagated by seeds, which may be easily procured from the *Babama* islands, from whence most of the good seeds which have come to *England* were brought; for most of those which have been sent from *Jamaica*, although brought in their pods, have not succeeded, whereas those from the *Babama* islands have grown as well as if they were immediately taken from the trees; the seeds should be sown in small pots filled with light sandy earth, and plunged into a hot-bed of tanners bark, giving them a gentle watering once a week; if the seeds are good, the plants will appear in a month or five weeks, and when the plants are two inches high, a sufficient number of small pots should be filled with light earth, and plunged into the tan-bed a day or two, that the earth may be warmed before the plants are put into the pots; then the young plants should be shaken out of the pots, and carefully separated, so as not to tear their roots, and each planted in a single pot, being careful to shade them till they have taken fresh root, after which they must be treated in the same manner as other tender plants from the same climate, being careful not to give them much water, especially in winter. If the plants are properly managed, they will make considerable progress; I have some plants now in the *Chelsea* garden eight or ten feet high, which are but of six years growth from seeds.

The third sort was discovered by the late Dr. *Houfston*, at *Campeachy*, from whence he sent the seeds to *England*; which succeeded in several gardens; when the doctor first observed these trees, they were destitute of leaves, but were loaded with ripe fruit; and on his second visit to the place, he found the trees in full verdure, but no appearance of flowers, so he was at a loss to know what genus it belonged to; but as the fruit of this tree agrees exactly with those of the two former species, so I have ventured to join it to them.

These trees usually rise to the height of eighty feet or upward, and divide into many large branches toward the top, which are garnished with leaves, somewhat resembling those of the Witch Hazel, but are broader at their base, and cut angular at their top; these are of an Ash colour underneath, and are set on the branches without any order; the fruit of

this tree is much larger than that of the *Barbadoes* Cedar, being broad at the base, and diminishing gradually to the top, where it terminates in a point, being upwards of two inches long; this has also a column, or woody core, running lengthways through the fruit, to which the winged seeds adhere as in the two former; but as both their fruit are smooth on the outside, this differs from them, in having five angles running from the base upward; at each angle the fruit, when ripe, separates, and exposes the winged seeds, which are dispersed by the winds.

We have no account of the wood of this tree, whether it is ever used in buildings, or for other purposes, as there have been few persons of any curiosity in that country, the cutters of Logwood being the chief people who inhabit there, from whom there can be little known of the produce. The plants which have been raised from the seeds in *England*, have made great progress for the two first years, but afterwards were but slow of growth; for, in six years more, they did not shoot so much as in the first year from the seed, when they grew more than three feet high. This may be managed in the same manner as the two foregoing sorts, and with them constantly kept in the bark stove.

CEIBA. See *Bombax*.

CELASTRUS. *Lin. Gen. Plant.* 239. *Euonymoides*. *Isnard. Ac. R. Sc.* 1716. The Staff tree.

The Characters are,

The flower hath five oval petals, which are equal, and spread open. It hath five stamina as long as the petals, and a small germen with a large receptacle, marked with ten deep channels, which afterwards becomes an oval, blunt, three-cornered capsule, opening in three cells, each containing an oval smooth seed.

The Species are,

1. CELASTRUS *inermis, foliis ovatis integerrimis.* *Lin. Sp. Pl.* 196. Smooth Staff tree with oval entire leaves.

2. CELASTRUS *inermis, caule volubili.* *Lin. Sp. Pl.* 196. Smooth Staff tree with a twining stalk.

3. CELASTRUS *spinis nudis, ramis teretibus, foliis acutis.* *Hort. Cliff.* 72. Staff tree with naked spines, taper branches, and pointed leaves.

4. CELASTRUS *spinis foliosis, ramis angulatis, foliis obtusis.* *Hort. Cliff.* 73. Staff tree with leaves on the spines, angular branches, and obtuse leaves.

The first sort grows naturally in *Virginia*, and many other parts of *North America*, where it rises to the height of eight or ten feet. It generally puts out two or three stems from the root, which divide upward into several branches, covered with a brown bark, and garnished with leaves near three inches long, which are placed alternately on the branches; the flowers come out on the side of the branches; these are white, made up of five oval petals, with a germen in the center, attended by five stamina; when the flowers fall off, the germen swells to a three-cornered capsule, of a scarlet colour, set full of small protuberances; this opens in three parts, each containing a hard oval seed, covered with a thin red pulp.

It is propagated here by layers, which will take root in one year; the young branches only are proper for this purpose, so that where there is not any of these near the ground, the main stalks should be drawn down, and fastened with pegs to prevent their rising, and the young shoots from them should be laid. The best time for doing this is in autumn, and by that time twelvemonth they will be sufficiently root-

ed, when they should be cut from the old plant, and planted in a nursery for a year or two to get strength, after which they must be removed to the places where they are to remain. This shrub grows naturally in moist places, so will not thrive well in a dry soil.

The second sort sends out several ligneous stalks from the root, which are flexible, and twist themselves about whatever trees and shrubs grow near them; or when they are at a distance from such support, they twine about each other, and rise to the height of twelve or fourteen feet; but when they fall themselves about trees they will grow much taller. These are garnished with oblong leaves, about three inches long, and near two broad, which are sawed on their edges. The flowers are produced in small bunches toward the end of the branches, which are of an herbaceous colour, composed of five roundish petals; these are succeeded by roundish three-cornered capsules, which are red, and, when ripe, spread open in three parts, disclosing the seeds in the same manner as our common Spindle tree. This sends out suckers from the root, so is easily propagated.

The third sort is a native of *Ethiopia*. This rises with an irregular stalk about three or four feet high, sending out several side branches, covered with brown bark, and garnished with leaves about two inches long, and more than half an inch broad, some of which are pointed, and others are obtuse; they are stiff, of a lucid green, and come out irregularly from the branches; these continue green through the year. The flowers are produced from the side of the branches in loose tufts, many of them arising from one point, standing upon long foot-stalks; they are of an herbaceous white colour, composed of five petals, which spread open, and five spreading stamina, which surround a swelling germen, which afterwards becomes an oval fruit, of a fine red colour, which opens in three cells, containing one oblong hard seed, the other two cells being generally abortive.

This plant is commonly propagated by cuttings in *Europe*, which is more expeditious than raising them from seeds, because the seeds rarely come up the first year. The cuttings may be planted any time in summer; but those which are planted early, will have more time to get strength before winter. When they have taken root they must be exposed to the open air, and placed in a sheltered situation; when they are separated, they must be each planted in a small pot filled with good earth, then placed in the shade till they have taken fresh root, after which they may be placed with other exotick plants in a sheltered situation till autumn, when they must be housed with Myrtles, and other of the hardy green-house plants, and will require the same treatment.

The fourth sort grows naturally at the *Cape of Good Hope*, from whence I received the seeds. This rises with a slender ligneous stalk, to the height of ten or twelve feet, covered with a light Ash-coloured bark, and full of joints, which are armed with long spines, upon which grow many small leaves; the branches are slender, and armed with the same spines at every joint, but the whole plant is so weak, as to require some support, without which they would fall to the ground. The leaves come out in clusters, without any order, which are shaped somewhat like those of the narrow leaved Box tree, but are longer, and of a loose texture; the branches are angular, and when young their bark is whitish.

This rises very easily from seeds, and the plants make great progress; for I have raised them four feet high in two years from seeds, without any artificial heat; and some of the plants have lived through two winters against a south-east wall, but these have shed their leaves in winter, whereas those which are removed into the green-house have retained their verdure through the year.

It may be propagated by cuttings, which should be planted in the spring, and treated in the same manner as hath been directed for the former sort; or if the young shoots are laid, they will take root in one year, and may then be transplanted either into pots, or against a good aspected wall, where I find they will endure our ordinary winters without any protection.

CÉLERY, or SALARY. See Apium.

CELOSIA. *Lin. Gen. Plant.* 255. Amaranth.

The Characters are,

The flower hath five erect sharp-pointed petals, which are permanent, stiff, and shaped like a flower cup. It hath a small nectarium joined to the border of the germen, to which adhere the five stamina, which are terminated by turning summits. The empalement afterward becomes a globular capsule with one cell opening horizontally, containing roundish seeds.

The Species are,

1. CELOSIA *foliis lanceolatis, pedunculis angulatis, spicâ ovatâ-oblongâ.* *Lin. Sp. Pl.* 205. Celosia with spear-shaped leaves, angular foot-stalks, and an oval oblong spike.

2. CELOSIA *foliis oblongo-ovatis, pedunculis teretibus substriatis, spicâ oblongâ.* *Lin. Sp. Plant.* 205. Celosia with oblong oval leaves, taper striated foot-stalks, and an oblong spike.

3. CELOSIA *foliis lanceolato-ovatis, paniculâ diffusâ filiformi.* *Flor. Virg.* 144. Celosia with oval spear-shaped leaves, and a slender diffused panicle.

Dr. *Linnaeus* has separated the plants of this genus from the Amaranths, which have been generally joined with them, because those have male and female flowers in the same plants, whereas these have only hermaphrodite flowers; so that by his system, the other are removed to the twenty-first class, and have been before mentioned under the article AMARANTHUS, to which the reader is desired to turn for the *Amaranthus tricolor*, &c.

The first sort here mentioned grows naturally in both *Indies*. This rises with an upright stalk about three or four feet high, garnished with long spear-shaped leaves ending in points, of a pale colour. Toward the upper part of the stalk, there are a few side branches sent out which stand erect; each of which is terminated by a slender spike of flowers, and the principal stalk is terminated by one which is much larger; this is two or three inches long, and about as thick as a man's middle finger, the whole spike being of a silvery colour.

The second sort is well known, by its common appellation of Cockscomb; which was given to it from the form of its crested head of flowers, resembling a cock's comb; of this there are many varieties, which differ in their form, magnitude, and colours; but as they vary from seeds, so they are not enumerated as distinct species. I have raised great varieties of these from seeds which came from *China*, and other countries, but have generally found them alter in a few years, notwithstanding great care has been taken in the saving of their seeds: the principal colours of their heads are red, purple, yellow, and white; but there are some, whose heads are variegated with two or three colours. I also raised some from seeds which I received from *Persia*, whose heads were divided like a plume of feathers, which were of a beautiful scarlet colour.

The third sort grows naturally in some of the sugar islands: it rises with a weak stalk near four feet high, which is garnished with oblong pointed leaves, that stand opposite at each joint, and are pretty far asunder. The flowers come out in loose panicles from the side of the stalks, and also at the end of the branches; these are divided into a great number of very slender spikes, which are of a pale yellow, shining with a gloss like silk. The plants of this perished in the autumn, without perfecting their seeds.

In order to have large fine Amaranths, great care should be taken in the choice of the seeds; for if they are not carefully collected, the whole expence and trouble of raising them will be lost. When you are provided with good seeds, they must be sown on a hot-bed (which should have been prepared a few days before, that the violent heat may be abated); about the beginning of *March* is a good time to sow the seeds, and in less than a fortnight the plants will appear; but as they are tender when they first come up, so they require great care for a few days till they get strength; in giving them a due proportion of air, to prevent their drawing up weak, and then to keep them from too much moisture; for a small share of moisture will cause their tender stems to rot: in sowing of the seeds, there should be care taken not to put them too close, for when the plants come up in clusters, they frequently spoil each other, for want of room to grow. In a fortnight or three weeks time, the plants will be fit to remove, when you must prepare another hot-bed, covered with good rich light earth, about four inches thick; which should be made a few days, that it may have a proper temperature of heat; then raise up the young plants with your finger, so as not to break off the tender roots, and prick them into your new hot-bed about four inches distance every way, giving them a gentle watering to settle the earth to their roots: but in doing this, be very cautious not to bear the young plants down to the ground by hasty watering, which rarely rise again, or at least so as to recover their former strength in a long time, but very often rot in the stems and die quite away.

After the plants are thus planted, they must be screened from the sun till they have taken fresh root; but as there is generally a great steam arising from the fermentation of the dung, which condenses to wet against the glasses, and this dropping upon the plants very frequently destroys them; so the glasses should be frequently turned in the day-time, whenever the weather will permit; but if the weather happens to prove bad that you cannot turn your glasses, it will be of great service to your plants, to wipe off all the moisture two or three times a day with a woollen cloth, to prevent the dropping upon the plants. When your plants are firmly rooted and begin to grow, you must observe to give them air every day (more or less, as the weather is cold or hot) to prevent their drawing up too fast, which greatly weakens their stems.

In about three weeks or a month's time, after these plants have grown so as to meet, they will stand in need of another hot-bed, which should be of a moderate temper, and covered with the same rich earth about six inches thick, in which they should be planted (observing to take them up with as much earth about their roots as possible) planting them seven or eight inches distance every way, giving them some water to settle the earth about their roots; but be very careful not to water them heavily, so as to bear down the plants, (as was before directed) and keep them shaded in the heat of the day, until they have taken fresh root, and be sure to refresh them often (but gently) with water.

In the beginning of *May* you must provide another hot-bed, which should be covered with a deep frame, that your plants may have room to grow: upon this hot-bed, you must set as many three-penny pots as can stand within the compass of the frame; these pots must be filled with good rich earth, and the cavities between each pot filled up with any common earth, to prevent the heat of the bed from evaporating, and filling the frame with noxious steams; then, with a trowel, or some such instrument, take up your plants (from the former hot-bed) with as much earth as possible to the roots, and place each single plant in the middle of one of the pots, filling the pot up with the earth before described, and settle it close to the root of the plant with

with your hands; water them gently, as before, and shade them in the heat of the day from the violence of the sun.

In about three weeks more, these plants will have grown to a considerable size and strength, so that you must now raise the glasses very much in the day-time; and when the air is soft and the sun is clouded, draw off the glasses, and expose them to the open air, and repeat this as often as the weather will permit, which will harden them by degrees, to be removed abroad into the places where they are to remain the whole season: but it is not adviseable to set these plants out until a week in July, observing to do it when the air is perfectly soft, and if possible, in a gentle shower of rain.

Let them at first be set near the shelter of a hedge for two or three days, where they may be screened from the violence of the sun and strong winds, to which they must be inured by degrees: these plants, when grown to a good stature, perspire very freely, and must be every day refreshed with water, if the weather proves hot and dry, otherwise they will stunt, and never produce their plumes so fine as they would do if taken care of.

In the beginning or middle of September, the Amaranths will have perfected their seeds, so that you must make choice of the largest, most beautiful, and least branching plants of each kind for seed; which you should remove under shelter, (especially if the weather proves wet, or the nights frosty) that the seeds may be maturely ripened; and in the choice thereof, be sure never to take any seeds from side branches, nor from the neck of the plume, but such only as are produced in the middle thereof, which in many plants, perhaps, may be but a small quantity; but I do assure you, it is those only you can depend upon, to have your kinds good the succeeding year.

CELSIA. *Lin. Gen. Pl.* 675. We have no English name for it.

The Characters are,

The flower is of one leaf, with a very short tube, spread open above, and cut into five unequal parts; the two upper being small, and the under larger. It hath four hairy stamina, which incline toward the upper segments of the petal. In the center is situated a roundish germen, which afterward becomes a roundish capsule compressed at the top, sitting upon the empalement, and hath two cells which are filled with small angular seeds.

There is but one Species of this genus at present known, which is,

CELSIA *foliis duplicato-pinnatis. Hort. Cliff.* 321. Celsia with double winged leaves.

This plant grows naturally in Armenia, from whence Dr. Tournefort sent the seeds to the royal garden at Paris. In its natural place of growth, this is an annual, but in England it will rarely ripen its seeds, unless the plants come up in the autumn, and live through the winter.

It sends out many oblong leaves, which are finely divided almost to the midrib on both sides; from the center arises a roundish herbaceous stalk two feet high, which is garnished the whole length with leaves of the same shape, but diminishing in their size gradually to the top: these are placed alternately, and at the foot-stalk of each come out the flowers more than half the length of the stalk, which are of an iron colour on their outside, but pale yellow within, spreading open like those of the common Mullen, but are not so regular: the short tube being turned downward, and the lower segments being larger than the upper, and the stamina being unequal, has occasioned Linnæus to remove it to his ringent flowers. The seed vessel is round, compressed, and hath two cells filled with small seeds. It may be sown on a poor dry soil in autumn, and when the plants come up, they will require no other care but to keep them clean from weeds, and thin them if they are too close; for they

do not bear removing well, so should be sown where they are intended to remain.

I have, sometimes when the seasons have proved warm, had ripe seeds from plants sown in the spring; but this cannot be depended on, therefore it is much better to raise the plants in autumn.

CELTIS. *Tourn. Inst. R. H.* 612. *tab.* 383. *Lin. Gen. Pl.* 1012. The Lote, or Nettle tree.

The Characters are,

It hath male and hermaphrodite flowers on the same tree: the hermaphrodite flowers are single, and situated above the male; these have no petals, but five short stamina. In the center is situated an oval germen, which afterward becomes a round berry with one cell, inclosing a roundish nut. The male flowers have their empalements divided into six parts, and have no germen or style, but in other parts are like the hermaphrodite.

The Species are,

1. CELTIS *foliis lanceolatis acuminatis, serratis, nervosis.* Nettle tree with spear-shaped pointed leaves, which are veined and sawed on their edges; or the Lote tree with a black fruit.

2. CELTIS *foliis obliquè-ovatis, serratis, acuminatis. Lin. Sp. Pl.* 1044. Nettle tree with oblique, oval leaves, which are pointed, or sawed on their edges; or Lote tree with a dark purple fruit.

3. CELTIS *foliis ovato-cordatis, denticulatis, petiolis brevibus.* Nettle tree with oval heart-shaped leaves, slightly indented, and short foot-stalks; or the Smaller eastern Lote tree, with smaller and thicker leaves, and a yellow fruit.

4. CELTIS *foliis oblongo-ovatis, obtusis, nervosis, supernè glabris, subtus aureis.* Nettle tree with oblong, oval, obtuse, nervous leaves, which are smooth on their upper surface, and of a gold colour beneath.

The first sort grows naturally in the south of France, in Spain and Italy, where it is one of the largest trees of those countries: yet this is not so plenty in England as the second, nor do I remember to have seen but two large trees of this sort in the English gardens.

This tree rises with an upright stem to the height of forty or fifty feet, sending out many slender branches, which have a smooth dark coloured bark; these are garnished with leaves placed alternately, which are near four inches long, and about two broad in the middle, ending in long sharp points, and deeply sawed on their edges; having several transverse veins, which are prominent on their under side. The flowers come out from the wings of the leaves all along the branches; they have a male and an hermaphrodite flower, generally at the same place, the male flowers being situated above the others: these have no petals, but a green herbaceous empalement, so make no figure; they come out in the spring, at the same time when the leaves make their first appearance, and generally decay before their leaves have grown to half their magnitude. After their flowers are past, the germen of the hermaphrodite flowers become a round berry, about the size of a Pea, which, when ripe, is black.

The second sort grows naturally in North America: it delights in a moist rich soil, in which it becomes a very large tree. This rises with a strait stem, which in young trees is smooth, and of a dark colour, but as they advance, it becomes rougher and of a lighter colour. The branches are much diffused on every side, which are garnished with oblique, oval leaves, ending in points, and sawed on their edges. The flowers come out opposite to the leaves upon pretty long foot-stalks, the male flowers standing above the hermaphrodite, as in the other species; after these decay, the hermaphrodite flowers are succeeded by roundish berries, which are smaller than those of the first sort, and, when ripe, are of a dark purple colour.

This tree is late in coming out in the spring, but in recompense for that, it continues as long in beauty in the autumn, for it is the latest in fading of any of the deciduous trees; nor do the leaves alter their colour long before they fall, but continue in full verdure, till within a few days of their dropping off. There is little beauty in the flowers or fruit of this tree; but as the branches are well clothed with leaves, which are of a fine green colour, so the trees, when mixed with others, in wildernesses, make a pleasing variety during the summer season. The wood of this tree being tough and pliable, is esteemed by coachmakers for the frames of their carriage.

The third sort was discovered by Dr. *Tourrefort* in *Armenia*. It rises with a stem about ten or twelve feet high, dividing into many branches, which spread horizontally on every side, and have a smooth greenish bark; they are garnished with leaves about an inch and a half long, and near an inch broad, inclining to an heart-shape, but are oblique; they are of a thicker texture than those of the common sort, and are of a paler green. They are placed alternate on the branches, and have short foot-stalks. The flowers come out from the foot-stalks of the leaves, in the same manner as the former, and are succeeded by oval yellow berries, which, when fully ripe, turn of a darker colour. The wood of this tree is very white.

These trees are propagated by seeds, which should be sown soon after they are ripe, when they can be procured at that season, for these frequently come up the following spring: whereas those which are sown in the spring, will not come up till a twelvemonth after; therefore it is the best way to sow them in pots or tubs, that they may be easily removed. In summer they must be constantly kept clean from weeds; if the season proves dry, they will require water two or three times a week. In autumn it will be proper to remove the pots, and place them under a hot-bed frame, to shelter them in winter from severe frost; or where there is not that conveniency, the pots should be plunged into the ground, near a wall or hedge; for as the plants, when young, are full of sap, and tender, so the early frosts in autumn frequently kill the upper parts of their shoots; therefore the plants should be either covered with mats, or a little straw or Pease haulm laid over to protect them.

In the following spring the plants should be taken out of the seed pots, and planted in the full ground: this should be done about the middle or later end of *March*, when the danger of the frost is over; therefore a bed or two should be prepared (according to the number of plants raised) in a sheltered situation; and, if possible, in a gentle loamy soil. The ground must be well trenched, and cleared from the roots of bad weeds, and when levelled, should be marked out in lines at one foot distance; then the plants should be carefully turned out of the pots and separated, so as not to tear their roots, and planted in the lines at six inches asunder, pressing the earth down close to the roots. If the ground is very dry when they are planted, and there is no appearance of rain soon, it will be proper to water the beds, to settle the ground to the roots of the plants; and after this, if the surface of the ground is covered with some old tan or rotten dung, it will keep the ground moist, and prevent the drying winds from penetrating to the roots of the plants.

The plants may remain in these nursery beds two years, by which time they will have obtained sufficient strength to be transplanted where they are designed to remain for good; because these plants extend their roots wide every way, so that if they stand long in the nursery, their roots must be cut in removing, which will be a prejudice to their future growth.

These sorts are hardy enough to thrive in the open air in

England, after they have acquired some strength; but for the two first winters after they come up from seeds, they require a little protection, especially the third sort, which is tenderer than either of the former. The young plants of this sort frequently have variegated leaves, but these are more impatient of cold than the plain leaved.

The fourth sort was first discovered by Father *Plumier*, in the *French* islands of *America*; it was also found growing in *Jamaica* by Dr. *Houssoun*, who sent the seeds to *England*. This rises with a strait trunk near twenty feet high, covered with a gray bark, divided into many branches upward, which are garnished with leaves near four inches long, and two and an half broad, rounded at their extremity, of a thick texture, very smooth on their upper surface, and on their under side are of a lucid gold colour, placed alternately on the branches. The fruit is round and red, but the flowers I have not seen.

The seeds of this sort rarely come up the first year, so they should be sowed in pots, and plunged into the tan bed in the stove, where they should remain till the plants come up. These plants must be constantly kept in the bark stove, and treated in the same manner as other tender exoticks.

CENTAUREA. *Lin. Gen. Plant.* 880. Greater Centaury, Knapweed, Blue Bottle, &c.

The Characters are,

It hath a compound flower, whose disk is composed of many hermaphrodite florets, and the border or rays of female florets, which are larger and looser; these are included in a common scaly empalement. The germen is situated under the petal, which afterward becomes a single seed shut up in the empalement. The female florets have a slender tube, but expands above, where it is enlarged, and cut into five unequal parts; these are barren.

The Species are,

1. CENTAUREA *calycibus inermibus globosis, squamis mucronatis, foliis pinnatis decurrentibus subtus argenteis.* Centaury with a globular empalement without spines, sharp pointed scales, and winged running leaves white underneath.

2. CENTAUREA *calycibus inermibus, squamis ovatis obtusis, foliis pinnatis glabris integerrimis.* *Hort. Cliff.* 421. Centaury with an empalement without spines, oval oblong scales, and smooth winged leaves, which are entire; or, Yellow Alpine Centaury.

3. CENTAUREA *calycibus inermibus, squamis ovatis, foliis pinnatis, foliolis serratis decurrentibus.* *Hort. Cliff.* 421. Centaury with an empalement without spines, oval scales, and winged leaves, whose lobes are sawed, and run along the midrib. Greater Centaury.

4. CENTAUREA *calycibus squamosis, foliis indivisis integerrimis decurrentibus.* *Hort. Cliff.* 121. Centaury with a scaly empalement, and undivided entire leaves, running along the stalks.

5. CENTAUREA *calycibus ciliatis oblongis, foliis pinnatifidis linearibus integerrimis.* *Prod. Leyd.* 140. Centaury with oblong hairy empalements, and winged pointed leaves, which are very narrow, and entire.

6. CENTAUREA *calycibus squamosis, foliis tomentosis, radicalibus lanceolatis, coulinis pinnatifidis caule simplici.* *Prod. Leyd.* 142. Centaury with a scaly empalement, woolly leaves, those near the root being spear-shaped, those on the stalk pointed, and a single stalk.

7. CENTAUREA *calycibus serratis, foliis lanceolatis decurrentibus, caule simplicissimo.* *Hort. Cliff.* 422. Centaury with sawed empalements, spear-shaped running leaves, and a single stalk; or, Greater Mountain Blue Bottle.

8. CENTAUREA *calycibus serratis, foliis lineari-lanceolatis decurrentibus, caule simplicissimo.* Centaury with sawed empalements, very narrow spear shaped running leaves, and a single stalk. Narrower and longer leaved *Belgick* Blue Bottle.

9. CENTAUREA

9. *CENTAUREA calycibus inermibus, subrotundis glabris, squamis ovatis, foliis sinuatis.* Hort. Cliff. 421. Centaury with unarmed, roundish, smooth empalements, oval scales, and sinuated leaves; commonly called Sweet Sultan.

10. *CENTAUREA calycibus inermibus, subrotundis, glabris, squamis ovatis obtusis, foliis laciniatis serratis.* Centaury with roundish, smooth, unarmed empalements, oval obtuse scales, and cut leaves, which are sawed on their edges; commonly called yellow Sweet Sultan.

11. *CENTAUREA calycibus serratis, foliis linearibus integerrimis, infimis dentatis.* Hort. Cliff. 422. Centaury with sawed empalements, very narrow entire leaves, indented below; or, Corn Blue Bottle.

12. *CENTAUREA calycibus inermibus, squamis mucronatis, foliis pinnatifidis obtusis decurrentibus.* Lin. Sp. Pl. 910. Centaury with unarmed empalements, having pointed scales, and winged pointed leaves, which are obtuse, running along the stalk.

13. *CENTAUREA calycibus ciliatis terminali-seffilibus, foliis tomentosiss pinnatifidis, lacinulis linearibus.* Hort. Cliff. 422. Centaury with hairy empalements, closely terminating the stalks, woolly leaves with winged points, and the segments very narrow.

14. *CENTAUREA calycibus ciliatis, foliis tomentosiss pinnatifidis, foliolis obtusis ovatis integerrimis exterioribus majoribus.* Hort. Cliff. 422. Centaury with hairy empalements, woolly leaves with winged points, the small leaves oval and obtuse, the outer larger; or, Silvery Knapweed of Ragusa.

15. *CENTAUREA calycibus palmato-spinosis setis æqualibus, foliis decurrentibus sinuatis spinulosiss.* Prod. Leyd. 141. Centaury with palmated spinous empalements, whose bristles are equal, and sinuated prickly leaves running along the stalks.

16. *CENTAUREA calycibus squamosiss, foliis ovato-oblongis denticulatis integris pctiolatis, subtus tomentosiss.* Hort. Cliff. 421. Centaury with scaly empalements, oval, oblong, indented entire leaves, having foot-stalks, and woolly underneath.

17. *CENTAUREA calycibus setaceo-spinosis, foliis lanceolatis pctiolatis, inferne dentatis.* Hort. Cliff. 423. Centaury with bristly prickly empalements, spear-shaped leaves, with foot-stalks, indented beneath.

18. *CENTAUREA calycibus squama ciliatis, foliis pinnatifidis, pinnis lanceolatis.* Lin. Sp. Pl. 913. Centaury with hairy scales to the empalement, and wing-pointed leaves, whose lobes are spear-shaped.

19. *CENTAUREA calycibus squamosiss obtusiss, foliis pinnatifidis linearibus integerrimis.* Centaury with an obtuse squamous empalement, and wing pointed, narrow, entire leaves.

20. *CENTAUREA calycibus ciliatis, foliis pinnatifidis brevibus, caule paniculato.* Centaury with hairy empalements, very short wing-pointed leaves, and a paniculated stalk.

There are many other species of this genus, which are preserved in botanick gardens for the sake of variety; some of which grow naturally in England, and are often troublesome weeds in the fields, so do not deserve a place in gardens, therefore I chose not to trouble the reader with mentioning their titles; but have here selected those species, which have some beauty to recommend them.

The first sort grows naturally on the Apennine mountains. This hath a perennial root, which strikes many strong roots deep in the ground: the lower leaves resemble those of the Artichoke; they are green on the upper side, and hoary underneath; the stalks rise about three feet high, and are garnished with leaves of the same form and colour as those below, but are much smaller. The upper part of the stalk branches out into three or four divisions, each being terminated with a large single head of flowers, which are of a purple colour; these are composed of many hermaphrodite flowers, which form the disk in the center, and a bor-

der of female flowers which compose the rays, included in a common scaly empalement, whose scales terminate in acute points. This is usually propagated by parting of their roots: the best time for doing this is early in October, that the plants may have time to take root before the frost comes on. These roots must not be removed or parted oftener than every fourth year, if they are designed to produce strong flowers; they should be planted in a dry soil, because wet in the winter will cause them to rot. This plant is never injured by frost, so may be fully exposed in open borders; but each root will require to have three feet to spread, so they must not be planted too near other plants.

The second sort grows naturally upon the Alps. This hath also a perennial root, which strikes deep into the ground, sending out a great number of long winged leaves, which are smooth, entire, and of a glaucous colour; the stalks rise near four feet high, and divide upward into many branches, which are garnished with small leaves of the same form as the lower; each of these stalks are terminated by a single head of yellow flowers, of the same form with those of the first, but not more than half the size. It may be propagated by parting of their roots, in the same manner as the first, and the plants do require the same treatment.

The third sort stands in the list of medicinal plants of the College, but is very rarely used; the root is reckoned to be binding, and good for all kind of fluxes, and of great use to heal wounds. This grows naturally on the mountains in Italy and Spain; it hath a strong perennial root, like the two former sorts, from which come out a great number of long winged leaves, which spread wide on every side; these are of a lucid green, and sawed on their edges; the flower-stalks are slender, but very stiff, and divide upward into many smaller, which rise six or seven feet high, having at each joint, one small winged leaf, of the same form with the other: each of these stalks is terminated by a single head of purplish flowers, which are considerably longer than the empalement. It may be propagated by parting of the roots, in the same manner as the former sorts, and the plants must be treated in the same way, but should have more room to grow.

The fourth sort was discovered by Dr. Tournefort, in the Levant. This hath a perennial root, which strikes deep into the ground, from which springs up a great tuft of long entire leaves, shaped like those of Woad, they grow upright; there also many upright stalks arise, which grow near five feet high, that are garnished with leaves coming out single at each joint, of the same shape as the under, but are less, and have a border, or wing, running along the stalk, from one to the other. The upper part of the stalk divides into two or three smaller, each of which is terminated by a single head of yellow flowers, included in a silvery scaly empalement. It may be propagated by parting of the roots, in the same manner as the former, and the plants may be treated in the same way, being equally hardy; and as this doth not spread so much as the two last, so it may be allowed a place in smaller gardens.

The fifth sort grows naturally in Austria. This hath a perennial root, as the former, from which come out, in the spring, many winged leaves, which are hoary, and the segments narrow and entire; the stalks rise near three feet high, dividing into several branches, which have a winged leaf at each joint, of the same shape with the other; at the end of each stalk is one head of purple flowers, inclosed in an oblong scaly empalement, each scale being bordered with small hairs, like an eye-brow. This is propagated by seeds, which may be sown in a bed of common earth, in a nursery; and when the plants come up, they must be thinned, and kept clean from weed; and the following autumn

the plants may be transplanted where they are designed to remain.

The sixth sort grows naturally in the south of *France*, and in *Italy*. It hath a biennial root, which doth not divide and spread as the former, but grows single, sending out in the spring, several entire spear-shaped leaves, and afterward a single stalk, more than a foot high, which is garnished at each joint with one divided hoary leaf, and at the top comes out a single, large, scaly head, shaped like a cone of the Pine tree, very taper at the top, where it closely surrounds the florets, whose tops just peep out of the empalement: they are of a bright purple colour, but are not succeeded by seeds in *England*; so cannot be propagated, unless the seeds are procured from abroad.

The seventh sort is the common perennial Blue Bottle, which by some is titled Batchelors Button. This is so well known as to need no description; the roots of this sort creep under ground to a great distance, whereby the plant propagates too fast, and often becomes troublesome in gardens; it will grow in any soil or situation.

The eighth sort differs from the seventh, in having much longer and narrower leaves, which are not so white, the heads of flowers are also smaller; but whether this is only a variety from the other, I cannot determine, having never raised either from seeds; for these plants spread very much by their creeping roots, which renders them barren, as is frequently the case with many other creeping rooted plants, few of which produce seeds. This is equally hardy, so may be planted in any soil or situation, where many other sorts will not thrive, and during its continuance in flower will make a variety in the garden.

The ninth sort is annual, so is only propagated by seeds. This has been many years propagated in the *English* gardens, under the title of Sultan Flower, or Sweet Sultan. This sends up a round channelled stalk, near three feet high, which divide into many branches, garnished with jagged leaves, of a pale green, smooth, and stand close to the branches; from the side of the branches come out long naked foot-stalks, each sustaining a single head of flowers shaped like those of the other species, which have a very strong odour, so as to be offensive to many people, but to others is very grateful; the flowers are in some purple, and others white, and likewise a flesh colour. There is also a variety of this with fistular flowers; and another with fringed flowers, commonly called Amberboi, or Emberboi; but these have degenerated to the common sort in a few years, although I have saved the seeds with great care, so I suppose they are only varieties. These seeds are commonly sown upon a hot-bed in the spring, to bring the plants forward, and in *May* they are transplanted into the borders of the flower garden; but if the seeds are sown on a warm border in autumn, they will live through the winter; and these plants may be removed in the spring into the flower garden, which will be stronger, and come earlier to flower, than those which are raised in the spring. The seeds may also be sown in the spring on a common warm border, where the plants will rise very well, but these will be later in flowering than either of the other.

The tenth sort has been supposed to be only a variety of the former, which is a great mistake; for although there is a great similitude in their appearance, yet they are specifically different. I have cultivated this sort upward of thirty years, and have never observed the least variation in it. This is much tenderer than the former, so the seeds must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be transplanted on a fresh hot-bed, to bring them forward. When the plants have obtained strength, they must be carefully taken up, and planted in separate pots, filled with light earth, and

some of them placed in the shade till they have taken root; then they may be placed with other annual plants in the pleasure garden, where they will continue long in beauty. But as these plants, which are placed in the open air, rarely produce good seeds, so there should be two or three plants kept in a moderate hot-bed, under a deep frame, where they will come earlier to flower; and being protected from wet and cold, they will ripen their seeds every year, which is the surest method to preserve the sort.

The eleventh sort is the common Blue Bottle, which grows naturally amongst the Corn in most parts of *England*; this stands in the list of medicinal plants; there is a distilled water of the flowers, which is esteemed good for the eyes. There are great varieties of colours in these flowers, some of which are finely variegated: the seeds of these are sold by seedsmen by the title of Bottles of all colours. These are annual plants, which will rise in any common border, and require no other care but to keep them clean from weeds, and thinned where they are too close.

The seeds of the twelfth sort were sent me by Dr. *Jussieu*, from *Paris*, who received them from Dr. *Lippi*, at *Grand Cairo*. This is an annual plant, which rises near two feet high, sending out two or three branches toward the top; the leaves are divided into many obtuse parts, and have a border running along the stalk; the flowers are small, of a bright purple, and have a scaly empalement. If the seeds are sown in the spring upon a border of light earth, where the plants are to remain, they will require no farther care but to keep them clean from weeds. It flowers in *July*, and the seeds ripen in autumn.

The thirteenth sort is a perennial plant, which retains its leaves through the year. This grows naturally in *Italy*, on the borders of the fields. The leaves are hoary, and divided into many narrow segments; the stalks rise near three feet high, branching upward into many divisions, each being terminated by a head of purple flowers. This sort will live abroad in moderate winters, if it has a warm situation and a dry soil, but in severe winters the plants are commonly killed; so one or two of them may be sheltered under a common frame in winter to preserve the kind. It may be easily propagated by the young branches, which do not shoot up to flower; if these are cut off, and planted in a shady border, any time in summer, they will take root, and in autumn may be removed to warm borders, or put into pots to be sheltered in winter.

The fourteenth sort grows naturally in *Mauritania*, and in several other places on the borders of the *Mediterranean* sea. This seldom rises more than three feet high in this country; it hath a perennial stalk, that divides into many branches, which are garnished with many white woolly leaves, divided into many obtuse lobes, that are entire; the small leaves, or lobes, on the exterior part of the leaf, being the largest. The flowers are produced from the side branches, upon short foot-stalks, which are of a bright yellow, and are included in a fine hairy empalement. It is propagated by planting of the young shoots in the same manner as the last, and the plants require protection from hard frost.

The fifteenth sort is annual. This grows naturally in the *Archipelago*. It rises with a branching stalk, about three feet high; the lower leaves are not much unlike those of the Turnep, being rounded at their ends, and their base is cut into many parts; those upon the stalks and branches are nearly of the same form, but diminish gradually in their size to the top; these have a border or wing running along the stalks, which connect them together; the flowers are produced at the end of the branches, which have prickly empalements; the spines come out from the border of the scales, divided like the fingers of a hand. The flowers are

of a bright purple, so make a pretty appearance. This sort may be treated in the same manner as the Corn Blue Bottle, by sowing the seeds in autumn, and keeping the plants clean from weeds.

The sixteenth sort grows naturally upon the *Helvetian* mountains. It hath a perennial root, and an annual stalk; the leaves are oblong, slightly indented on their edges, and woolly on their under side; these have much resemblance of those of Elecampane, generally standing upright; the stalks rise little more than a foot high, and are terminated by large single heads of purple flowers, inclosed in scaly empalements. This, like the sixth sort, is very difficult to propagate in *England*, unless good seeds can be procured from the countries where it naturally grows.

The seventeenth sort grows naturally in *Austria*, and *Hungary*. The lower leaves of this plant spread flat on the ground; they are soft, hairy, and end in sharp points; but toward their base, are cut into several narrow segments; the stalks rise near three feet high, garnished at each joint by spear-shaped leaves, which are entire; and are terminated by single large heads of flowers, of a gold colour, inclosed in a prickly scaly empalement. It hath a perennial root, which sends out offsets; these may be taken from the old plants in autumn, whereby it may be easily propagated. It is very hardy in respect to cold, but should have a dry soil, the roots being very apt to rot in winter with much wet.

The eighteenth sort grows naturally in *Siberia*. This sends out many long winged leaves from the root, which are divided into several spear-shaped lobes; the stalks rise near five feet high, and divide upward into many smaller branches, which are garnished with leaves of the same form with the lower, but are much smaller, and the segments very narrow; each of these is terminated by a head of yellow flowers, inclosed in a scaly empalement; the borders of the scales are set with fine hairs like an eye-brow. This hath a perennial root, and an annual stalk, which, with the leaves, decay in autumn, and arise new from the root in the spring. It may be propagated by either seed, or by parting of the roots, in the same manner as the sixth sort.

The nineteenth sort grows naturally in *Zant*. This is an annual plant, which rises with a slender stalk a foot and an half high, which is garnished with wing-pointed leaves, which are very narrow, and a little hoary; the flowers are small, of a purple colour, and are inclosed in an obtuse scaly empalement.

The twentieth sort came also from the same island with the former. This hath a perennial root, but an annual stalk; the leaves winged, very narrow, and hoary; the stalk rises a foot high, and is garnished with small leaves of the same form; the flowers are purple, and are inclosed in scaly empalements. It flowers in *July*, but seldom ripens seeds in *England*. This must have a dry soil, and a warm situation.

CENTAURIUM MINUS. See *Gentiana*.

CENTINODIUM, Knot Grass. See *Polygonum*.

CEPA, the Onion.

The botanick difference of the Onion, from Garlick, is the swelling pipy stalk, which is much larger in the middle than at either end.

The Varieties of the common Onion are,

The *Straßburgh*. This is the *Cepa oblonga*. C. B. P. 71.

The *Spanish* Onion. This is the *Cepa vulgaris, floribus & tunicis purpurascens*. C. B. P. 71.

The *white Egyptian* Onion. This is the *Cepa floribus & tunicis candidis*. C. B. P. 71.

All these vary from seeds, so that there are several intermediate differences, which are not worth enumerating.

These three varieties are propagated by seeds, which should

be sown the latter end of *February*, or (the beginning of *March*, on good, rich, light ground, which should be well dug and levelled, and cleared from the roots of all bad weeds; then the seeds should be sown, in a dry time, when the surface of the ground is not moist; and where they are intended for a winter crop, they must not be sown too thick. The common allowance of seed is six pounds to one acre of land, but the generality of gardeners sow more; because many of them allow for a crop to draw out, which they call cullings.

In about six weeks after sowing, the Onions will be up forward enough to hoe; at which time (choosing dry weather) you should, with a small hoe about two inches and an half broad, cut up lightly all the weeds from amongst the Onions; and also cut out the Onions, where they grow too close in bunches, leaving them at this first hoeing, at least two or three inches apart. This, if well performed, and in a dry season, will preserve the ground clear of weeds, at least a month; when you must hoe them over a second time, cutting up all the weeds, as before, and also cut out the Onions to a larger distance, leaving them this time four or five inches asunder. This also, if well performed, will preserve the ground clean a month or six weeks longer, when you must hoe them over the third and last time.

Now you must carefully cut up all weeds, and single out the Onions to six inches square, by which means they will grow much larger than if left too close. This time of hoeing, if the weather proves dry, and it is well performed, will keep the ground clean until the Onions are fit to pull up; but if the weather should prove moist, and any of the weeds should take root again, you should, about a fortnight or three weeks after, go over the ground, and draw out all the large weeds with your hands; for the Onions having now begun to bulb, they should not be disturbed with a hoe.

Toward the middle of *August*, your Onions will have arrived to their full growth, which may be known by their blades falling to the ground and shrinking; you should therefore, before their necks or blades are withered off, draw them out of the ground, cropping off the extreme part of the blade, and lay them abroad upon a dry spot of ground to dry, observing to turn them over every other day at least, to prevent their striking fresh root into the ground; which they will quickly do, especially in moist weather.

In about a fortnight's time your Onions will be dry enough to house, which must be performed in perfect dry weather; in doing of this, you must carefully rub off all the earth, and be sure to mix no faulty ones amongst them, which will in a short time decay, and spoil all those that lie near them; nor should you lay them too thick in the house, which would occasion their sweating, and thereby rot them; these should not be put in a lower room, or ground floor, but in a loft or garret; and the closer they are kept from the air, the better they will keep. You should, at least, once a month, look over them to see if any of them are decayed; which if you find, must be immediately taken away, otherwise they will infect all that lie near them.

But notwithstanding all the care you can possibly take in the drying and housing of your Onions, many of them will grow in the loft, especially in mild winters, which are generally moist; therefore those who would preserve them late in the season, should select a parcel of the firmest and most likely to keep, from the others, and with a hot iron slightly singe their beards, or roots, which will effectually prevent their sprouting; but in doing of this there must be great caution used not to scorch the pulp of the Onions, for that will cause them to perish soon after.

In order to save seeds, you must in the spring make choice of some of the firmest, largest, and best shaped Onions (in quantity proportionable to the seed you intend to save); and having prepared a piece of good ground (which should be well dug, and laid out in beds about three feet wide), in the beginning of *March* you must plant your Onions in the following manner. Having strained a line about four inches within the side of the bed, you must, with a spade, throw out an opening about six inches deep, the length of the bed, into which you should place the Onions, with their roots downward, at about nine inches distance from each other, and with a rake draw the earth into the opening again to cover the bulbs; then proceed to remove the line again about a foot farther back, where you must make an opening as before, and so again till the whole is finished; by which you will have four rows in each bed, between each bed you must allow the space of two feet for an alley to go among them to clear them from weeds, &c. In a month's time their leaves will appear above ground, and many of the roots will produce three or four stalks each; you must therefore keep them cleared from weeds, and about the beginning of *June*, when the heads of the flowers begin to appear upon the tops of the stalks, you must provide a parcel of stakes about four feet long, which should be driven into the ground, in the rows of Onions, at about six or eight feet apart, to which you should fasten some pack-thread, rope yarn, or small cord, which should be run on each side of the stems of the Onions, a little below their heads, to support them from breaking down with the wind and rain, for when the seeds are formed, the heads will be heavy; so are very often broken down by their own weight, where they are not well secured; and if the stalks are broken before the seeds have arrived to maturity, they will not be near so good, nor keep so long as those which are perfectly ripened.

About the end of *August* the Onion seed will be ripe, which may be known by its changing brown, and the cells in which the seeds are contained opening; so that if it be not cut in a short time, the seeds will fall to the ground; when you cut off the heads, they should be spread abroad upon coarse cloths in the sun, observing to keep it under shelter in the night, as also in wet weather; and when the heads are quite dry, you must beat out the seeds, which are very easily discharged from their cells; then having cleared it from all the husks, &c. after having exposed it one day to the sun to dry, you must put it up in bags to preserve it for use.

The directions here given is for the general crop of winter Onions, but there are two other crops of this common sort of Onions, cultivated in the gardens about *London* to supply the market, one of which is commonly called *Michaelmas* Onions. These are sown in beds pretty close the beginning of *August*, and must be well weeded when they come up. In the spring of the year, after the winter Onions are over, they are tied up in bunches to supply the markets; but from the thinning of these they carry to market young green Onions in *March*, for sallads, &c.

And in the spring they sow more beds in the same manner, to draw up young for sallads, after the *Michaelmas* Onions are grown too large for that purpose, and where a supply of these are required, there may be three different sowings, at about three weeks distant from each other, which will be sufficient for the season.

There are also the following sorts of Onions cultivated in the kitchen gardens.

The Shallot, or Eschalottes, which is the *Cepa Ascalonica*. *Matth.* 556.

The Ciboule, or *Cepa fistilis*. *Matth. Lugd.* 1539.

The Cives, or *Cepa scitilis juncifolia perennis*. *Mor. Hist.* 2. 383.

The *Welch* Onion I suppose to be the same with the *Ciboule*, although they pass under different appellations, for I have several times received the *Ciboule* from abroad, which, when planted, proved to be what is generally known here by the title of *Welch* Onions.

The Scallion, or Escallion, is a sort of Onion which never forms any bulbs at the roots, and is chiefly used in the spring for green Onions, before the other sorts sown in *July*, are big enough; but this sort of Onion, how much soever in use formerly, is now so scarce as to be known to few people, and is rarely to be met with. The gardeners near *London* substitute another sort for this, which are those Onions which decay and sprout in the house: these they plant in a bed early in the spring, which in a short time will grow large enough for use; when they draw them up, and after pulling off all the outer coat of the root, they tie them up in bunches, and sell them in the market for Scallions.

The true Scallion is easily propagated by parting the roots, either in spring or autumn, but the latter season is preferable, because of their being rendered more fit for use in the spring; these roots should be planted three or four in a hole, at about six inches distance every way, in beds or borders three feet wide, which in a short time will multiply exceedingly, and will grow upon almost any soil, and in any situation.

The Cives are a very small sort of Onion, which never produce any bulbs, and seldom grow above six inches high in the blade, which is very small and slender, and are in round bunches like the former; this was formerly in great request for sallads in the spring, as being milder than the *Welch* Onions. These are propagated by parting their roots like the former, and are also very hardy, and will be fit for use early in the spring.

The *Welch* Onions are only propagated for spring use; these never make any bulbs, and are therefore only fit to be used green for sallads, &c. They are sown about the end of *July*, in beds about three feet and an half wide, leaving alleys of two feet broad to go between the beds to clean them, and in a fortnight's time they will appear above ground, and must be carefully cleared from weeds; towards the middle of *October* their blades will die away, so that the whole spot will seem to be naked, which hath led many people to dig up the ground again, supposing the crop totally lost; whereas, if they stand undisturbed, they will come up again very strong in *January*, and from that time grow very vigorously, resisting all weathers, and by *March* will be fit to draw for young Onions, and were some years past in the markets, more valued than any other sort; for they are extremely green and fine, though they are much stronger than the common Onion in taste, approaching nearer to Garlick, which hath occasioned their being less esteemed for the table: but as no winter, however hard, will hurt them, it is proper to have a few of them to supply the table, in case the common sort should be destroyed by frosts.

The roots of these Onions, if planted out at six or eight inches distance, in *March*, will produce ripe seeds in autumn, but it will be in small quantities the first year; therefore the same roots should remain unremoved, which the second and third year will produce many stems, and afford a good supply of seeds; these roots will abide many years good, but should be transplanted and parted every second or third year, which will cause them to produce strong seeds.

CÉPHALANTHUS. *Lin. Gen. Pl.* 105. Button Wood.

The Characters are,

It hath a number of small flowers, which are collected into a spherical head; each particular flower hath a funnel-shaped empalement, divided into four parts at the top; the flower is funnel-shaped,

shaped, of one petal, divided at the top into four parts, inclosing four stamina, which are inserted in the petal. The germen is situated under the flower, which afterward becomes a globular hairy capsule, inclosing one or two oblong angular seeds; these are joined to an axis, and form a round head.

The Species are,

1. CEPHALANTHUS foliis oppositis ternisque. Flor. Virg. 15. Button tree with leaves growing opposite by threes.

2. CEPHALANTHUS foliis oppositis. Flor. Zeyl. 53. Cephalanthus with leaves growing opposite.

The first sort grows naturally in North America, from whence the seeds are annually sent to Europe, and of late years great numbers of the plants have been raised in the gardens of the curious.

This seldom rises higher than six or seven feet in this country. The branches come out opposite; the leaves also stand opposite, sometimes by pairs, and at other times there are three arising at the same joint; these are near three inches long, and one and a quarter broad, having a strong vein running longitudinally through the middle: they are of a light green, and their foot-stalks change to a reddish colour next the branches; the ends of the branches are terminated by spherical heads, about the size of a marble, each of which are composed of many small flowers, which are funnel-shaped, of a whitish yellow colour, fastened to an axis that stands in the middle.

These plants are propagated chiefly by seeds (though there has been some raised from cuttings;) these seeds should be sown in pots, for the greater conveniency of removing them, either into a shady situation, or where they may have shelter, for they generally remain a year in the ground; therefore, in such case, the pots should be placed in the shade the first summer, and placed the autumn following under a common frame to shelter them from frost, and the spring following the plants will come up.

The first year, when the plants come up, it will be necessary to shade them in hot dry weather while they are young, at which time they are often destroyed by being too much exposed; nor should the watering be neglected, for as these plants naturally grow on moist ground, so when they are not duly watered in dry weather, the young plants will soon decay.

The next autumn, when the leaves begin to drop, they may be transplanted into nursery beds, which should be a little defended from the cold winds; and, if the soil is moist, they will succeed much better than in dry ground; but where it happens otherwise, it will be absolutely necessary to water them in dry weather, otherwise there will be great danger of the plants dying in the middle of summer, which has been the case in many gardens where these plants were raised.

In the nursery beds the plants may remain a year or two (according to the progress they have made, or the distance they were planted); then they may be taken up in October, and transplanted where they are to remain for good. Although I have mentioned but one season for transplanting them, yet this may also be performed in the spring, especially if the ground is moist into which they are removed, or that the plants are duly watered, if the spring should prove dry, otherwise there will be more hazard of their growing when removed at this season.

The second sort grows naturally in Africa, and also in India. This is very rare at present in the English gardens; in the natural places of its growth it becomes a large tree, but the plants which are in Europe, make but little progress. It is tender when young, so requires a stove to preserve it through the winter; but after it obtains strength, it will live in a good green-house. It is very difficult to propagate here, which occasions its scarcity.

CERASTIUM. Lin. Gen. Pl. 518. Mouse-ear, or Mouse-ear Chickweed.

The Characters are,

The flower hath five obtuse bifid petals; it hath ten slender stamina. In the center is situated an oval germen with five styles; the empalement afterward becomes an oval, cylindrical, or globular capsule with one cell, containing many roundish seeds.

The Species are,

1. CERASTIUM foliis lanceolatis, pedunculis ramosis, capsulis subrotundis. Lin. Sp. Plant. 439. Cerastium with spear-shaped leaves, branching foot-stalks; and roundish capsules.

2. CERASTIUM foliis oblongis, tomentosis, pedunculis ramosis, capsulis globosis. Lin. Sp. Plant. 440. Cerastium with oblong woolly leaves, branching foot-stalks, and globular capsules.

3. CERASTIUM foliis lanceolatis, caule dichotomo ramosissimo, capsulis erectis. Prod. Leyd. 450. Cerastium with spear-shaped leaves, a very branching stalk divided in pairs, and upright capsules.

4. CERASTIUM floribus pentandris, petalis integris. Lin. Sp. Plant. 438. Cerastium with flowers having five stamina, and entire petals.

5. CERASTIUM foliis connatis. Hort. Cliff. 173. Cerastium whose leaves are joined.

The first sort grows naturally in France and Italy, and was formerly cultivated in the English gardens under the title of Sea Pink; one of the uses made of it was to plant it as an edging, to keep up the earth of borders; but this was before the Dwarf Box was brought to England, since which all those plants which were formerly applied for this purpose have been neglected. This plant was by no means fit for this use, because its creeping branches would spread into the walks, where they put out roots into the gravel, so that unless they are frequently cut off, they cannot be kept within compass.

This sort sends out many weak stalks which trail upon the ground, and put out roots at their joints, whereby it propagates very fast; the leaves are placed by pairs opposite: these are very hoary; those next the root are much smaller than the upper; the flowers come out from the side of the stalks upon slender foot-stalks, which branch out into several smaller, each supporting a white flower, composed of five petals, which are split at the top.

The seeds of the second sort I received from Istria, where it naturally grows; this is by Parkinson titled hoary narrow-leaved Pink. The leaves of this sort are narrower than those of the former, and are much whiter; the stalks grow more erect, and the seed vessels are rounder, in which their chief difference consists.

The third sort is annual; this grows naturally on arable land in Spain. It is allowed a place in botanick gardens for the sake of variety, but hath not much beauty; this hath branching stalks, which grow about six inches high, dividing by pairs, the flowers coming out in the middle of the divisions, which are shaped like those of Chickweed; the whole plant has a clammy moisture, which sticks to the fingers of those that handle it. If the seeds are permitted to fall, the plants will rise without care.

The fourth sort is very like the third in its whole appearance, and differs from it, in having but five stamina in the flower, whereas the other hath ten.

The fifth sort was discovered by Dr. Tournefort, in the Levant. It is an annual plant, which rises with an upright stalk a foot high; the lower leaves of this plant have much resemblance to those of the Lychnis, which is called Lobel's Catchfly, so that when the plants are young, it is not easy to distinguish them. The stalks are garnished with leaves of the same shape, but smaller; these are placed by pairs, and embrace the stalks at their base. The flowers come out at the top of the stalks, and also from the wings of the leaves,

on the upper part of the stalks, which are white, and shaped like those of Chickweed.

If the seeds of this sort are sown in autumn, they will more certainly grow than those which are sown in the spring; or if the seeds are permitted to scatter, the plants will come up and live through the winter, and will require no other care but to keep them clean from weeds.

CERASUS, the Cherry tree.

The botanical characters of this genus, according to the system of *Linnaeus*, are the same with those of *Prunus*, therefore he has joined the Apricock Cherry, Laurel, and Bird Cherry together, making them only species of the same genus; but those who admit of the fruit, as a character to determine the genus, must separate the Cherry from the others, because they differ greatly in the shape of their stones; but there is a more essential difference in nature between them, which is, that the Cherry will not grow upon a Plum stock, by budding or grafting, nor will the Plum take upon a Cherry stock, and yet we know of no trees of the same genus which do not unite with each other, by budding or grafting.

I shall first enumerate the sorts which are specifically different from each other, and then mention the varieties of these fruits, which are cultivated in the *English* gardens, many of which seem to differ so essentially from each other, that they may be allowed as specific differences; but as I have not had an opportunity of trying the various sorts from seeds, to see if they alter, so I chose to insert them only as varieties, till farther observation may better settle their boundaries.

The Species are,

1. CERASUS *foliis ovato-lanceolatis, serratis*. The common, or *Kentish* Cherry.

2. CERASUS *foliis serratis lanceolatis*. Cherry tree with spear-shaped sawed leaves; or, Black Cherry.

3. CERASUS *foliis ovato-lanceolatis, floribus confertis*. Cherry tree with oval spear-shaped leaves, and flowers growing in clusters; commonly called the Cluster Cherry.

4. CERASUS *floribus corymbosis, foliis ovatis*. *Lin. Sp. Pl.* 474. Cherry tree with flowers growing in round bunches, and oval leaves. The Mahaleb, or perfumed Cherry.

5. CERASUS *foliis lanceolatis, glabris, integerrimis, subtus, caesius, ramis patulis*. Cherry tree with smooth, spear-shaped, entire leaves, of a bluish green on their under side, and spreading branches.

The first sort is the common or *Kentish* Cherry, which is so well known in *England*, as to need no description. From this sort, it hath been supposed, most of the varieties which are cultivated in the *English* gardens have been raised; but as there are very great differences in the size and shape of their leaves, as also in the shoots of the trees, from those of this sort, so I think it is very doubtful, where the boundaries of their specific differences terminate: however, I shall comply with the generality of modern botanists, in supposing the following sorts to have been produced from the seeds of this, as we have not sufficient experiments to determine otherwise.

The Early <i>May</i> Cherry.	The Ox Heart.
The <i>May</i> Duke Cherry.	The Lukeward.
The Archduke Cherry.	The Carnation.
The <i>Flemish</i> Cherry.	The <i>Hertfordshire</i> Heart.
The Red Heart.	The Morello.
The White Heart.	The Bleeding Heart.
The Black Heart.	Yellow <i>Spanish</i> Cherry.
The Amber Heart.	

Two sorts with double flowers, one larger and fuller than the other. These are propagated for ornament.

The second sort is the Black Cherry, which is supposed to be a native of *England*. This grows to be a large tree

fit for timber, and is frequently found growing as such in the woods. From this the only varieties which I have ever known raised by seeds, are the Black Coroun, and the small Wild Cherry; of which there are two or three varieties, which differ in the size and colour of their fruit.

The stones of this sort are generally sown for raising stocks, to graft or bud the other sorts of Cherries upon, being of quicker growth, and of longer duration than either of the other; so are very justly esteemed, and preferred to them.

The wood of the fourth sort, is by the *French* greatly esteemed for making of cabinets, because it hath an agreeable odour. This, and the wood of the Bird Cherry, are often blended together, and pass under the appellation of *Bois de Sainte Lucie*; but the Bird Cherry is the true sort.

The fifth sort was brought from *Canada*, where it grows naturally. This is a low shrub, which seldom grows more than three or four feet high, sending out many horizontal branches, which spread on every side, and are very subject to fall on the ground, where they will put out roots, and thereby multiply. The young branches have a very smooth bark, inclining toward red; the leaves are long, narrow, very smooth, and entire, having the appearance of some sorts of Willow leaves; of a light green on their upper side, but of a bluish, or sea-green, on their under: the flowers come out from the side of the branches, two, three or four arising at the same joint; these are shaped like those of the common Cherry, but are smaller, standing upon long slender foot-stalks. The fruit is like those of the small wild Cherry, but hath a bitterish flavour.

It is easily propagated by laying down the branches early in the spring, which will take root by the following autumn, when they may be taken off, and either planted in a nursery to get strength, or to the places where they are designed to remain. It may also be propagated by sowing of the stones, in the same manner as other Cherries.

All the sorts of Cherries which are usually cultivated in fruit gardens, are propagated by budding or grafting the several kinds into stocks of the black or wild red Cherries, which are strong shooters, and of a longer duration than any of the garden kinds. The stones of these two kinds are sown in a bed of light sandy earth in autumn (or are preserved in sand till spring, and then sowed): these young stocks should remain in these nursery beds till the second autumn after sowing; at which time you should prepare an open spot of good fresh earth, which should be well worked. In this ground, in *October*, you should plant out the young stocks at three feet distance row from row, and about a foot asunder in the rows; being careful, in taking them up from their seed beds, to loosen their roots well with a spade, to prevent their breaking, as also to prune their roots; and if they are inclinable to root downwards, you should shorten the tap root, to cause it to put out lateral roots; but do not prune their tops, for this is what by no means they will endure.

The second year after planting out, if they take to growing well, they will be fit to bud, if they are intended for dwarfs; but if they are for standards, they will not be tall enough till the fourth year; for they should be budded or grafted near six feet from the ground, otherwise the graft will not advance much in height; so that it will be impossible to make a good tree from such as are grafted low, unless the graft is trained upward.

The usual way with the nursery gardeners is, to bud their stocks in summer, and such of them as miscarry, they graft the succeeding spring, (the manner of these operations will be described under their proper heads). Those trees where the buds have taken, must be headed off the beginning of *March*, about six inches above the bud; and when the bud hath shot in summer, if you fear its being blown out by the winds,

winds, you may fasten it up with some bafs, or fuch foft tying, to that part of the flock which was left above the bud. The autumn following thefe trees will be fit to remove; but if your ground is not ready to receive them, they may remain two years before they are tranfplanted; in the doing of which, you muft obferve not to head them, as is by many praftifed; for this, very often, is immediate death to them; but if they furvive it, they feldom recover this amputation in five or fix years.

If thefe trees are intended for a wall, I would advife the planting dwarfs between the ftandards; fo that while the dwarfs are filling the bottom of the walls, the ftandards will cover the tops, and will produce a great deal of fruit: but thefe, as the dwarfs arife to fill the walls, muft be cut away to make room for them: and when the dwarf trees cover the walls, the ftandards fhould be entirely taken away. But I would advife, never to plant ftandard Cherries over other fruits, for there is no other fort of fruit that will prosper well under the drip of Cherries.

When thefe trees are taken up from the nursery, their roots muft be fhortened, and all the bruifed parts cut off; as alfo all the fmall fibres, which would dry, grow mouldy, and be a great prejudice to the new fibres in their coming forth; you muft alfo cut off the dead part of the flock which was left above the bud, clofe down to the back part of it, that the flock may be covered by the bud. If thefe trees are defigned for a wall, obferve to place the bud direftly from the wall, that the back part of the flock that was cut, may be hid from fight. The foil that Cherries thrive beft in, is a frefh Hazel loam; for if the foil is a dry gravel, they will not live many years, and will be perpetually blighted in the fpring.

The forts commonly planted againft walls are the Early *May*, and *May Duke*, which fhould have a fouth afpected wall. The *Hearts* and common *Duke* will thrive on a weft wall; and in order to continue the *Duke* later in the feafon, they are frequently planted againft north and north-weft afpected walls, where they fucceed very well; and the *Morello* on a north wall, which laft is chiefly planted for preferring. The *Hearts* are all of them ill bearers, for which reafon they are feldom planted againft walls: but I am apt to believe, if they were grafted on the *Bird Cherry*, and managed properly, that defect might be remedied; for this flock (as I am informed) will render Cherries very fruitful; and having the fame effect on Cherries, as the *Paradife* flock hath on Apples, they may be kept in lefs compafs; which is an experiment well worth the trial.

Your trees, if planted againft a wall, fhould be placed at leaft twenty, or twenty-four feet afunder, with a ftandard tree between each dwarf: this will be found a reasonable diftance, when we confider, that Cherry trees will extend themfelves as far, or farther than *Apricocks*, and many other forts of fruit.

In pruning thefe forts of fruit, you fhould never fhorten their fhoots; for the moft part of them produce their fruit buds at their extreme part, which, when fhortened, are cut off, and this often occasions the death of the fhoot: their branches fhould be therefore trained in at full length horizontally, obferving in *May*, where there is a vacancy in the wall, to flop fome ftrong adjoining branches, which will occafion their putting out two or more fhoots; by which means, at that feafon of the year, you may always get a fupply of wood for covering the wall; and at the fame time fhould all foreright fhoots be difplaced by the hand, for if they are fuffered to grow till winter, they will not only deprive the bearing branches of their proper fupply of nourifhment, but when they are cut out, it occasions the tree to gum in that part (for Cherries bear the knife the worft of any fort of fruit trees); but be careful not to rub off the

fides or furs, which are produced upon the two and three years old wood: for it is upon thefe that the greateft part of the fruit are produced, which furs will continue fruitful for feveral years. And it is for want of duly obferving this caution, that Cherry trees are often feen fo unfruitful, efpecially the *Morello*, which the more it is cut, the weaker it fhoots; and, at laft, by frequent pruning, I have known a whole wall of them deftroyed; which, if they had been fuffered to grow without any pruning, might probably have lived many years, and produced large quantities of fruit.

Cherry trees are alfo planted for orchards in many parts of *England*, particularly in *Kent*, where there are large plantations of thefe trees. The ufual diftance allowed for their ftanding is forty feet fquare, at which fpace they are lefs fubject to blight, than when they are clofer planted; and the ground may be tilled between them almoft as well as if it were entirely clear, efpecially while the trees are young; and the often ftirring the ground, provided you do not difturb their roots, will greatly help the trees; but when they are grown fo big as to over-ftadow the ground, the drip of their leaves will fuffer very few things to thrive under them.

The forts beft approved of for an orchard, are the common *Red*, or *Kentifh Cherry*, the *Duke*, and *Lukeward*; all which are plentiful bearers. But orchards of thefe trees are now fcarcely worth planting, except where land is very cheap; for the uncertainty of their bearing, with the trouble in gathering the fruit, together with the fmall price it commonly yields, hath occafioned the deftroying many orchards of this fruit in *Kent*, within a few years paft.

There are fome perfons who graft the *Duke*, and other forts of Cherries, upon the *Morello Cherry*, which is but a weak fhooter, in order to check the luxuriant growth of their trees, which will fucceed for three or four years; but they are not of long duration, nor have I ever feen one tree fo grafted, which had made fhoots above fix or eight inches long; but they were clofely covered with bloffoms, fo may produce fome fruit in a fmall compafs; but thefe are experiments unfit to be carried into general ufe, and only proper to fatisfy curiofity; for is it not much better to allow the trees a greater fhare of room againft the walls, when one tree, fo planted, and properly managed, will produce more fruit than twenty of thefe trees, or twice that number, when they are planted too clofe, though they are grafted upon the *Black Cherry*, or any other free flock?

The *Early*, or *May Cherry*, is the firft ripe; fo one or two trees of this fort may be allowed a place in a garden, where there is room for variety. The next ripe is the *May Duke*, which is a larger fruit than the other, and is more valuable. After this comes the *Archduke*, which, if permitted to hang upon the tree till the fruit is quite ripe, is an excellent Cherry; but few perfons have patience to let them hang their full time, fo rarely have them in perfection; for thefe fhould not be gathered before *Midsummer*, and if they hang a fortnight longer they will be better. This is to be underftood of the fituation near *London*, where they ripen a fortnight earlier than in places forty miles diftant, unlefs they have a very warm fheltered fituation. When this fort is planted againft north walls, the fruit may be continued till the end of *Auguft*, but they muft be protected from the birds, otherwife they will deftroy them.

The *Hertfordfhire Cherry*, which is a fort of *Heart Cherry*, but a firmer and better flavoured fruit, will not ripen earlier than the end of *July*, or the beginning of *Auguft*, which makes it the more valuable, for its coming when the other forts of Cherries are gone.

The *Morello Cherry*, which is generally planted againft walls to a north afpect, and the fruit commonly ufed for preferring,

preserving, or for tarts, yet where they are planted to a better aspect, and suffered to hang upon the trees until they are thoroughly ripe, is a very good fruit for the table; therefore two or three of the trees of this sort should have place where there is plenty of walling, upon a south-west wall, where they will ripen perfectly by the middle or end of *August*, at which time they will be an acceptable fruit.

The Carnation Cherry is also valuable for coming late in the season; this is a very firm fleshy fruit, but is not the best bearer. This sort will ripen very well on *Espaliers*, and by this means the fruit may be continued longer in the season.

The large *Spanish* Cherry is nearly allied to the Duke Cherry, from which it seems to be only a variety accidentally obtained; it ripens soon after the common Duke Cherry, and very often passes for it.

The yellow *Spanish* Cherry is of an oval shape, and of an Amber colour; this ripens late, and is a sweet Cherry, but not of a rich flavour, and being but a middling bearer, is not often admitted into curious gardens, unless where variety is chiefly considered.

The Corone, or Coroun Cherry, is somewhat like the Black Heart, but a little rounder; this is a very good bearer, and an excellent fruit, so should have a place in every good fruit garden. This ripens the middle of *July*.

The Lukeward ripens soon after the Corone Cherry; this is a good bearer, and a very good fruit; it is of a dark colour, not so black as the Corone, and will do well in standards.

The Black Cherry is seldom grafted or budded, but is generally sown for stocks to graft the other kinds of Cherries upon; but where persons are curious to have the best flavoured of this sort of fruit, they should be propagated by grafting from such trees as produce the best fruit. This sort of Cherry is frequently planted in wildernesses, where it will grow to a large size, and, at the time of its flowering, will make a variety, and the fruit will be food for the birds.

The double-flowering Cherry is also propagated for the beauty of the flowers, which are extremely fine, the flowers being as double and large as a Cinnamon Rose; and these being produced in large bunches on every part of the tree, render it one of the most beautiful trees of the spring. Some of the flowers, which are less double, will often produce fruit, which the very double flowers will not; but this defect is sufficiently recompensed in the beauty of its flowers. This is propagated by budding or grafting on the Black or Wild Cherry stock, and the trees are very proper to intermix with the second growth of flowering trees.

CERASUS RACEMOSA. See *Padus*.

CERATONIA. *Lin. Gen. Plant.* 983. The Carob, or St. John's Bread.

The Characters are,

It is male and female in distinct trees. The male flowers have no petals, but have five long stamina. The female flowers have no petals, but a fleshy germen situated within the receptacle, which afterward becomes a long fleshy compressed pod, divided by transverse partitions, each having one large roundish compressed seed.

We have but one Species of this plant, viz.

CERATONIA. H. L. The Carob tree, or St. John's Bread.

This tree is very common in *Spain*, but particularly in *Andalusia*, and in some parts of *Italy*, as also in the *Levant*, where it grows in the hedges, and produces a great quantity of long, flat, brown coloured pods, which are thick, mealy, and of a sweetish taste. These pods are many times eaten by the poorer sort of inhabitants, when they have a scarcity of other food, but they are apt to loosen the belly, and cause gripings of the bowels. These pods are directed by the College

of Physicians to enter some medicinal preparations, for which purpose they are often brought from abroad.

In *England* the tree is preserved by such as delight in exotick plants, as a curiosity; the leaves always continue green, and being different in shape from most other plants, afford an agreeable variety, when intermixed with *Oranges*, *Myrtles*, &c. in the green-house.

It is propagated from seeds, which, when brought over fresh in the pods, will grow very well, if they are sown in the spring in the pots and plunged into a moderate hot-bed. In *June* you must inure them to the open air by degrees, and in *July* they should be removed out of the hot-bed, and placed in a warm situation, where they may remain until the beginning of *October*, when they should be removed into the green-house, placing them where they may have free air in mild weather; for they are pretty hardy, and require only to be sheltered from hard frosts. When the plants have remained in the pots three or four years, and have gotten strength, some of them may be turned out of the pots in the spring, and planted into the full ground, in a warm situation, where they will endure the cold of our ordinary winters very well, but must have some shelter in very hard weather.

CERBERA. *Lin. Gen. Plant.* 260.

The Characters are,

The flower is of one leaf, funnel-shaped, spread open at the top, where it is divided into five large segments; it hath five stamina in the middle of the tube. In the center is situated a roundish germen, which afterward becomes a large, fleshy, roundish berry, divided into two cells, each containing a single, large, compressed nut.

The Species are,

1. CERBERA foliis ovatis. *Lin. Sp. Plant.* 208. Cerbera with oval leaves.

2. CERBERA foliis linearibus, longissimis, confertis. *Lin. Sp. Plant.* 209. Cerbera with very long narrow leaves, growing in clusters.

The first sort grows naturally in the *Brazils*, and also in the *Spanish West-Indies* in plenty; and there are some of the trees growing in the *British* islands of *America*: this rises with an irregular stem, to the height of eight or ten feet, sending out many crooked diffused branches, which toward their tops are garnished with thick succulent leaves, of a lucid green, smooth, and very full of a milky juice. The flowers come out in loose bunches at the end of the branches, which are of a cream colour, having long narrow tubes, and at the top cut into five obtuse segments, which seem twisted, so as to stand oblique to the tube. The wood of this tree stinks most abominably, and the kernels of the nuts are a most deadly poison, so that the *Indians* always caution their children against eating them, for they know of no antidote to expel this poison; nor will any of them use the wood of this tree for fuel, but they take the kernels out of the shells, into which they put small stones, then bore a hole through each shell, and string them; these they tie about their legs to dance with, as the *morris-dancers* use bells.

The second sort grows naturally in the *Spanish West-Indies*, and also in some of the *French* islands in *America*, and hath lately been introduced into the *British* islands.

This rises with a round stalk, about the same height as the former, dividing upward into many branches. These, when young, are covered with a green smooth bark, but as they grow older, the bark becomes rough, and changes to a gray or Ash colour. The leaves are four or five inches long, and half an inch broad in the middle, ending in sharp points; these are of a lucid green, and come out in clusters without order, and are full of a milky juice, which flows out when they are broken. The flowers come out from the

side of the branches, upon long foot-stalks, each supporting two or three yellow flowers with long tubes, spreading open in the same manner as the former.

These plants may be propagated from their nuts, which must be procured from the countries where they grow naturally; which should be put into small pots filled with light earth, and plunged into a hot-bed of tanners bark in the spring, and treated in the same manner as other tender exotick seeds, giving them now and then a little water to promote their vegetation. When the plants are come up about two inches high, they should be transplanted each into a separate pot, and plunged again into a hot-bed of tanners bark, observing to shade the glasses in the heat of the day, until the plants have taken new root. As the summer advances, these plants should have air admitted to them, in proportion to the warmth of the season; and when they have filled these small pots with their roots, they should be turned out, and transplanted into pots of a larger size. After they are new potted, they should be plunged into the hot-bed again. When the plants are grown about a foot high, they should have a larger share of air, in order to harden them before the winter, but they should not be wholly exposed to the open air. In the winter these plants should be placed in a warm stove, and during that season they should have very little water given them, especially in cold weather, lest it should rot their roots. These plants will not thrive well unless they are constantly kept in tan; and as they abound with milky juice, so they should be sparingly watered, for they are impatient of moisture, especially during the winter season.

When by any accident the tops of these plants are injured, they frequently put out shoots from their roots, which, if carefully taken up and potted, will make good plants, so that they may be this way increased.

CERCIS. *Lin. Gen. Pl.* 458. The Judas tree.

The Characters are,

The flower hath five petals, which are inserted in the empalement, and greatly resemble a papilionaceous flower. The standard is of one roundish petal, and the keel is composed of two petals. It hath ten distinct stamina, four of which are longer than the rest. It hath a long slender germen, which after-ward becomes an oblong pod with an oblique point, having one cell, inclosing several roundish compressed seeds.

The Species are,

1. *CERCIS foliis cordato-orbiculatis glabris.* *Hort. Cliff.* 156. Cercis with round, heart-shaped, smooth leaves. The common Judas tree.

2. *CERCIS foliis cordatis pubescentibus.* *Hort. Cliff.* 156. Cercis with downy heart-shaped leaves; commonly called *Canada Arbor Judæ*, or Red Bud tree.

The first sort grows naturally in the south of *France*, in *Spain*, and *Italy*. This rises with an upright trunk to the height of twelve or fourteen feet, covered with a dark reddish bark, and divides upward into many irregular branches, garnished with round, heart-shaped, smooth leaves, placed irregularly on the branches, having long foot-stalks. The flowers come out on every side the branches, and many times from the stem of the tree in clusters, arising many from the same point, having short foot-stalks; they are of a very bright purple colour, so make a fine appearance, especially when the branches are covered pretty thick with them, for they come out in the spring with the leaves, so are in full beauty before the leaves have obtained to half their size; these have an agreeable poignancy, so are frequently eaten in fallads. When the flowers fall off, the germen becomes a long flat pod, with one cell, containing one row of roundish seeds, which are a little compressed.

These trees are usually planted with other flowering trees

and shrubs, as ornamental to pleasure gardens; and for their singular beauty, deserve a place, as well as most other sorts, for when they are arrived to a good size, they are very productive of flowers, so as that the branches are often closely covered with them; but the birds peck them off the trees, being inticed thereto by the honey liquor in the empalement. The singular shape of their leaves make a very pretty variety in the summer, after the flowers are past, and are never damaged by insects, so that they are often entire, when many other trees have their leaves almost eaten up. This tree flowers in *May*, when planted in the full air, but against warm walls it is a fortnight or three weeks earlier.

The wood of this tree is very beautifully veined with black and green, and takes a fine polish, so may be converted to many uses.

There are two other varieties of this tree, one with a white, and the other hath a flesh-coloured flower, but these have not half the beauty of the first. *Tournefort* also mentions one with broader pods and pointed leaves, which I believe is only a variety of this.

The second sort grows naturally in most parts of *North America*, where it is called Red Bud, I suppose from the red flower buds appearing in the spring, before the leaves come out; this grows to a middling stature in the places where it is a native, but in *England* rarely rises with a stem to any great height, but branches out near the root. The branches of this are weaker than those of the first sort; the leaves are downy, and terminate in points, whereas those of the first are smooth, and round at the end where they are indented. The flowers of this are also smaller, so do not make so fine appearance as those of the first, but the trees are equally hardy, so will thrive in the open air very well.

These plants may be propagated by sowing their seed upon a bed of light earth, towards the latter end of *March*, or the beginning of *April* (and if you put a little hot dung under the bed, it will greatly facilitate the growth of the seeds); when your seeds are sown, you should sift the earth over them about half an inch thick; and, if the season prove wet, it will be proper to cover the bed with mats, to preserve it from great rains, which will burst the seeds, and cause them to rot; these seeds will often remain till the spring following before they come up, so the ground must not be disturbed till you are convinced that the plants are all come up, for some few may rise the first year, and a greater number the second.

When the plants are come up, they should be carefully cleared from weeds, and in very dry weather must be now and then refreshed with water, which will greatly promote their growth. The winter following, if the weather is very cold, it will be proper to shelter the plants, by covering them either with mats, or dry straw, in hard frosts, but they should constantly be opened in mild weather, otherwise they will grow mouldy, and decay.

About the beginning of *April*, you should prepare a spot of good fresh ground, to transplant these out (for the best season to remove them is just before they begin to shoot;) then you should carefully take up the plants, being careful not to break their roots, and plant them in the fresh ground as soon as possible, because if their roots are dried by the air, it will greatly prejudice them.

The distance these should be planted, must be proportionable to the time they are to remain before they are again transplanted; but commonly they are planted two feet row from row, and a foot asunder in the rows, which is full room enough for them to grow two or three years, by which time they should be transplanted where they are designed to remain; for if they are too

old when removed, they seldom succeed so well as younger plants.

When they have remained in this nursery two or three years, they should be transplanted in the spring where they are designed to remain, which may be in wilderness quarters, among other flowering trees, observing to place them with trees of the same growth, so as that they may not be overhung, which is a great prejudice to most plants.

CEREFOLIUM. See Chærefolium.

CEREUS. Par. Bat. 122. The Torch Thistle.

The Characters are,

The flower is composed of a great number of narrow pointed petals, which spread open like the sun's rays. It hath a great number of declining stamina, which are inserted to the base of the petals. The germen, which is situated under the empalement, afterwards becomes an oblong succulent fruit, with a prickly skin, full of small seeds inclosed in the pulp.

The Species are,

1. CEREUS erectus, sexangularis, longus, angulis distantibus. Tallest upright Torch Thistle of Surinam.

2. CEREUS erectus quadrangularis, angulis compressis. Upright Cereus with four compressed angles.

3. CEREUS erectus octangularis, angulis obtusis, supernè inermibus. Upright Cereus with eight obtuse angles, having no spines on the upper part.

4. CEREUS erectus octangularis, angulis obtusis, spinis robustioribus patulis. Upright Cereus with eight angles which are obtuse, and strong spreading spines.

5. CEREUS erectus novemangularis, obsoletis angulis, spinis lanâ brevioribus. Upright Cereus with nine angles, and spines shorter than the down.

6. CEREUS erectus octangularis, spinis lanâ longioribus. Upright Cereus with eight angles, and spines longer than the down.

7. CEREUS erectus novemangularis, spinis lanâ æqualibus. Upright Torch Thistle with nine angles, and spines of equal length with the down.

8. CEREUS erectus gracilior novemangularis spinis brevibus, angulis obtusis. Slenderer upright Torch Thistle having nine obtuse angles, and short spines.

9. CEREUS repens triangularis, fructu maximo rotundo, rubro, esculento. Creeping triangular Torch Thistle, with a very large, round, red, eatable fruit; commonly called in the West-Indies, the true prickly Pear.

10. CEREUS repens triangularis, angulis compressis. Creeping, triangular Torch Thistle, with compressed angles.

11. CEREUS repens subquingularis. Creeping Torch Thistle with five angles.

12. CEREUS repens decemangularis. Creeping Cereus with ten angles.

The first sort has been the most common in the English gardens. This grows naturally in Surinam.

This rises with an upright stalk, having six large angles, which are far asunder, and are armed with sharp spines, which come out in clusters at certain distances, arising from a point, but spread open every way like a star; the outer substance of the stem is soft, herbaceous, and full of juice, but in the center there is a strong fibrous circle running the whole length, which secures the stem from being broke by winds. This will rise to the height of thirty or forty feet, provided their tops are not injured, if they have room to grow; but some of them have grown too tall to be kept in the stoves, so have been either cut off, or the plants laid down at length in winter; but whenever the stems are cut, or otherwise injured, they put out one, two, or sometimes three shoots, from the angles immediately under the wounded part, and frequently one or two lower down. These shoots, if they are not cut off, form so many distinct stems, and grow upright; but these are seldom so large as the prin-

cipal stem, especially if more than one is left at the same place. The flowers come out from the angles, on the side of the stem; these have a thick fleshy foot-stalk, which is scaly, round, channelled, and hairy, supporting a swelling germen, upon the top of which sits the scaly prickly empalement, closely surrounding the petals of the flowers, till a little time before they expand, which in most of the sorts is in the evening; and their duration is very short, for before the next morning they wither and decay. The flower of this sort is composed of many concave petals, which, when fully expanded, are as large as those of the Holly-hock; the inner petals are white, and are crenated at their extremity. The empalement is green, with some purple stripes; the middle of the flower is occupied by a great number of stamina, which decline in the middle, and rise at their extremities, having roundish summits. The flowers of this kind are never succeeded by fruit in this country; nor do the plants often produce their flowers here, but when they do, there are generally several on the same plant. I have some years had more than a dozen upon a single plant, which have all flowered within a few days of each other.

This sort is not so tender as the others, so may be preserved in a warm green-house, without any artificial heat; but the plants should have no water given them in winter, when they are thus situated; for unless they are placed in a stove, where the moisture is soon evaporated, the wet will occasion them to rot.

The second sort rises with an upright stem like the first, but it hath only four angles, which are compressed, and stand far asunder. This is very subject to put out many shoots from the sides, which stops its upright growth, so that the plants rarely rise more than four or five feet high.

The third, fourth, fifth, sixth, seventh, and eighth sorts, grow naturally in the British islands of America. These have the same form as the first, but differ in the size of their stems, the number of their angles, and the length of their spines, as is before expressed in their titles; but, except the eighth sort, not any of them have flowered in England as yet, though there are many of the plants which are more than twelve feet high: the eighth sort hath the smallest stem of any of the upright sorts which I have yet seen; this hath nine obtuse angles, which are armed with short spines, placed at farther distances than those of the other sorts, nor are the channels between the angles near so deep. The flowers of this are produced from the angles, in the same manner as the first, but are smaller, and the empalement is of a light green, without any mixture of colour. The fruit is about the size and shape of a middling Bergamot Pear, having many soft spines on the skin; the outside is a pale yellow, the inside very white, full of pulp, having a great number of small black seeds lodged in it. This sort frequently flowers in July, and in warm seasons will perfect its fruit, which hath very little flavour in this country.

These sorts are more impatient of cold than the first, so require a stove to preserve them in winter; nor should they be exposed abroad in summer, but kept constantly in the house, giving them a large share of air in warm weather.

The twelfth sort grows naturally in Peru. This is not so tender as the other sorts, so may be preserved in a green-house, or under a good frame, in winter, and in summer should be exposed to the open air, which will prevent the shoots from drawing weak, and thereby a greater number of flowers will be produced; but during the time they remain in the open air, they should have very little water; and if the season should prove wet, the plants should be screened from it, otherwise it will cause them to rot the following winter. This sort produces its flowers in great plenty

plenty in *May*, and sometimes earlier, when the season is warm.

The ninth sort is, by the inhabitants of *Barbadoes*, trained up against their houses, for the sake of its fruit, which is about the bigness of a Bergamot Pear, and of a most delicious flavour. This, and also the tenth, eleventh, and twelfth sorts, are very tender, so require a very warm stove to preserve them. These should be placed against the walls of the stove, into which they will insinuate their roots, and extend themselves to a great length; and with a little help in fastening them to the wall here and there, may be led up about the cieling of the house, where they will appear very handsome. And the eleventh sort, when arrived to a sufficient strength, will produce many exceeding large, beautiful, sweet scented flowers; but they are (like all the flowers of these kinds) of very short duration, scarcely continuing full blown six hours; nor do the same flowers ever open again, when once closed: they begin to open in the evening between seven and eight of the clock, are fully blown by eleven, and by three or four the next morning fade, and hang down quite decayed; but, during their continuance, there is scarce any flower of greater beauty, or that makes a more magnificent appearance; for the calyx of the flower, when open, is near a foot diameter, the inside of which, being of a splendid yellow colour, appears like the rays of a bright star, the outside of a dark brown, and the petals of the flowers being of a pure white, adds to the lustre, and the vast number of recurved stamina, surrounding the style in the center of the flower, make a fine appearance; add to this the fine scent of the flower, which perfumes the air to a considerable distance, there is scarce any plant which deserves a place in the hot-house so much as this, especially as it is to be trained against the wall, where it will not take up room. The usual season of its flowering is in *July*; when the plants are large, they will produce a great number of flowers, so that there will be a succession of them for several nights, and many of them will open the same night. I have frequently had six or eight flowers open at the same time upon one plant, which have made a most magnificent appearance by candle-light, but none of them have been succeeded by any appearance of fruit.

The tenth sort produces a flower little inferior to the former, as I have been informed by persons who have seen them, but I never had the good fortune to have any of these plants which have been under my care flower; nor have I heard of more than two gardens where they have as yet flowered in *England*; the first of them was many years since in the royal gardens at *Hampton-Court*, when there was a curious collection of exotick plants kept in good order in those gardens, which have since been greatly neglected; the other was produced in the gardens of the right honourable the marquis of *Rockingham*, at *Wentworth-Hall*, in *Yorkshire*. These are the only gardens in this country, where I have heard of this sort having produced flowers; although there are many of these plants in several gardens, which are of a considerable age, and extend their branches to a very great distance.

The ninth sort hath never produced any flowers as yet in *England*, nor have we any good figure of the flower in any of the botanick books; but I have been informed by some curious persons who have resided in *America*, that the flowers are not near so beautiful as those of the tenth and eleventh, but the fruit is greatly esteemed by all the inhabitants.

The twelfth sort produces a greater number of flowers than either of the other; these are of a fine Pink colour, both within and without; the petals are not so numerous, and the tube of the flower is longer than those of the other species; and, contrary to all the other sorts, keep open three

or four days, provided the weather is not too hot. During the continuance of these flowers, they make a fine appearance. This sort has very slender trailing branches, which require to be supported; but they do not extend so far as those of the other sort, nor are their branches jointed as those are, so they cannot be trained so far against the walls of the house: but as it produces such beautiful flowers, and in so great plenty, it may be placed among the first class of exotick plants. This plant has produced fruit in the garden at *Chelsea*.

These are all propagated by cuttings, so that if you intend to increase the number of them, you must cut off their stems at what length you please; and the cuttings should be laid in a dry place to heal, at least ten days or a fortnight, before they are planted; but if they lie three weeks it is much the better, and will be in less danger of rotting, especially those sorts which are the most succulent.

These cuttings should be planted in pots filled with the mixture of earth before directed, laying some stones in the bottom of the pots to drain off the moisture; then place the pots into a gentle hot-bed of tanners bark, to facilitate their rooting, giving them once a week or ten days a gentle watering.

The best season for this work is in *June*, or the beginning of *July*, that they may have time to root well before winter; toward the middle of *August* you must begin to give them air by degrees, to harden them against winter, but they should not be wholly exposed to the open air or sun; at the end of *September* they must be removed into the stove, where they are to abide the winter, during which season you must be very careful not to let them have much water; and always observe to place the young plants, for the first winter, in a little warmer situation than the older, as being somewhat tenderer.

When you have once cut off the tops of any of these plants, in order to increase them, the lower parts will put forth fresh shoots from their angles, which, when grown to be eight or nine inches long, may also be taken off to make fresh plants; and, by this means, the old plants will continually afford a supply, so that you never need cut off above one plant of a sort, which you should preserve for to multiply.

These plants being succulent, they will bear to be a long time out of the ground, therefore whoever hath a mind to get any of them from the *West-Indies*, need give no other instructions to their friends, but to cut them off, and let them lie two or three days to dry, then put them up in a box with dry hay, or straw, to keep them from wounding each other with their spines, and if they are two or three months on their passage, they will keep very well, provided no wet get to them.

CERINTHE. *Lin. Gen. Plant.* 171. Honeywort.

The Characters are,

The flower hath one petal, with a thick short tube, and at the brim is quinquefid; it hath five short stamina. In the bottom are situated four germen, two of which afterward become so many seeds, which are hard, smooth, plain on one side, but convex on the other, and are inclosed in the empalement.

The Species are,

1. CERINTHE *foliis ovato-oblongis, asperis, amplexicaulis, corollis obtusiusculis, patulis*. Honeywort with oval, oblong, rough leaves, embracing the stalk, and spreading blunt petals.

2. CERINTHE *foliis oblongo-ovatis, glabris, amplexicaulis, corollis obtusiusculis, patulis*. Honeywort with a purplish red flower.

3. CERINTHE *foliis amplexicaulis, integris, fructibus geminis, corollis acutis, clausis*. *Lin. Sp. Plant.* 137. Smaller Honeywort.

4. CERINTHE *foliis amplexicaulibus emarginatis, fructibus geminis, corollis acutis clausis. Lin. Sp. Pl. 137.* Honeywort, or Greater Mountain Hounds Tongue.

5. CERINTHE *foliis lanceolato-linearibus, hispida, seminibus quaternis distinctis. Hort. Cliff. 48.* Honeywort with narrow spear-shaped leaves, which are set with prickly hairs, and four distinct seeds; or, Greater Yellow Alkanet.

The first sort grows naturally in *Germany* and *Italy*. It is an annual plant, with smooth branching stalks a foot and an half high, garnished with oval, oblong, prickly leaves, which are of a sea-green, spotted with white, and embrace the stalks with their base; the flowers are produced at the end of the branches, standing between the small leaves; these are long, tubulous, and blunt at the top, where the tube is greatly enlarged; they are yellow, and have a mellifluous liquor in their tubes, with which the bees are much delighted; these flowers have each four embryos, or germen, but only two of them are fruitful. If the seeds are not taken as soon as they change black, they drop out of the empalement in a short time, so unless they are carefully gathered up, they will vegetate with the first moist weather.

The second sort is like the first, but the leaves are larger, and smooth, having no prickles on them. The flowers of this are of a purplish red colour, and the plants grow larger. This grows in *Italy*, and the south of *France*; it is also an annual plant.

The third sort grows naturally on the *Alps*, and other mountainous places; it hath slenderer stalks than either of the former, which rise two feet high; the leaves embrace the stalks with their base, and are of a bluer green colour. The flowers are small, their upper part is deeply cut into five segments, but the mouth of the tube is closely shut up. If the seeds of this are permitted to scatter, the plants will come up in autumn, and these will grow much taller, and flower earlier than those which are sown in the spring.

The fourth sort is very like the third, but the leaves are not spotted, and they are indented at their ends. The flowers are smaller, not so deeply cut at the top, and the segments are more acute.

The fifth sort grows naturally in *Austria*, *Hungary*, and in *Italy*; this hath long, narrow, thick leaves, which are covered closely with rough prickly hairs, and spread upon the ground; between these come out the stalk, which rises a foot high, garnished at each joint with one leaf of the same sort, but smaller, which are placed alternately on the stalks; toward the upper part the stalks branch out into two or three smaller, upon which the flowers stand between the leaves, and form a short reflexed spike, like the true Alkanet. The flowers are of a pale yellow, and are shaped like those of the other sorts, but are smaller.

There are two other varieties of the first sort, which differ only in the colour of their flowers, so are not constant.

The several varieties of this plant are propagated by seeds, which should be sown soon after they are ripe; for, if they are kept till spring, the growing quality of some of them is often lost; the plants are hardy, and if the seeds are sown in a warm situation, they will endure the winter's cold very well without shelter; these autumnal plants are also much surer to produce ripe seeds than those which are sown in the spring, which are generally late in the season before they flower; and consequently, if the autumn should not prove very warm, their seeds would not be perfected.

CESTRUM. *Lin. Gen. Pl. 231.* Bastard Jasmine.

The Characters are,

The flower is funnel-shaped, of one petal, having a long cylindrical tube, which spreads open at the top, and is cut into five equal segments; it hath five slender stamina. The oval cylindrical germen is situated in the empalement, which afterward becomes an oval oblong berry, with one cell, inclosing several roundish seeds.

The Species are,

1. CESTRUM *floribus pedunculatis. Hort. Cliff. 490.* Cestrum with flowers standing upon foot-stalks.

2. CESTRUM *floribus sessilibus. Hort. Cliff. 491.* Cestrum with flowers sitting close to the branches.

3. CESTRUM *foliis lanceolatis oppositis nervis transversalibus, pedunculis ramosis.* Cestrum with spear-shaped leaves growing opposite, having transverse veins, and branching foot-stalks to the flowers.

4. CESTRUM *foliis ovato-lanceolatis, floribus spicatis, alaribus & terminalibus.* Cestrum with oval spear-shaped leaves, and flowers growing in spikes from the sides and tops of the branches.

5. CESTRUM *foliis oblongo-ovatis, obliquis, floribus alaribus confertis, tubo longissimo & tenuissimo.* Cestrum with oblong oval leaves which are oblique, and flowers growing in clusters from the sides of the branches, with a very long, slender tube.

6. CESTRUM *foliis lanceolatis obliquis, floribus alaribus, pedunculis foliosis.* Cestrum with oblique spear-shaped leaves, flowers proceeding from the sides of the branches, and leafy foot-stalks.

The first sort was many years past raised in the curious gardens of the dukes of *Beaufort*, at *Badmington*, in *Gloucestershire*, and was from thence communicated to several gardens in *England* and *Holland*, where in the latter it passes under the title of *Badmington Jasmine* to this time. This grows naturally in the island of *Cuba*, from whence I received the seeds by the title of *Dama de Noche, i. e.* Lady of the Night, which appellation I suppose was given it from the flowers sending out a strong odour after the sun is set.

It rises with an upright stalk about six or seven feet high, covered with a grayish bark, and divides upward into many slender branches, which generally incline to one side; these are garnished with leaves placed alternate, which are near four inches long, and one and an half broad, smooth on their upper side, of a pale green, and on their under side they have several transverse veins, standing on short foot-stalks. The flowers are produced at the wings of the leaves in small clusters, upon short foot-stalks, each sustaining four or five flowers, which have very short empalements, with long slender tubes, which are enlarged at the top, where they are cut into five parts which are reflexed; these are of an herbaceous colour.

The seeds of the second sort were sent me from the *Havannah*, by the title of *Dama de Dio*, or Lady of the Day; this rises with an upright stalk to the height of eight or ten feet, covered with a smooth light green bark, and divides upward into many smaller branches, garnished with smooth leaves near three inches long, and one and an half broad, of a lively green colour; these are ranged alternately on the branches. Toward the upper part of the shoots come out the flowers from the wings of the leaves, standing in clusters close to the branches; they are very white, shaped like those of the former sort, and smell sweet in the day time, from whence it had the appellation of Lady of the Day.

The third sort was sent me from *Carthage* in *New Spain*, near which place it grows naturally; this rises with a shrubby stalk five or six feet high, covered with a brown bark, and divides upward into many small branches, garnished with spear-shaped leaves, about four inches long, and little more than one broad; they are smooth, of a light green, and have many horizontal veins running from the midrib to the sides, and are placed opposite by pairs. From the wings of the leaves, toward the upper part of the branches, are produced the flowers, standing upon branching foot-stalks, each sustaining four or five flowers, whose tubes are swelling at their base, just above the empalement, but contract

tract upward to the mouth, where the petal is cut into five broad segments which spread flat; they are white, but without scent.

The fourth sort was sent me from *Carthage*, with the former. This rises with a shrubby stalk, ten or twelve feet high, covered with a light gray bark, sending out many branches the whole length, garnished with oval spear-shaped leaves, standing without order; they are two inches and an half long, and one and an half broad, of a light green, with slender foot-stalks. The flowers come out in loose spikes from the side, and also the end of the branches, which are shaped like those of the first sort, and are of a whitish green colour, without scent.

The fifth sort rises with several shrubby stalks, which grow eight or ten feet high, covered with a white smooth bark, and send out many irregular branches, which are garnished with oblong oval leaves, which at their base are longer on one side, so that the foot-stalk is oblique; they are placed on the branches without order, and are of a pale green. The flowers come out in clusters from the side of the branches, many of them arising from the same point; these have very slender long tubes, which are cut at the top into five acute segments which are erect. These are of a pale yellow, and without scent.

The sixth sort grows naturally in *Jamaica*. This rises with a woody stem eight or nine feet high, covered with a smooth whitish bark, sending out many branches toward the top, which are garnished with spear-shaped leaves, whose foot-stalks are oblique; they are three inches long, and little more than one broad, smooth, of the consistence with Bay leaves, and are placed alternate on the branches. From the wings of the leaves the flowers are produced; the foot-stalks of the flowers are garnished with small leaves, standing between each flower in a singular manner, the flowers rising one above the other, and between, or opposite to each, is one, and sometimes two-leaves of the same form with those on the branches. The flowers are of a pale yellow, and emit a disagreeable odour.

All these plants grow naturally in very hot countries, so cannot be preserved in *England* without artificial heat; therefore require to be placed in a warm stove, especially in the winter. The two first are hardier than the others; these I have kept several years in a dry stove, with a moderate share of heat in winter, and in the middle of summer have set them in the open air, in a warm situation. With this management I have found them thrive, and produce flowers much better than when they have been placed in a greater heat; but I have often endeavoured to keep these plants through the winter, in a green-house, or a glass case, without fire, but could never succeed, for by the end of *January* they commonly decayed.

These plants may be propagated either by seeds, or cuttings. Those which come from seeds are always the most vigorous, and straightest plants; but as they do not produce seeds in *England*, so the other method is generally practised, because their seeds are rarely brought hither.

The best time to plant these cuttings, is about the end of *June*, by which time the shoots will have had time to recover their strength, after their confinement during the winter season. The shoots which come out from the lower part of the stalks, should always be chosen for this purpose. These should be cut about four inches long, and five or six of them may be planted in one halfpenny pot, for the cuttings of most sorts of exotick plants, will succeed better when they are planted in these small pots, than they do in larger, as I have many years experienced. When the cuttings are planted, the earth must be pressed pretty close to them, and then gently watered; after which the pots must be plunged into a moderate hot-bed of tanners bark, and shaded from the

sun. With this management the cuttings will put out roots in a month or six weeks, when they should be gradually exposed to the sun, and when they begin to put out shoots, they must have a greater share of fresh air admitted to them, to prevent their drawing up weak. When they have made good roots, they should be carefully shaken out of the pots, and each put into a separate small pot; then give them some water, to settle the earth to their roots, and plunge them again into the tan bed; observing if any of their leaves hang down, to shade them from the sun in the middle of the day, until they have taken fresh root; after which they should have a large share of air in warm weather, to strengthen them before winter.

In the autumn the plants must be removed into the bar's stove, and plunged into the tan bed, where they must be treated in the same manner as other tender exotick plants; for although the two first sorts may be treated otherwise when they have obtained strength, yet in the first winter they may be managed in the same way as the others. There must be great care had in watering of these plants in winter, for they are all (except the second sort) very impatient of moisture; so that they are soon killed by being over watered.

If the seeds of these are procured from the countries where they grow naturally, they should be sowed in small pots, and plunged into a moderate hot-bed of tanners bark, giving them now and then a little water. Sometimes the seeds will come up the same year, but they very often lie in the ground till the spring following; so that if the plants do not appear in six or seven weeks after the seeds are sown, they will not come up that season; in which case the pots may be plunged in the tan bed of the stove, between the other plants, where they will be shaded from the sun, and but little water given them; in this situation they may remain till the following spring, when they should be removed, and plunged into a fresh hot-bed, which will bring up the plants in a short time, provided the seeds were good.

CETERACH. See *Asplenium*.

CHÆROPHYLLUM. *Lin. Gen. Pl.* 320. Chervil.

The Characters are,

It is a plant with umbellated flowers; the principal umbel is spreading, and composed of several small ones, called rays; the flowers have five heart-shaped inflexed petals, and five stamina. The germen is situated below the flower, supporting two reflexed styles, which afterward becomes an oblong pointed fruit, dividing in two parts, each having one seed, which is convex on one side, and plain on the other.

The Species are,

1. CHÆROPHYLLUM *flosculis omnibus fertilibus, caule æquali. Lin. Sp. Plant.* 258. Wild Myrrh with smooth seeds.
2. CHÆROPHYLLUM *caule lævi, geniculis tumidis. Lin. Sp. Pl.* 258. Chervil with a smooth stalk, and swelling knots.
3. CHÆROPHYLLUM *caule scabro, geniculis tumidis. Lin. Sp. Pl.* 258. Wild Chervil.
4. CHÆROPHYLLUM *caule æquali, foliolis incisus acutis. Lin. Sp. Plant.* 258. Chervil with an equal stalk, and leaves cut into acute segments.
5. CHÆROPHYLLUM *feminibus lævibus, umbellis ad nodos sessilibus. Bahm. Lips.* 492. Garden Chervil.

The first sort grows naturally on the side of highways, and the borders of the fields in most parts of *England*, so is never cultivated in gardens. It is frequently called Cow Parsley, but for what reason I cannot say, because there are few animals who care to eat it, except the ass, for it is reckoned to have something of the quality of Hemlock, but in a less degree. It is a weed which should be rooted out from all pastures early in the spring, for it is one of the most early plants in shooting, so that by the beginning of *April*, the leaves are near two feet high.

The second sort grows naturally in *Hungary* and *Istria*; this plant hath a thick tuberous root, from which come forth several leaves resembling those of Wild Chervil. The stalks rise seven or eight feet high, which are spotted with purple, and are garnished with leaves of the same form as those below. The knots at the joints of the stalks swell out on every side, at which is placed one of these divided leaves, and the stalks are terminated by small umbels of white flowers, which are succeeded by long narrow seeds. If the seeds of this plant are permitted to scatter, the plants will come up without any farther care, and only require to be kept clean from weeds.

The third sort grows naturally on the sides of foot walks, and on the borders of woods in many parts of *England*, so is not cultivated in gardens.

The fourth sort grows naturally in the pastures about *Geneva*, and in *Switzerland*; this hath a perennial root, the leaves are shaped like those of the first, but are broader, hairy, and more divided. The stalks rise three feet high, which are channelled, and are terminated by large umbels, formed of many small ones, which are composed of white or red flowers, sometimes both colours in the same umbel, having five heart-shaped petals, which turn inward; these are succeeded by two long pointed seeds; the whole plant has an aromattick smell and taste.

The fourth sort is the Garden Chervil, which was formerly much more cultivated in the *English* gardens, than at present; it is an annual plant, which perishes soon after the seeds are ripe. The best time to sow the seeds is in autumn, soon after they are ripe, for those which are sown in the spring do rarely come up, and, if they do, the plants seldom thrive; for as soon as the warm weather sets in, these soon wither and decay; but the plants which rise in autumn, continue green all the winter, and in *April* they flower, soon after which the seeds ripen, and the whole plants decay.

The leaves of this plant are frequently used in soups in the winter and spring, but especially by the *Dutch*, who are great lovers of this herb; but whoever makes use of it should be cautious not to take the leaves of the Annual Myrrhis, instead of this, as some of the *Dutch* soldiers who were in *England* in 1745, did, some of whom were poisoned with it.

It will thrive on any soil, or in any situation. The seeds may be either sown in drills, or broad-cast, and require no particular culture, so may be treated in the same way as Parsley.

CHAMÆRIPHES. See *Chamærops*.

CHAMÆROPS. *Lin. Gen. Plant.* 1084. Dwarf Palm, or Palmetto.

The Characters are,

It hath male and hermaphrodite flowers in distinct plants; the hermaphrodite flowers are all included in one common spathe; the spadix, or club, is branching; each flower hath a small three pointed empalement, and one thick upright petal, which is cut into three parts, with five compressed stamina which join at their base.

They have three roundish germen, which afterward become so many round berries, having one cell, each containing a single seed. The male flowers are like the hermaphrodite, but the stamina are not distinct, nor have they any germen.

The Species are,

1. CHAMÆROPS *frondibus palmatis, plicatis, stipitibus spinosis.* *Hort. Cliff.* 482. Dwarf Palm with folding palmated leaves, and prickly foot-stalks.

2. CHAMÆROPS *foliis flabelliformibus, maximis, stipitibus glabris.* Dwarf Palm with very large fan-shaped leaves, and smooth foot-stalks; commonly called small Palmetto Royal.

The first sort grows naturally in *Spain*, particularly in *Andalusia*, where, in the sandy land, the roots spread and propagate so fast, as to cover the ground in the same manner as the Fern in *England*. The leaves of these plants are tied together to make besoms for sweeping.

This never rises with a stem, but the foot-stalks of the leaves rise immediately from the head of the root, and are armed on each side with strong spines, they are flat on their upper surface, and convex on the under; to their ends the center of the leaves are fastened, which spread open like a fan, having many foldings, and at the top are deeply divided like the fingers of a hand. The bezlers of the leaves are finely sawed, and have white narrow edgings; these leaves spread out on every side of the plant, they are from nine to eighteen inches long, and near a foot broad in their widest part; as the lower leaves of the plants decay, so their vestiges remain, and form a short stump above ground, in the same manner as our common male Fern does; from between the leaves come out the spadix, or club, which sustains the flowers; this is covered with a thin spathe, or hood, which falls off when the bunches open and divide. As all the plants of this sort which I have seen flower were male, so I cannot give any particular description of their fructification.

These plants are best propagated by seeds, which should be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanners bark. If the seeds are fresh, the plants will come up in six weeks, or two months; these rise with a single long pointed leaf. If the plants are not too close to each other in the pots, they will not require to be transplanted the first year, therefore they should remain in the tan bed all the summer, but in warm weather they must have plenty of air admitted to them. In autumn the pots should be removed into the stove, and, if they are plunged into the bark bed the first winter, it will greatly forward the growth of the plants. The following spring the plants should be carefully turned out of the pots, so as to preserve their roots entire, for all the sorts of Palms have tender roots, which, if they are cut off, or broken, frequently kills the plants; then they should be each planted into a separate small pot, and plunged into a fresh hot-bed, to encourage their taking root; the following summer they should be gradually hardened, by raising the glasses pretty high, so as to admit a large share of air to them, but they should not yet be wholly exposed to the open air. The autumn following the plants may be placed in a dry stove, but as the plants advance and get strength, they may be treated more hardily, and in summer placed in the open air in a warm situation, and in winter may be preserved in a warm green-house without artificial heat.

As the plants advance in growth, so they should be put into larger pots; but when this is done, there must be great care taken, that their roots are not cut or broken, nor should they have pots too large. In winter they must have but little water, and if they are exposed to the open air in summer, they will not require much, unless the season proves very warm and dry, in which case they may be sparingly watered two or three times a week.

The second sort grows naturally in the *West-Indies*, where it never rises with a tall stem; the foot-stalks of the leaves are rounder than those of the former, and have no spines on their sides. When the plants are old their leaves are three or four feet long, and upward of two broad; these are folded in the same manner as those of the first, but the folds are broader, and the leaves are of a darker green; some of these plants have put out slender bunches of male flowers in *England*, which were too imperfect to form a description.

This sort rises freely from seeds, which may be easily procured from the islands in *America*; these must be sown in the same manner as the former, and the plants treated in the same way, but as they are natives of a warmer climate, so they should be constantly kept in the bark stove, where, if they are carefully managed, they will make good progress.

CHAMÆRUBUS. See Rubus.

CHAMÆSYCE. See Euphorbia.

CHEIRANTHUS. *Lin. Gen. Plant.* 730. Stock Gilliflower and Wall-flower.

The Characters are,

The flower hath four petals in form of a cross; it hath six parallel stamina, two of which are between the swelling leaves of the empalement, the other are a little shorter. It hath a four-cornered prismatic germen, which afterward becomes a long compressed pod with two cells, opening with two valves, filled with compressed seeds.

The Species are,

1. CHEIRANTHUS *foliis lineari lanceolatis serratis caule erecto, siliquis tetragonis*. Cheiranthus with narrow, indented, spear-shaped leaves, an upright stalk, and four-cornered pods.

2. CHEIRANTHUS *foliis lanceolatis integerrimis, caule erecto, siliquis tetragonis*. Cheiranthus with spear-shaped entire leaves, an upright stalk, and quadrangular pods.

3. CHEIRANTHUS *foliis lanceolatis, acutis, glabris*. *Hort. Cliff.* 334. Cheiranthus with spear-shaped, pointed, smooth leaves; or, Wall-flower.

4. CHEIRANTHUS *foliis linearibus, unguibus petalorum calyce longioribus*. Cheiranthus with narrow leaves, and the necks of the petals longer than the empalement.

5. CHEIRANTHUS *foliis lanceolatis, subdentatis, obtusis, incanis, siliquis cylindricis apice acutis, caule herbaceo*. *Lin. Sp. Plant.* 662. Cheiranthus with spear-shaped leaves, somewhat indented, obtuse, and hoary; cylindrical pods with acute points, and an herbaceous stalk; commonly called the Ten Weeks Stock.

6. CHEIRANTHUS *foliis lanceolatis, integerrimis, obtusis, incanis, siliquis apice truncatis, compressis, caule suffruticoso*. *Hort. Upsal.* 187. Cheiranthus with very entire spear-shaped leaves, which are obtuse and hoary, compressed pods with truncated points, and a shrubby stalk; commonly called the Queen's Stock Gilliflower.

7. CHEIRANTHUS *foliis lanceolatis undatis, caule erecto indiviso*. Cheiranthus with waved spear-shaped leaves, and an upright undivided stalk; commonly called the Brumpton Stock Gilliflower.

8. CHEIRANTHUS *foliis lanceolatis, integerrimis, obtusis, incanis, ramis floriferis axillaribus, caule suffruticoso*. Cheiranthus with hoary, entire, spear-shaped, obtuse leaves, flower branches proceeding from the sides, and a shrubby stalk. The Purple, or Violet Stock Gilliflower.

9. CHEIRANTHUS *foliis lanceolatis, acutis, petiolatis, viridibus, caule suffruticoso*. Cheiranthus with spear-shaped acute leaves, which are green, and have foot-stalks, and a shrubby stalk; commonly called white Wall-flower.

10. CHEIRANTHUS *foliis conferto-capitatis, recurvatis, undatis*. *Lin. Sp. Pl. App.* 1198. Cheiranthus with leaves growing close together in heads, which are turned backward, and are waved.

11. CHEIRANTHUS *foliis linearibus, obtusis, incanis, integerrimis, siliquis acuminatis, caule suffruticoso*. Cheiranthus with narrow obtuse leaves, which are hoary, and very entire sharp pointed pods, and a shrubby stalk; or, Narrow-leaved Sea Stock Gilliflower.

12. CHEIRANTHUS *caule diffuso, foliis lanceolatis, sessilibus, floribus alternis*. Cheiranthus with a diffused stalk, spear-shaped leaves fitting close to the stalks, and flowers placed alternate; commonly called Dwarf, or *Virginia* Stock Gilliflower.

13. CHEIRANTHUS *foliis lanceolatis, subdentatis, retusis; siliquis apice subulatis*. *Hort. Upsal.* 187. Cheiranthus with spear-shaped leaves indented at bottom, and pods with awl shaped points.

14. CHEIRANTHUS *siliquarum apicibus tridentatis*. *Hort. Cliff.* 335. Cheiranthus with pods indented in three parts at the point.

The first sort grows naturally in the south of *France*, in *Spain*, and *Italy*; this is an annual plant, which rises a foot high, with an angular channelled stalk, which branches upward, garnished with long, narrow, green leaves, resembling those of the common Wall-flower, but are sharply sawed on their edges, fitting close to the stalks; at the extremity of the branches the flowers are produced in loose spikes; these are yellow, having four petals situated in the form of a cross, greatly resembling those of the common yellow Wall-flower, but have no scent, and are succeeded by long four-cornered pods filled with brown seeds.

The second sort grows naturally in *Hungary* and *Istria*; this is also an annual plant, rising with an upright stalk, nearly the same height as the other, but doth not branch out as that doth. The leaves are broader, smoother, and not sawed as those of the other. The flowers come out in loose spikes at the top of the stalks; these are small, and of a pale yellow without scent, and are succeeded by four-cornered pods like those of the former.

The third sort grows naturally upon old walls and buildings, in many parts of *England*, but is also cultivated in gardens for the fragrancy of its flowers. When these plants grow upon walls, or buildings, they seldom rise more than six or eight inches high, having very tough roots, and firm stalks; the leaves are short, and sharp pointed, and the flowers are small, but in gardens the plants will grow two feet high, and branch out wide on every side; the leaves are broader, and the flowers much larger, but, in severe winters, when these plants are frequently killed in the gardens, those upon walls will receive no injury, though they are much more exposed to the winds and frosts; for as these plants are stunted, and of a firmer texture, having but little juice, so the cold never affects them.

There is a variety of this with very double flowers, which is propagated in the gardens from slips, planted in the spring, which readily take root. There is one sort of this with variegated leaves, which is preserved in the gardens, but this is not quite so hardy as the plain.

The large, yellow, and bloody Wall-flower, are also supposed to be varieties of this, which have been improved by culture; and this I am inclinable to believe, because I have frequently observed many of them degenerate to the common sort; but although I have many years sowed the seeds of the common sort from the walls, yet I could never find them alter, except in being larger, but not any of them approached toward the other varieties. The large bloody Wall-flower will frequently rise with double flowers from seeds, if they are carefully saved from such plants as have five petals; and these double flowers may be propagated by slips, as the common sort, but the plants so raised will not produce such large spikes of flowers as those which are propagated by seeds.

There:

There is also another variety with double blood coloured flowers, whose petals are shorter and more numerous, approaching nearer to the common double Wall flower, but much larger. This is called the Old Bloody Wall-flower. It is propagated from slips in the same manner as the other double sorts.

The fourth sort grows naturally upon the *Alps*, and the mountains in *Italy*, where it rarely rises above six inches high; the leaves are very narrow, and the flowers grow in close spikes, at the end of the branches; they are of a pale yellow, or brimstone colour, and the necks of the petals are much longer than the empalement; they have but little scent. It was titled the Straw-coloured Wall-flower by the gardeners.

The sorts with single flowers produce seeds in plenty, from which the plants are raised, but the largest and deepest coloured flowers should always be selected for seeds, because from seeds carefully saved, there will be fewer of the plants degenerate. The seeds should be sown upon poor, or undunged soil, and when the plants are fit to remove, they should be transplanted into nursery beds, at about six inches distance each way. In the autumn they may be transplanted into the borders of the flower garden, where they are designed to remain, that the plants may get good roots before the frost comes on. This is the method which is commonly practised with these flowers; but if the seeds are sown upon poor land, where they are designed to remain, and not transplanted, they will thrive, and endure the frost in winter, much better than those which are removed; so that upon ruins or rubbish the seeds of these plants may be sown, where they will thrive and continue much longer than in good land; and in such places, if they are properly disposed, they will be very ornamental, and their flowers having a strong odour, will perfume the air to a considerable distance.

The fifth sort is now generally known by the appellation of *Ten Weeks Stock*, but it is what was formerly titled *Annual Stock Gilliflower*, which of late has been applied to another species, which is biennial. This rises with a round smooth stalk, about a foot high, dividing into several branches upward, garnished with spear-shaped hoary leaves, which are rounded at their ends, and placed without order, of unequal sizes; at the end of the branches the flowers are produced in loose spikes, which are placed alternate; the empalement of the flower is large, erect, and slightly cut into several acute parts at the top; the petals are large and heart-shaped, spreading open in form of a cross; the pods are long, cylindrical, and have a longitudinal furrow on one side, which opens into two cells, which are filled with flat roundish seeds, having a thin border.

Of this sort there are the red, the purple, the white, and striped, with single flowers, and the same colours with double flowers; these are very great ornaments in the borders of the flower garden, in the autumn, when there is a scarcity of other flowers; and if the seeds are sown at two or three different times, the flowers may be continued in succession near three months.

The first sowing should be about the middle of *February*, upon a very slender hot-bed, just to bring up the plants, which must be guarded against frost, and when they are fit to remove, they should be transplanted into nursery beds, at about three or four inches distance. In these beds they may remain six or seven weeks to get strength, and may then be planted into the borders of the flower garden, where they are to remain: if these are transplanted when there is rain, they will soon take root, after which they will require no farther care. From these early plants good seeds may be expected, therefore some of the finest plants of each colour should be preserved, and marked for seeds, which, when

ripe, should be carefully cut before the frost pinches it, and the stalks tied up in small bundles, and hung up in a dry room, till the pods are well dried, when the seeds may be rubbed out, and preserved for use.

The sixth sort is a biennial plant, though when the seeds are sown early in the spring, the plants often flower the following autumn; but these plants which are so forward, are often killed in winter; therefore it is much better to sow them in *May*, that the plants may not grow too rank the first season, so will live through the winter, and these will produce large spikes of flowers the second year.

This is commonly called the *Queen's Stock Gilliflower*, by the gardeners, and differs greatly from the other sorts by its branching stalk.

It rises with a strong stalk, which is almost shrubby, a foot high or more, having oblong, spear-shaped, hoary leaves, which are frequently waved on their edges; from the stalk is sent out many lateral branches, which are garnished with the same shaped leaves, but are smaller; these side branches are each terminated by a loose spike of flowers, each having an oblong woolly empalement, and consist of four large roundish petals, which are indented at the end. When these plants grow in dry rubbish, they will last two or three years, and become shrubby; but those with single flowers, are not worth preserving after they have perfected their seeds.

The flowers of this sort vary in their colour, some are of a pale red, others are of a bright red, and some are curiously variegated, but those of the bright red are generally most esteemed. There are always a great number of double flowers produced, if the seeds are well chosen, frequently three parts in four of the plants will be double; and as the plants divide into many branches, so they make a fine appearance during their continuance in flower.

The seventh sort is known by the title of *Brumpton Stock Gilliflower*, I suppose from its having been there first cultivated in *England*. This rises with an upright, strong, undivided stalk, to the height of two feet or more, garnished with long hoary leaves, which are reflexed, and waved on their edges; and at the top form a large head, out of the center of which arise the flower stalk; when the plant is strong, it is frequently a foot and an half long, putting out two or three short branches toward the bottom; the flowers of this kind have longer petals than any of the other sorts, and are formed into a pyramidal spike, but those with single flowers are loosely disposed, because the flowers having but few petals, do not fill the spike, as those do which are double; for these often have so many petals, as to render each flower as large and full as small *Roses*; and when they are of a bright red, make a noble appearance, being excelled by none of the flowery tribe; but the plants of this sort produce but one spike, in which it differs from all the other kinds, and being constant in this particular, I think is sufficient to establish a distinct species. This sort is generally biennial, though many times the plants are preserved longer, but they are always stronger the first year of their flowering, than they will be after; so that the seeds are sown every spring, to continue a succession of flowering plants.

The eighth sort is the white *Stock Gilliflower*, which is of longer duration than either of the other sorts; I have frequently had these plants live three or four years, which have become shrubby; their stalks have been three feet high, and branched out on every side, so as to appear like shrubs; these seldom send out flower-stalks from the center of the plant, but it is the side branches which produce the flowers, and these side branches divide into several other, which is not common to the other sorts. There are always many double flowers rise from seeds of this sort, when they are well chosen; some years I have scarce had enough single flowers to preserve their kind.

The ninth sort is known by the title of white Wall-flower, among the gardeners and florists. This rises with a greenish stalk a foot or little more high, dividing into many branches, garnished with narrow, smooth, spear-shaped leaves, of a lucid green, of thicker consistence than those of any of the other sorts, and come out without any order; they are near three inches long, and about half an inch broad in the middle; the flowers are produced in loose spikes at the end of the branches, which are of a pure white, and have a great fragancy, especially in an evening, or in cloudy weather; the flowers are succeeded by oblong compressed pods, like those of the other species. There is a variety of this with double flowers, which is propagated by cuttings or slips, in the same manner as the double Wall-flowers; but these plants require protection from great rains, and frost in winter; so if they are planted in pots, and placed under a common frame in winter, where in mild weather they may enjoy the open free air, and covered from hard rains and frost, they may be preserved several years.

Sometimes many of the double flowers will come up from seeds, but not so frequent as some of the other sorts. I have frequently raised more than one hundred plants in a season, without obtaining one double flower, and from the seeds of these, have the following year had more than half the plants with double flowers: but this is not to be expected often.

The seeds of the tenth sort were sent me by Dr. *Linnaeus*, from *Upsal* in *Sweden*. This plant rises about nine inches high, with an herbaceous swelling stalk; the leaves are produced in clusters at the top, which are very hoary, waved on their edges, have obtuse points, and set very close to the stalk; the flowers are produced in slender spikes, from the side of the stalk; these are purple, but not so fragrant as many of the other sorts; the pods are woolly, and recurve backward at the end. This is an accidental variety, which has sprung up with me from seeds of the Queen's Stock Gilliflower.

All these sorts flower in *May* and *June*, at which time they are the greatest ornament to the flower garden, therefore deserve our care to cultivate them as much as any of the flowery tribe; but in order to have many double flowers, there must be great care taken in the choice of plants for seeds, without which there can be little hopes of having these flowers in perfection. The only sure way of getting many double flowers, is to make choice of those single flowers which grow near many double ones; for I have always found those seeds which have been saved from plants growing in beds close to each other, where there happened to be many double flowers among them, have produced a much greater number of plants with double flowers, than those which have been saved from plants of the same kinds, which grew single in the borders of the flower garden; so that there should be a small bed of each kind planted on purpose to save seeds in the flower nursery; or if they are sown there, and the plants thinned properly when they are young, they need not be transplanted; for I have always observed the plants which have come up from scattered seeds, that have not been transplanted, endure the frost much better than those which have been removed; for as these plants send out horizontal roots, which spread near the surface of the ground, so when they are transplanted, the roots are forced downward, out of their natural direction; and if their stalks were grown tall before removal, they are generally planted low in the ground, whereby they are apt to rot, if the ground is moist, or the winter should prove wet; therefore where they can be left unremoved, there will be a better chance of their living through the winter; and as these beds need not be of great extent, so when the winter proves very severe, it will not be much trouble or expence to arch the beds over with hoops, and cover them with mats in frosty weather, by which method they may be always preserved.

The time for sowing of the seeds before mentioned, must be understood to be for the sorts which are biennial; for the annual, or Ten Weeks Stock Gilliflower, should be for the first season, sown in *February*, as was before directed; and to succeed these, there should be another parcel sown in *March*; and those who are curious to continue these flowers late in the autumn, should sow a parcel of the seed the latter end of *May*; and if these last sown plants are upon a warm border, where they may be covered, by placing glasses before them in winter, or covering them with mats, they may be continued in flower till *Christmas*; and if some of the plants are potted, and put under a hot-bed frame in autumn, where they may enjoy the open air in mild weather, and screened from hard rains and frost, these plants may be kept flowering all the winter, when the winters are not very severe.

There are some who propagate the double Stock Gilliflower by slips and cuttings, which will take root when properly managed; but the plants so raised are never so strong as those which come from seeds, and their spikes of flowers are always very short, so have not half the beauty; therefore it is not worth while to practise this method, unless for those sorts which cannot be obtained with any certainty from seed.

The eleventh sort grows naturally in the south of *France*, in *Spain* and *Italy*, near the sea coast. This rises near a foot high, with a ligneous stalk, dividing into many small branches, garnished with narrow hoary leaves, which are entire, and rounded at their extremity; the flowers are produced in loose spikes at the end of the branches, which are smaller than either sort before mentioned, of a bright red at their first appearing, but fade to a purple before they fall off. The stalks, leaves, and the whole plant is very white, and by its woody stalks hath the appearance of a perennial plant, but it constantly perishes in autumn. The seeds of this sort should be sown in autumn, upon a warm border, where the plants are designed to remain; when the plants come up, they will require no farther care but to keep them clean from weeds, and thin them where they come up too close. These autumnal plants will flower early in *June*, so will produce good seeds; but those which are sown in the spring will flower in *July* and *August*, so that from these there cannot be any certainty of having ripe seeds; however, by sowing the seeds at two or three different seasons, there may be a succession of flowers continued for three or four months.

The twelfth sort is commonly sown in gardens, sometimes as an edging for borders, but more generally in patches between taller growing flowers: it is titled sometimes Dwarf Annual Stock Gilliflower, and by others it hath the appellation of *Virginia* Stock Gilliflower. This seldom rises more than six inches high, sending out many branches from the root, which spread near the ground, and grow irregular; these are garnished with spear-shaped leaves, rounded at their ends, and sit close to the branches at their base; the flowers come out in loose spikes at the end of the branches, which are of a purple colour, composed of four petals in form of a cross, and are succeeded by slender pods, like those of the other sorts.

The thirteenth sort rises near two feet high, sending out many upright branches from the bottom, which are thinly garnished with spear-shaped leaves, the lower ones being a little indented; the flowers come out single, at great distances from each other, toward the upper part of the branches; these are small, of a purplish red colour, and soon fall away, being succeeded by long taper pods, with awl-shaped points. This is an annual plant, which may be treated in the same manner as the last mentioned sort; but as it hath little beauty, it is not often cultivated in gardens.

The fourteenth sort grows naturally on the sea coasts in *Italy, Spain and Portugal*. This is also an annual plant, which branches out from the root, into many declining stalks; the lower leaves are about two inches long, and three quarters of an inch broad, very deeply sinuated on their edges, and hoary, those upon the stalks are of the same form, but much smaller; the flowers are produced from the side of the stalks singly, and at the top in loose spikes; the empalements of the flowers are covered with a white down, as are also the ends of the branches; the flowers are purple, composed of four leaves placed in form of a cross; the pods are about three inches long, taper, woolly, and at their ends are divided into three parts, which spread into a triangle. If the seeds are sown in autumn, on a warm border, the plants will live through the winter, and these will flower early in *June*, so from these good seeds may be obtained.

CHELIDONIUM. *Tourn. Inst. R. H. 231. tab. 116. Celandine and Horned Poppy.*

The Characters are,

The flower hath four large roundish petals; in the center is situated a cylindrical germen, attended by a great number of stamina. The germen afterward becomes a cylindrical pod, with one or two cells, opening with two valves, and filled with many small seeds.

The Species are,

1. CHELIDONIUM *pedunculis umbellatis. Lin. Gen. Plant. 505.* Celandine with an umbellated foot-stalk; or the common Celandine.

2. CHELIDONIUM *foliis quinque lobatis, lobis angustis acutè laciniatis.* Celandine whose leaves are composed of five narrow lobes, which are cut into many acute segments.

3. CHELIDONIUM *pedunculis unifloris, foliis amplexicaulibus sinuatis, caule glabro. Lin. Sp. Plant. 506.* Celandine with single flowers on the foot-stalks, sinuated leaves which embrace the stalks, and a smooth stalk; or, Yellow horned Poppy.

4. CHELIDONIUM *pedunculis unifloris, foliis sessilibus pinnatifidis, caule hispido. Lin. Sp. Plant. 506.* Celandine with single flowers upon the foot-stalks, leaves set close to the stalks which have winged points, and a rough stalk. Hairy Glaucium, or horned Poppy, with a scarlet flower.

5. CHELIDONIUM *pedunculis unifloris, foliis semiamplexicaulibus, dentatis, glabris.* Celandine with foot-stalks having a single flower, and smooth indented leaves, which half embrace the stalks. Smooth horned Poppy with a scarlet flower.

6. CHELIDONIUM *pedunculis unifloris, foliis pinnatifidis, linearibus, caule lævi. Lin. Sp. Plant. 506.* Celandine with single flowers upon the foot-stalk, many pointed narrow leaves, and a smooth stalk. Horned Poppy with a Violet-coloured flower.

The first sort is the common Celandine which is used in medicine, and is esteemed aperitive and cleansing, opening obstructions of the spleen and liver; and is of great use in curing the jaundice and scurvy. This grows naturally on the side of banks, and in shady lanes in many parts of *England*, so is seldom cultivated in gardens; for if the seeds are permitted to scatter, the ground will be plentifully stored with plants to a considerable distance. It flowers in *May*, at which time the herb is in the greatest perfection for use.

The second sort is found growing in a few particular places, where the seeds have been formerly sown, or the plants cast out of gardens. This is by some supposed to be only a variety of the first, but I have propagated this by seeds above thirty years, and have constantly found the plants the same, without variation. The leaves of this are divided into narrow long divisions, which are deeply jagged on their edges in acute segments, and the petals of the flower are cut into many parts, in which it differs from the

first. If the seeds of this sort are permitted to scatter, they will fill the ground with plants. They both delight in shade.

The third sort is known by the title of Horned Poppy; it was so called from the resemblance which the flower bears to the Poppy, and the long seed vessels which is like a horn. It grows naturally upon the sandy and gravelly shores by the sea, in many parts of *England*, from whence the seeds have been brought into gardens, where it is sometimes allowed to have place for the sake of variety. This plant abounds with a yellow juice which flows out from every part, when broken. It sends out many thick gray leaves, which are deeply jagged; the stalks are strong, smooth, and jointed, which rise near two feet high, and divide into many branches. These are garnished with leaves at each joint; those on the lower part of the stalks are long, broad, and deeply jagged, but the upper leaves are entire and almost heart-shaped: they closely embrace the stalks with their base, from the bosom of the leaves come out the short foot-stalks of the flowers, each supporting one large yellow flower, composed of four broad petals, which spread open like the Garden Poppy, in the center of which are a great number of yellow stamina, surrounding a long cylindrical germen, crowned by a narrow pointed stigma, which is permanent, remaining upon the top of the horned seed vessel, which grows nine or ten inches long, having a longitudinal furrow on one side, where it opens when ripe, and lets out the seeds. This is a biennial plant, which flowers the second year, and perishes soon after the seeds are ripe.

If the seeds of this plant are permitted to scatter, they will fill the ground near them with plants, so that it is not a proper plant for a flower garden; but if a few of the seeds are scattered about in rock work, the plants will rise without trouble, and in such places will have a pretty effect.

The fourth sort grows naturally in *Spain, Italy*, and some parts of *Germany*. The leaves of it are deeply jagged and hairy, of a pale green, growing close to the stalks: those at the bottom lie on the ground, and are broader than those above. The stalks are a foot and an half high, having a single jagged leaf placed at each joint; these have many divisions, from their origin to the point, which is extended longer than the lower leaves. The flowers come out from the bosom of the leaves; these are composed of five broad obtuse petals, which are of a dark scarlet colour, and soon fall off. In the center of each is situated an oblong germen, having no style, but supports a bifid stigma; this is attended by a great number of short stamina, terminated by obtuse summits. The germen afterward becomes a long taper pod, on the apex of which the bifid stigma remains, sitting on the middle partition, which divides the pod into two cells, which are filled with small seeds. It flowers in *June* and *July*, and the seeds ripen in autumn. As the flowers of this plant are of but short duration, so they do not make any considerable figure; but the foliage of the plant is very elegant, and might be introduced by way of ornament to furniture to great advantage, being very picturesque; it may also be wrought into patterns for silks, and painted upon porcelaine, where it would have a very good effect. If the seeds of this plant are sown in the autumn, they will more certainly grow, than those which are sown in the spring, which frequently in dry seasons do not come up the same year, or at least not before autumn; whereas those sown in autumn come up in the spring, and these plants come early to flower, so that good seeds may always be obtained from them. They should be sown where the plants are to remain, and will require no other care but to thin them where they are too close, and keep them clean from weeds.

The fifth sort differs from the fourth, in having broader leaves, which are not so deeply divided; the whole plant

is smooth, and the flowers are larger, but are of the same colour: this is also an annual plant, and requires the same treatment as the last.

The sixth sort grows naturally among the corn, in some parts of *England*. This is also an annual plant, whose seeds should be sown in autumn, for those which are sown in the spring seldom succeed. The leaves of this sort are finely jagged, and divided into narrow segments, somewhat like those of Buckhorn Plantain; they are smooth, of a lucid green, and are commonly opposite. The stalks rise little more than a foot high, dividing into two or three branches upward, which are garnished with small leaves of the same form as those below. The flowers are sustained by slender foot-stalks, which come out from the wings of the leaves; these are composed of four obtuse petals, of a Violet colour, in the center of which is situated a cylindrical germen, attended by a great number of stamina; the germen afterward becomes a long cylindrical pod, like those of the other species. The flowers of this plant are very fugacious, seldom lasting above three or four hours before the petals drop off, especially in clear weather. If the seeds are permitted to scatter, the plants will come up without care as the others.

CHELONE. *Tourn. Art. R. S. 1706. tab. 7. fol. 2.*

The Characters are,

The flower is of the ringent kind, having a short cylindrical tube, which is swollen at the chaps, where it is oblong, convex above, and plain below; the mouth is almost closed. It hath four stamina, the two side ones being a little longer than the other. It hath an oval germen, which afterward becomes an oval capsule having two cells, which are filled with flat roundish seeds having a border.

The Species are,

1. CHELONE *foliis lanceolatis, acuminatis, sessilibus obsolete serratis, radice reptatrice*. Chelone with pointed, spear-shaped leaves, set close to the stalks, with small serratures on their edges, and a creeping root; or, Chelone of *Acadia*, with a white flower.

2. CHELONE *foliis lanceolatis, obliquis, petiolatis, oppositis, marginibus acutè serratis*. Chelone with oblique, spear-shaped leaves, growing opposite on foot-stalks, and their borders sharply sawed. Chelone with a purple flower.

3. CHELONE *caule foliisque hirsutis*. *Lin. Sp. Plant. 611.* Chelone with hairy stalks and leaves.

The first sort grows naturally in most parts of *North America*. This is called by *Joscelin*, in his *New England Rarities*, the Humming Bird tree. It hath a pretty thick jointed root, which creeps under ground to a considerable distance, sending up smooth channelled stalks, which rise about three or four feet high, garnished with two leaves at each joint, standing opposite without foot-stalks; they have small serratures on their edges, which scarcely appear. The flowers grow in a close spike at the end of the stalks, they are white, and have but one petal, which is tubular, and narrow at the bottom, but swells upward, almost like the Foxglove flower; the upper side is bent over and convex, but the under is flat, and slightly indented in three parts at the end. It flowers in *August*, and when the autumn proves favourable, the seeds will ripen in *England*; but as the plants propagate so fast by their creeping roots, the seeds are seldom regarded. The best time to transplant the roots is in autumn, that they may be well established in the ground before the spring, otherwise they will not flower so strong, especially if the season proves dry. They will thrive in almost any soil or situation, but their roots are apt to creep too far, if they are not confined, and then their stalks stand so far distant from each other, as to make but little appearance; therefore they should be planted in pots, which will confine their roots, so that in each pot there will be eight

or ten stalks growing near each other, when they will make a tolerable good appearance. This plant is very hardy, so is not injured by cold, but it must have plenty of water in hot weather.

The second sort grows naturally in *Virginia*. The roots of this do not creep so far as those of the first, the stalks are stronger, and the leaves much broader, and are oblique; they are deeply sawed on their edges, and stand upon short foot-stalks: the flowers are of a bright purple colour, so make a finer appearance. This flowers at the same time with the first, and is propagated by parting of the roots in the same manner.

The third sort I received from *New England*, where it grows naturally: this is near to the first sort, but the stalks and leaves are very hairy, and the flower is of a pure white. It flowers at the same time with the former, and requires the same treatment.

As these plants flower in the autumn, when there is a scarcity of other flowers, so it renders them more valuable, especially the second sort, whose flowers make a very pretty appearance when they are strong; and if some of them have a shady situation in the summer, they will flower later in the autumn.

CHENOPODIA-MORUS. See Blitum.

CHENOPODIUM. *Tourn. Inst. R. H. 506. tab. 288.* Goose-foot, or Wild Orach.

The Characters are,

The flower hath no petal, but in the center it hath five stamina placed opposite to the leaves of the empalement. It hath a round germen, which afterward becomes a five-cornered fruit inclosed in the empalement, containing one roundish depressed seed.

The Species are,

1. CHENOPODIUM *foliis triangulari-sagittatis, integerrimis*. *Hort. Cliff. 84.* Goose-foot, with arrow-shaped triangular leaves which are entire; called *English Mercury*, All Good, or Good Henry.

2. CHENOPODIUM *foliis integerrimis rhombo-ovatis, floribus conglomeratis*. *Flor. Suec. 216.* Goose-foot with entire oval rhomboidal leaves, and flowers growing in clusters. Stinking Orach.

3. CHENOPODIUM *foliis lineari-lanceolatis, planis, integerrimis*. *Hort. Cliff. 86.* Goose-foot with narrow spear-shaped leaves, which are plain and entire; commonly called *Belvedere*, or Summer Cypress.

4. CHENOPODIUM *foliis oblongis, sinuatis, racemis nudis multifidis*. *Hort. Cliff. 84.* Goose-foot with oblong sinuated leaves, and naked multifid spikes of flowers; commonly called *Oak of Jerusalem*.

5. CHENOPODIUM *foliis lanceolatis, dentatis, racemis foliatis simplicibus*. *Hort. Cliff. 84.* Goose-foot with spear-shaped indented leaves, and single leafy spikes of flowers; commonly called *Oak of Cappadocia*.

6. CHENOPODIUM *foliis lanceolatis, dentatis, caule fruticoso*. Goose-foot with spear-shaped indented leaves, and a shrubby stalk; called *Shrubby Mexican Orach*.

7. CHENOPODIUM *foliis linearibus, teretibus, carnosis, caule fruticoso*. *Hort. Cliff. 86.* Goose-foot with narrow, taper, fleshy leaves, and a shrubby stalk; called *Stone Crop tree*, or *shrubby Glasswort*.

There are many other species of this genus, some of which grow naturally on dunghills, and the side of ditches, in most parts of *England*, where they often become very troublesome weeds; for which reason, I have not enumerated them here.

The first sort is found growing naturally in shady lanes in many parts of *England*, but it is very doubtful if the seeds have not been cast out of gardens originally, because this plant was formerly cultivated in kitchen gardens for use; and in some of the northern counties, the people still pre-

serve it in their gardens as an esculent herb; which in the spring season, they dress in the same manner as Spinage, for which it is a substitute. But, as the latter is a much better herb, so it has obtained the preference very justly, in all the countries where the culture of the kitchen garden is understood and practised.

The second sort is very common upon dunghills and in gardens, in most parts of *England*: it is seldom cultivated, except in some physick gardens; for the markets in *London* are supplied with it by the herbwomen, who gather it in the places where it grows wild.

The third sort is sometimes cultivated in gardens; it is a beautiful plant, which is naturally disposed to grow very close and thick, and in as regular a pyramid as if cut by art. The leaves are of a pleasant green; and were it not for that, it hath so much of the appearance of a Cypress tree, that at some distance it might be taken for the same, by good judges: the seeds should be sown in autumn, and in the spring, when the plants are come up, they may be planted into pots of good earth, and kept supplied with water in dry weather: these pots may be intermixed with other plants to adorn court yards, &c. where they will appear handsome, until their seeds begin to swell and grow heavy, which weigh down and displace the branches; at which time the pots should be removed to some abject part of the garden, to perfect their seeds; which, if permitted to fall upon the ground, will come up the next spring; so that you need be at no more trouble in propagating these plants, but only to transplant them where you intend they should grow.

The fifth sort was formerly used in medicine; but although it still continues in the catalogue of simples annexed to the *London Dispensatory*, yet is very seldom used at present. This plant may be propagated by sowing the seeds in an open border of good earth in the spring, where it will perfect its seeds in autumn; which, if permitted to shed upon the ground, will arise as the former.

The fourth sort was brought from *America*, where the seeds are called worm seed; I suppose from some quality contained in it, which destroys worms in the body.

This is propagated by sowing the seeds in the spring, as the before-mentioned sorts, and will perfect its seed in autumn; after which, the plant decays to the ground: but if the root be preserved in shelter under a common frame in winter, the stalks will rise again the following spring.

The leaves of this plant emit a very strong odour when bruised, somewhat like those of the Ambrosia, for which the plants are preserved in gardens, for the flower hath no beauty. This plant grows naturally in most parts of *North America*, where it is generally much used to destroy worms in children. It sends up several stalks from the root, which rise about two feet high, garnished with oblong leaves a little indented on their edges, of a light green, and placed alternately on the stalks; the flowers come out from the wings of the leaves, on the upper part of the branches, in loose spikes: these appear in *July*, and the seeds ripen in *September*; which, if permitted to scatter, the plants will come up in plenty the following spring.

The seeds of all the species of this genus will succeed best, if they are sown in autumn; for when they are sown in the spring, they frequently lie a whole year before the plants come up: therefore where the seeds of any of them scatter, the plants will come up much better than those which are sown by hand.

The fifth sort is annual: this also grows naturally in *North America*, from whence I have frequently received the seeds. It is also a native of many of the warm countries in *Europe*. It hath many oblong leaves at the bottom, which are deeply sinuated on both sides, somewhat like those of the

Oak tree, from whence it received the title of Oak of *Jerusalem*. These are purple on their under side, and when bruised, emit a strong odour. The stalks rise about eight or nine inches high, dividing into several smaller branches. The lower part of these is garnished with leaves of the same shape with those below, but are smaller. The flowers grow in naked loose spikes, divided into many parts: they are small, herbaceous, and are succeeded by small round seeds. This sort flowers in *June* and *July*, and the seeds ripen in autumn.

The sixth sort hath leaves very like those of the fourth, and have the same scent; but it hath a shrubby stalk, which rises five or six feet high, and divides into many branches. It is a native of *America*, and must be housed in the winter, for it will not live through the winter in *England* in the open air. It is easily propagated by cuttings during any of the summer months, which, if planted in a shady border and duly watered, will soon take root; and then may be planted in pots, and placed in the shade till they have taken new root, after which they may be placed with other hardy exotick plants in a sheltered situation during summer; and when the frosts come on, they must be removed into the green-house, but they only require protection from hard frosts, so should have plenty of air in mild weather.

The seventh sort grows naturally on the sea coast in *Devonshire* and *Cornwall*, but is propagated in the nurseries for sale. This sends out from the root many slender shrubby stalks, which rise five or six feet high, and divide upward into smaller ligneous branches, which grow erect, and are closely garnished with small taper succulent leaves, like those of the lesser Houseleek; these remain all the year, for which the shrub is chiefly valued. The flowers are small, and have no beauty. This is propagated by suckers, which it sends out from the roots in plenty. It may be transplanted either in spring or autumn, and will thrive almost any where.

CHERRY-LAUREL. See *Padus*.

CHERRY-TREE. See *Cerasus*.

CHERVIL. See *Chærefolium*.

CHESTNUT. See *Castanea*.

CHESTNUT, the Horse. See *Esculus*.

CHIONANTHUS. *Lin. Gen. Plant.* 21. The Fringe or Snowdrop tree.

The Characters are,

The flower is of one petal, divided into four very long narrow segments, which are erect. It hath two short stamina inserted in the tube of the petal. In the center is placed the oval germen, which afterward becomes a round berry, with one cell inclosing one hard seed.

We have but one Species of this plant in the *English* gardens at present, viz.

CHIONANTHUS *pedunculis trifidis trifloris*. *Lin. Sp. Pl.* 3. Snowdrop tree, or Fringe tree, with trifid foot-stalks supporting three flowers.

This shrub is common in *South Carolina*, where it grows by the side of rivulets, and seldom is more than ten feet high: the leaves are as large as those of the Laurel, but are of a much thinner substance; the flowers come out in *May*, hanging in long bunches, and are of a pure white, from whence the inhabitants call it Snowdrop tree; and, from the flowers being cut into narrow segments, they give it the name of Fringe tree: after the flowers have fallen away, the fruit appears, which becomes a black berry, about the size of Sloes, having one hard seed in each.

This tree is now more common in the curious gardens in *England*, than it was a few years since; there having been many young plants raised from the seeds, which have been brought from *America* lately: there have also been some plants

plants propagated by layers, though there is great uncertainty of their taking root, which they seldom do in less than two years: nor will they ever take root, unless they are well supplied with water in dry weather.

The best way to obtain good plants, is from the seeds, which must be procured from *America*, for they never have produced any fruit in this country: the seeds should be sown in small pots filled with fresh loamy earth soon after they arrive, and should be placed under a hot bed frame, where they may remain till the beginning of *May*, when they must be removed to a situation exposed to the morning sun, and screened from the sun in the middle of the day; for as these seeds lie in the ground a whole year before the plants will come up, so they should not be exposed to the sun the first summer, but the following autumn they should be removed, and placed under a frame, to protect the seeds from being injured by the frost. And if the pots are plunged into a moderate hot-bed the beginning of *March*, it will bring up the plants much sooner than they will otherwise rise; by which means they will get more strength the first summer, and be better able to resist the cold of the next winter: while these plants are very young, they will be in danger of suffering by severe frost; but, when they have obtained strength, they will resist the greatest cold of our climate in the open air; therefore for the two or three first winters, it will be proper to keep them under shelter. In the spring, before they begin to shoot, they should be shaken out of the pots, and carefully separated so as not to break off their roots, and each planted in a small pot, filled with light loamy soil, and plunged into a very moderate hot-bed, just to forward the taking fresh root; then they should be gradually inured to the open air, and during the following summer, the pots should be plunged into the ground, to prevent the earth from drying, in a situation where they may enjoy the morning sun, but screened from the great heat at noon. The autumn following, they should be again placed under a hot-bed frame to screen them from frost, but they should enjoy the free air at all times, when the weather is mild. The *April* following, the plants may be shaken out of the pots, with the ball of earth to their roots, and planted where they are designed to remain.

This shrub delights in a moist, soft, loamy soil, and if it is planted in a sheltered situation, will endure the cold of our winters very well in the open air; but in dry land, it is very subject to decay in warm seasons.

In the places where this shrub grows naturally, it produces great quantities of flowers, so that they seem covered with snow, which gave occasion to the inhabitants for titling it Snowdrop tree; but in *England* it flowers but sparingly, and the bunches of flowers are generally produced very thinly, so that they make but little appearance.

CHIRONIA. *Lin. Gen. Plant.* 227.

The Characters are,

The flower hath one petal, with a roundish tube the size of the empalement, which is divided into five equal parts above: it hath five short broad stamina, which are fastened to the top of the tube. It hath an oval germen, situated in the center, which after-ward becomes an oval capsule with two cells, filled with small seeds.

The Species are,

1. *CHIRONIA frutescens, capsulifera.* *Lin. Sp. Plant.* 190. Shrubby Chironia bearing capsules.

2. *CHIRONIA frutescens baccifera.* *Lin. Sp. Plant.* 190. Shrubby berry-bearing Chironia.

These plants grow naturally at the *Cape of Good Hope*.

The first sort has a fibrous root, which spreads near the surface of the ground. The stalks are round, and inclining to be ligneous, but are of a very soft texture; these grow from two to three feet high, sending out several branches which grow erect; these are garnished with succulent leaves,

which are an inch or more in length, and an eighth part of an inch broad, ending in an obtuse point. At the ends of each shoot the flowers are produced, which are tubulous, and spread open at the top like those of *Periwinkle*; these are of a bright red colour, and when there are a large number of the flowers open on the same plant, they make a very fine appearance. In the center of the flower is placed an oval germen, upon which there is fixed a recurved style, terminated by a blunt stigma; this is surrounded by five incurved stamina, each supporting a large summit. When the flowers fall away, the germen becomes an inflated capsule, which is filled with small seeds. The flowers are produced from *June* to autumn, and the seeds ripen in *October*. This plant should be placed in an airy glass case in winter, where it may enjoy a dry air and much sun, but will not thrive in a warm stove, nor can it be well preserved in a common green-house, because a damp moist air will soon cause it to rot.

The seeds of this plant should be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed; sometimes the seeds will lie a long time in the ground, so that if the plants do not appear the same season, the pots should not be disturbed, but preserved in shelter till the following spring, and then plunged into a fresh hot-bed, which will bring up the plants in a short time if the seeds are good. When the plants are fit to remove, they should be transplanted into small halfpenny pots, four or five in each pot, then plunge the pots into a moderate hot-bed, where they must have a large share of air in warm weather, to prevent their drawing up weak; when the plants have obtained some strength, they must be gradually inured to bear the open air; but when they are exposed abroad, if there should happen much rain, the plants must be screened from it, otherwise it will cause them to rot; they must be placed in a warm sheltered situation in summer, and mixed with such other plants as require but little water; where they may remain till autumn, when they must be placed in a dry airy glass case, and in the winter should have very little wet, but must enjoy the sun as much as possible, and in mild weather should have fresh air admitted to them, but must be protected from frost; with this management, the plants will thrive and produce flowers the second year from seed; the cuttings of this sort will take root, if properly managed.

The second sort rises with a firmer stalk than the first, which is round, jointed, and divides upward into a greater number of branches, which are garnished with short, narrow, pretty thick succulent leaves. The flowers are produced at the end of the branches, in the same manner as the first, which are of a fine red colour, but not half so large as those of the first; when these fall away, they are succeeded by oval pulpy berries, in which are included many small seeds. This sort continues flowering great part of summer and autumn, and in warm seasons the seeds will ripen in *England*.

It is propagated by seeds in the same manner as the former sort, and the plants require the same treatment.

CHONDRILLA. *Lin. Gen. Pl.* 815. Gum Succory.

The Characters are,

The flower is composed of many hermaphrodite florets, which are uniform, included in a cylindrical scaly empalement; these have one petal, which is stretched out on one side like a tongue; they have each five short hairy stamina. The germen is situated under the floret, which after-ward becomes a single, oval, compressed seed, crowned with a single down, and inclosed in the empalement.

We have but one Species of this genus, viz.,

CHONDRILLA. *Lin. Hort. Cliff.* 383. Gum Succory.

This plant grows naturally in *Germany*, *Helvetia*, and *France*, on the borders of the fields, and is seldom preserved in gardens, because the roots are very apt to spread, and become troublesome weeds; and the seeds having down on

thei.

their tops, are carried by the wind to a great distance, so that the neighbouring ground is filled with the plants; the roots of this strike deep into the ground, and spread out with thick fibres on every side, each of which, when cut, or broken into many parts will shoot up a plant, so that when this plant hath obtained possession of the ground, it is very difficult to root out. The root sends out a great number of slender stalks, which at the bottom are garnished with oblong sinuated leaves, but those above are very narrow and entire. The flowers are produced from the side and top of the branches, which are like those of Lettuce, and are succeeded by seeds of the same form, crowned with down. It flowers in July, and the seeds ripen in September.

CHRISTMAS FLOWER, or Black Hellebore. See Helleborus.

CHRISTOPHORIANA. See Aſtea.

CHRISANTHEMOIDES OSTEOSPERMON. See Osteospermum.

CHRYSANTHEMUM. *Tourn. Inst. R. H. 491. tab. 280.* Corn Marigold.

The Characters are,

It hath a compound flower; the rays are composed of female florets, which are extended on one side like a tongue; these have an oval germen. The hermaphrodite flowers which compose the disk, are funnel-shaped, divided into five parts at the top; these have five short hairy stamina and an oval germen, which afterward becomes a single, oblong, naked seed.

The Species are,

1. CHRYSANTHEMUM *foliis amplexicaulibus, supernè laciniatis, infernè dentato-ferratis. Hort. Cliff. 416.* Corn Marigold with leaves embracing the stalks, the upper being jagged, and the lower indented like a saw.

2. CHRYSANTHEMUM *foliis amplexicaulibus, oblongis, supernè ferratis, infernè dentatis. Hort. Cliff. 416.* Corn Marigold with oblong leaves embracing the stalks, the upper ones being sawed, and the lower indented; or, Greater wild or Ox-eye Daisy.

3. CHRYSANTHEMUM *foliis lanceolatis, supernè ferratis, utrinque acuminatis. Hort. Cliff. 416.* Corn Marigold with spear-shaped leaves, those above being sawed, and pointed at both ends.

4. CHRYSANTHEMUM *foliis imis spatulato-lanceolatis, serratis, summis linearibus. Sawv. Monsp. 87.* Corn Marigold, with lower leaves pointed like a spear-shaped spatula, and sawed, and the upper ones linear.

5. CHRYSANTHEMUM *foliis linearibus, subintegerrimis. Sawv. Monsp. 87.* Corn Marigold with narrow leaves, which are entire.

6. CHRYSANTHEMUM *foliis pinnatifidis, laciniis parallelis, integris, caule unifloris. Lin. Sp. Plant. 389.* Corn Marigold with many pointed leaves, whose segments are parallel and entire, and one flower on each stalk.

7. CHRYSANTHEMUM *foliis pinnatis, inciso-ferratis, caule multifloro. Prod. Leyd. 174.* Corn Marigold with winged leaves with sawed segments, and many flowers upon a stalk.

8. CHRYSANTHEMUM *foliis pinnatifidis, incis, extrorsum latioribus. Hort. Cliff. 416.* Corn Marigold with wing-pointed cut leaves, whose exterior parts are broadest.

9. CHRYSANTHEMUM *foliis imis palmatis, foliolis linearibus, pinnatifidis. Sawv. Monsp. 304.* Corn Marigold, whose lower leaves are palmated, and the smaller ones linear, and ending in many points.

10. CHRYSANTHEMUM *fruticosum, foliis linearibus dentato-trifidis. Hort. Cliff. 417.* Shrubby Corn Marigold with narrow leaves, having three points, and indented.

11. CHRYSANTHEMUM *flesculis omnibus uniformibus, hermaphroditis. Hort. Cliff. 417.* Corn Marigold, whose florets are all uniform and hermaphrodite.

The first sort is the common Corn Marigold, which grows

naturally amongst the Corn, and in the borders of the Corn fields in divers parts of *England*, so is rarely admitted into gardens, but we have inserted this and the next to introduce the other species.

The second sort is the greater Daisy, which stands in the list of the medicinal plants in the *College Dispensatory*; this grows naturally in moist pastures, almost every where in this country. It rises with stalks near three feet high, which are garnished with oblong indented leaves, that embrace the stalks with their base. The stalks are each terminated by one white flower, shaped like those of the Daisy, but four times as large. It flowers in June.

The third sort grows naturally in *North America*; the roots of this plant creep far under the surface, and send up strong stalks more than four feet high, garnished with long sawed leaves, ending in points; these stalks divide upward into many smaller, each being terminated by a large, white, radiated flower; these appear the end of August and September; it multiplies very fast by its creeping roots, and will thrive in any soil or situation.

The fourth sort grows naturally upon the *Alps*, and other mountainous places; this sends up a single stalk a foot high, garnished with entire leaves above, but the under leaves are sawed on their edges. The stalk is terminated by one large white flower, shaped like those of the third sort. This sort may be propagated by seeds, which, if sown in a shady border, will come up in about six weeks, and the plants when fit to remove, may be transplanted into a shady border where they are to remain, and will require no other care but to keep them clean from weeds.

The fifth sort grows naturally about *Montpelier*; it hath a perennial root, from which spring up many narrow grass-like leaves, and between them, stalks which rise a foot and an half high, garnished with leaves of the same sort as those below. The stalks are each terminated by one large white flower, with a yellow disk, or middle. It is propagated by parting of the roots; the best time for this is in autumn, that the plants may get good root before winter.

The seventh sort grows naturally on the *Alps*, or other mountainous places in *Germany*; this sends out upright stalks, which are garnished with leaves cut into many parallel segments, somewhat like those of Buckshorn Plantain. The stalks rise a foot and an half high, and are each terminated by a single flower of the same form with those of the last; it hath a perennial root, and may be propagated in the same manner as the other.

The eighth sort hath been many years cultivated in the gardens for the beauty of its flowers; of this there are single and double with white flowers, and the same with yellow. As these do not differ from each other in any respect except in the colour of their flowers, therefore they are generally esteemed but one species; but this is constant, for I have never found the seeds saved from the white, produce plants with yellow flowers, nor those of the yellow produce white.

There is also a variety of these colours with fistular florets, which has accidentally risen from seeds of the other; these are generally titled Quilled-leaved Chrysanthemums, but as the seeds saved from these degenerate to the common sorts, so they do not merit a particular denomination.

These plants are always esteemed as annual, so the seeds are usually sown upon a slender hot bed in the spring, and the plants treated in the same manner as the *African Marigold*, for the culture of which we shall refer the reader to that article; but as the plants which rise from seeds, do many of them produce single flowers, although the seeds are saved from the best double flowers, therefore many persons now propagate these plants from cuttings, whereby they continue the double sorts only; these cuttings, taken from the plants the beginning of September, and planted in

pots, will readily take root; and if they are placed under a hot bed frame to screen them from the frost in winter, letting them have free air in mild weather, they will live through the winter, and in the spring these plants may be transplanted into the border of the flower garden, where they will flower in *June*, and continue in succession till the frost puts a stop to them; by this method all the varieties may be continued without variation, but the plants which are propagated this way by cuttings will become barren soon, so will not produce seeds.

The ninth sort is a perennial plant, which sends out many stalks from the root, which divide into branches on every side, and are garnished with pretty thick leaves, deeply cut into many segments, like those of the last sort; these are of a pale green, the flowers are produced at the end of the branches, standing upon pretty long naked foot-stalks; these are very like those of the common Greater Daisy in size and colour. It flowers in *June*, and continues till the end of *September*. This sort ripens seeds every year in *England*, by which the plant is easily propagated. As these plants extend their branches pretty far on every side, so they should be allowed at least two feet room; therefore they are not very proper furniture for small gardens, where there is not room for these large growing plants, but in large gardens these may have a place for the sake of variety.

If these plants are planted in good dry land, or upon lime rubbish, they will not grow so vigorous as in good ground, so they will endure the cold better, and continue longer; for when their leaves and branches are replete with moisture, they are very apt to rot in the winter, so are seldom of long duration; but where the plants have grown from the joints of old walls, I have known them continue in vigour several years.

The tenth sort grows naturally in the *Canary* islands, from whence it was first brought to *England*, where it has been long an inhabitant in some curious gardens. It has been frequently called by the gardeners Pellitory of *Spain*, from the very warm taste which it hath, much resembling the taste of that plant.

This rises with a shrubby stalk near two feet high, dividing into many branches, which are garnished with pretty thick succulent leaves, of a grayish colour, cut into many narrow segments, that are divided into three parts at their extremity. The flowers come out from the wings of the leaves, standing upon naked foot stalks, singly, which greatly resemble those of the common Chamomile; there is a succession of flowers upon the same plants great part of the year, for which it is chiefly esteemed. This plant will perfect seeds in *England*, when the seasons are favourable; but as the cuttings of it do take root so easily, if planted during any of the summer months, so the seeds are rarely sown.

As this plant is a native of warm countries, so it will not live in the open air in *England* during the winter season; therefore when the cuttings have made good roots, they should be each planted into a separate pot, and placed in the shade till they have taken fresh root; then they may be removed to a sheltered situation, where they may remain till autumn, at which time they must be removed into the greenhouse to protect them from frost, but in mild weather they should have plenty of free air, and, during the winter, they should be frequently refreshed with water, but it must not be given them in too great plenty; in summer they will require more moisture, and should be treated in the same manner as other hardier kinds of exotick plants.

The eleventh sort grows naturally at the *Cape of Good Hope*. It rises with a shrubby stalk about two feet high, which divides into many slender branches upward, garnished with oblong leaves, much indented on their edges, each indenture terminating in a soft spine; these are of a pale green,

set close to the branches. The flowers are produced on short foot-stalks from the wings of the leaves, toward the upper part of the branches; these are globular, and formed of a great number of hermaphrodite florets, which are tubular and even, having no rays, so are naked, and of a deep yellow colour. The flowers appear in *June*, and continue in succession till the frost stops them; this may be propagated by cuttings in the same manner as the last, and the plants should be treated in the same way.

CHRYSOBALANUS. *Lin. Gen. Pl.* 585. Cocoa Plum.

The Characters are,

The flower hath five petals and ten stamina, five of which are longer than the petals, the other are shorter. In the center is situated an oval germen, which afterward becomes an oval fleshy berry, inclosing a nut, with five longitudinal furrows.

The Species are,

1. CHRYSOBALANUS *foliis ovatis, emarginatis, scrobis racemosis, caule fruticoso*. Chryso-balanus with oval indented leaves, flowers growing in bunches, and a shrubby stalk; commonly called the Cocoa Plum.

2. CHRYSOBALANUS *foliis decompositis, foliolis ovatis integerrimis*. Chryso-balanus with decomposed leaves, whose lobes are oval and entire,

The first sort grows naturally in the *Babana* islands, and in many other parts of *America*, but commonly near the sea. It rises with a shrubby stalk about eight or ten feet high, sending out several side branches, which are covered with a dark brown bark, spotted with white; these are garnished with oval stiff leaves, which are indented at their ends, in form of a heart, and are placed alternately on the branches; from the wings of the leaves, and also at the division of the branches, the flowers are produced, which grow in loose bunches; these are small and white, having ten stamina in each, five of which stand out beyond the petals of the flowers, the other five are shorter, and are terminated by yellow summits. The flowers are succeeded by oval Plums about the size of Damsons; some of these are blue, some red, and others yellow, they have a sweet luscious taste. The stone of the Plum is shaped like a Pear, and hath five longitudinal ridges on it.

The seeds of the second sort were sent me from *Jamaica*; the stones were exactly the same shape of those of the former, but the plants have winged leaves, which are branched, each having six or seven pair of pinnæ (or lobes). This sort hath not flowered in *England*, so I can give no farther account of it.

As these trees are natives of the warm parts of *America*, so they will not thrive in *England*, unless they are kept in a warm stove. They are propagated by seeds, which must be obtained from the countries where the plants naturally grow; which must be sown in the spring in small pots, and plunged into a hot-bed of tanners bark. In six weeks the plants will come up, and, if properly managed, will be fit to remove in a month's time after, when they should be carefully separated, and each planted into a separate small pot, and then plunged into the hot-bed again, observing to shade them from the sun till they have taken fresh root, after which they must have air every day in proportion to the warmth of the season, and their waterings during the summer should be frequent, but sparing. In the autumn the plants must be removed into the bark stove, and plunged into the tan-bed, and in winter the plants must not have too much water. In summer they must have a good share of air, but the plants should be constantly treated in the same manner as other tender plants from the same countries.

CHRYSOCOMA. *Lin. Gen. Pl.* 845. Goldylocks.

The Characters are,

The flower is composed of many hermaphrodite florets, contained in an imbricated empalement, which are tubular, and funnel-shaped,

shaped, cut into five parts at the brim; these have five short slender stamina. They have an oblong germen, which afterward becomes a single oblong compressed seed, crowned with hairy down.

The Species are,

1. CHRYSOCOMA herbacea, foliis linearibus, glabris, calycibus laxis. Lin. Sp. Pl. 841. Herbaceous Goldylocks with narrow smooth leaves, and loose empalements; or, German Goldylocks.

2. CHRYSOCOMA herbacea paniculata, foliis lanceolatis trinerviis, punctatis, nudis. Lin. Sp. Pl. 841. Herbaceous Goldylocks with flowers growing in panicles, and spear-shaped leaves, having three nerves.

3. CHRYSOCOMA fruticosa foliis linearibus dorso decurrentibus. Hort. Cliff. 397. Shrubby Goldylocks with very narrow leaves, whose back parts run along the stalks.

4. CHRYSOCOMA subfruticosa, foliis linearibus subtus pilosis, floribus ante florescentiam cernuis. Hort. Cliff. 397. Shrubby Goldylocks with very narrow leaves, which are hairy on their under side, and flowers nodding before they are blown.

5. CHRYSOCOMA suffruticosa, foliis linearibus recurvis, scabris, ciliatis, floribus erectis. Lin. Sp. Plant. 841. Shrubby Goldylocks with narrow rough leaves which are recurved and hairy, and erect flowers.

The first sort grows naturally in Germany, and also in France and Italy; it hath a perennial root and an annual stalk, which rises about a foot and an half high, is round, stiff, and closely garnished with long, narrow, smooth leaves, which come out without any order; the upper part of the stalk divides into many slender foot-stalks, each sustaining a single head of flowers, which are composed of many hermaphrodite florets, contained in one common empalement, having very narrow scales. The flowers are of a bright yellow, and stand disposed on the top of the stalk, in form of an umbel.

This plant is generally propagated by parting of the roots, that being the most expeditious method; for the seedling plants do not flower till the second or third year. The best time to remove the plants and part their roots, is soon after the stalks decay in autumn, that the plants may get fresh roots before winter. It delights in a dry loose soil, in which it will live in the open air, and propagate by its roots very fast, but in strong wet land, the roots often rot in winter.

The second sort grows naturally in Siberia. This plant hath a perennial creeping root, which spreads on every side to a considerable distance, sending up many erect stalks, which are garnished with flat spear-shaped leaves, ending in points; these are rough, and have three longitudinal veins; the upper part of the stalks branch out, and form loose panicles of yellow flowers, which are larger than those of the former sort.

It propagates too fast by its creeping roots to be admitted into the flower garden, for the roots will often extend two or three feet every way, in the compass of one year, so that they will interfere with the neighbouring flowers; but as the plants will grow in any soil or situation, so a few roots may be planted on the side of extensive rural walks round the borders of fields, where they will require no care, and their flowers will make a good appearance, and continue long in beauty.

The third sort grows naturally at the Cape of Good Hope. This rises with a ligneous stalk about a foot high, dividing into many small branches, which are garnished with narrow leaves, of a deep green, coming out on every side without order; the back part of each leaf hath a small short appendix, which runs along the stalks. The flowers are produced at the end of the branches, on slender naked foot-stalks; these are of a pale yellow, and shaped like those of the former sorts, but are larger.

The most expeditious method of propagating this plant is

by cuttings, which, if planted in a common border, in any of the summer months, and covered with hand glasses, will easily take root, provided they are shaded from the sun. When these have gotten good roots they should be carefully taken up, and each planted in a separate pot, placing them in the shade till they have taken new root; then they may be exposed with other hardy exotick plants till autumn, when they must be removed into the green-house during the winter season; they should enjoy a large share of free air in mild weather, for they only require protection from frost, so must not be too tenderly treated.

The fourth sort is a native of the Cape of Good Hope; this is a much less plant than the former, seldom rising above a foot high; it hath a shrubby stalk, branching out in the same manner; the leaves are shorter, and a little hairy; the flowers are not half so large, of a pale sulphur colour, and nod on one side before they are blown. It is generally propagated in the same manner as the former, and the plants require the same treatment.

The fifth sort is also a native of the same country as the two former; this hath a low shrubby stalk, which seldom rises above six inches high, branching out on every side; the leaves come out on every side the branches, which are very narrow, short, rough, and reflexed; the flowers stand single on the top of the foot-stalks, which arise from the upper part of the branches; these flowers are larger than those of the last, and stand erect. This plant requires the same treatment as the two former, and is propagated by cuttings in the same manner.

CHRYSOPHYLLUM. Lin. Gen. Pl. 233. Star Apple.

The Characters are,

It hath a bell shaped flower cut at the brim into ten segments, which are alternately spread open; and five short stamina, with a roundish germen, which afterward becomes a pulpy fruit with ten cells, in four or five of which is lodged a single seed.

The Species are,

1. CHRYSOPHYLLUM floribus racemosis terminalibus. Lin. Syst. 937. The Star Apple.

2. CHRYSOPHYLLUM floribus lateralibus. Lin. Syst. 937. The Damson tree.

Both these trees grow naturally in the West-Indies, where the first sort is often cultivated for its fruit; but the other grows wild in those parts of the islands, which are not cleared of trees.

The first rises thirty or forty feet high, with a large trunk, covered with a brown bark, and divides into many flexible slender branches, which generally hang downward, garnished with spear-shaped leaves, whose under side are of a bright russet colour. The flowers come out at the extremity of the branches, disposed in oblong bunches, which are succeeded by fruit of the size of a Golden Pippin, that are very rough to the palate, and astringent; but if kept some time mellow, as is here practised with Medlars, they have an agreeable flavour.

The second sort never rises to the height of the first, nor do the trunks grow to half the size of those; but the branches are slender, and garnished with leaves like those of the first. The flowers come out in clusters from the side of the branches, which are succeeded by oval smooth fruit about the size of Olives, inclosing three or four hard compressed seeds.

The plants of both these sorts are frequently preserved in those English gardens, where there are large stoves for keeping of exotick plants; for although there is little hopes of having fruit from them in England, yet the colour of their leaves, being so different from those of most other plants, makes a pleasing variety in the stove; and as they retain their leaves all the year, so the plants are as deserving of care as many other which are here cultivated.

They

They are both propagated by seeds, which are frequently brought from the *West-Indies*. They should be sown in small pots, four or five seeds in each, and the pots plunged into a hot-bed of tanners bark: if the seeds are fresh, the plants will come up in five or six weeks after, and in a few weeks more will be fit to remove; then they should be shaken out of the pots, and their roots carefully separated, and each planted in a small pot; then they should be plunged again into a hot-bed of tanners bark, shading them every day until they have got fresh roots, and afterward the plants should be treated in the same way, as has been directed for the tender sorts of *Annona*.

CHRYSOSPLENIUM. *Lin. Gen. Plant.* 493. Golden Saxifrage.

The Characters are,

The flower hath no petals, but eight or ten stamina, which are short, erect, and stand opposite to the angles of the empalement. The germen is immersed in the empalement, which afterward becomes a capsule with two beaks, opening with two valves, and filled with small seeds.

The Species are,

1. **CHRYSOSPLENIUM foliis alternis.** *Flor. Suec.* 317. Golden Saxifrage with alternate leaves.

2. **CHRYSOSPLENIUM foliis oppositis.** *Sauv. Monsp.* 128. Golden Saxifrage with opposite leaves.

These two plants are found growing wild in many parts of *England*, upon marshy soils and bogs, as also in moist shady woods, and are seldom propagated in gardens; where, if any person have curiosity to cultivate them, they must be planted in very moist shady places, otherwise they will not thrive. They flower in *March* and *April*.

CIBOULS, or CHIBOULS. See *Cepa*.

CICER. *Lin. Gen. Pl.* 783. Cicer, or Chich Pease.

The Characters are,

The flower is of the butterfly kind; the standard is large, roundish, and plain; the wings are much shorter and obtuse, the keel is shorter than the wings, and is sharp pointed. It hath ten stamina, nine of them being joined, and the tenth is separate. It hath an oval germen, which afterward becomes a turgid swelling pod of a rhomboidal figure, inclosing two roundish seeds, with a protuberance on their side.

There is but one Species of this genus, viz.

CICER foliolis ferratis. *Hort. Cliff.* 370. Chich Pease with fawed leaves. This is the *Cicer sativum*, *G. B. P.* 347. Garden Chich Pease.

There is a variety of this with a red seed, which differs from it in nothing but the colour.

It is much cultivated in *Spain*, being one of the ingredients in their olios, and is there called *Garavance*; it is also cultivated in *France*, but in *England* it is rarely sown.

The plant is annual, shooting out several stalks from the root, which are about two feet long; these are hairy, and garnished with long winged leaves of a grayish colour, composed of seven or nine pair of small roundish leaves (or lobes) terminated by an odd one, which are fawed on their edges. From the side of the branches come out the flowers, sometimes one, at other times two together. They are shaped like those of Pease, but are much smaller and white, standing on long foot-stalks, and are succeeded by short hairy pods, including two seeds in each, which are the size of common Pease, but have a little knob or protuberance on one side.

The seeds of this plant may be sown in the spring, in the same manner as Pease, making drills with a hoe, about an inch and an half deep, in which the seeds should be sown at about two inches asunder, then with a rake draw the earth into the drill to cover the seeds. The drills should be made at three feet distance from each other, that there may be room for their branches to spread, when the plants are fully grown, as also to hoe the ground between them, to

keep it clean from weeds, which is all the culture these plants require.

This plant flowers in *June*, and the seeds ripen in *August*; but unless the season proves warm and dry, the plants decay before the seeds are ripe.

CICHORIUM. *Lin. Gen. Plant.* 825. Succory.

The Characters are,

The flower hath a common scaly empalement, which at first is cylindrical, but is afterward expanded; the scales are narrow, spear-shaped, and equal. The flower is composed of many hermaphrodite florets, with one petal, which is tongue-shaped, and cut into five segments. These have five short hairy stamina. The germen is situated under the petal, which afterward becomes a single seed, inclosed with a down, and shut up in the empalement.

The Species are,

1. **CICHORIUM caule simplici, foliis dentato sinuatis.** *Flor. Suec.* 650. Succory, with a single stalk and indented sinuated leaves; or, Wild Succory.

2. **CICHORIUM caule dichotomo spinoso.** *Hort. Cliff.* 388. Succory with a prickly stalk divided by pairs.

3. **CICHORIUM caule simplici, foliis integris, crenatis.** *Hort. Cliff.* 389. Succory with a single stalk, and entire crenated leaves.

4. **CICHORIUM caule simplici, foliis fimbriatis, crispis.** Succory with a single stalk, and fringed, curled leaves.

The first sort grows naturally by the sides of roads and in shady lanes, in many parts of *England*: this has been supposed to be no other way differing from the Garden Succory, but by the latter being cultivated in gardens; indeed, most of the writers on botany, have confounded the two sorts together; for the Garden Succory which is described in most of the old books, I take to be the broad-leaved Endive, which is the third sort here enumerated, for I have many years cultivated both sorts in the garden, without finding either of them alter. There is an essential difference between these, for the wild Succory hath a perennial creeping root, whereas the other is at most but a biennial plant; and if the seeds of the latter are sown in the spring, the plants will flower and produce seeds the same year, and perish in autumn, so that it may rather be called annual. The wild Succory sends out from the roots long leaves, which are jagged to the midrib, each segment ending in a point; from between these arise the stalks, which grow from three to four feet high, garnished with leaves, shaped like those at the bottom, but smaller, and embrace the stalks at their base. These branch out above into several smaller stalks, which have the same leaves, but smaller and less jagged; the flowers are produced from the side of the stalks, which are of a fine blue colour, and are succeeded by oblong seeds, inclosed in a down.

The second sort grows naturally on the sea coasts in *Sicily* and the islands of the *Archipelago*. This sends out from the root many long leaves, which are indented on their edges, and spread flat on the ground; from between these arise the stalks, which have very few leaves, and those are small and entire: these stalks are divided in forks upward, from between these come out the flowers, which are of a pale blue, and are succeeded by seeds shaped like those of the common sort; the ends of the smaller branches are terminated by star-like spines, which are very sharp. This plant is biennial with us in *England*, and in cold winters is frequently killed. It flowers and seeds about the same time with the former sort, and may be treated in the same way as the Endive.

The broad-leaved Succory or Endive, differs from the wild sort in its duration, the root always perishing after it has ripened seeds: the leaves are broader, rounder at the top, and not lacinated on the sides as the leaves of the wild; the branches are more horizontal, and the stalks never rise so high.

There is also a variety with very long broad leaves, called in *Spain* *Escharole*, which is very tender and good, but

is often injured by frosts in the autumn, so is less esteemed on that account in *England*.

All the sorts of Succory are esteemed aperitive and diuretick, opening obstructions of the liver, and good for the jaundice; it provokes urine, and cleanses the urinary passages of slimy humours, which may stop their passage.

The curled Endive is now much cultivated in the *English* gardens, being one of the principal ingredients in the fallads of autumn and winter, for which purpose it is continued as long as the season will permit. I shall therefore give directions for the managing of this plant, so as to have it in perfection during the autumn and winter months.

The first season for sowing of these seeds is in *June*, for those which are sown earlier in the year, generally run up to seed, before they have arrived to a proper size for blanching; and it frequently happens, that the seeds sown in *June* in the rich grounds near *London*, will run to seeds the same autumn; but in situations that are colder, they are not so apt to run up, therefore there should be some seeds sown about the middle or latter end of that month. The second sowing should be about the beginning of *July*, and the last time in the middle of *July*. From these three different crops, there will be a supply for the table during the whole season; for there will be plants of each sowing, very different in their growth, so that there will be three different crops from the same beds.

When the plants come up they must be kept clean from weeds, and in dry weather duly watered, to keep them growing till they are fit to transplant, when there should be an open spot of rich ground prepared to receive the plants, in size proportionable to the quantity intended. When the ground is well dug and levelled, if it should be very dry, it must be well watered to prepare it to receive the plants; then the plants should be drawn up from the seed bed carefully, so as not to break their roots, drawing out all the largest plants, leaving the small ones to get more strength; which, when they have room to grow, by taking away the large ones, they will soon do. As the plants are drawn up, they should be placed with their roots even, all the same way, and every handful as they are drawn, should have the tops of their leaves shortened, to make them of equal length: this will render the planting of them much easier, than when the plants are promiscuously mixed, heads and tails: then the ground should be marked out in rows at one foot asunder, and the plants set ten inches distant in the rows, closing the earth well to their roots; let them be well watered, and repeat this every other evening, till the plants have taken good root, after which they must be kept clean from weeds.

When the plants of the seed bed have been thus thinned, they should be well cleaned from weeds, and watered, which will encourage the growth of the remaining plants, so that in ten days or a fortnight after, there may be another thinning made of the plants, which should be transplanted in the same manner. And at about the same distance of time, the third and last drawing of plants may be transplanted.

Those plants which were the first transplanted, will be fit to blanch by the latter end of *August* at farthest; and if they are properly managed, in three weeks or a month, they will be sufficiently blanched for use, which will be as soon as these fallads are commonly required; for during the continuance of good Cos Lettuce, few persons care for Endive in their fallads; nor, indeed, is it so proper for warm weather. If any of the plants should put out flower stems, they should be immediately pulled up and carried away, being good for nothing, so should not be left to incommode the neighbouring plants. As the quantity of roots necessary for the supply of a middling family is not very great, so there should not be too many plants tied up to blanch at the same time; therefore the largest should be first tied, and in a week after those

of the next size; so that there may be three different times of blanching the plants, on the same spot of ground. But as in some large families there is a great consumption of this herb for soups, so the quantities of plants should be proportionably greater, at each time of planting and blanching. The manner of blanching is the next thing to be treated of, therefore in order to this you should provide a parcel of small Osier twigs (or bafs mat) to tie up some of the largest heads to blanch; which should be done in a dry afternoon, when there is neither dew nor rain to moisten the leaves in the middle of the plants, which would occasion their rotting soon after their being tied up. The manner of doing it is as follows, *viz.* You must first gather up all the inner leaves of the plant in a regular order, into one hand, and then take up those on the outside that are sound, pulling off and throwing away all the rotten and decayed leaves which lie next the ground; observing to place the outside leaves all round the middle ones, as near as possible to the natural order of their growth, so as not to cross each other: then having got the whole plant close up in your hand, tie it up with the twig, bafs, &c. at about two inches below the top, very close; and about a week after go over the plants again, and give them another tie about the middle of the plant, to prevent the heart leaves from bursting out on one side; which they are subject to do, as the plants grow, if not prevented this way.

In doing of this you need only tie up the largest plants first, and so go over the piece once a week, as the plants increase in their growth; by which means you will continue the crop longer, than if they were all tied up at one time: for when they are quite blanched, which will be in three weeks or a month after tying, they will not hold sound and good above ten days or a fortnight, especially if the season proves wet: therefore it is that I would advise you to sow and plant at three or four different seasons, that you may have a supply as long as the weather will permit. But in order to this, you must transplant all the plants of the last sowing under warm walls, pales, or hedges, to screen the plants from frost; and if the winter should prove very sharp, you should cover them with some Pease haulm, or such other light covering, which should be constantly taken off in mild weather: these borders should also be as dry as possible, for these plants are very subject to rot, if planted in a moist soil in winter.

Although I before directed the tying up of the plants to blanch them, yet this is only to be understood for the two first sowings; for after *October*, when the nights begin to be frosty, those plants which are so far above ground will be liable to be much prejudiced thereby, especially if they are not covered in frosty weather; therefore the best method for the late crops is, to take up your plants in a very dry day, and with a large flat pointed dibble, plant them into the sides of trenches of earth, which should be laid very upright, sideways, towards the sun, with the tops of the plants only out of the ground, so that the hasty rains may run off, and the plants be kept dry, and secured from frosts.

The plants thus planted, will be blanched fit for use in about three weeks or a month's time, after which it will not keep good long; you should therefore keep planting some fresh ones into trenches every week or fortnight at farthest, that you may have a supply for the table; and those which were last transplanted out of the seed beds, should be preserved till *February* or *March*, before they are planted to blanch, so that from this you may be supplied until the beginning of *April*, or later: for at this last planting into the trenches, it will keep longer than in winter, the days growing longer; and the sun, advancing with more strength, dries up the moisture much sooner than in winter, which will prevent the rotting of these plants.

When your Endive is blanched enough for use, you must dig it up with a spade; and after having cleared it from all the outside green and decayed leaves, you should wash it well in two or three different waters to clear it the better from slugs, and other vermin, which commonly shelter themselves amongst the leaves thereof, and then you may serve it up to the table with other fallading.

But in order to have a supply of good seeds for the next season, you must look over those borders where the last crop was transplanted, before you put them into the trenches to blanch; and make choice of some of the largest, soundest, and most curled plants, in number according to the quantity of seeds required: for a small family, a dozen of good plants will produce seeds enough; and for a large, two dozen or thirty plants.

These should be taken up and transplanted under a hedge or pale, at about eighteen inches distance, in one row, about ten inches from the hedge, &c. This work should be done in the beginning of *March*, if the season is mild, otherwise it may be deferred a fortnight longer. When the flower stems begin to advance, they should be supported with a packthread, which should be fastened to nails driven into the pale, or to the stakes of the hedge, and run along before the stems, to draw them upright close to the hedge or pale, otherwise they will be liable to break with the strong winds. Observe also to keep them clear from weeds, and about the beginning of *July* your seeds will begin to ripen; therefore, as soon as you find the seeds quite ripe, you must cut off the stalks, and expose them to the sun upon a coarse cloth to dry; and then beat out the seeds, which must be dried, and put up in bags or paper, and preserved for use in some dry place. But I would here caution you, not to wait for all the seeds ripening upon the same plant; for if so, all the first ripe and best of the seeds will scatter and be lost before the other are near ripe; so great a difference is there in the seeds of the same plant being ripe.

The wild Succory (of which there are some varieties in the colour of the flowers) is seldom propagated in gardens; it growing wild in unfrequented lanes and dunghills in divers parts of *England*, where the herbwomen gather it, and supply the markets for medicinal use.

CICUTA. *Lin. Gen. Pl.* 316. Water Hemlock.

The Characters are,

It is a plant with an umbellated flower; the principal umbel is composed of several smaller. The great umbel hath no involucre, but the smaller have, which are composed of many short leaves. The flowers have each five oval petals; they have five hairy stamina. The germen is situated below the flower, which afterward becomes a roundish channelled fruit dividing in two parts, containing two oval seeds, plain on one side and convex on the other.

The Species are,

1. CICUTA *umbellis folio oppositis, petiolis marginatis obtusis.* *Lin. Sp. Plant.* 255. Hemlock with umbels opposite to the leaves, and obtuse marginated foot-stalks. Water Hemlock.

2. CICUTA *foliorum serraturis mucronatis, petiolis membranaceis, apice bilobis.* *Lin. Sp. Pl.* 256. Hemlock with pointed serratures to the leaves, and membranaceous foot-stalks ending in two lobes.

The first sort grows naturally in standing waters in many parts of *England*, so is never propagated; for unless there is a considerable depth of standing water for the plants to root in, they will not grow.

It rises four or five feet high, with a branching hollow stalk, garnished with winged leaves: the stalks are terminated by umbels of yellowish flowers, which are succeeded by small channelled seeds like those of Parsley. It flowers in *June* and *July*, and the seeds ripen in autumn.

The second sort grows naturally in *North America*. This is

propagated by seeds, which should be sown in autumn, in a shady border, where the plants will come up in the spring, and require no other care but to keep them clean.

CICUTARIA. See Ligusticum.

CINARA. See Cynara.

CINERARIA. See Othonna.

CIRCEA. *Lin. Gen. Pl.* 24. Enchanter's Nightshade.

The Characters are,

The flower hath two heart-shaped petals; it hath two erect hairy stamina. The germen is situated under the flower; the empalement afterward becomes an oval capsule with two cells opening lengthways, each containing a single oblong seed.

The Species are,

1. CIRCEA *caule erecto, racemis pluribus.* *Lin. Sp. Plant.* 9. Common Enchanter's Nightshade.

2. CIRCEA *caule adscendente, racemo unico.* *Lin. Sp. Pl.* 9. Least Enchanter's Nightshade.

The first sort grows naturally in shady woods, and under hedges, in many parts of *England*. It hath a creeping root, by which it multiplies greatly. The stalks are upright, and rise a foot and half high, garnished with heart-shaped leaves placed opposite, upon pretty long foot-stalks: they are of a dark green on their upper side, but are pale on their under. The stalks are terminated by loose spikes of flowers, which are branched out into three or four small divisions. The flowers are small and white, having but two petals, opposite to which are situated the two stamina. After the flowers fall away, the empalement of the flower becomes a rough capsule, inclosing two oblong seeds.

The second sort grows at the foot of mountains in many parts of *Germany*; it also grows naturally in a wood near the *Hague*, from whence I brought it to *England*. This sort seldom rises more than six inches high, with a slender stalk, garnished with leaves shaped like those of the former sort, but smaller, and are indented on their edges. The flowers are produced on single loose spikes at the top of the stalks, which are smaller than those of the former sort, but of the same form and colour. They both multiply exceedingly by their creeping roots, so are seldom kept in gardens, unless for the sake of variety.

CIRSIUM. See Carduus.

CISSAMPELOS. *Lin. Gen. Pl.* 993.

The Characters are,

It is male and female in different plants; the male flowers have no petals, but a single style rises in the center, which extends beyond the empalement, terminated by a large summit having four lobes. The female flowers have four nectariums standing round the oval germen, which is hairy, and afterward becomes a succulent berry inclosing a single seed.

The Species are,

1. CISSAMPELOS *foliis peltatis cordatis subtus villosis, floribus racemosis alaribus.* Cissampelos with target heart-shaped leaves which are hairy, and flowers growing in bunches rising from the side of the stalks.

2. CISSAMPELOS *foliis cordatis, tomentosiss, floribus racemosis, alaribus.* Cissampelos with woolly heart-shaped leaves, and flowers growing in bunches from the sides of the stalks; called Velvet Leaf in *America*.

These plants grow naturally in the warmest parts of *America*, where they twist themselves about the neighbouring shrubs, and rise to the height of five or six feet. The first sort hath round heart-shaped leaves, whose foot-stalks are set within the base of the leaf, resembling an ancient target; these are hairy on the under side, and have pretty long slender foot-stalks. Toward the upper part of the stalks, the flowers come out from the wings of the leaves; those of the male plants grow in short spikes or clusters, and are of a pale herbaceous colour; but the female flowers are produced in long loose racemi from the side of the stalks,

and are succeeded by a single pulpy berry inclosing a single seed.

The second sort hath round heart-shaped leaves, which are extremely woolly and soft to the touch; these have their foot-stalks placed at the base, between the two ears; the flowers of this come out in bunches from the side of the stalks, in the same manner as the first. The stalks and every part of the plant, is covered with a soft woolly down.

These plants are propagated by seeds, which should be sown upon a hot-bed in the spring; and the plants must afterward be treated in the same way as other tender exoticks, keeping them constantly in the bark stove, otherwise they will not live in this country.

The first sort is supposed to be the Pareira, whose root has been so much esteemed as a diuretick.

CISTUS. *Lin. Gen. Plant.* 598. Rock-rose.

The Characters are,

The flower hath five large roundish petals which spread open; it hath a great number of hairy stamina, which are shorter than the petals. In the center is situated a roundish germen, which afterward becomes an oval close capsule, having in some five, and others ten cells, filled with small roundish seeds.

The Species are,

1. CISTUS *arborescens foliis ovatis, sessilibus, utrinque villosis, rugosis, floribus terminalibus.* Tree Rock-rose with oval leaves growing close to the branches, which are hairy and rough, and flowers growing at the end of the branches.

2. CISTUS *arborescens foliis sessilibus, utrinque villosis, rugosis: inferioribus ovatis basi connatis, summis lanceolatis.* *Hort. Cliff.* 205. Tree Rock-rose with leaves set close to the branches, which are hairy and rough on each side, the under being oval and joined at their base, but the upper spear-shaped.

3. CISTUS *arborescens, foliis ovato-lanceolatis, basi connatis, hirsutis, rugosis, pedunculis florum longioribus.* Tree Rock-rose with oval spear-shaped leaves, joined at their base, which are hairy and rough, and longer foot-stalks to the flowers.

4. CISTUS *arborescens, foliis ovatis, obtusis, villosis, subtus nervosis rugosis, floribus amplioribus.* Tree Rock-rose, with oval, obtuse, hairy leaves, which are nervous and rough on their under side, and larger flowers.

5. CISTUS *arborescens villosus, foliis lanceolatis, viridibus, basi connatis, floribus alaribus & terminalibus sessilibus, calycibus acutis.* Hairy Tree Rock-rose with green spear-shaped leaves joined at their base, flowers proceeding from the sides and ends of the branches, fitting close to the stalks, and sharp pointed empalements.

6. CISTUS *arborescens foliis lanceolatis, supra lævibus, petiolis basi coalitis vaginantibus.* *Hort. Cliff.* 205. Tree Rock-rose with spear shaped leaves, smooth on their upper side, and their foot-stalks joining like sheaths.

7. CISTUS *arborescens foliis oblongis, tomentosis, incanis, basi connatis, supra lævibus infernè nervosis.* Tree Rock-rose, with oblong, hoary, woolly leaves, joined at their base, smooth above, but nervous on their under side.

8. CISTUS *frutescens, ramis patulis, foliis ovatis, petiolatis, hirsutis, pedunculis nudis.* Shrubby Rock-rose, with spreading branches, oval, hairy leaves having foot-stalks, and the foot-stalks of the flowers naked.

9. CISTUS *arborescens, foliis ovato-lanceolatis, hirsutis, marginibus undulatis, floribus terminalibus.* Tree Rock-rose with oval, spear-shaped, hairy leaves, waved on their borders, and flowers terminating the branches.

10. CISTUS *fruticosus, foliis lineari-lanceolatis, hirsutis, sessilibus, floribus terminalibus.* Shrubby Rock-rose with narrow, spear-shaped, hairy leaves, fitting close to the branches, and flowers terminating the stalks.

11. CISTUS *arborescens, foliis lanceolatis, supra lævibus, pe-*

tiolis basi, coalitis vaginantibus. *Lin. Sp. Pl.* 523. Tree Rock-rose, with spear-shaped leaves, smooth on their upper side, with foot-stalks joined at their base.

12. CISTUS *foliis oblongo-cordatis, glabris, petiolis, longioribus, caule fruticoso.* Rock-rose with oblong, heart-shaped, smooth leaves, longer foot-stalks, and a shrubby stalk.

13. CISTUS *arborescens, foliis lanceolatis, sessilibus, utrinque villosis, trinerviis, alis nudis.* *Hort. Cliff.* 205. Tree Rock-rose with spear-shaped leaves fitting close to the branches, hairy on both sides, having three nerves.

14. CISTUS *arborescens, foliis lineari-lanceolatis, subtus incanis, trinerviis, petalis subrotundis.* Tree Rock-rose with narrow spear-shaped leaves, hoary on their under side, having three nerves, with roundish petals.

15. CISTUS *foliis lanceolatis, supernè glabris, infernè incanis, trinerviis, margine undulatis, caule fruticoso.* Rock-rose with spear-shaped leaves, which are smooth on their upper side, and hoary on their under, having three nerves, waved edges, and a shrubby stalk.

16. CISTUS *arborescens foliis cordatis lævibus acuminatis petiolatis.* *Lin. Sp. Pl.* 523. Tree Rock-rose with heart-shaped, pointed leaves.

17. CISTUS *foliis ovatis, incanis, infernè petiolatis, supernè coalitis, caule fruticoso.* Rock-rose with oval, hoary leaves, those beneath having foot-stalks, the upper ones joined at their base, and a shrubby stalk.

18. CISTUS *foliis lineari-lanceolatis, incanis, sessilibus, floribus racemosis caule fruticoso.* Rock-rose with narrow spear-shaped leaves, which are hoary, and fit close to the branches, flowers growing in clusters, and a shrubby stalk.

These plants grow naturally in the south of France, Spain, and Portugal.

The first sort hath a strong woody stem, covered with a rough bark, which rises three or four feet high, dividing into many branches, so as to form a large bushy head; these are garnished with oval hairy leaves, placed opposite, and fit close to the branches, having several smaller leaves of the same form rising from the same joint. The flowers are produced at the end of the branches, four or five standing together, almost in the form of an umbel, but rarely more than one is open at the same time: these are composed of five large roundish petals of a purple colour, which spread open like a Rose, having a great number of stamina. These flowers are of but short duration, generally falling off the same day they expand, but there is a succession of fresh flowers every day for a considerable time. After the flowers are past, the germen swells to an oval seed vessel, sitting in the empalement, which is hairy; these capsules have ten cells, which are full of small roundish seeds.

The second sort differs from the first in the shape of the leaves, which are longer and whiter; those on the lower part of the branches are oval, and join at their base, surrounding the stalks, but the upper leaves are spear shaped and distinct; the flowers are larger, and of a paler purple colour.

The third sort differs from both the former, in having shorter and greener leaves, which are joined at their base, and are hairy. The foot-stalks of the flowers are much longer, and the flowers are smaller, but of a deeper purple.

The fourth sort hath much larger and rounder leaves than either of the former, which are hairy, and smooth on their upper side, but rough and full of veins on their under: the branches are white and hairy, and the flowers are very large, and of a light purple colour.

The fifth sort doth not rise so high as either of the former, but sends out branches near the root, which are hairy and erect; these are garnished with spear-shaped leaves, which are of a dark green colour, and join at their base, surrounding the stalk. At each joint comes out a very slender branch,

branch, having three pair of small leaves of the same shape with the other, terminated by a single flower, and the ends of the branches have three or four flowers sitting close without foot-stalks. The flowers are of a deep purple colour, and like those of the first.

The sixth sort rises to the height of five or six feet, with a strong woody stalk, sending out many hairy branches, which are garnished with spear-shaped leaves, smooth on their upper side, but veined on their under, having short foot-stalks, which join at their base, where they form a sort of sheath to the branch. The flowers come out at the end of the branches, which are large, of a light purple colour, resembling those of the fourth sort.

The seventh sort hath erect branches, which come out from the lower part of the stalk, and are woolly; these are garnished with oblong hoary leaves, covered with a white down, which are smooth above, but veined on the under side, joining at their base, where they surround the stalk; the flowers are produced at the end of the branches, which are of a bright purple colour, and large.

The eighth sort hath a slender smooth stalk, covered with a brown bark, which never rises more than two feet high, sending out many horizontal weak branches, which spread very wide, and are garnished with small oval leaves, which are hairy, standing upon short foot-stalks. The flowers come out at the wings of the leaves, upon long naked foot-stalks; these are white, and somewhat smaller than those of the other sorts.

The ninth sort grows naturally in the islands of the *Archipelago*, and is the plant which produces the *Ladanum*, as is hereafter mentioned; it rises three or four feet high, with a woody stalk, sending out many lateral branches covered with a brown bark, garnished with oval, spear shaped, hairy leaves, waved and curled on their borders; these in warm seasons sweat a glutinous liquid, which spreads on the surface of the leaves, is very clammy and sweet-scented. The flowers come out at the end of the branches, on short hairy foot-stalks; they are of a deep purple colour, and about the size of a single Rose.

The tenth sort rises with a shrubby stalk about four feet high; the branches are very hairy, glutinous, and grow erect, and are garnished with long narrow leaves, ending in points, which are hairy, and of a deep green on both sides, having a deep longitudinal furrow on their upper side, made by the midrib, which is prominent on the under side; the flowers stand upon long foot-stalks at the end of the branches, which are of a pale sulphur colour, having a bordered empalement, which is cut into five acute parts at the top.

The eleventh sort rises with a strong woody stem, to the height of five or six feet, sending out many erect branches, which are garnished with spear-shaped leaves ending in points; these are thick, white on their under side, of a dark green above, and very glutinous in warm weather. The flowers are produced at the end of the branches, upon long naked foot-stalks, which branch on their sides into small foot-stalks, each sustaining one large white flower, having a hairy empalement.

The twelfth sort rises with a smooth shrubby stalk, four or five feet high, sending out many slender ligneous branches, covered with a smooth brown bark, garnished with oblong heart-shaped leaves, which are smooth, and have long foot-stalks. The flowers are white, and are produced at the end of the branches, standing upon pretty long foot-stalks.

The thirteenth sort rises with a slender shrubby stalk, from three to four feet high; sending out many branches from the bottom upward, which are hairy, garnished with spear-shaped leaves, of a very dark green colour, having

three longitudinal veins in each; in warm weather they are covered with a glutinous sweet-scented substance, which exudes from their pores. The flower-stalks which come out at the end of the branches, are long, naked, and sustain many white flowers, rising above each other; their empalements are bordered, and end in sharp points.

The fourteenth sort rises with a woody stem to the height of five or six feet, sending out many side branches from the bottom; these are smooth, covered with a reddish brown bark, garnished with narrow spear-shaped leaves, whitish on their under side, of a dark green above, having three longitudinal veins. The flowers are produced at the end of the branches, on short foot-stalks, and are composed of five very large roundish petals, each having a large purple spot at their base. The whole plant exudes a sweet glutinous substance in warm weather, which hath a very strong balsamick scent, so as to perfume the circumambient air to a great distance.

There is a variety of this with white flowers, having no purple spots, which is in all other respects the same as this.

The fifteenth sort rises with a shrubby stalk to the same height as the last, sending out many branches on every side, which are garnished with spear-shaped leaves, of a thick consistence, which are smooth on their upper side, of a very dark green colour, and white on their under side; these are very clammy, especially in warm weather; the flowers are produced at the end of the branches, on short foot-stalks; they are very large, white, and have a broad, dark, purple spot at the base of each petal; this differs from the former sort in the shape and size of their leaves; those of this sort being much shorter and broader, and are very white on their under side. The side branches are shorter, and the leaves stand much closer on them; the flowers are larger, and the whole plant is much more glutinous.

The sixteenth sort hath a stiff, slender, woody stalk, which sends out many branches, it rises to the height of six or seven feet; the leaves are large, heart-shaped, thin, and of a light green colour; these sit close to the branches, and have many nerves; the flowers are produced at the end of the branches, upon naked foot-stalks; they are white, and fade to a pale sulphur colour when they fall off.

The seventeenth sort hath an upright shrubby stalk, which rises four or five feet high, sending out many branches from the ground upward, so as to form a large bush. The branches are channelled, and hoary. The leaves are oval, standing opposite; those on the lower part of the branches have foot-stalks, but upward they coalesce at their base, and surround the stalk; these are very white. The foot-stalks of the flowers which rise at the end of the branches, are a foot in length, naked, hairy, and put out two or four shorter foot-stalks on the side, each supporting three or four flowers, each standing on a short foot-stalk. The flowers are large, of a bright yellow colour, but of short duration, seldom continuing longer than three or four hours.

The eighteenth sort rises with a slender woody stalk, three or four feet high, sending out many slender branches, garnished with narrow, spear-shaped, hoary leaves, which sit close to them; from the wings of the leaves come out slender branches, which have two or three pair of small leaves, terminated by loose bunches of flowers, each standing on a slender foot-stalk. The flowers are of a dirty sulphur colour.

This sort will not live abroad in the winter, so is always placed in a green-house.

These plants are all of them, except the last, hardy enough to live in the open air in *England*, unless in very severe winters, which sometimes destroy them, so that a plant or two of each sort may be kept in pots, and sheltered in winter, to preserve the kinds; the rest may be intermixed with

other

other shrubs, for where they are sheltered by other plants, they will endure the cold much better than where they are scattered singly in the borders. Many of these plants will grow to the height of five or six feet, and will have large spreading heads, provided they are permitted to grow uncut; but if they are ever trimmed, it should be only so much as to prevent their heads from growing too large for their stems; for whenever this happens, they are apt to fall on the ground, and appear unsightly.

These shrubs are propagated by seeds, and also from cuttings; but the latter method is seldom practised, unless for those sorts which do not produce seeds in *England*; these are the twelfth, seventeenth, and eighteenth sorts; all the others generally produce plenty of seeds, especially those plants which came from seeds, for those which are propagated by cuttings, are very subject to become barren, which is also common to many other plants.

The seeds of these plants may be sown in the spring upon a common border of light earth, where the plants will come up in five or six weeks, and, if they are kept clear from weeds, and thinned where they are too close, they will grow eight or ten inches high the same year; but as these plants, when young, are liable to injury from hard frost, therefore they should be transplanted when they are about two inches high, some into small pots filled with light earth, that they may be removed into shelter in winter, and the others into a warm border, at about six inches distance each way; those which are potted must be set in a shady situation till they have taken new root, and those planted in the border must be shaded every day with mats till they are rooted, after which the latter will require no other care but to keep them clean from weeds till autumn, when they should have hoops placed over them, that they may be covered in frosty weather; those in the pots may be removed into an open situation, so soon as they have taken new root, where they may remain till the end of *October*; then they should be placed under a hot-bed frame to screen them from the cold in winter, but, at all times, when the weather is mild, they should be fully exposed to the open air, and only covered in frosts; with this management the plants will thrive much better than when they are more tenderly treated.

In the spring following, these plants may be turned out of the pots, with all the earth preserved to their roots, and planted in the places where they are to remain (for they are bad plants to remove when grown old), observing to give them now and then a little water, until they have taken fresh root; after which time they will require no farther care, than to train them upright in the manner you would have them grow. The plants which were planted in the border also may be transplanted abroad the succeeding spring. In removing of these you should be careful to preserve as much earth about the roots as you can; and if the season should prove hot and dry, you must water and shade them, until they have taken fresh root, after which they will require no other culture than was before directed.

The fourteenth and fifteenth sorts are by much the most beautiful of all these *Cistus*; the flowers, which are as big as a large Rose, are of a fine white, with a deep purple spot on the bottom of each leaf. These plants also abound with a sweet glutinous liquor, which exudes through the pores of the leaves in so plentiful a manner, in hot weather, that the surface of the leaves are covered therewith; from this plant *Clusius* thinks might be gathered great quantities of the *Ladanum* which is used in medicine, in the woods in *Spain*, where he saw vast quantities of this shrub growing.

But it is from the ninth sort, which *Monf. Tournefort* says, the *Greeks*, in the *Archipelago*, gather this sweet gum; in the doing of which (*Bellonius* says) they make use of an instrument like a rake without teeth, which they call *Ergastiri*;

to this are tied many thongs of raw and untanned leather, which they rub gently on the bushes that produce the *Ladanum*, that so that liquid moisture may stick upon the thongs; after which they scrape it off with knives; this is done in the hottest time of the day, for which reason the labour of gathering this *Ladanum* is excessive, and almost intolerable, since they are obliged to remain on the mountains for whole days together, in the very heat of summer, or the dog days, nor is there any person almost that will undertake this labour, except the *Greek* monks.

CITHAREXYLON. *Lin. Gen. Pl.* 678. Fiddle Wood.

The Characters are,

The flower is of one leaf, funnel-shaped, and divided at the top into five equal parts. It hath four stamina which adhere to the tube, two of them being longer than the other. In the center is situated the roundish germen, which after-ward becomes a capsule with two cells, each having a single seed.

The Species are,

1. CITHAREXYLON *foliis ovato-lanceolatis venosis, dentatis, ramis angulatis, floribus racemosis, sparsis.* This is the common Fiddle Wood of *America*.

2. CITHAREXYLON *foliis oblongo-ovatis, integris, oppositis, ramis angulatis, floribus spicatis.* Fiddle Wood with oblong, oval, entire leaves growing opposite, angular branches, and flowers growing in spikes.

The first sort grows common in most of the islands in the *West-Indies*, where it rises to a great height, and becomes a very large timber tree, the wood of which is greatly esteemed for buildings, being very durable.

This rises with an upright trunk to the height of fifty or sixty feet, sending out many branches, which have several angles or ribs, running longitudinally, garnished by oval, spear-shaped leaves at every joint, standing in a triangle, upon short foot-stalks. The leaves are about four inches long, and one and an half broad, of a lively green colour, pretty much notched on their edges, having several deep Orange-coloured veins running from the midrib to the edges. The flowers come out from the sides, and also at the end of the branches, in loose bunches, which are succeeded by small pulpy berries, inclosing two seeds in each.

The second sort is a native of the same islands with the first. This is also a very large tree, whose timber is greatly valued in *America*, for buildings, being very durable, and from thence I have been informed the *French* gave it the name of *Fidelle Wood*, which the *English* have rendered *Fiddle Wood*.

This tree rises with a strong upright trunk, to the height of sixty feet, or more, sending out many angular branches, standing opposite, garnished with oval oblong leaves, standing opposite, on short foot-stalks; these are of a lucid green, and are rounded at their ends. The flowers come out in long loose spikes toward the end of the branches, which are white, and smell very sweet; these are followed by small, roundish, pulpy berries, each inclosing a single seed.

The seeds of both sorts should be sown in small pots early in the spring, and plunged into a fresh hot-bed of tanners bark, and treated in the same manner as other exotick seeds, which are brought from hot countries. If the seeds are fresh, the plants will appear in five or six weeks, and in about one month more will be fit to transplant; when each should be planted in a small pot, and plunged into the hot-bed again, observing to shade them till they have taken fresh root, after which they should have a large share of air in warm weather; in autumn the plants should be removed into the bark stove, where it will be proper to keep them the first winter, till they have obtained strength, but after-ward they may be kept in a dry stove in winter, and in the middle of summer they may be exposed in the open air for two months, in a warm situation, with which management the plants

plants will make better progress than when they are more tenderly treated.

If the cuttings of this plant are planted in small pots during the summer months, and plunged into a moderate hot-bed, they will take root, and may afterward be treated in the same manner as the seedling plants.

CITRUS. *Lin. Gen. Pl.* 807. The Citron tree.

The Characters are,

The flower hath five oblong thick petals; it hath ten stamina, which are not equal, and join in three bodies at their base. The oval germen in the center afterward becomes an oblong fruit, with a thick fleshy skin filled with a succulent pulp, having many cells, each containing two oval hard seeds.

The Species are,

1. **CITRUS fructu oblongo, majori, mucronato, cortice crasso rugoso.** Citron with a larger, oblong, pointed fruit, having a thick rough rind; or, Sweet Citron.

2. **CITRUS fructu oblongo, cortice tuberoso rugoso.** The common Citron.

There are several other varieties of this fruit, with which the English gardens have been supplied from Genoa, where is the great nursery for the several parts of Europe for this sort, as also Orange and Lemon trees.

The several sorts of Citrons are cultivated in much the same manner as the Orange tree, to which I shall refer the reader, to avoid repetition; but shall only remark, that these are somewhat tenderer than the Orange, and should therefore have a warmer situation in winter, otherwise they are very subject to cast their fruit. They should also continue a little longer in the house in the spring, and be carried in again sooner in the autumn. And as their leaves are larger, and their shoots stronger, than those of the Orange, they require a little more water in the summer; but in the winter they should have little water at each time, which must be the oftener repeated.

The common Citron is much the best stock to bud any of the Orange or Lemon kinds upon, it being the straightest and freest growing tree; the rind is smoother, and the wood less knotty, than either the Orange or Lemon, and will take either sort full as well as its own kind, which is what none of the other sorts will do: and these stocks, if rightly managed, will be very strong the second year after sowing, capable to receive any buds, and will have strength to force them out vigorously; whereas it often happens, when these buds are inoculated into weak stocks, they frequently die, or remain till the second year before they put out; and those that shoot the next spring after budding, are oftentimes so weak as hardly to be fit to remain, being incapable to make a straight handsome stem, which is the great beauty of these trees.

CITRUL. See Pepo.

CLARY. See Sclarea.

CLAYTONIA. *Gron. Flor. Virg. Lin. Gen. Pl.* 253.

The Characters are,

The flower hath five oval petals which are indented at the top, and five recurved stamina, which are shorter than the petals. In the center is situated an oval germen, which afterward becomes a roundish capsule having three cells, opening with three elastic valves, and filled with round seeds.

We have but one sort of this genus in the English gardens, viz.

CLAYTONIA foliis linearibus. *Lin. Sp. Pl.* Claytonia with very narrow leaves.

This plant grows naturally in Virginia. It hath a small tuberous root, which sends out low slender stalks in the spring, about three inches high, which have two or three succulent narrow leaves about two inches long, of a deep green colour; at the top of the stalk are four or five flowers produced, standing in a loose bunch, composed of five

white petals which spread open, spotted with red on their inside; after these fall away, the germen becomes a roundish capsule divided into three cells, which are filled with roundish seeds.

It is propagated by seeds, and also from offsets sent out from the roots: the seeds should be sown on a border of light earth, soon after they are ripe; for if they are kept out of the ground till spring, the plants will not come up till the next year; whereas those which are sown early in the autumn, will grow the following spring, so that a whole year is gained. When the plants come up, they will require no other care but to keep them clean from weeds; and in the autumn, if some old tanners bark is spread over the surface of the ground, it will secure the roots from being injured by frost; which, if it should prove very severe, might be the case with young plants, but after the first winter they will not require protection.

The best time to transplant the roots is about Michaelmas, when they are inactive; but as they are small, so if great care is not taken in opening the ground, the roots may be buried and lost; for they are of a dark colour, so are not easily distinguished from the ground.

CLEMATIS. *Lin. Gen. Pl.* 626. Virgin's Bower.

The Characters are,

The flowers have each four loose oblong petals, with a great number of stamina; the summits adhere to their side. They have many compressed germina, which afterward become so many roundish compressed seeds, with the style sitting on their top.

The Species are,

1. **CLEMATIS foliis pinnatis, foliolis ovato-lanceolatis, integerrimis, caule erecto.** *Hort. Cliff.* 225. Upright white Climber.

2. **CLEMATIS foliis simplicibus, ovato-lanceolatis.** *Hort. Cliff.* 225. Upright blue Climber.

3. **CLEMATIS foliis pinnatis, foliolis cordatis, scandentibus.** *Hort. Cliff.* 225. Climber with broad entire leaves, commonly called Viorna, or Traveller's Joy.

4. **CLEMATIS foliis ternatis, foliolis cordatis, acutis, dentatis, scandentibus.** Broad-leaved Canada Climber, having three leaves.

5. **CLEMATIS foliis inferioribus, pinnatis, laciniatis, summis simplicibus, integerrimis, lanceolatis.** *Hort. Cliff.* 225. Creeping Climber.

6. **CLEMATIS cirrhis scandens.** *Hort. Cliff.* 226. Clematis with climbing tendrils.

7. **CLEMATIS foliis compositis decompositisque, foliolis ovatis, integerrimis.** *Hort. Cliff.* 225. Single blue Virgin's Bower.

8. **CLEMATIS foliis ternatis, ternatisque, foliolis ovatis, acutè serratis, scandentibus.** Clematis with trifoliate leaves, which have three oval lobes, sharply sawed, and climbing.

9. **CLEMATIS foliis compositis decompositisque, foliolis quibusdam trifidis.** *Flor. Virg.* 62. Creeping purple Climber, with coriaceous petals to the flower.

10. **CLEMATIS foliis compositis, foliolis incis, angulatis, lobatis, cuneiformibus.** *Lin. Sp. Plant.* 543. Eastern Climber with a Smallage leaf, and a reflexed greenish yellow flower.

11. **CLEMATIS foliis compositis & decompositis, foliolis ternatis, serratis.** *Gmel.* Climber with compound and decomposed leaves, whose small leaves are sawed and trifoliate.

12. **CLEMATIS foliis simplicibus, ternatisque: foliolis integris trilobisve.** *Lin. Sp. Plant.* 543. Climber with single and trifoliate leaves, whose small leaves are either entire, or have three lobes.

The first sort grows naturally in the south of France, in Italy, Austria, and several parts of Germany. This hath a perennial root and annual stalks, which grow upright, about five feet high, garnished with winged leaves standing opposite; these are composed of three or four pair of lobes, terminated by an odd one; the flowers are produced in large loose panicles, at the top of the stalks; these are composed

of four white petals, which spread open; and the middle is occupied by a great number of stamina, surrounding five or six germen, which afterward become so many compressed seeds, each having a long tail or beard fitting on the top.

The second sort grows naturally in *Hungary* and *Tartary*. This is perennial, sending up many slender upright stalks, from five to six feet high, garnished with single leaves at each joint, which stand opposite, on very short foot-stalks; they are near four inches long, and an inch and half broad in the middle, smooth, and entire, ending in a point: the flowers come out from the upper part of the stalks, standing upon very long naked foot stalks which nod down, each supporting a single blue flower, composed of four narrow thick petals which spread open, and many hairy stamina surrounding the germen in the center. After the flowers are past, the germen become so many compressed seeds, each having a tail or beard.

The third sort grows naturally in the hedges, in most parts of *England*. This hath a rough climbing stalk, sending out clasps, by which it fastens to the neighbouring bushes and trees, and sometimes rises more than twenty feet high, often covering all the trees and bushes of the hedge. This puts out many bunches of white flowers in *June*, which are succeeded by flat seeds joined in a head, each having a long twisted tail fitting on the top, covered with long white hairs; in autumn, when the seeds are near ripe, they appear like beards, from whence the country people call it Old Man's Beard. The branches of this being very tough and flexible, are often used for tying up faggots, from whence in some counties, it is called Bindwith.

The fourth sort grows naturally all over *North America*. This is in its first appearance very like the last sort, but the leaves are broader, and grow by threes on the same foot-stalk, whereas those of the former have five or seven lobes in each leaf: the flowers appear at the same time with the former.

The fifth sort hath a climbing stalk, like the third; the lower leaves of this are winged, and deeply cut on their edges, but the upper leaves are single, spear-shaped, and entire; the flowers of this sort are white. This grows naturally in the south of *France*, and in *Italy*.

The sixth sort grows naturally in *Spain* and *Portugal*. This hath a climbing stalk, which will rise to the height of ten or twelve feet, sending out branches from every joint, whereby it becomes a very thick bushy plant; the leaves are sometimes single, at other times double, and frequently trifoliate, being indented on their edges. These keep their verdure all the year; opposite to the leaves come out clasps, which fasten themselves to the neighbouring shrubs, by which the branches are supported, otherwise they would fall to the ground. The flowers are produced from the side of the branches; these are large, of an herbaceous colour, and appear always about the end of *December*, or beginning of *January*.

The seventh sort is cultivated in the nursery gardens for sale, and is known by the title of *Virgin's Bower*. There are four varieties of it which are preserved in the gardens of the curious, and have been by some treated as so many distinct species; but as their only differences consist either in the colour of their flowers, or the multiplicity of their petals, so they are now only esteemed as feminal variations; but as they are distinguished by the nursery gardeners, so I shall just mention them.

1. Single blue *Virgin's Bower*.
2. Single purple *Virgin's Bower*.
3. Single red *Virgin's Bower*.
4. Double purple *Virgin's Bower*.

The stalks of these plants are very slender and weak, having many joints from whence come out side branches, which

are again divided into smaller: if these are supported, they will rise to the height of ten or twelve feet, and are garnished with compound winged leaves placed opposite. These branch out into many divisions, each of which hath a slender foot-stalk, with three small leaves which are oval and entire; from the same joint, generally four foot-stalks arise, two on each side; the two lower have three of these divisions, so that they are each composed of nine small leaves; but the two upper have only two opposite leaves on each, and between these arise three slender foot-stalks, each supporting one flower. The flowers have each four petals, which are narrow at their base, but are broad at the top and rounded: in one they are of a dark worn-out purple, in another blue, and the third of a bright purple or red colour. The double sort, which is common in the *English* gardens, is of the worn-out purple colour. The double flowers have no stamina or germen, but in lieu of them, there is a multiplicity of petals, which are narrow, and turn inward at the top.

The eighth sort grows naturally on the *Alps*, and other mountains in *Italy*. This hath a slender climbing stalk, which rises three or four feet high, supporting itself by fastening to the neighbouring plants or shrubs. The leaves of this are composed of nine lobes or small leaves, three standing upon each foot-stalk. The flowers come out at the joints of the stalk in the same manner as the common *Traveller's Joy*, which are white, so make no great appearance.

The ninth sort grows naturally in *Virginia* and *Carolina*. This hath many slender stalks, garnished with compound winged leaves at each joint; these are generally composed of nine leaves, standing by threes, like those of the eighth sort, but the small leaves of this are nearly of a heart-shape. The flowers of this stand upon short foot-stalks, which come out from the wings of the leaves, one on each side the stalk. They are composed of four thick petals, which are purple on their outside, and blue within.

The tenth sort grows in the *Levant*. This hath weak climbing stalks, which fasten themselves by their clasps, to any plants or shrubs which stand near them, and thereby rise to the height of seven or eight feet; these are garnished with compound winged leaves, consisting of nine small leaves (or lobes) which are angular, and sharp pointed. The flowers come out from the wings of the leaves, which are of a yellowish green, and the petals are reflexed backward.

The eleventh sort grows naturally in *Tartary*. This plant hath weak climbing stalks which require support, they grow from four to eight feet high; the joints are far asunder, at each of these come two compound winged leaves, whose small leaves are placed by threes; these are deeply sawed on their edges and terminate in sharp points. The flowers come out from the wings of the leaves single, standing upon long naked foot-stalks, and are composed of four narrow spear-shaped petals, which spread open in form of a cross; they are of a yellowish white colour. After these are past, the germen become so many compressed seeds, each having a bearded tail.

The twelfth sort grows naturally in *Carolina*. This hath weak stalks which rise near four feet high, and by their clasps fasten themselves to the neighbouring plants, whereby they are supported. The leaves come out opposite at the joints: these are sometimes single, at others trifoliate, and some of the leaves are divided into three lobes. The flowers come out singly from the side of the branches upon short foot-stalks, with one or two pair of leaves below the flower, which are oblong, and sharp pointed. The flowers have four thick petals, like those of the ninth sort; of a purple colour, and their inner surface is curled, with many longitudinal furrows.

The two first sorts have perennial roots, which multiply pretty fast, but their stalks die down every autumn, and new ones arise in the spring, in which particular they differ from the other species, therefore require different management.

They are propagated either by seeds, or parting of their roots; but the former being a tedious method, the latter is generally practised. The best season for parting these roots is in *October*, just before their branches decay.

They will grow almost in any soil or situation; the roots may be cut through their crowns with a sharp knife, observing to preserve to every offset some good buds or eyes; and then it matters not how small you divide them, for their roots increase very fast; but if you part them very small, you should let them remain three or four years before they are again removed, that their flowers may be strong, and the roots multiplied in eyes.

The plants are extreme hardy, enduring the cold of our severest winters in the open air, and are very proper ornaments for large gardens, either to be planted in large borders, or intermixed with other hardy flower roots in quarters of flowering shrubs. They begin to flower about the beginning of *June*, and often continue to produce fresh flowers until *September*.

The third sort is found wild in most parts of *England*, growing upon the sides of banks, under hedges, and extends its trailing branches over the trees and shrubs that are near it. This plant in the autumn is generally covered with seeds, which are collected into little heads, each of which having, as it were, a rough plume fastened to it, hath occasioned the country people to give it the name of Old Man's Beard. It is titled by *Lobel* and *Gerard*, *Viorna*; and by *Dodonæus*, *Vitis alba*: in *English* it is commonly called Travellers Joy.

The fourth and fifth sorts have no more beauty than the third, so are seldom preserved in gardens, unless for the sake of variety. They are both as hardy as the common sort, and may be propagated either by seeds or laying down their branches.

The sixth sort retains its leaves all the year, which renders it valuable.

This sort doth not produce seeds in *England*, so it is propagated by layers, and also from cuttings. If they are propagated by layers, the shoots of the same year only should be chosen for this purpose, for the older branches do not put out roots in less than two years, whereas the tender shoots will make good roots in one: these must be pegged down into the ground in *October*, in the same manner as is usually practised for other layers, to prevent their rising. If the shoots have two inches of earth over them, it will be better than a greater depth. These layers will have strong roots by the following autumn, when they may be taken from the old plant, and transplanted where they are designed to remain.

All the varieties of Virgin's Bower, are easily propagated by laying down their branches; for although the single flowers do sometimes produce seeds in *England*, yet as these seeds, when sown, remain a whole year in the ground before they vegetate, so the other being the more expeditious method of increasing these plants, is generally practised: but in order to succeed, these layers should be put down at a different season from the former sort; for when they are layed in the autumn, their shoots are become tough, so do rarely put out roots under two years; and after lying so long in the ground, not one in three of them will have made good roots, so that many have supposed these plants were difficult to propagate; but since they have altered the season of doing it, they have found these layers have succeeded as well as those of other plants.

The best time for laying down of the branches is in *July*, soon after they have made their first shoots, for it is the young branches of the same year, which do freely take root; but as these are very tender, and apt to break, so there should be great care taken in the operation: therefore those branches from which these shoots are produced, should be first brought down to the ground, and fastened to prevent their rising; then the young shoots should be laid into the earth, with their tops raised upright, three or four inches above ground, and after the layers are placed down, if the surface of the ground be covered with Moss, rotten tanners bark, or other mulch, it will prevent the ground from drying, so that the layers will not require watering above three or four times, which should not be at less than five or six days interval; for when these layers have too much wet, the tender shoots frequently rot, or when the young fibres are newly put out, they are so tender, as to perish by having much wet: therefore where the method here directed is practised, the layers will more certainly take root, than by any other yet practised.

As these plants have all of them climbing branches, so they should be always planted where they may be supported, otherwise the branches will fall to the ground and appear unsightly; so that unless they are properly disposed, instead of being ornaments to a garden, they will become the reverse. Where there are arbours or seats with trellis work round them, these plants are very proper to train up against it; or where any walls or other fences require to be covered from the sight, these plants are very proper for the purpose; but they are by no means proper for open borders, nor do they answer the expectation when they are intermixed with shrubs; for unless their branches have room to extend, they will not be productive of many flowers.

The sort with double flowers is the most beautiful, so that should be preferred to those with single flowers, of which a few only should be planted for variety. They are all equally hardy, so are seldom injured by frost, excepting in very severe winters, when sometimes the very tender shoots are killed; but if these are cut off in the spring, the stems will put out new shoots.

The twelfth sort is also a very hardy plant, with climbing branches, so may be disposed in the same manner as the other. It is also propagated by layers, which will succeed, if performed at the same time, and in the same manner as is directed for the former.

CLEOME. *Lin. Gen. Plant.* 740.

The Characters are,

The flower hath four petals which are inclined upward, the lower being less than the other; in the bottom there are three mellous glands, which are separated by the empalement. It hath six or more incurved stamina fixed to their side: and a single style supporting an oblong germen, which afterward becomes a long cylindrical pod, having one cell opening with two valves, and filled with roundish seeds.

The Species are,

1. CLEOME *floribus gynandris, foliis digitatis.* *Hort. Cliff.* 341. Smooth five-leaved smaller Indian Bastard Mustard, with a flesh-coloured flower.
2. CLEOME *floribus hexandris, foliis ternatis; foliolis lanceolatis.* *Lin. Sp. Pl.* 672. Cleome with flowers having six stamina, trifoliolate leaves, and spear-shaped lobes.
3. CLEOME *floribus hexandris, foliis ternatis, foliolis linearilanceolatis, siliquis bisvalvibus.* Cleome with flowers having six stamina, trifoliolate leaves, narrow spear-shaped lobes, and pods having two valves.
4. CLEOME *floribus dodecandris, foliis quinatis ternatisque.* *Flor. Zeyl.* 241. Cleome with flowers having twelve stamina, and trifoliolate and quinquefoliate leaves.

5. *CLEOME floribus hexandris, foliis ternatis, foliolo intermedio majori.* Cleome with flowers having six stamina, and trifoliate leaves, whose middle lobe is the largest.

6. *CLEOME floribus hexandris, foliis septenis, caule spinoso, siliquis pendulis.* Cleome with flowers having six stamina, leaves with seven lobes, a prickly stalk, and hanging pods.

7. *CLEOME floribus hexandris, foliis quinatis ternatisque, caule spinoso.* Cleome with flowers having six stamina, leaves composed of five and three lobes, and a prickly stalk.

8. *CLEOME floribus hexandris, foliis simplicibus, ovato lanceolatis.* *Flor. Zeyl.* 243. Cleome with six stamina to the flowers, and single leaves, which are ovally spear-shaped.

The first sort grows naturally in *Asia, Africa, and America.* It rises with an herbaceous stalk about a foot high, garnished with smooth leaves, composed of five small leaves or lobes, joining at their base to one center, and spread out like the fingers of a hand. The leaves on the lower part of the stalk stand upon long foot-stalks, which are gradually shortened to the top of the stalk, where they almost join it: the flowers terminate the stalks in loose spikes. These have four petals of a flesh colour, which stand erect, spreading from each other, and below these are placed the stamina and style which coalesce at the bottom, and are stretched out beyond the petals. After the flower is past, the germen which sits upon the style, becomes a taper pod, about two inches long, filled with round seeds.

The second sort grows naturally in the *Levant.* This rises with an upright stalk about a foot high, garnished with leaves composed of three spear-shaped lobes, standing upon short foot-stalks; the flowers come out singly from the side of the stalks, and have four red petals, which stand in the same form as those of the former sort: these are succeeded by slender pods two inches long, which swell in every division, where each seed is lodged, so as to appear like joints, as those do of the Bird's-foot Trefoil; when the seeds are ripe, the whole plant decays. If the seeds of this sort are permitted to scatter, the plants will come up without care, and require only to be thinned and kept clean from weeds, for they will not bear transplanting.

The third sort grows naturally in *Portugal and Spain.* This rises with an herbaceous stalk about a foot high, sending out a few short side branches, garnished with leaves composed of three narrow lobes, standing upon short foot-stalks. The flowers come out singly from the side of the stalks, of a deep red colour, and are succeeded by thick taper pods, filled with round seeds. This is an annual plant, which will thrive in the open air, and requires the same treatment as the former.

The fourth sort grows naturally in the island of *Ceylon.* This rises a foot and an half high, sending out several side branches, garnished with leaves, some of which have five, and others three roundish lobes, standing upon short hairy foot-stalks. The flowers come out singly at the foot-stalks of the leaves, they are of a pale yellow, and are succeeded by taper pods between two and three inches long, ending in a point, which are full of round seeds. The whole plant sweats out a viscous clammy juice.

The fifth sort is an annual plant which rises two feet high, sending out many side branches, garnished with leaves, having one large spear-shaped lobe in the middle, and two very small ones on the side; these sit close to the branches. The flowers come out singly from the side of the branches, upon long foot-stalks: they have four large flesh-coloured petals, and six long stamina, which stand out beyond the petals; when the flowers fade, the germen which sits upon the style becomes a taper pod four inches long, filled with round seeds.

The sixth sort grows naturally in *Egypt and America.* This rises with a strong thick herbaceous stalk two feet and

an half high, dividing into many branches, which are garnished with leaves composed of seven long spear-shaped lobes, joining in a center at their base, where they sit upon a long slender foot-stalk: just below the foot-stalk, comes out one or two short thick yellow spines which are very sharp. The flowers come out singly from the side of the branches, forming a long loose spike at their extremities; this spike hath single broad leaves, which half surround the stalks at their base, from the bosom of which, come out the foot-stalks of the flowers, which are two inches long, each sustaining a large flesh-coloured flower, whose style and stamina are extended two inches beyond the petals. After the flower is past, the germen which sits upon the style, becomes a thick taper pod five inches long, which hangs downward, and is filled with round seeds.

The seventh sort grows naturally in the *Havannah.* This is also an annual plant, which rises near two feet high, branching out on every side: the lower leaves are composed of five oblong lobes standing upon long foot-stalks, but those on the stalks and branches have but three lobes, and have short foot-stalks: the main stalk and also the branches, are terminated by loose spikes of purple flowers, each sitting upon a slender foot-stalk, at the base of which is placed a single oval leaf. The stalks are armed with slender stiff spines, which are situated just under the foot-stalks of the leaves; when the flowers fade, the germen becomes a taper pod two inches long, filled with round seeds.

The eighth sort grows naturally in *Ceylon;* this is an annual plant which rises with an herbaceous stalk a foot high, garnished with long narrow single leaves, standing alternately on the stalks; from the wings of the leaves come out the foot-stalks of the flower, each sustaining a single yellow flower, which is succeeded by a very slender taper pod. All these plants except the second and third sorts, are natives of very warm countries, so will not thrive in *England,* without artificial heat; therefore their seeds must be sown upon a good hot-bed in the spring, and when the plants are fit to remove, they should be planted in separate small pots, and plunged into a fresh hot-bed, observing to shade them until they have taken root; after which, they should have plenty of air in warm weather. The plants when they are too tall to remain longer in the hot-bed, should be removed into an airy glass case, where they may be screened from cold and wet, but in warm weather may enjoy the free air. With this management the plants will flower soon after, and perfect their seeds in autumn. The second and third sorts may be sown in the open borders of the garden, where they are designed to remain, for they do not require any artificial warmth.

CLETHRA. Gron. Fl. Virg. 43.

The Characters are,

The flower hath five oblong petals; it hath ten stamina which are as long as the petals. In the center is situated a roundish germen, which afterward becomes a roundish capsule inclosed by the empalement, having three cells, which are full of angular seeds.

We know but one Species of this genus at present, viz.

CLETHRA. Gron. Fl. Virg. 43. There is no English title to this plant.

This shrub is a native of *Virginia and Carolina,* where it grows in moist places, and near the sides of rivulets, rising to the height of eight or ten feet. The leaves are in shape like those of the Alder tree, but are longer; these are placed alternately upon the branches: the flowers are produced at the extremity of the branches, in close spikes: they are composed of five leaves, are white, and have ten stamina in each, which are nearly of the same length with the petals.

This is hardy enough to bear the open air of *England,* and is one of the most beautiful shrubs at the season of its flowering; which is very little later than in its native country, being.

being commonly in flower here by the beginning of *July*; and if the season is not very hot, there will be part of the spikes in beauty till the beginning of *September*; and as most of the branches are terminated with these spikes of flowers, so when the shrubs are strong, they make a fine appearance at that season.

This shrub will thrive best in moist land, and requires a sheltered situation, where it may be defended from strong winds, which frequently break off the branches, where they are too much exposed to its violence. It is propagated by layers, but they are generally two years before they get root. They may also be propagated by suckers, which are sent out from their roots; if these are carefully taken off with fibres in the autumn, and planted into a nursery bed, they will be strong enough in two years to transplant where they are to remain.

CLIFFORTIA. *Lin. Gen. Plant.* 1004.

The Characters are,

It hath male and female flowers in different plants: the male flowers have a spreading empalement, composed of three small oval concave leaves, but no petals, with a great number of hairy stamina. The female flowers have a permanent empalement composed of three leaves, sitting upon the germen; these have no petals, but the oblong germen which is situated below the empalement, supports two long slender feathered styles; the germen afterward becomes an oblong taper capsule, with two cells crowned by the empalement, including one narrow taper seed.

The Species are,

1. CLIFFORTIA *foliis subcordatis, dentatis.* *Lin. Sp. Plant.* 1308. Cliffortia with heart-shaped, indented leaves.

2. CLIFFORTIA *foliis ternatis, intermedio tridentato.* *Prod. Leyd.* 253. Three-leaved Cliffortia, whose middle leaf is cut in three parts.

3. CLIFFORTIA *foliis lanceolatis, integerrimis.* *Hort. Cliff.* 463. Cliffortia with spear-shaped leaves which are entire.

The first sort grows naturally at the *Cape of Good Hope*. It rises with a weak shrubby stalk four or five feet high, sending out many diffused branches, which spread on every side, requiring some support: these are garnished with leaves, which are heart-shaped at their base, but are broad at their ends, where they are sharply indented. They are very stiff, of a grayish colour, and closely embrace the stalks with their base, and are placed alternate on the branches; and from the bosom of these arise a single flower, sitting close to the branch, having no foot-stalk. Before the empalement is spread open, it forms a bud, in shape and size of those of the *Caper*; this empalement is composed of three green leaves, which afterwards spread open, and then the numerous stamina appear standing erect.

This plant is easily propagated by cuttings, which may be planted in any of the summer months, which will soon take root, provided they are screened from the sun, and duly watered; when they have taken root, they may be each transplanted into a separate small pot, and placed in the shade until they have taken fresh root, after which they may be placed with other of the hardy kinds of exotick plants, in a sheltered situation till *October*, when they should be removed into the green-house, or placed under a common hot-bed frame, where they may be screened from the hard frost, but enjoy the free air at all times when the weather is mild. This plant has endured the cold of our ordinary winters, planted near a south-west wall without covering; but in severe winters they are always destroyed.

The second sort is a native of the same country as the first, this hath very slender ligneous stalks, which must be supported, otherwise they will fall to the ground. The branches are garnished with trifoliate leaves standing close to them; the middle lobes of these are much larger than the two side, and are indented in three parts. The

flowers of this come out from the bosom of the leaves, having very short foot-stalks, and are shaped like those of the first, but are smaller. This sort requires the same management as the first, and is equally hardy, but must not be over watered in winter. The leaves of this sort continue green all the year.

The third sort rises with a weak shrubby stalk about four feet high, sending out lateral branches, which are covered with a whitish bark, and garnished with leaves, placed in clusters without order; these are stiff, of the consistence and colour of the *Butchers Broom*, but are narrower, and run out to a longer point. Between these clusters of leaves the flowers come out in loose bunches; these have a great number of yellowish stamina, included in a three-leaved empalement.

This plant is tenderer than either of the former sorts, so should be placed in a good warm green-house in winter, and during that season, they must have but little water. In the summer they may be exposed to the open air in a sheltered situation, but they should not remain too late abroad in the autumn; for if there should be much rain at that season, it would endanger these plants, if they are exposed to it.

CLINOPODIUM. *Lin. Gen. Pl.* 644. Field Basil.

The Characters are,

The flower is of the lip kind, with a short tube enlarging to the mouth; the upper lip is erect, and indented at the top; the under lip is trifid, the middle segment being broad and indented. It hath four stamina under the upper lip, two of which are shorter than the other. In the center is situated the quadripartite germen, which afterward become four oval seeds skat up in the empalement.

The Species are,

1. CLINOPODIUM *capitulis subrotundis, hispidis, bracteis setaceis.* *Lin. Sp. Plant.* 587. Field Basil with roundish prickly heads, and bristly bractea.

2. CLINOPODIUM *foliis subtus tomentosis, verticillis explanatis, bracteis lanceolatis.* *Lin. Sp. Pl.* 588. Field Basil with leaves which are woolly on the under side, broad plain whorls, and spear-shaped bractea.

3. CLINOPODIUM *foliis rugosis, capitulis axillaribus, pedunculatis, explanatis, radiatis.* *Lin. Sp. Plant.* 588. Field Basil with rough leaves, plain heads growing on the sides of the stalks, which have foot-stalks, and are radiated.

4. CLINOPODIUM *humile ramosum, foliis rugosioribus, capitulis explanatis.* Low branching Field Basil with rougher leaves, and plain heads.

5. CLINOPODIUM *caule erecto, non ramoso, foliis subtus villosis, verticillis paucioribus, bracteis calyce longioribus.* Field Basil with an upright, unbranching stalk, leaves hairy on their under side, fewer whorls, and bractea longer than the empalement.

6. CLINOPODIUM *foliis ovatis rugosis, verticillis distantibus, i. e.* Field Basil with oval rough leaves, and the whorls of flowers standing at a great distance.

The first sort grows naturally by the side of hedges, and in thickets, in most parts of *England*; this hath a perennial fibrous root, which sends up several stiff square stalks, a foot and an half high, which send out a few lateral branches toward the top, garnished with oval hairy leaves, placed by pairs; at the top of the stalks the flowers come out in round whorls, or heads; one of these terminate the stalk, and there is generally another which surrounds the stalk at the joint immediately below it. The flowers are sometimes purple, at others white. The whorls (or heads) grow very close, and each foot-stalk sustains several flowers. At the base of the empalement stand two bristly spines, which *Linnaeus* terms the bractea; these stand almost horizontal under the empalement. The flower is of the labiated, or lip kind. The upper lip is broad and trifid, but the under is cut into two narrow segments; each flower is suc-

ceeded by four naked seeds, sitting at the bottom of the empalement.

The second sort grows naturally in *Pensylvania* and *Carolina*; this hath a perennial root, which sends up many square stalks about two feet high, which put out a few short side branches toward the upper part, garnished with oblong oval leaves, about the size of those of Water Mint, standing by pairs close to the stalk; they are hoary, and soft to the touch, and have a strong odour, between that of Marjoram and Basil. The flowers grow in flat smooth whorls round the stalks; each stalk hath generally three of these whorls, the upper which terminates the stalk being smaller, the two other increasing, so that the lower is the greatest. The flowers are of a pale purple colour, and shaped like those of the first sort, but the stamina of this stands out beyond the petal, and the bractea at the base of the empalement are large, spear-shaped, and indented on their sides.

The third sort grows naturally in *Carolina*. This hath a perennial root, sending up several square stalks, which are closely covered with brownish hairs; these rise between two and three feet high; they are garnished with leaves, which are very unequal in their size, those at the bottom, and also toward the top being above three inches long, and one inch and a quarter broad, whereas those in other parts of the stalk are not half so large; they are rough on their upper side, hairy below, sawed on their edges, and stand opposite by pairs: all the lower part of the stalk, but immediately below the foot-stalks of the flower heads, there are three large leaves standing round the stalks; between these arise two slender hairy foot-stalks, about three inches long, one on each side the stalk; these sustain small heads of flowers, shaped like those of the Scabious; they are white, shaped like those of the other but smaller; the bractea immediately under the empalement, spread out like rays.

The fourth sort grows also in *Carolina*. This hath some appearance of our common sort, but the stalks do not grow more than half so high, and divide into many long side branches; the leaves are smaller and rougher, and the whorls of flowers are produced half the length of the branches, whereas the common sort hath rarely more than two; the bractea at the base of the empalement are also much longer.

The fifth sort grows in *Carolina*. This hath a perennial root, sending up strait hairy stalks, which are almost round; the joints of these are four or five inches asunder, at each of these come out two oblong leaves, hairy on their under side, standing upon short foot-stalks; at the bottom of these come out on each side, a slender branch, half an inch long, having two or four small leaves, shaped like the other. The flowers are produced in small whorls, standing thinly; these are white, and the bractea are longer than the empalement.

The sixth sort is a native of *Egypt*. It hath a perennial root, but annual stalks, which grow a foot and an half high, garnished with oval leaves, having many transverse deep furrows, and are of a dark green colour, placed opposite, at about five or six inches asunder. There are commonly two or four side branches from the main stems, produced toward the bottom; and the whorls of flowers are produced at every joint, toward the upper part of the stalks; these are pretty large and hairy. The flowers are somewhat larger than those of the common Field Basil, and are of a deeper colour, stretching a little more out of the empalement. The leaves of this have at first sight much the same appearance, but when they are observed with attention, the difference is soon perceived between the two sorts: but the greatest difference is in the leaves and whorls of flowers being placed at a greater distance, and the stalks

growing sparsedly in this species; nor do the plants continue so long as those of the common sort.

This plant approaches near to the *Clinopodium Orientale* *Origani folio, flore minimo*. *Tour. Corol.* 12. But by comparing this with a specimen of that sort from the *Paris* garden, I find the leaves of that are smoother, and placed much nearer together on the stalks than those of this sort, and the flowers are smaller.

These plants may be propagated by seeds, and also by parting of their roots; the latter is generally practised in *England*. The best time to transplant and part their roots is in autumn, that they may take root before winter; if these are planted in a dry soil, they are all of them, except the third sort, hardy enough to thrive in the open air in *England*, and require no other care but to keep them clean from weeds, and every other year they may be transplanted and parted.

The third sort must be planted in pots, and in winter sheltered under a frame, where the plants may enjoy the free air in mild weather, but screened from frost, otherwise it will not live in this country.

CLITORIA. *Lin. Gen. Plant.* 796.

The Characters are,

The flower is of the butterfly kind, having a large spreading standard, which is erect; the two wings are oblong, and shorter than the standard. The keel is shorter than the wings, and is hooked. It hath ten stamina, nine of which are joined, and one stands separate. In the center is situated an oblong germen, which afterward becomes a long narrow compressed pod, with one cell, opening with two valves, inclosing several kidney-shaped seeds.

The Species are,

1. CLITORIA *foliis pinnatis*. *Hort. Cliff.* 360. Clitoria with winged leaves.

2. CLITORIA *foliis ternatis, calycibus campanulatis solitariis*. *Hort. Upsal.* 215. Clitoria with trifoliate leaves, and a single flower with a bell-shaped empalement.

3. CLITORIA *foliis ternatis, calycibus campanulatis geminis*. *Flor. Virg.* 83. Three-leaved Clitoria with two flowers joined, whose empalements are bell-shaped.

4. CLITORIA *foliis ternatis, calycibus cylindricis*. *Lin. Sp. Plant.* 753. Clitoria with trifoliate leaves, and cylindrical empalements to the flowers.

The first sort grows naturally in *India*. There is a variety of this with white flowers, and another with large blue flowers, which make a fine appearance.

This rises with a twining herbaceous stalk, to the height of four or five feet, in the same manner as the Kidney-bean, and requires the like support, for in the places where it grows naturally, it twists itself about the neighbouring plants; the stalks are garnished with winged leaves, composed of two or three pair of lobes, terminated by an odd one; these are of a beautiful green, and are placed alternate on the stalks; from the appendages of the leaves, come out the foot-stalks of the flowers; each of these is encompassed by two very fine leaves about the middle, where they are bent, sustaining a very large gaping beautiful flower, whose bottom part seems as if growing to the top.

The second sort grows naturally in the *Brazils*, from whence the seeds were brought to *Europe*; this hath a twining stalk like the former, which rises five or six feet high, and is garnished at each joint with one trifoliate leaf, standing upon a long foot-stalk. The flowers come out singly from the foot-stalk of the leaves, standing upon pretty long foot-stalks, which are encompassed about the middle with two small oval leaves; the flowers are very large, the standard being much broader than that of the first sort, and the two wings are larger; the flowers are of a fine blue colour, so make a fine appearance.

There is one with a double flower of this, which I raised in the *Chelsea* garden some years past, from seeds sent me from *India*, but the plants did not produce seeds here, and being annual, the sort was lost. The flowers of this were very beautiful.

The seeds of the third sort were sent me from the *Babama* islands; this sends out from the root two or three slender twining stalks, which rise to the height of six or seven feet, and are garnished at each joint with one trifoliate leaf, whose lobes are oblong, and pointed. At the opposite side of the stalk, the foot-stalk of the flower arises, which is little more than an inch long, naked, and sustains a single flower, which is of a purple colour within, but of a greenish white on the outside, not half so large as either of the former. These flowers are each succeeded by long, slender, compressed pods, ending in a point, which contain one row of roundish kidney-shaped seeds.

The seeds of the fourth sort were sent me from *Carolina*, where the plants grow naturally. This rises with a twining weak stalk about five feet high, and is garnished with trifoliate leaves like the former, whose lobes are narrower, and of a grayish colour on their under side; the flowers come out by pairs on the foot-stalks, and their empalements are cylindrical: the flowers are small, and of a pale blue colour within, but of a dirty white on the outside.

All these sorts are annual with us in *England*, so that unless the seeds ripen, the species are lost; and as the two sorts with double flowers, have not formed any pods in this country, so far as I have been able to learn, therefore the seeds of these must be procured from the countries where they naturally grow.

The seeds of these plants must be sown upon a good hot-bed early in the spring, and when the plants are two inches high, they should be carefully taken up, and each planted in a small pot, and plunged into a hot-bed of tanners bark, observing to shade them till they have taken fresh root. After they are well rooted in the pots, they must have air every day in proportion to the warmth of the season, to prevent their drawing up weak; their waterings should be repeated two or three times a week, but they should not have too much at each time. As these plants have climbing stalks, so they will soon grow too tall to remain under common frames, therefore they must then be removed into the stove, and plunged into the bark bed, and afterward they must be treated in the same manner as other plants from the same countries.

CLUSIA. *Lin. Gen. Plant.* 577. *Plum. Nov. Gen.* 20. tab. 20. The Balsam tree.

The Characters are,

The flower hath five large roundish concave spreading petals. In the bottom is situated a globular nectarium, including the germen, which is pervious at the top. It hath a great number of single stamina; the oblong oval germen is terminated by a plain star-like stigma with six obtuse indentures, which afterward becomes an oval capsule with six furrows and six cells, opening with six valves, which spread in form of a star, including many angular seeds fixed to a column, surrounded with pulp.

The Species are,

1. CLUSIA foliis crassis subrotundis nitidis, caule arboreo. Clusia with thick shining roundish leaves, and a tree-like stalk; commonly called Balsam tree in *America*.

2. CLUSIA foliis venosis. *Lin. Sp. Pl.* 510. Clusia with veined leaves.

There are two or three varieties of the first sort, which differ in the size and colour of their flowers and fruit; one hath a white flower and scarlet fruit, another hath a Rose flower and a greenish fruit, and the third hath a yellow fruit: but these are only supposed to be feminal variations.

The first sort is pretty common in the *British* islands of

America, where the trees grow to the height of twenty feet, and shoot out many branches on every side, which are furnished with thick round succulent leaves placed opposite. The flowers are produced at the ends of the branches, each having a thick succulent cover. After the flowers are past, they are succeeded by oval fruit. From every part of these trees there exudes a sort of turpentine, which is called in the *West-Indies* hog-gum; because they say, that, when any of the wild hogs are wounded they repair to these trees, and rub their wounded parts against the stems of these trees, till they have anointed themselves with this turpentine, which heals their wounds.

As these plants are tender, so they must be constantly kept in the stove, otherwise they will not live through the winter in *England*; they must also be watered very sparingly, especially in winter; for they naturally grow in those parts of the islands, where it seldom rains, therefore they cannot bear much moisture.

They may be propagated by cuttings, which must be laid to dry when they are cut off from the plants for a fortnight or three weeks, that the wounded part may be healed over, otherwise they will rot: when the cuttings are planted, the pots should be plunged into a hot-bed of tanners bark, and now and then gently refreshed with water. The best time for planting these cuttings is in *July*, that they may be well rooted before the cold weather comes on in autumn. In winter these plants may be placed upon stands in the dry stove; but if in summer they are plunged into the tan bed, they will make great progress, and their leaves will be large, in which consists the great beauty of these plants.

The second sort was discovered by the late Dr. *Houfston* at *Campeachy*. This hath very large oval spear-shaped leaves ending in points, which are placed alternate on the branches, and have seven ribs, which go off from the midrib alternate; and also a great number of small veins running horizontally between these ribs. The borders of the leaves are sawed, and their under sides are of a shining brown colour. The branches are covered with a woolly down, and the flowers are produced in loose spikes at the end of the shoots; these are smaller than those of the former sort, and are of a Rose colour. This tree rises to the height of twenty feet; it is propagated by seeds. The plants are tender, so must be placed in the tan bed of the bark stove, otherwise they will not thrive in this country; and they must be treated in the same manner as is directed for other tender plants from the same countries.

CLUTIA. *Lin. Gen. Plant.* 1009.

The Characters are,

It is male and female in different plants. The male flowers have five heart-shaped petals which are shorter than the empalement, and spread open. They have five exterior nectariums, which are situated in a circle at the bottom of the petals; and five interior, which are situated within the other. They have five stamina situated in the middle of the style. The female flowers have petals like those of the male; these have five double exterior nectariums, but no interior; they have a roundish germen, which afterward becomes a globular capsule with six furrows and three cells, each containing a single seed.

The Species are,

1. CLUTIA foliis sessilibus lanceolatis. *Hort. Cliff.* 500. Clutia with spear-shaped leaves sitting close to the stalks.

2. CLUTIA foliis ovatis integerrimis, floribus lateralibus. *Lin. Sp. Plant.* 1042. Clutia with oval entire leaves, and flowers growing from the side of the branches.

3. CLUTIA foliis cordato lanceolatis. *Flor. Zeyl.* Clutia with heart-formed spear-shaped leaves.

4. CLUTIA foliis lanceolatis acutis integerrimis petiolatis. *Lin. Sp. Pl.* 1042. Clutia with entire spear-shaped pointed leaves, having foot-stalks.

The two first sorts are natives of *Africa*. The first sort with female flowers has been long an inhabitant of some curious gardens in *England*, but that with male flowers has been but few years here.

The second sort has also been some years in the *English* gardens, and was ranged in the genus of *Alaternoides*, but we have not the male of this sort in *England* at present.

The first sort rises with a shrubby stalk to the height of six or eight feet, putting out many side branches, garnished with small spear-shaped leaves, placed alternate, sitting close to the branches: they are of a grayish colour and entire. The flowers come out from the joints, at the sitting on of the leaves, toward the upper part of the branches: these are small and of a greenish white: they appear in *June*, *July*, and *August*, but being small make no great appearance.

The second sort rises about the same height with the first, but hath a stronger stem; the branches are garnished with oval leaves, which are much larger than those of the first sort, having foot-stalks which are an inch long; these are of a sea-green, and entire; the flowers are like those of the first sort in shape and colour, but those on the male plants are smaller, and grow closer together than those of the female, but both are sustained upon short foot-stalks; the seeds ripen in autumn.

These plants are easily propagated by cuttings during any of the summer months, when they will soon take root, and then may be each put into a separate small pot, and placed in a sheltered situation, where they may remain until the middle of *October*, or later, if the weather continues mild, when they should be removed into the green-house, and placed where they may have the free air in mild weather, for they only require to be protected from frost. In summer they must be placed abroad, in a sheltered situation, with other hardy exotick plants.

The third sort grows naturally in *India*, from whence the seeds were brought. This rises with an upright shrubby stalk, not more than three or four feet in *England*; but in the places where it grows naturally, it rises upward of twenty feet high, and sends out many branches at the top, so as to form a large spreading head: the branches are garnished with leaves, shaped like those of the black Poplar, which are of a lucid green, and are placed alternate, standing upon slender foot-stalks.

This plant will live through the winter in an airy glass case, without artificial heat, but in that situation they should have very little water in the winter; for the plants abound with a milky juice like the *Euphorbia*, so must at no season of the year have too much wet. This sort may be propagated by cuttings during the summer season; but the cuttings should be laid in a dry place for a few days, when they are taken from the old plants, that their wounded parts may dry and be healed over, before they are planted. These must be planted in small pots, and plunged into a moderate hot-bed of tanners bark; and if the season is very warm, the glasses should be shaded in the heat of the day; they must be very sparingly watered, for much wet will cause them to rot. When they have taken root, and begin to shoot, they must have a greater share of air, and by degrees inured to the open air, and each planted in a separate pot, and placed in the shade till they have gotten fresh root, after which they may be exposed gradually to the open air. In the summer they should have free air constantly in warm weather, but they must be screened from heavy rain, and in winter placed in an airy glass case, where they may enjoy the sun, and during that season have very little wet.

The fourth sort grows naturally in the *Bahama* islands, and also near the *Havannah*. This rises about twelve or fourteen feet high, with several shrubby stems, which divide into many branches, garnished with narrow pale green leaves, placed

alternate, standing upon pretty long foot-stalks; the flowers come out in long loose spikes from the side of the branches; these are white, with yellow summits, and are succeeded by small round capsules, having three cells, in each of which is lodged a single black seed. The bark of this tree, when burned, emits a fine perfume; and if infused in wine or water, gives either a fine aromattick bitter. This plant may be propagated in the same manner as the former, but requires a stove to preserve it through the winter, and is very impatient of moisture, so should have very little water.

CLYPEOLA. *Lin. Gen. Pl.* 723. Treacle Mustard.

The Characters are,

The flower hath four oblong entire petals, placed in form of a cross, and six stamina, two of which standing opposite are shorter than the other. In the center is situated a roundish compressed germen, which after-ward becomes an orbicular pod, which is compressed, erect, and indented at the top, with a longitudinal fissure, opening in two cells, containing round compressed seeds.

The Species are,

1. CLYPEOLA *siliculis unilocularibus monospermis*. *Hort. Cliff.* 329. Clypeola with pods having but one cell and a single seed.

2. CLYPEOLA *siliculis bilocularibus tetraspermis*. *Hort. Cliff.* 329. Clypeola with pods having two cells and four seeds.

3. CLYPEOLA *annua siliculis bilocularibus dispermis, calycibus persistentibus*. *Sauv. Monsp.* 71. Annual Clypeola with pods having two cells and two seeds, and a permanent empalement.

4. CLYPEOLA *perennis, siliculis bilocularibus ovatis dispermis*. *Sauv. Monsp.* 71. Perennial Clypeola with oval pods, having two cells and two seeds.

The first sort is a low annual plant, which seldom rises more than four inches high; the slender branches commonly lie prostrate on the ground; these are garnished with small leaves, narrow at their base, but are broader at their ends, where they are obtuse. The flowers are produced in short close spikes at the extremity of the branches, which are small, yellow, and composed of four leaves placed in form of a cross; these are succeeded by orbicular compressed seed vessels, each having one cell, containing a single seed.

The second sort rises with slender ligneous stalks, near six inches high; which grow erect, and are garnished with small, oblong, hairy leaves, placed alternate, standing close to the stalks. The flowers are produced in long spikes at the end of the branches, which are yellow, and shaped like those of the first sort, but larger; these are succeeded by roundish flat pods, having two cells, each containing two seeds.

The third sort hath several weak ligneous stalks, about four inches long, which are garnished with very narrow hoary leaves, and are terminated by short spikes of yellow flowers, which are smaller than those of the last sort; the pods are also much less, and have two cells, each containing a single seed.

The fourth sort is perennial; this branches out from the root into several slender branches, garnished with very narrow hoary leaves, sitting close to the branches. The flowers are produced in spikes at the end of the branches; these are small, white, and shaped like those of the other sorts, but the spikes terminate in a roundish bunch.

The three first sorts are low annual plants, which grow naturally in the south of *France*, in *Spain*, and *Italy*; they are all of a hoary white, both leaves and stalks, which is much lighter in the warm countries than in *England*; they are propagated by seeds, which should be sown where they are to remain, and will require no other culture, but to thin them, and keep them clean from weeds. The seeds may be sown either in the spring, or autumn; those which are

sown

sown in autumn will grow much larger, and flower earlier than those which are sown in the spring, and from them there will be a greater certainty of having ripe seeds.

The fourth sort is a perennial plant, so should be sown upon a warm border; this grows naturally on the borders of the sea, in the south of *France* and *Italy*, but when it is cultivated in a garden, if the soil is rich and moist, the plants generally grow luxuriant in summer, and are thereby too replete with moisture, so that they are frequently killed by the frost in winter; but when they grow on a poor dry gravelly soil, or on a wall, their stalks will be short, ligneous, and tough, so will endure the cold of this climate, and continue several years; this is propagated by seeds, which should be sown where the plants are designed to remain; or if any of them are removed, it should be done when the plants are young, for they do not bear transplanting well, when they are grown pretty large.

CNEORUM. *Lin. Gen. Pl.* 47. Widow-wail.

The Characters are,

The flower hath three narrow oblong petals, and three stamina, which are shorter than the petals. In the center is situated an obtuse three-cornered germen, which afterward becomes a globular dry berry, with three lobes, having three cells, each containing one round seed.

We have but one Species of this genus, viz.

CNEORUM. *Hort. Cliff.* 18. Widow-wail. This is the *Chamelæa tricoccus* of *Dodonæus* and *Cospar Baubin*.

It is an humble shrub, which seldom rises more than two feet and an half high in this country, but spreads out on every side with many lateral branches, so as to form a thick bush. The stems are almost as hard as those of the Box tree, and the wood is of a pale yellow colour under the bark. The branches are garnished with leaves, which are stiff, of an oval shape, about an inch and an half long, and a quarter of an inch broad, of a dark green colour, having a strong vein, or rib, through the middle. The flowers are produced single from the wings of the leaves, toward the extremity of the branches, which are of a pale yellow colour, composed of three petals, which spread open, and a round germen at the bottom, having a single style, which doth not rise above half the length of the stamina, which are three in number, standing erect, and are situated between the petals. After the flowers are fallen, the germen becomes a fruit, composed of three seeds joined together after the same manner as those of *Tithymalus*, or *Spurge*; these are first green, afterwards turn of a brown colour, and when ripe are black.

As this is a low ever-green shrub, so it may be very ornamental, if placed in the front of plantations of ever-green trees and shrubs; for as the branches grow pretty compact, and are well garnished with leaves, so it will hide the ground between the taller shrubs better than most other plants; and, being a durable shrub, will not want to be renewed; it rises better from scattered seeds, than if sown with care.

It is propagated by seeds, which should be sown in autumn soon after they are ripe, and then the plants will come up the following spring; whereas those which are not sown till the spring, will remain a year in the ground, and often miscarry; these seeds may be sown in a bed of common earth, covering them half an inch deep, and will require no other care but to keep the plants clear from weeds the following summer; and in the autumn following, the plants may be transplanted where they are to remain.

CNICUS. *Lin. Gen. Pl.* 833. Blessed Thistle.

The Characters are,

The empalement of the flower is scaly. The flower is composed of several hermaphrodite florets, which are uniform; these are funnel shaped, and cut at the top into five equal segments, having five short hairy stamina. In the center is situated a short

germen, crowned with down, which afterward becomes a single seed, crowned with down, and shut up in the empalement.

The Species are,

1. CNICUS caule diffuso, foliis dentato-sinuatis. *Hort. Cliff.* 395. Blessed Thistle with a diffused stalk, and leaves indented in sinuses; Hairy, or Blessed Thistle.

2. CNICUS caule erecto, foliis inferioribus laciniatis, superioribus integris concavis. *Hort. Cliff.* 394. Cnicus with an upright stalk, whose lower leaves are lacinated, the upper entire and concave.

3. CNICUS foliis amplexicaulibus, sinuato-pinnatis, spinosis, caule simplici, floribus sessilibus. *Lin. Sp. Pl.* 826. Cnicus with winged, sinuated, prickly leaves, embracing the stalk, which is single, and flowers sitting close on the top.

4. CNICUS foliis cordatis, petiolis crispis, spinosis, amplexicaulibus, floribus cernuis. *Hort. Upsal.* 251. Cnicus with heart-shaped leaves, having curled prickly foot-stalks, which embrace the stalks, and a nodding flower.

The first sort is the common *Carduus* which is used in medicine; this is an annual plant, which perishes soon after the seeds are ripe. It grows naturally in *Spain*, and the islands of the *Archipelago*, but is cultivated in gardens in *England* to supply the markets. This plant is so well known, as to require no description.

The seeds of this plant should be sown in autumn on a bed of common earth, and in the spring the plants should be transplanted, placing them in rows at two feet distant, and one foot asunder in the rows; if the season proves dry, it will be necessary to water the plants two or three times, till they have taken root, after which they will require no other culture but to keep them clean from weeds.

The best time to cut this plant for use, is when the flowers are fully blown, before the lower leaves decay; when it is cut, it should be spread in a dry shady place for three or four days, then tied up in bunches, and hung up in a dry room upon strings in rows, that the air may pass freely between them, which will prevent their growing mouldy, or rotting.

The second sort grows naturally in the northern parts of *Europe*. This hath a perennial root, which sends out many long jagged leaves spreading on every side near the ground, so as to form a thick bunch; these are jagged almost to the midrib, in form of a winged leaf. The stalks are striated, smooth, and rise about four feet high. The leaves, which grow upon the stalks, are entire and heart-shaped; they are sawed on the edges, each indenture ending in a weak spine. The stalks are terminated by large heads of flowers, growing in clusters; they are of a whitish yellow colour, and inclosed in a scaly empalement. These are succeeded by small oblong seeds, crowned with a bristly down.

This sort may be propagated by seeds, or parting of the roots; the latter is commonly practised where there are any of the plants, but the seeds are more easily conveyed to a distant place. The best time to part the roots is in autumn; it delights in shade, and requires no farther care but to keep it clean from weeds.

The third sort grows naturally on the *Alps*, and on the mountains of *Austria*; this rises with an upright single stalk near four feet high, garnished with sinuated leaves, which are very prickly, and embrace the stalks with their base; the flowers are produced at the top of the stalk, surrounded by a cluster of broad prickly leaves, sitting close to the stalk. This is a perennial plant, which may be propagated in the same manner as the former, and requires a moist soil and a shady situation.

The fourth sort grows naturally in *Siberia*. This hath a perennial root, composed of thick fleshy fibres. The leaves which rise immediately from the root, are near a foot long, and six inches broad in the middle, diminishing toward each

each end; these have scarce any foot-stalks; they are of a deep green on their upper side, but white on their under, and sharply sawed on their edges. The stalks rise more than six feet high, and are striated, of a reddish colour, garnished with heart-shaped leaves, which almost embrace the stalks with their base; each branch is terminated by one large globular head of yellowish flowers, included in a scaly empalement, each scale ending with a sharp spine. It may be propagated in the same manner as the two former sorts, but requires a moist soil and shady situation. The inhabitants of *Siberia* eat the tender stalks of this plant, when boiled, instead of other vegetables.

COA. See Hippocratea.

COAST-MARY. See Tanacetum.

COCCIGRIA. See Rhus.

COCCOLOBA. *Brown. Hist. Jam.* 209. The Sea-side Grape.

The Characters are,

The flower has one permanent petal which is cut into five segments; it has a fleshy umbilical nectarium which surrounds the germen, and six, seven, or more erect spreading stamina, and an oval germen, which afterwards turn to a fleshy berry including an oval nut, which is wrapped up in the petal of the flower.

The Species are,

1. COCCOLOBA *foliis crassis orbiculatis, sinu aperto. Hist. Jam.* 209. Sea-side Grape with round thick leaves which are open at the base.

2. COCCOLOBA *foliis cordato-oblongis, racemo terminatrice, caule arboreo. Burm.* The Sea-side Grape with oblong heart-shaped leaves, and a tree-like stalk, terminated by long bunches of fruit.

3. COCCOLOBA *foliis cordato-ovatis, racemo terminatrice.* Sea-side Grape with heart-shaped oval leaves, and the branches terminated by long bunches of fruit.

4. COCCOLOBA *foliis peltato-cordatis.* Sea-side Grape with target heart-shaped leaves.

5. COCCOLOBA *foliis lanceolatis venosis, uvis minoribus punctatis.* Sea-side Grape with spear-shaped veined leaves, and small spotted fruit; called Checquered Grape in *America*.

6. COCCOLOBA *foliis ovato-lanceolatis acuminatis, caule arboreo.* Mountain Grape with oval spear-shaped leaves ending in acute points, and a tree-like stalk.

The first sort grows naturally in most of the islands in the *West-Indies*, upon the sandy sea shores, from whence the inhabitants have given it the title of Sea-side or Mangrove Grape; this sends up several woody stalks from the root, which rise eight or ten feet high, with a light brown smooth bark, garnished with leaves which are placed alternately; they are very thick and stiff, almost round, from five to seven inches diameter, of a lucid green on their upper side, and veined on their under, standing upon short foot-stalks. The flowers come out from the wings of the stalks; they are disposed along the foot-stalk in long slender bunches, like those of the common Currant; these bunches are five or six inches long. The flowers are white, and the petal is cut into six parts; these are succeeded by berries about the size of a common Grape, of a purplish red colour, inclosing a nut of the same shape.

This plant is figured by *Lobel* under the title of *Populus novi orbis*, and has been copied by *Parkinson* in his *Herbal*, and several others.

The second sort grows naturally about *Carthage*; this sends out many strong stalks from the root, which rise near twenty feet high, and are covered with a smooth gray bark. The leaves are from seven to nine inches long, and from three to four broad; they are indented at the foot-stalk like a heart, but end in a point, having several transverse veins running alternately from the midrib to the border, of a thick

stiff consistence, and of a lucid green on their upper side. The flowers are produced in long slender bunches at the end of the branches; they are composed of five white acute-pointed petals, which spread open in form of a star; these are succeeded by roundish purple fruit, smaller than those of the former sort, and not so well flavoured.

The third sort grows naturally at *La Vera Cruz* in *New Spain*; this sends up many shrubby stalks from the root, which rise five or six feet high, having a light gray bark. The leaves are oval and heart-shaped, three inches long, and two and an half broad, indented at their foot-stalks; these are not so stiff as those of the two former sorts. The fruit is disposed in a slender bunch at the end of the branches; they are small, and of a dark purple colour, and are never eaten by the inhabitants.

The fourth sort grows naturally at *Campeachy*; this sends up many slender ligneous stalks from the root, which rise to the height of seven or eight feet, covered with a gray bark, garnished with heart-shaped leaves about four inches long and three broad, whose foot-stalks are joined to the under part of the leaves, like the handle of a target. The leaves are of a lucid green, and smooth on their upper side; the flowers and fruit of this sort I have not seen.

The fifth sort grows naturally in *Jamaica*; this sends up many slender ligneous stalks from the root, which rise four or five feet high, covered with a brown bark. The leaves are six inches long and three broad, having many strong veins running from the midrib toward the border; they are of a light green colour, and are not so stiff at the former. The fruit is small, of a purple colour, growing in slender bunches from the end of the branches.

The sixth sort grows naturally on the north side of the island of *Jamaica* upon the mountains, so is generally there called the Mountain Grape; this sort grows to a large size, and is esteemed for its wood, which is ranked among their best sort of timber. The trunk of this tree grows to the size of a man's body; it rises to the height of thirty feet, sending out side branches, which are garnished with oval spear-shaped leaves, ending in acute points; they are six inches long, and two and a half broad toward their base; of a bright green on their upper side, but are pale on their under, of a thick consistence, and stand upon short foot-stalks. The fruit of this is produced on long slender foot-stalks; they are of a purplish colour, and are almost as large as those of the first sort.

These plants rise easily from seeds, if they are sown in pots, and plunged into a hot-bed of tan; but as they do not produce fruit in *England*, the seeds must be procured from the *West-Indies*. When the plants are come up about two or three inches high, they should be each transplanted into a separate small pot, and plunged into a fresh hot-bed of tan, where they must be shaded from the sun until they have taken new root; after which they must be treated in the same manner as the *Annona* and other tender plants from hot countries, giving them a proper share of air in warm weather, and gently refreshing them with water; but they should not have too much wet, for they do not perspire much, their leaves being of a very close contexture, especially those of the first and second sorts. In autumn these plants should be removed into the hot-house, and plunged into the bark bed, otherwise they will not make great progress; therefore they should always remain in the tan bed, giving them plenty of air in summer, when the weather is warm.

The leaves of these plants continue in verdure all the year, so make a fine appearance in the hot-house in winter; but I have never seen the flowers of either sort produced here.

COCHLEARIA. *Lin. Gen. Plant.* 720. Spoonwort, or Scurvy Grafs.

The Characters are,

The flower hath four petals, placed in form of a cross; it hath six stamina, four of which are longer than the other two. The germen is heart-shaped, which afterward becomes a gibbous, heart-shaped, compressed pod, fastened to the style, having two cells, in each of which are lodged four roundish seeds.

The Species are,

1. COCHLEARIA *foliis radicalibus subrotundis, caulinis oblongis subsinuatis. Flor. Lapp.* 256. Common or round-leaved Scurvy Grafs.

2. COCHLEARIA *foliis radicalibus lanceolatis, integerrimis, caulinis sinuatis.* Sea Scurvy Grafs.

3. COCHLEARIA *foliis reniformibus, integris. Hort. Cliff.* 498. Leaf Welch Scurvy Grafs.

4. COCHLEARIA *foliis hastatis, angulatis. Flor. Suec.* 196. Danish, or Ivy-leaved Scurvy Grafs.

5. COCHLEARIA *foliis radicalibus lanceolatis, crenatis, caulinis incis. Hort. Cliff.* 332. Horse Radish.

6. COCHLEARIA *foliis caulinis cordato-sagittatis, amplexicaulibus. Hort. Cliff.* 332. Tallest Scurvy Grafs with a Woad leaf.

The first sort grows naturally on the sea shore in the north of England, and in Holland, but is cultivated for use in the gardens near London: this is an annual plant, for the seeds are sown, and the plants decay within the compass of one year, but the seeds should be sown early in autumn; it hath a fibrous root, from which arise many round succulent leaves, which are hollowed like a spoon; the stalks rise from six inches to a foot high; these are brittle, and garnished with leaves which are oblong and sinuated. The flowers are produced in clusters at the end of the branches, consisting of four small white petals, which are placed in form of a cross; and are succeeded by short, roundish, swelling seed vessels, having two cells, divided by a thin partition; in each of these is lodged four or five roundish seeds.

This is propagated in gardens for medicinal uses; which is done by sowing the seeds in July, soon after they are ripe, in a moist shady spot of ground; and when the plants are come up, they should be thinned, so as to be left at about six inches distance each way. The plants that are taken out may be transplanted into other shady borders, if you have occasion for them; and at the same time all the weeds should be hoed down, so as to clear the plants entirely from them, that they may have room to grow strong. In the spring these plants will be fit for use; and those that are suffered to remain will run up to seed in May, and perfect their seeds in June. If this plant is sown in the spring, the seeds seldom grow well, therefore the best time is soon after they are ripe.

The Sea Scurvy Grafs is also used in medicine; but this grows in the salt marshes in Kent and Essex, where the salt water overflows it almost every tide; and can rarely be made to grow in a garden, or at least to last longer there than one year; but it being easily gathered in the places beforementioned, the markets are supplied from thence by the herb-women, who make it their business to gather herbs.

The little Welch Scurvy Grafs is a biennial plant, and may be preserved in a garden, if planted in a strong soil and a shady situation. This plant grows plentifully in Muscovy, as also in Davis's Streights.

The fourth sort is a low trailing plant, whose stalks grow six inches long, and lie prostrate on the ground; the leaves are angular, and in shape like those of Ivy. This is found growing naturally in some parts of England, and is annual.

The sixth sort is a biennial plant, which usually grows about a foot and an half high, with upright stalks, which are garnished with angular heart-shaped leaves, embracing

the stalks with their base; the flowers are produced in loose spikes at the end of the branches, they are very small, white, and are succeeded by short swelling pods filled with round seeds. This may be propagated by seeds, as the common sort: and if sown in autumn, will more certainly succeed than in the spring.

The Horse Radish is propagated by cuttings or buds from the sides of the old roots. The best season for this work is in October or February; the former for dry lands, the latter for moist; the ground should be trenched at least two spits deep, or more if it will allow of it. The manner of planting it is as follows: Provide yourself with a good quantity of offsets, which should have a bud upon their crowns, but it matters not how short they are; therefore the upper part of the roots which are taken up for use, should be cut off about two inches long with the bud to it, which is esteemed the best for planting. Then make a trench ten inches deep, in which you should place the offsets at about four or five inches distance, with the bud upward, covering them up with the mould that was taken out of the trench: then proceed to a second trench in like manner, and continue the same till the whole spot of ground is planted. After this, level the surface of the ground even, observing to keep it clear from weeds, until the plants are so far advanced, as to be strong enough to over-bear and keep them down. With this management, the roots of the Horse Radish will be long and strait, and free from small lateral roots; and the second year after planting will be fit for use.

CODLIN-TREE. See Malus.

COFFEA. *Lin. Gen. Pl.* 209. The Coffee-tree.

The Characters are,

The flower hath one petal, which is funnel-shaped, having a narrow cylindrical tube, and is plain at the top, where it is indented in five parts; it hath five stamina which are fastened to the tube. The roundish germen afterward becomes an oval berry, containing two hemispherical seeds, plain on one side, and convex on the other.

We have but one Species of this genus, viz.

COFFEA. *Hort. Cliff.* 59. The Coffee tree.

This tree is supposed to be a native of Arabia Felix, where it was first cultivated for use, and to this day, is the country from whence the best Coffee is brought to Europe, though the plant is now propagated in many parts of both Indies; but the produce of those countries being greatly inferior to that of Arabia, hath occasioned its present disrepute in England, so that it is scarce worth importing; but this might be remedied, if the Coffee planters in the West-Indies, could be prevailed on to try a few experiments, which I shall hereafter propose, being founded on those which have been made in England, upon the berries produced here. But I shall first treat of the plant, with its culture in England.

This is a low tree in the native country of its growth, where it seldom rises more than sixteen or eighteen feet high; the main stem grows upright, and is covered with a light brown bark; the branches are produced horizontally and opposite, which cross each other at every joint, so that every side of the tree is fully garnished with them, and form a sort of pyramid, the leaves also stand opposite; these when fully grown, are about four or five inches long, and two inches broad in the middle, decreasing toward each end; the borders are waved, and the surface is of a lucid green. The flowers are produced in clusters at the base of the leaves, fitting close to the branches; these are tubulous, and spread open at the top, where they are divided into five parts; they are of a pure white, and have a very grateful odour, but are of short duration. These are succeeded by oval berries, which are first green; when fully grown, they turn red, and afterward change to black when

fully ripe. These have a thin pulpy skin, under which are two seeds joined, which are flat on the joined sides, with a longitudinal furrow, and convex on their outer side.

As the Coffee tree is an ever-green, so it makes a beautiful appearance at every season in the stove, but particularly when it is in flower, and also when the berries are red, which is generally in the winter, so that they continue a long time in that state; therefore there is scarce any plant, that more deserves a place in the stove than this.

It is propagated by the berries, which must be sown soon after they are gathered from the trees, for if they are kept out of the ground any time they will not grow. I have frequently sent the berries abroad by the post, but when they have been a fortnight in their journey they have all failed, and this has constantly happened every where, for the berries that were sent from *Holland* to *Paris* did not grow; nor did those that were sent from *Paris* to *England* grow: so that wherever these trees are desired, the young plants must be sent, if it be at any distance from the place where they grow.

The berries should be planted in small pots, and plunged into a hot-bed of tanners bark. If the bed be of a proper temperature of warmth, the plants will appear in a month or five weeks time, and in about six weeks more will be fit to transplant. For as many of the berries will produce two plants, so the sooner they are parted, the better; for when they grow double till they have made large roots, they will be so intermixed and entangled, as to render it difficult to separate them, without tearing off their fibres, which will greatly prejudice the plants. When these are transplanted, they must each be put into a separate small pot, and plunged into the tan bed again; which should be stirred up to the bottom, and if required, some new tan should be mixed with it, to renew the heat. Then the plants should be gently watered, and the glasses of the hot-bed must be shaded every day till they have taken new root; after which the plants should have fresh air admitted to them every day, in proportion to the warmth of the season: during the summer they will require frequently to be refreshed with water, but they must not have it in too great plenty: for if the roots are kept too moist, they are very subject to rot, then the leaves will soon decay and drop off, and the plants become naked; when this happens, they are seldom recovered again. The first sign of these plants being disordered, is, their leaves sweating out a clammy juice, which attracts the small insects, which frequently infest those plants in stoves, which are not in health, and these cannot be destroyed, till the plants are recovered to vigour: for although the plants are ever so carefully washed and cleared from these insects, yet they will be soon attacked by them again, if they are not recovered to health, for these insects are never seen upon any of the plants while they are in perfect vigour; but when they are disordered, they soon spread over all the leaves and tender parts of the plants, and multiply exceedingly; so that upon the first attack, the plants should be shifted into fresh earth, and all possible care taken to recover them, without which all the washing and cleaning of the plants will be to little purpose. The disorders attending the Coffee trees, generally proceed from either being put into pots too large for them, nothing being of worse consequence than over potting them; or from the earth being too stiff, or over watered. If these errors are avoided, and the stove kept always in a proper temperature of heat, the plants will thrive, and produce plenty of fruit annually.

I have made trial of several compositions of earth, for these plants, but have found none of them equal to that of a kitchen garden, where the soil is naturally loose, and not subject to bind; especially if it has constantly been

well wrought and properly dunged, this without any mixture, is preferable to any other.

When the plants are transplanted, their roots should not be too much cut or trimmed; the decayed or rotten fibres should be pruned off, and those which are closely matted to the side of the pots should be trimmed, but not cut too near to the stem, for the old fibres do not put out new roots very kindly, especially those which are become tough, so that there should always be a sufficient number of young fibres left to support the plants, till new ones are produced.

The Coffee plants were first carried from *Arabia* to *Batavia* by the *Dutch*, and from thence they were afterward brought to *Holland*, where great number of the plants were raised from the berries which those plants produced, and from these most of the gardens in *Europe* have been furnished. A great number of these young plants, which were raised at *Amsterdam*, were sent to *Surinam* by the proprietors of that island; where the trees were soon propagated in great plenty, and from thence the plants have been dispersed to most of the islands in the *West-Indies*: for as the plants raised from the berries, produce fruit in eighteen months from planting, in the warm countries, so plantations of these trees may be soon made in any of those countries, where the temperature of the air is proper for their production; but the trees will not grow in the open air in any country where there is a winter, so that without the tropicks they cannot be expected to grow abroad.

The *French* have made great plantations of these trees in their settlements in the *West-Indies*, and also in the isle of *Bourbon*, from whence they import great quantities of Coffee annually to *France*; which, although greatly inferior in quality to the *Arabian*, yet it is consumed, otherwise they would not continue that branch of commerce. In the *British* colonies of *America*, there have been some large plantations made of Coffee trees; and it was proposed to the parliament, some years past, to give a proper encouragement for cultivating this commodity in *America*, so as to enable the planters to undersell the importers of Coffee from *Arabia*; accordingly there was an abatement of the duty payable on all the Coffee which should be of the growth of our colonies in *America*, which was at that time supposed would be a sufficient encouragement, for the planters to improve this branch of commerce: but the productions of those countries, being greatly inferior in quality to that of *Arabia*, hath almost ruined the project; and unless the planters can be prevailed on to try some experiments to improve its quality, there can be little hope of its becoming a valuable branch of trade; therefore I shall beg leave to offer my sentiments on this article, and sincerely wish what I have to propose may be found useful for the instruction of the Coffee planters; for as my opinion is founded upon experiments, so it is not mere theory or supposition.

The great fault of the Coffee which grows in *America*, is the want of flavour, or having a disagreeable one. The berries are much larger than those which are imported from *Arabia*, and consequently have not so much spirit or flavour. This may be owing to several causes; the first is that of its growing in a soil too moist, which is always known to increase the size of fruit and vegetables, but their quality is greatly diminished thereby. The second is from the gathering of the berries too soon; for I have been credibly informed, that it is the constant practice of the planters, to gather the fruit when it is red; at which time the berries are much larger, and of greater weight, than those which are permitted to ripen perfectly on the trees, which is not till they are turned black, and their outer pulp becomes dry, and the skins shrink; then the berries are much smaller than before, and the outer cover will easily separate from the berry; which I have always been informed has been

the complaint of the planters, that this was with great difficulty and trouble effected. A third cause I imagine may be in the drying of the berries when gathered; which must be constantly attended to, for they cannot be too much exposed to the sun and air in the day time, but they must be every evening removed under cover, and carefully screened from dews and rain; nor should they be placed near any sort of liquid or moisture, for these berries are very subject to imbibe moisture, and thereby acquire the flavour of the liquid, of whatever sort it be; and the berries will be enlarged, but the flavour diminished by it, as from many experiments I can affirm: for a bottle of rum being placed in a closet, in which a canister of Coffee berries closely stopped, was standing on a shelf at a considerable distance, in a few days had so impregnated the berries, as to render them very disagreeable; the same also hath happened by a bottle of spirits of wine standing in the same closet with Coffee and Tea, both which were in a few days spoiled by it. Therefore from many experiments of this nature, which I have made upon Coffee, it appears to me that it should never be brought over in ships freighted with rum, nor should the berries be laid to dry in the houses where the sugars are boiled, or the rum distilled. I have also been informed by a gentleman who has a very good estate in *Jamaica*, and who has lived many years in that island, that the planters frequently boil the Coffee berries before they are dried. As this information comes from a gentleman of great skill and veracity, I cannot doubt of the fact; and if so, this alone is sufficient to spoil the best Coffee in the world; so that I am at a loss to guess the reason for this practice, which, as it appears to me, can only be intended to increase the weight, therefore must be imputed to avarice, the bane of every publick good.

There was some time past an imperfect account printed in the papers, of the cause why the *American* Coffee was not so good as that which comes from *Arabia*, in which it was supposed that the goodness of the latter proceeded from the length of time which the berries had been kept: therefore the author proposes, that the *American* Coffee berries should be kept many years, which he says will render them equally good. This is contrary to all the experience I have had, or can learn, from those who have seen the whole progress of Coffee in *Arabia*, with their manner of drying and packing it to send abroad; for two gentlemen who had lived there some years assured me, that the berries, when first gathered, were much better than those which are kept any time. And a curious gentleman who resided in *Barbadoes* two years, also told me, that he never drank better Coffee in any part of the world, than what he made from the fresh berries, which he gathered himself, and roasted as he had occasion for them; which is also confirmed by the trials which have been made with the berries which grow in the stoves in *England*, which make a better flavoured liquor, than the best *Arabian* Coffee berries which can be procured in *England*; therefore I wish those who are inclinable to cultivate these trees in *America*, would make choice of a soil rather dry than moist, in which the trees will not make so great progress, as those which grow in a wet soil, nor will the produce be so great; but as the quality of the produce will be so much improved, so it will certainly be of greater advantage to them.

The next thing is, to permit the berries to remain so long upon the trees, till their skins are shrivelled, and will fall from the trees when they are shaken, which it is true will greatly diminish their weight, but then the commodity will be more than double the value of that which is gathered sooner: for in *Arabia*, they always shake the berries off the trees, spreading cloths under them to receive them, and only take such as readily fall at each time.

When the berries are full ripe, they should be shaken off when the trees are perfectly dry, and spread abroad upon cloths in the sun to dry, carrying them every evening under cover, to prevent the dews from falling on them, or the rain if any should happen: and when they are perfectly dry, they should have their outer skins beaten off; then carefully packed up in cloths or bags, three or four times double, and consequently kept in a dry situation. When they are shipped for *England*, it should be on board those vessels which have no rum, lest the Coffee should imbibe the flavour, which cannot be prevented when stowed in the same place. Some years past, a Coffee ship from *India*, had a few bags of pepper put on board, the flavour of which was imbibed by the Coffee, and the whole cargo spoiled thereby.

As the quantity of Coffee now consumed in *Britain* is very much increased of late years, so it will certainly be worthy of publick consideration, how far it may be necessary to encourage the growth of it in the *British* colonies: and certainly it deserves the attention of the inhabitants of those colonies, to improve this commodity to the utmost of their power; and not to have so much regard to the quantity, as to the quality of it; for although the former may appear to have the advantage of the latter in point of profit, yet the goodness of every commodity, must always claim the preference, and thereby will be found of more lasting advantage to the cultivator.

COIX. *Lin. Gen. Plant.* 927. Job's Tears.

The Characters are,

It hath male and female flowers on the same plant; the male flowers are disposed in a loose spike. The petal has two oval valves. These have each three hairy stamina, terminated by oblong four-cornered summits. There are a few female flowers situated at the base of the male spike in the same plant; the petal hath two oval valves. They have a small oval germen, which afterward becomes a hard roundish smooth seed.

The Species are,

1. COIX *feminibus ovatis*. *Hort. Cliff.* 434. Coix with oval seeds; or, Job's Tears.
2. COIX *feminibus angulatis*. *Hort. Cliff.* 438. Coix with angular seeds; or, *American* Job's Tears.

The first sort grows naturally in the islands of the *Archipelago*, and is frequently cultivated in *Spain* and *Portugal*, where the poor inhabitants grind the grain to flour in a scarcity of Corn, and make a coarse sort of bread of it.

It is an annual plant, which seldom ripens its seeds in *England*, unless the season proves very warm; from a thick fibrous root is sent out two or three jointed stalks, which rise two feet high, garnished with single, long, narrow leaves at each joint, resembling those of the Reed; at the base of the leaves come out the spikes of flowers, standing on short foot stalks; these spikes are composed of male flowers only, and below them is situated one or two female flowers; the male flowers decay soon after they have shed their farina; but the germen of the female flowers swell to a large oval seed, which is hard, smooth, and of a gray colour, greatly resembling the seeds of Gromwel, from whence this plant has been by several writers titled, *Lithospermum*.

Those who are desirous to cultivate this plant in *England*, may procure the seeds from *Portugal*; these should be sown on a moderate hot-bed in the spring, to bring the plants forward, and afterward transplant them on a warm border, allowing each two feet room at least; and when the plants have taken root, they will require no farther care, but to keep them clean from weeds. These will flower about *Midsummer*, and in warm seasons the seeds will ripen at *Michaelmas*.

The second sort will grow to the height of seven or eight feet; and the stems become hard, like the Reed, or *Indian*

Corn: these branch out, and produce several spikes of flowers; but this sort will not live in the open air in *England*, therefore should be planted in pots, and plunged in the bark stove, where it will live through the winter, and produce ripe seeds the second year; and may be continued longer, if desired.

COLCHICUM. *Lin. Gen. Plant.* 415. Meadow Saffron.

The Characters are,

The flower hath neither empalement or spatba; it hath one petal, rising with an angular tube from the root, and is divided at the top into six oval concave segments; it hath six stamina with four valves. The germen is situated near the root, which afterwards becomes a capsule with three lobes, having a seam on the inside, dividing it into three cells, which contain several roundish rough seeds.

The Species are,

1. COLCHICUM *foliis planis lanceolatis, erectis.* *Hort. Cliff.* 140. Colchicum with plain, erect, spear-shaped leaves; or, Common Meadow Saffron.
2. COLCHICUM *foliis linearibus patentissimis.* *Lin. Sp. Pl.* 342. Meadow Saffron with very narrow spreading leaves.
3. COLCHICUM *foliis undulatis patentibus.* *Hort. Cliff.* 140. Meadow Saffron with waved spreading leaves, and chequered flowers.

There are several varieties of these flowers, which differ in their colour, and other little accidents, which are not lasting, so must not be ranged as distinct species. But as they are cultivated in flower gardens, so I shall beg leave to mention those varieties, which I have seen cultivated. These are most of them feminal variations from the first sort.

The most common Meadow Saffron hath a purplish flower.

The Meadow Saffron with white flowers.

Meadow Saffron with striped flowers.

Broad-leaved Meadow Saffron.

Striped leaved Meadow Saffron.

Many flowered Meadow Saffron.

Meadow Saffron with double purplish flowers.

Meadow Saffron with double white flowers.

Meadow Saffron with many white flowers.

The first sort grows naturally both in the west and north of *England*. I have observed it in great plenty in the meadows in *Warwickshire* in the beginning of *September*. The country people call the flowers Naked Ladies, because they come up naked, without any leaves or cover. This hath a bulbous root, about the size and shape of the Tulip root, but not so sharp pointed at the top, the skin or cover is also of a darker colour. The flowers come out in autumn; these arise with long slender tubes from the root, about four inches high, shaped like those of the Saffron, but are larger; they are of a pale purple colour, and divided into six parts at the top; the number of flowers is generally in proportion to the size of the roots, from two to seven or eight: in *March* the green leaves appear, these are commonly four to a full grown root; they are folded over each other below, but spread open above ground, standing cross-ways: they are of a deep green, and when fully grown, are five or six inches long, and one broad. The seed vessel comes out from between the leaves, in *April*, and the seeds ripen in *May*, soon after which the leaves decay.

The other varieties are supposed to have accidentally risen from the seeds of this, so that those who are desirous to obtain a variety of these flowers, should propagate them from seeds, by which means there may be more obtained.

The second sort grows naturally on the mountains in *Spain* and *Portugal*. This hath a smaller root than the first, and a darker coat; the flowers appear in *August* or *September*; these are cut into six long narrow segments, of a reddish purple colour, having six yellow stamina. The leaves

of this sort come up soon after the flowers decay, and continue green all the winter, like the Saffron; these are long narrow, and spread on the ground; in *June* these decay like the first sort.

The third sort grows naturally in the *Levant*, but is commonly cultivated in the *English* gardens. It flowers at the same time as the first sort, and the green leaves come up in the spring. The root of this species is supposed to be the *Hermodactyl* of the shops.

These are all very pretty varieties for a flower garden, producing their flowers in autumn, when few other plants are in beauty; and are therefore, by some, called Naked Ladies. The green leaves come up in the spring, which are extended to a great length in *May*, then the green leaves begin to decay; soon after which time, is the proper season to transplant their roots; for if they are suffered to remain in the ground till *August*, they will send forth fresh fibres, after which time it will be too late to remove them. The roots may be kept above ground till the beginning of *August*, at which time, if they are not planted, they will produce their flowers as they lie out of the ground, but this will greatly weaken their roots. The manner of planting their roots being the same as for Tulips, &c. I shall forbear mentioning it here, referring the reader to that article: and also for sowing the seeds, by which means new varieties may be obtained, I shall refer to the article *XIPHION*, where will be proper directions for this work.

COLDENIA. *Lin. Gen. Plant.* 159.

The Characters are,

It hath a funnel-shaped flower of one petal, spreading at the top, and obtuse; it hath four stamina, which are inserted in the tube of the petal. In the center is situated four oval germen, each supporting a hairy style. The germen afterwards become so many oval compressed rough fruit, terminated by four beaks, inclosed by the empalement.

We know but one Species of this genus, viz.

COLDENIA. *Flor. Zeyl.* 69. This is by Dr. *Plukenet* titled, *Teucris facie bisnagarica tetracoccus rostrata.* *Alm.* 363.

This is a native of *India*. It is an annual plant, whose branches trail on the ground; they extend about six inches from the root, garnished with short leaves sitting close to the branches; these are deeply crenated on their edges, and have several deep veins; they are of a glaucous colour, and come out without order. The flowers are produced at the wings of the leaves, growing in small clusters; these have four stamina, and but one petal, which is funnel-shaped, and cut into four segments at the top; they are of a pale blue colour, and very small; when the flower decays, the germen becomes a fruit composed of four cells, wrapped up in the empalement, each containing a single seed.

This plant is propagated by seeds, which must be sown upon a hot-bed in the spring; when the plants are fit to remove, they should each be put into a separate small pot, and plunged into a hot-bed of tanners bark, observing to shade them till they have taken fresh root, after which they should have air admitted to them every day in proportion to the warmth of the season, and gently watered two or three times a week in warm weather; but they must not have too much moisture. These plants must remain in the hot-bed, where they will flower in *June*, and the seeds ripen in *September*.

COLEWORTS. See *Brassica*.

COLOCASIA. See *Arum*.

COLLINSONIA. *Lin. Gen. Plant.* 38.

The Characters are,

The flower is funnel-shaped, of one petal which is unequal, cut into five parts at the top, the upper part being short and obtuse, and two of them being reflexed; the lower lip or beard is longer, ending

ending in many points. It hath two long bristly stamina, which are erect. It hath a quadrifid obtuse germen, with a large gland, supporting a bristly style, which afterward becomes a single roundish seed, situated in the bottom of the empalement.

We have but one sort of this plant, viz.

COLLINSONIA foliis cordatis oppositis. Collinsonia with heart-shaped leaves growing opposite.

This plant was brought from Maryland, where it grows wild; as it doth also in most other parts of North America, by the sides of ditches, and in low moist grounds, where it usually rises to the height of four or five feet.

This hath a perennial root and an annual stalk, which decays in the autumn, and fresh shoots come out in the spring. The stalks are square, and garnished with heart-shaped leaves placed opposite, which are sawed on their edges. The flowers are produced at the extremity of the stalks, in loose spikes; these have long tubes, and are divided into five parts at the top; the flowers are of a purplish yellow, and the lower segment is terminated by long hairs. The flowers appear in July, and the seeds ripen in autumn.

This plant may be easily propagated by parting of the roots in October. These roots should be planted at three feet distance, for they require much nourishment, otherwise they will not thrive. This plant should be planted in a moist soil and a sheltered situation.

COLOCYNTHIS. See Cucurbita.

COLUMBINE. See Aquilegia.

COLUMNEA. Lin. Gen. Plant. 710.

The Characters are,

The flower hath one petal, of the ringent or grinning kind, with a swelling tube, divided above into two lips; the upper being erect and entire, the lower is divided into three parts which spread open: it hath four stamina, two being longer than the other; these are inclosed in the upper lip. In the center is situated the roundish germen, which afterward becomes a globular berry with two cells, sitting on the empalement, containing several oblong seeds.

There is but one Species of this genus at present known, viz.

COLUMNEA. Lin. Sp. Plant. 638. Climbing Columnea, with a scarlet flower and a white fruit.

Plumier mentions a variety of this, with a yellowish flower and white fruit. But this is only a feminal variation, supposed to have accidentally risen from the seeds of the first.

This hath a climbing stalk, which fastens itself to the neighbouring plants whereby it is supported. The leaves are oval, sawed on the edges, and stand upon short foot-stalks; these, and also the stalks, are very hairy; but the plants, which were raised at Chelsea, decayed the following year, before they produced any flowers, so that I can give no description of them.

These plants are natives of the warmest parts of America, so are too tender to live in England, unless they are preserved in the stove. They are propagated by seeds, which must be sown in a good hot-bed; and when the plants come up, they must be treated in the same way as other tender exotick plants, which are kept in the bark stove.

COLUTEA. Tourn. Inst. R. H. 649. tab. 417. Bladder Sena.

The Characters are,

The flower is of the butterfly kind. The standard, wings, and keel, vary in their figure in different species. It hath ten stamina, nine of which are joined, and the other stands separate. In the center is situated an oblong germen, which afterward becomes a broad swollen pod with one cell, including several kidney-shaped seeds.

The Species are,

1. *COLUTEA arborea, foliolis obcordatis.* Hort. Cliff. 365. Common Bladder Sena.

2. *COLUTEA foliolis ovatis, integerrimis, caule fruticoso.* Shrubby Bladder Sena with oval leaves, which are entire.

3. *COLUTEA foliolis cordatis minoribus, caule fruticoso.* Eastern Bladder Sena with a blood-coloured flower, spotted with yellow.

4. *COLUTEA foliolis ovato-oblongis.* Hort. Cliff. 366. Ethiopian Bladder Sena with a scarlet flower.

5. *COLUTEA foliolis ovatis, emarginatis, leguminibus oblongis compressis acuminatis, caule arborco.* Bladder Sena with oval leaves indented at the top, oblong, compressed, pointed pods, and a tree-like stalk.

6. *COLUTEA herbacea foliis linearibus.* Hort. Upsal. 266. African annual Bladder Sena with small pointed leaves, and compressed pods.

7. *COLUTEA caulibus procumbentibus, foliolis ovato-linearibus, tomentosis, floribus alaribus pedunculis longissimis.* Bladder Sena with trailing stalks, oval narrow leaves, which are woolly, and flowers growing from the sides of the stalks with very long foot-stalks.

The first sort is commonly cultivated in the nursery gardens, as a flowering shrub, to adorn plantations. This grows naturally in Austria, and in the south of France and Italy. It hath several woody stems, which grow to the height of twelve or fourteen feet, dividing into many woody branches garnished with winged leaves, composed of four or five pair of oval leaves placed opposite, terminated by an odd one; these are indented at the top, and are of a grayish colour. The flowers come out from the wings of the leaves upon slender foot-stalks, about two inches long, each sustaining two or three flowers of the butterfly kind, whose standard is reflexed and large. The flowers are yellow, with a dark coloured mark on each petal; these are succeeded by inflated pods, an inch and an half long, having a seam on the upper side, containing a single row of kidney-shaped seeds, fastened to a placenta. There is a variety of this with reddish pods, which is equally common in the gardens, and is supposed to be only an accidental variety, for the plants do not differ in any other respect.

The seeds of the second sort were brought from the Levant by the Rev. Dr. Pococke, now bishop of Ossory. This seldom grows more than six or seven feet high; the branches are very slender, and spread out on every side; they are garnished with winged leaves, composed of nine pair of small, oval, entire lobes, terminated by an odd one; the flowers stand upon slender foot-stalks, about the same length of the former. The flowers also are like those, but are of a brighter yellow. This sort begins to flower early in May, and continues flowering till the middle of October.

The third sort was discovered by Dr. Tournefort in the Levant. This hath a woody stem, which sends out many branches on every side, which do not rise above seven or eight feet high; these are not so strong as those of the first sort, and are garnished with winged leaves, composed of five or six pair of small heart-shaped lobes, terminated by an odd one. The flowers proceed from the side of the branches, standing upon foot-stalks, each sustaining two or three flowers, shaped like those of the first sort, but smaller; they are of a dark red colour, marked with yellow.

The fourth sort grows naturally in Ethiopia, from whence the seeds were brought to Europe. This hath a weak shrubby stalk, which sends out many side branches growing erect, garnished with equal winged leaves, composed of ten or twelve pair of small, oval, oblong, hoary lobes. The flowers are produced at the upper part of the branches from the wings of the leaves, each foot-stalk sustaining three or four scarlet flowers, which are longer than those of the other sorts, and are not reflexed; these are succeeded by inflated pods, containing one row of kidney-shaped seeds.

The fifth sort grows naturally at *La Vera Cruz*, in *New Spain*. This hath a shrubby stalk, which rises to the height of twelve or fourteen feet, sending out many branches, garnished with winged leaves, composed of three pair of oval lobes, terminated by an odd one; these are indented at the top, and are of a light green. The flowers are of a bright yellow, and stand two or three upon each foot-stalk, and are succeeded by compressed pods near four inches long, which end in long points.

The sixth sort grows naturally at the *Cape of Good Hope*. This is an annual plant of little beauty, so is rarely cultivated but in botanick gardens for the sake of variety. It rises with a slender herbaceous stalk about two feet high, dividing upward into three or four branches, which are garnished with winged leaves, composed of five or six pair of very narrow lobes, near an inch long, which are a little hoary. The flowers are small, of a purplish colour, standing three together on slender foot stalks, which are succeeded by flat oval pods, each containing two or three kidney-shaped seeds.

The seeds of the seventh sort were sent me from the *Cape of Good Hope*. This plant hath many slender herbaceous stalks, which frequently trail on the ground, and are garnished with winged leaves, composed of twelve or fourteen pair of small, narrow, oval lobes, terminated by an odd one; these, and also the stalks, are covered with a whitish down. The flowers are very small, of a purple colour, and stand upon very long slender foot-stalks, each sustaining three or four flowers, which are succeeded by compressed pods little more than half an inch long, which are a little bent like a sickle, each containing a single row of small kidney-shaped seeds. This is a perennial plant, which, if sheltered in the winter, will continue several years, but the branches do not extend more than a foot in length, and unless they are supported, always trail upon the ground.

The three first sorts are very hardy shrubs, which thrive in the open air extremely well, so they are generally propagated for sale in the nursery gardens, but the first sort hath been long in *England*, so is more generally known and propagated than either of the other.

These are propagated by sowing their seeds any time in the spring, in a bed of common earth; and when the plants are come up, they must be kept clear from weeds; and the *Michaëlnas* following, they should be transplanted either into nursery rows, or in the places where they are designed to remain; for if they are let grow in the seed bed too long, they are very subject to have tap roots, which renders them unfit for transplantation; nor should these trees be suffered to remain too long in the nursery before they are transplanted, for the same reason.

The first sort will grow to the height of twelve or fifteen feet, and are very proper to intermix with trees of a middling growth in wilderness quarters, or in clumps of flowering trees.

The third sort does not grow so tall as the common, but makes a more regular shrub than that. The flowers of this sort are of a dusky red colour, spotted with yellow, so it makes a very pretty variety, and is as hardy as the common sort, therefore may be propagated by seeds in the same manner.

The fourth sort is tender, so will not live through the winters (when they are severe) in the open air in *England*; but, in mild winters, if they are planted in a dry soil and a warm situation, they will thrive very well; and those plants which live abroad, will flower much stronger, and make a finer appearance, than those which are preserved in the green-house; for these plants require a large share of air, otherwise they are apt to draw up weak, so seldom produce their flowers in plenty; therefore when any of the

plants are sheltered in winter, they must be placed as near the windows as possible, that they may have all the advantages of air; and in the spring, they must be hardened to bear the open air as soon as possible.

This sort is propagated by seeds as the former; if the seeds are sown early in the spring, upon a warm border of light earth, the plants will flower in *August*; and, if the autumn proves favourable, they will ripen their seeds very well; but there are some persons who sow the seeds upon a moderate hot-bed in the spring, whereby they bring the plants so forward as to flower in *July*, so that the seeds are always perfected from these plants: when these plants are transplanted, it should always be done while they are young, for they do not bear removing well when they are large.

The fifth sort grows naturally in a warm country, so is too tender to thrive in the open air in this country; this is propagated by seeds, which must be sown on a hot-bed in the spring, and when the plants are two inches high, they should be each transplanted into a separate small pot, and plunged into a hot-bed of tanners bark, observing to shade them till they have taken fresh root; after which they must be treated in the same way as other plants from the same climate, always keeping them in a stove, which should be of a moderate temperature of heat.

The sixth sort is a low annual plant, which seldom grows more than a foot and a half in height; the flowers being small, and having little beauty, it is seldom preserved but in botanick gardens; the seeds of this sort must be sown upon a moderate hot-bed in the spring, and the plants must be planted into small pots, and brought forward in another hot-bed; in *July* they will flower, when they may be exposed to the open air, in a warm situation, where the seeds will ripen in *September*, and the plants will soon after decay.

The seventh sort may be raised on a moderate hot-bed in the spring, and afterward exposed to the open air in summer; but in winter they must be sheltered under a frame, otherwise the frost will destroy them.

COLUTEA SCORPIOIDES. See *Emerus*.

COMA AUREA. See *Chrysocoma*.

COMARUM. *Lin. Gen. Plant.* 563. Marsh Cinquefoil.

The Characters are,

The flower hath five oblong petals, which are inserted in the empalement, but are much smaller. It hath twenty permanent stamina, which are inserted into the empalement, and a great number of small roundish germen collected into a head. The common receptacle afterward becomes a large fleshy fruit, having many pointed seeds adhering to it.

We know but one Species of this genus, which is,

COMARUM. *Fl. Lapp.* 214. Red Marsh Cinquefoil.

This plant hath creeping woody roots, which send out many black fibres, penetrating deep into the ground, from which arise many reddish stalks, about two feet high, which generally incline to the ground; these are garnished at each joint with one winged leaf, composed of five, six, or seven lobes, which rise above each other, the middle being the largest, the lower diminishing, and with their base embrace the stalks. The flowers are produced at the top of the stalks, three or four together on short foot-stalks, which have a large spreading empalement, red on the upper side, and divided at the top into ten parts; in the center sits the five petals, which are red, and not more than a third part the size of the empalement; within these are situated many germen, attended by about twenty stamina, terminated by dark summits. After the flower is past, the receptacle, which sits in the bottom of the empalement, becomes a fleshy fruit, somewhat like a Strawberry, but flatter, including a great number of pointed seeds.

As this plant grows naturally on bogs, so it is with difficulty preserved in gardens, for it must be planted in a soil as near to that of its natural growth as possible; it is very apt to spread much at the root, when in a proper situation; so whoever is inclinable to preserve this plant, may remove it from the places of its growth in *October*, and plant it on a bog, where there will be no danger of the plants succeeding. There are a few of these plants now growing upon a bog at *Hampstead*, which were planted there some years ago; but the nearest place to *London*, where it grows wild in plenty, is in the meadows near *Guildford* in *Surry*.

COMMELINA. *Lin. Gen. Plant.* 58.

The Characters are,

It hath a permanent heart-shaped spatha; the flower hath six concave petals, three of which are small and oval, the other are large, roundish, and coloured. It hath three nectariums, (which have been supposed to be stamina); there are three awl-shaped stamina, which recline; in the center is situated a roundish germen, which afterward becomes a naked globular capsule, with three furrows, having three cells, each containing two angular seeds.

The Species are,

1. COMMELINA *corollis inæqualibus, foliis ovato-lanceolatis, acutis, caule procumbente, glabro. Hort. Upsal.* 18. Commelina with unequal petals, oval, spear-shaped, pointed leaves, and a smooth trailing stalk.

2. COMMELINA *corollis inæqualibus, foliis ovato-lanceolatis, caule erecto, scabro, simplicissimo. Hort. Upsal.* 18. Commelina with unequal petals, oval spear-shaped leaves, and a single, upright, rough stalk.

3. COMMELINA *corollis inæqualibus, foliis lanceolatis, glabris, obtusis, caule repente. Lin. Sp. Plant.* 41. Commelina with unequal petals, smooth, spear-shaped, obtuse leaves, and a creeping stalk.

4. COMMELINA *corollis æqualibus foliis ovato-lanceolatis, subciliatis. Hort. Upsal.* 18. Commelina with equal petals, and oval spear-shaped leaves, which are hairy on their under side.

5. COMMELINA *corollis æqualibus, pedunculis incrassatis, foliis lineari lanceolatis. Lin. Sp. Plant.* 41. Commelina with equal petals, thick foot-stalks to the flower, and narrow spear-shaped leaves.

The first sort grows naturally in the islands in the *West-Indies*, and also in *Africa*; this is an annual plant, which hath several trailing stalks, two or three feet long, which put out roots at the joints, and strike into the ground; at each joint is placed one oval, spear-shaped leaf, ending in a point, which embraces the stalk with its base, and hath several longitudinal veins: it is of a deep green, and smooth. The flowers come out from the bosom of the leaves, included in a spatha, which is compressed and shut up, each having two or three flowers, standing upon short foot-stalks, composed of two large blue petals, and four smaller green ones, which have generally been termed the empalement of the flower; within these are situated three nectariums, each having a slender stamina fixed on the side; these surround the germen, which afterward becomes a roundish capsule having three cells; in each of these is lodged two angular seeds.

The second sort grows naturally in *Pensylvania*; this hath a perennial root, composed of many white fibres; the stalks rise two feet high, are upright, rough, herbaceous, and about the size of quills; these have a single leaf at each joint, which is shaped like those of the first sort, and embrace the stalks with its base; the flowers come out from the bosom of the leaves at the upper part of the stalk, sitting upon short foot-stalks; these are of a pale bluish colour, and are succeeded by seeds as the first sort.

The third sort grows naturally in *Africa*; this hath a fi-

brous root, which sends out many trailing stalks three or four feet long, which put out roots at every joint, and from them many more shoots are produced; so that where they have room to spread, they will cover a large surface of ground. The leaves of this sort are very like those of the first, but the flowers are larger and of a deep yellow; the petals of this are heart-shaped, and the seed vessels are larger.

The fourth sort grows naturally near old *Vera Cruz* in *New Spain*; this hath a thick fleshy root composed of several tubers, somewhat like those of *Ranunculus*; from this arise one or two inclining stalks, which send out side branches from their lower parts, which are garnished with oval, spear-shaped leaves, part of which have long foot-stalks, the others embrace the stalks with their base; they have short hairs on their under side, and toward the stalk, but are smooth above, of a deep green colour, and close every evening, or in cold weather. The flowers are produced toward the upper part of the stalks, from the bosom of the leaves, standing upon slender foot-stalks, which are composed of three blue petals, pretty large and roundish, and three smaller which are green; the seeds are like those of the other sorts.

The fifth sort grows naturally in the *West-Indies*; this hath trailing stalks like the first, which are garnished with narrow grassy leaves, embracing the stalks with their base; the flowers are produced at the end of the stalks, upon thick foot-stalks, three flowers generally sitting on each; they have three equal large petals of a sky blue, and three smaller which are green.

All the sorts are propagated by seeds; the first will thrive in the full ground, but if the seeds are sown upon a warm border of light earth in autumn, the plants will rise early in the spring; so from these good seeds may be expected, if the season proves favourable; whereas those which are sown in the spring, often lie long in the ground, so that they rarely ripen their seed. These plants have but little beauty, so that two or three of each sort, is as many as most people choose to have; therefore if the seeds are sown in autumn, where the plants are designed to remain, or the seeds permitted to scatter, the plants will require no farther care, but to keep them clear from weeds.

The second sort hath a perennial root; this seldom ripens seeds in *England*, but the roots send out offsets, by which the plant is easily propagated; this sort will live in the full ground in winter, provided it is planted in a sheltered situation: the best time to transplant and part these roots is about the end of *March*.

The other sorts are tender, so their seeds must be sown on a moderate hot bed in the spring, and when the plants are two inches high, they should be transplanted to a fresh hot bed to bring them forward; when they have taken root, they should have a large share of fresh air admitted to them every day in warm weather, to prevent their growing weak; and in *June* they may be carefully taken up and transplanted on a warm border of light earth, observing to shade them till they have taken root, after which they will require no other care, but to keep them clean from weeds. With this management the plants will flower and produce good seeds.

The third and fourth sorts may be continued if they are planted in pots, and in autumn placed in the bark stove; or if the roots of the fourth sort are taken out of the ground in autumn, and kept in a warm place in winter, they may be planted again in the spring, placing them on a hot-bed, to forward their shooting, and these will produce stronger plants than those which rise from seeds.

CONIUM. *Lin. Gen. Plant.* 299. Hemlock.

The Characters are,

It is an umbelliferous plant; the petals of the greater umbel are uniform;

uniform; each flower is composed of five unequal heart-shaped petals which turn inward; they have five stamina; the germen, which is situated under the flower, supports two reflexed styles, and afterward becomes a roundish channelled fruit, divided into two parts, containing two seeds.

The Species are,

1. *CONIUM semininibus striatis.* Hort. Upp. 92. Greater Hemlock.
2. *CONIUM semininibus aculeatis.* Hort. Cliff. 92. Hemlock with prickly seeds.

The first sort grows naturally on the side of banks and roads, in many parts of *England*; this is a biennial plant, which perishes after it hath ripened seeds. It hath a long taper root like a Parsnep, but much smaller. The stalk is smooth, spotted with purple, and rises from four, to upwards of six feet high, branching out toward the top into several stalks, which are garnished with decomposed leaves, whose small leaves are cut at the top into three parts; these are of a lucid green, and have a disagreeable smell. The stalks are terminated by umbels of white flowers, each being composed of about ten rays (or small umbels) which have a great number of flowers, spread open, each sitting upon a slender foot-stalk; the seeds are small and channelled, and like those of Anise.

The second sort grows naturally near the *Cape of Good Hope*, in *Africa*. This plant rarely grows more than nine inches high; the lower leaves are divided somewhat like those of the small wild Rue, and are of a grayish colour; those upon the stalk are much narrower, but of the same colour; the stalks are terminated by umbels of white flowers, each of these large umbels being composed of three small ones; and the involucre hath three narrow leaves, situated under the umbel.

The first sort grows wild in most parts of *England*, so is seldom allowed room in gardens, because it is supposed to have a poisonous quality; some physicians have affirmed, that it is so to all animals, while others have assured us, that it is eaten by the inhabitants of some parts of *Italy* when it is young, and is by them esteemed a great dainty. Mr. Ray mentions, that he has found the gizzard of a thrush full of Hemlock seeds, with four or five grains of Corn intermixed with it, which, in the time of harvest, that bird had neglected for Hemlock, so very fond was it of that seed, which has been reckoned pernicious: however, it is very certain, that scarce any animal will eat the green herb; for it is very common to see the Grass, and most other weeds, eat close where cattle are allowed to feed, and all the plants of Hemlock which were growing left untouched.

This plant is esteemed, by many physicians, as an excellent remedy to dissolve scirrhus tumours; and some have greatly recommended it for cancers; and most of them agree, that it may be prescribed as a good narcotick.

The second sort is an humble plant, and, being tender, will never become troublesome: for, unless the winters are very favourable, this plant will not live in the open air in *England*. The seeds of this sort should be sown in pots in autumn, soon after they are ripe, and placed under a common frame in winter, where they may be exposed to the open air at all times when the weather is mild, and only covered in bad weather. The plants will come up very early in the spring, and must then be exposed to the open air constantly, when the weather will permit, otherwise they will draw up very weak. As these plants do not bear transplanting well, so they should be thinned, and not more than four or five left in each pot; and, as the plants have no great beauty, so a few of them will be sufficient to continue the sort, where a variety of plants are preserved. The other culture is only to keep them clean from weeds, and, in very dry weather, to water them.

CONOCARPODENDRON. See Protea.

CONOCARPOS. *Lin. Gen. Plant.* 213. Button Tree.

The Characters are,

The flowers are collected in a globular head, each standing in a scaly empalement. At the bottom is situated a large compressed germen, divided into five parts at the top. The flower hath one petal, which is cut into five equal parts, and five slender stamina, which extend beyond the petal. The germen afterward becomes a single seed, inclosed in the scale of the fruit, which is shaped like the cone of the Alder tree.

The Species are,

1. *CONOCARPOS erecta foliis oblongis.* Upright Conocarpos with oblong leaves, commonly called Button Tree in the *West-Indies*.
2. *CONOCARPOS frutescens, caulibus procumbentibus.* Shrubby, trailing Conocarpos.

The first sort grows plentifully in most of the sandy bays in all the islands of the *West-Indies*. It rises with a woody upright stem, about sixteen feet high, sending out many side branches, which also grow erect, garnished with spear-shaped leaves, having broad short foot-stalks, and are placed alternate on every side the branches. The flowers grow upon short branches, which arise from the wings of the leaves; these have three or four small leaves on their lower part, under the flowers; each of these branches are terminated by six or eight conical heads of flowers, which have some resemblance to those of Acacia, but each of these come out of a scaly covering; the flowers are small, of a reddish colour, having five slender stamina, and one style, which stand out farther than the petal. The flowers are succeeded by single seeds, which are included in the scales of the conical fruit.

The second sort hath short crooked branches, which divide and spread out on every side, upon the ground; these are covered with a grayish bark, and their upper parts are garnished with oval thick leaves, a little larger than those of the Dwarf Box; they have very short foot-stalks, and are placed on every side the branches without order. The flowers are collected in small round heads, which come out single from the side of the branches, and in loose spikes at the end; these are small, and of an herbaceous colour; the scales are rough, and the cones are of a looser texture than those of the former sort.

Both these sorts are preserved in some curious gardens for the sake of variety, but they are plants of no great beauty. They are propagated from seeds, which must be obtained from the places of their natural growth. These seeds, if they are fresh, will come up very soon, if they are sown upon a good hot-bed; and if the plants are potted, and preserved in the bark stove, they will make great progress; but they are too tender to live in this country, unless they are constantly kept in the stove, and treated in the same manner with other exotick plants of the same country; observing, as they are natives of swamps, to supply them often with water; but in winter they must have it sparingly.

CONSOLIDA MAJOR. See Symphytum.

CONSOLIDA MEDIA. See Bugula.

CONSOLIDA MINIMA. See Bellis.

CONSOLIDA REGALIS. See Delphinium.

CONVAL LILY. See Convallaria.

CONVALLARIA. *Lin. Gen. Plant.* 383. Lily of the Valley.

The Characters are,

The flower hath one petal, which is bell-shaped, spread open and reflexed. It hath no empalement. It hath six stamina, which are inserted into the petal. In the center is situated a globular germen, which afterward becomes a globular berry, with three cells, containing one roundish seed.

The *Species* are,

1. CONVALLARIA *scapo nudo*. *Flor. Lapp.* 113. White Lily of the valley. There is a variety of this with reddish flowers, which is preserved in gardens.

2. CONVALLARIA *scapo nudo, foliis lateralibus*. Broad-leaved Lily of the valley. There is also a variety of this with double variegated flowers which is preserved in gardens.

3. CONVALLARIA *foliis alternis, floribus axillaribus*. *Flor. Suec.* 274. Common broad-leaved Solomon's Seal.

4. CONVALLARIA *foliis alternis, semiamplexicaulibus, floribus majoribus axillaribus*. Broad-leaved Solomon's Seal with a larger sweet flower.

5. CONVALLARIA *foliis amplexicaulibus, caule tereti, pedunculis axillaribus multifloris*. *Lin. Phil. Bot.* 218. Greatest broad-leaved Solomon's Seal.

6. CONVALLARIA *foliis alternis petiolatis, pedunculis axillaribus trifloris*. Broad-leaved Solomon's Seal with a white Hellebore leaf.

7. CONVALLARIA *foliis verticillatis*. *Flor. Lapp.* 114. Convallaria with leaves growing in whorls.

8. CONVALLARIA *foliis sessilibus, racemo terminali composito*. *Lin. Sp. Plant.* 315. Convallaria with leaves sitting close to the stalks, which are terminated by compound spikes of flowers.

9. CONVALLARIA *foliis amplexicaulibus plurimis, racemo terminali simplici*. *Lin. Sp. Plant.* 316. Convallaria with many leaves embracing the stalks, which are terminated by single bunches of flowers.

10. CONVALLARIA *foliis cordatis*. *Flor. Lapp.* 113. Convallaria with heart-shaped leaves.

The first sort grows naturally in great plenty in the woods near *Woburn*, in *Bedfordshire*, from whence the markets in *London* are generally supplied with the flowers. It is also cultivated in gardens, for the sweetness of the flowers; formerly it grew in great plenty on *Hampstead Heath*, but of late years it has not been so common there; for since all the trees have been destroyed, the plants have not flowered there as formerly, nor have the roots increased.

This hath a slender fibrous root, which creeps under the surface of the ground, and thereby propagates in great plenty. The leaves come up by pairs; their foot-stalks, which are about three inches long, are wrapped together in one cover, and at the top divide into two parts, each sustaining a single leaf, one of which arises a little above the other; these leaves are from four to five inches long, and near an inch and an half broad in the middle, lessening gradually to both ends; the foot-stalks of the flowers arise immediately from the root, on one side the leaves; these are naked, about five inches long, and are adorned towards their upper parts with pendulous white flowers, ranged on one side the stalk, which decline to one side; each flower stands upon a short separate foot-stalk, which are crooked. The flowers are open, of the short bell-shaped kind; they have six stamina, which are inserted in the petal of the flower, and are shorter than the tube, and a single style arising from the germen, which is triangular, and crowned by a three-cornered stigma: the germen afterward becomes a globular berry, of a red colour when ripe, inclosing three roundish seeds.

The second sort grows on the *Alps*; this has retained its difference in the garden, where it grew in the same soil and situation with the common sort, so I make no doubt of its being a distinct species. The other with a double variegated flower is supposed to be only a variety of this, therefore I have not enumerated it as a distinct species, though the flowers are much larger, and beautifully variegated with purple and white.

These plants require a loose sandy soil, and a shady situation; they are propagated by parting of their roots, which

multiply in great plenty. The best time to transplant and part the roots, is in autumn. They should be planted near a foot asunder, that their roots may have room to spread; for if they agree with the soil and situation, they will meet and fill the ground in one year. If these roots are planted in a rich soil, they will spread and multiply greatly, but will not be so productive of flowers.

The only culture which these plants require, is to keep them clean from weeds, and to transplant and separate the roots every third or fourth year, otherwise they will be so greatly matted together, as not to have proper nourishment, so the flowers will be but small, and few in number.

The third sort is the common *Solomon's Seal*, which is said to grow naturally wild in *England*, but I doubt ours is a different sort from that mentioned by *Caspar Baubin* under that title; for in two places where I have found it growing, the stalks were much shorter, the leaves were broader, and their borders turned inward; and this difference continues in the garden, where it grows in the same soil and situation with the common sort of *Germany*.

This plant hath a fleshy white root, as large as a man's finger, which creeps in the ground, and is full of knots, from whence it had the name of *Polygonatum*. In the spring arises several taper stalks, which grow near two feet high, adorned with oblong oval leaves, placed alternate, which embrace the stalks with their base; on the opposite side come out the foot-stalks of the flowers, which are about an inch long, dividing at the top into three or four smaller, sustaining a single tubulous flower, cut into six parts at the brim: these have each six slender stamina, surrounding a single style, which arises from the germen, and is crowned by a blunt stigma; the germen afterward becomes a round berry, about the size of *Ivy berries*, each inclosing three seeds.

The fourth sort doth not rise so high as the third, the leaves are broader, and half embrace the stalks with their base. It hath fewer flowers on each foot-stalk, and those are much larger, and smell sweet.

The fifth sort rises much higher, the leaves are broader, and embrace the stalks with their base; there are many more flowers on each foot-stalk, which have longer and narrower tubes than either of the former. This grows naturally in the northern parts of *Europe*.

The sixth sort hath large fleshy roots, full of knots, or joints, which send up many stalks four feet high, garnished with oblong oval leaves, near five inches long, and above two inches broad in the middle, having many deep longitudinal furrows, running parallel to the midrib, somewhat like those of white *Hellebore*. The flowers come out on the opposite side of the stalks from the leaves, having short foot-stalks, which divide into three smaller, each sustaining one flower, with a long slender tube, more closed at the top, than those of the other species, but the colour is the same.

The seventh sort rises with an upright stalk, about two feet high, garnished with long narrow leaves, which stand in whorls round the stalk, there are generally five of these placed at each joint; they are four inches long, and half an inch broad, smooth, and of a light green. The flowers come out from the same joints, standing upon short foot-stalks, each supporting five or six flowers, which are smaller, and have much shorter tubes than either of the former sorts; they are of a dirty white, tipped with green, and slightly cut into six parts at the top.

The eighth sort grows naturally in most parts of *North America*. This rises with an upright stalk above two feet high, garnished with oblong leaves, ending in sharp points, which are near five inches long, and two and an half broad; having three large longitudinal veins, with several smaller between, which join at both ends. The leaves are alternate, standing close to the stalks, and are of a light green.

on their upper side, but are paler on their under. The flowers are produced in branching spikes at the extremity of the stalks, each being composed of several small loose spikes of star-like flowers, of a pale yellow, which fall away without producing any seed.

The ninth sort is a native of the same countries as the eighth; this sends up stalks two feet high, which are garnished with many oblong leaves embracing them with their base. The flowers are produced in single spikes at the top of the stalks, which are in shape and colour like those of the eighth; but these are succeeded by small red berries, about the size of those of the Lily of the valley.

All these sorts of Solomon's Seal are very hardy plants, and delight in a light soil and a shady situation, so are very proper to plant in wilderness quarters under tall trees, where, if they are not crowded by lower shrubs, they will thrive and multiply exceedingly, and during the summer season will make an agreeable variety, the whole appearance of the plants being very singular.

They all multiply very fast by their creeping roots, especially when they are planted in a proper soil and situation. The best time to transplant and part the roots is in the autumn, soon after their stalks decay; those which are removed at that season, will grow much stronger, than those which are planted in the spring; but they may be safely transplanted any time after the stalks decay, till the roots begin to shoot in the spring. As these roots greatly increase, so they should be planted at a wide distance from each other, that they may have room to spread, for they should not be removed oftener than every third or fourth year, where they are expected to grow strong, and produce a good number of stalks, in which their beauty consists. The only culture these plants require, is to dig the ground between them every spring, and keep them clean from weeds.

The tenth sort is an humble plant, which, when transplanted into gardens, seldom rises above six inches high, and where it grows naturally not much more than half so high; this hath a fibrous creeping root, which spreads and multiplies greatly in the ground, sending up many slender stalks, each having for the most part two heart-shaped leaves, one standing above the other. The stalks are terminated by loose spikes of white star-like flowers, which are succeeded by small red berries.

It grows naturally in all the northern parts of Europe, and delights in a moist soil and shady situation, where it will spread and multiply in great plenty.

CONVOLVULUS. *Lin. Gen. Pl.* 198. Bindweed.

The Characters are,

The flower hath one large bell-shaped petal, which spreads open. It hath five short stamens, and a roundish germen. The empalement after-ward becomes a roundish capsule, with one, two, or three valves, containing several seeds which are convex on their outside, but on their inside angular.

The Species are,

1. CONVOLVULUS *foliis sagittatis utrinque acutis, pedunculis unifloris. Flor. Suec.* 173. Smaller Field Bindweed, commonly called Gravel Bindweed.

2. CONVOLVULUS *foliis sagittatis posticè truncatis, pedunculis unifloris. Prod. Leyd.* 427. Larger white Bindweed, called Bearbind.

3. CONVOLVULUS *foliis sagittatis posticè truncatis, pedunculis bifloris. Prod. Leyd.* 427. Syrian Bindweed, or Scammony.

4. CONVOLVULUS *annuus, foliis cordatis calycibus acutis, villosis.* Purple Bindweed with a roundish heart-shaped leaf, commonly called *Convolvulus major*, or greater Bindweed:

5. CONVOLVULUS *foliis cordatis, acuminatis, pedunculis trifloris.* Bindweed with heart-shaped, pointed leaves, and three flowers on each foot-stalk.

6. CONVOLVULUS *foliis cordatis trilobis villosis, calycibus*

lævibus, capsulis hirsutis, pedunculis bifloris. Blue Bindweed, with an angular Ivy leaf.

7. CONVOLVULUS *foliis cordatis angulato-nervosis, caule repente tubifero. Lin. Sp. Plant.* 154. Bindweed with heart-shaped leaves, having angular nerves, and a creeping stalk bearing tubers; commonly called *Spanish Potatoes*.

8. CONVOLVULUS *foliis palmatis, lobis septem-finuatis acutis, pedunculis unifloris, calycibus maximis patentibus.* Five-leaved Bindweed with smooth indented leaves and hairy stalks.

9. CONVOLVULUS *foliis hastato-lanceolatis, auriculis rotundatis, pedunculis multifloris.* Bindweed with spear-pointed leaves having rounded ears, and many flowers on each foot-stalk.

10. CONVOLVULUS *foliis cordatis subhastatisque villosis, caule petiolisque pilosis, pedunculis multifloris. Lin. Sp. Pl.* 159. Bindweed with heart-shaped leaves, somewhat spear-pointed and downy, with hairy stalks and foot-stalks, and many flowers on each.

11. CONVOLVULUS *foliis ovato-oblongis, glabris pedunculis unifloris, calycibus decempartitis.* Bindweed with oval, oblong, smooth leaves, and foot-stalks having a single flower, whose empalement is cut into ten parts.

12. CONVOLVULUS *hirsutissimus, foliis quinquelobatis, pedunculis longissimis bifloris.* Very hairy Bindweed, with leaves having five lobes, and very long foot-stalks with two flowers.

13. CONVOLVULUS *caule fruticoso, glabro, foliis quinquelobis, pedunculis geniculatis, unifloris, capsulis maximis.* Bindweed with a shrubby, smooth stalk, leaves having five lobes, many jointed foot-stalks with one flower, and very large seed vessels.

14. CONVOLVULUS *foliis emarginatis, pedunculis trifloris. Lin. Sp. Pl.* 159. Bindweed with indented leaves, and foot-stalks having three flowers.

15. CONVOLVULUS *foliis cordatis, glabris, pedunculis multifloris, seminibus villosis ferrugineis.* Bindweed with smooth, heart-shaped leaves, foot-stalks having many flowers, and seeds covered with an iron-coloured down.

16. CONVOLVULUS *foliis cordatis pubescentibus, caule perenni, villoso, pedunculis multifloris. Lin. Sp. Pl.* 155. Bindweed with soft, woolly, heart-shaped leaves, a hairy perennial stalk, and foot-stalks having many flowers.

17. CONVOLVULUS *foliis triangularibus acutis, floribus plurimis sessilibus patulis, calycibus acutis multifidis.* Bindweed with sharp-pointed triangular leaves, many spreading flowers set close to the stalk, and acute empalements ending in many points.

18. CONVOLVULUS *foliis cordatis, acuminatis, pedunculis bifloris.* Bindweed with heart-shaped, pointed leaves, and foot-stalks having two flowers.

19. CONVOLVULUS *foliis sagittatis posticè obtusis, caule repente, pedunculis unifloris. Lin. Sp. Plant.* 158. Bindweed with narrow-pointed leaves, which are obtuse at the foot-stalk, a creeping stalk, and one flower on each foot-stalk.

20. CONVOLVULUS *foliis cordato-sagittatis, pedunculis unifloris.* Bindweed with heart-shaped, arrow-pointed leaves, and foot-stalks having a single flower.

21. CONVOLVULUS *foliis cordato-ovatis, pedunculis unifloris, bracteis lanceolatis, flore sessile. Hort. Cliff.* 68. Bindweed with oval heart-shaped leaves, foot-stalks having one flower, spear-shaped bractæ, and the flower sitting close to the stalk.

22. CONVOLVULUS *foliis palmatis sericeis, pedunculis bifloris, calycibus acutis.* Bindweed with silky, palmated leaves, foot-stalks having two flowers, and sharp-pointed empalements.

23. CONVOLVULUS *foliis cordatis incisè & incanis, pedunculis bifloris, calycibus obtusis.* Bindweed with hoary heart-shaped leaves, which are jagged, foot-stalks having two flowers, and obtuse empalements.

24. CONVULVULUS *foliis lanceolato-ovatis glabris, caule declinato, floribus solitariis.* Lin. Vir. Cliff. Bindweed with smooth, oval, spear-shaped leaves, a declining stalk, and one flower upon each foot-stalk, commonly called *Convolvulus minor*.

25. CONVULVULUS *villosus, foliis lineari lanceolatis, caule recto, pedunculis multifloris.* Hairy Bindweed with narrow spear-shaped leaves, an upright stalk, and foot-stalks having many flowers.

26. CONVULVULUS *foliis lanceolatis, sericeis, caule declinato, radice repente, pedunculis multifloris.* Bindweed with silky spear-shaped leaves, a declining stalk, creeping root, and foot-stalks having many flowers.

27. CONVULVULUS *foliis lanceolatis, obtusis sericeis pedunculis multifloris.* Hort. Cliff. 68. Bindweed with blunt, spear-shaped, silky leaves, and foot-stalks having many flowers.

28. CONVULVULUS *foliis lineari-lanceolatis, acutis caule ramoso, recto, pedunculis unifloris.* Hort. Cliff. 68. Bindweed with narrow spear-shaped leaves, which are pointed, an upright branching stalk, and foot-stalks with one flower.

29. CONVULVULUS *foliis subovatis, obtusis, petiolatis pilosis, caule diffuso, pedunculis trifloris.* Flor. Zeyl. 76. Bindweed with oval, obtuse leaves, having hairy foot-stalks bearing three flowers, and diffused stalks.

30. CONVULVULUS *foliis reniformibus, pedunculis unifloris.* Hort. Cliff. 67. Bindweed with kidney-shaped leaves, and one flower on each foot-stalk; or, Sea Bindweed.

31. CONVULVULUS *foliis cordatis, angulatis, caule membranaceo, quadrangulari, pedunculis multifloris.* Flor. Zeyl. 72. Bindweed with angular heart-shaped leaves, a quadrangular membranaceous stalk, and foot-stalks having many flowers.

32. CONVULVULUS *foliis variis, pedunculis unifloris, radice tuberosâ cathartica.* Bindweed with variable leaves, foot-stalks with single flowers, and a tuberous root; or, the true Jalap.

The first sort is very common upon dry banks, and in gravelly grounds, in most parts of *England*, and is generally a sign of gravel lying near the surface. The roots of this shoot very deep into the ground, from whence some country people call it Devils Guts: this is a troublesome weed in gardens, so should be constantly rooted out.

The second sort is also a troublesome weed in gardens, when the roots are intermixed with those of trees and shrubs, or under hedges, where the plants cannot be easily destroyed: but in an open clear spot of ground, where they are constantly hoed down for three or four months, they may be effectually destroyed; for when the stalks are broken or cut, a milky juice flows out, and thereby the roots are soon exhausted and decay; as every small piece of the root will grow, so it renders this a troublesome weed to destroy, where they are intermixed with other roots.

The third sort grows naturally in *Syria*, where the roots of the plants are wounded, and shells placed under the wounds to receive the milky juice which flows out, which is inspissated, and afterward put up and exported: this is what is called Scammony in the shops: it is a very hardy plant, and will thrive very well in the open air in *England*, provided it is on a dry soil. The roots of this are thick, run deep into the ground, and are covered with a dark bark. The branches extend themselves on every side to the distance of ten or twelve feet, they are slender and trail on the ground, and are garnished with narrow arrow-pointed leaves. The flowers are of a pale yellow, and come out from the side of the branches, two sitting upon each long foot-stalk; these are succeeded by roundish seed vessels, having three cells, filled with seeds shaped like those of the former sort, but smaller. If the seeds of this sort are sown in the spring, on a border of light earth, the plants will come up, and require no other culture but to keep them clean from weeds, and thin the plants where they grow too close; for as the branches extend very far,

the plants should not be nearer than five feet asunder. The stalks decay in autumn, but the roots will abide many years.

The fourth sort is an annual plant, which grows naturally in *Asia* and *America*, but has been long cultivated for ornament in the *English* gardens, and is generally known by the title of *Convolvulus major*. Of this there are three or four lasting varieties; the most common hath a purple flower, but there is one with a white, another with a red, and one with a whitish blue flower, which hath white seeds. All these varieties I have cultivated many years, without observing them to change. If the seeds of these sorts are sown in the spring, upon a warm border where the plants are designed to remain, they will require no other culture, but to keep them clean from weeds, and place some tall stakes down by them, for their stalks to twine about, otherwise they will spread on the ground, and make a bad appearance. These plants, if they are properly supported, will rise ten or twelve feet high; they flower in *June*, *July*, and *August*, and will continue till the frost kills them. Their seeds ripen in autumn.

The fifth sort grows naturally in *Jamaica*. This sends out long branches, which twine about the trees and rise to a great height; the leaves are smooth, heart-shaped, ending in long points, and the ears at the base are large and rounded; they stand upon long slender foot-stalks. The flowers come out on the opposite side of the stalks, upon long foot-stalks, each sustaining three flowers, with longer tubes than those of the former, and are of a deeper blue colour. This is not so hardy as the former; so the seeds should be sown upon a hot-bed in the spring, to bring the plants forward, and toward the end of *May*, they should be planted out in warm borders, and treated in the same manner as the former sort.

The sixth sort grows naturally in *Africa* and *America*. It is an annual plant, which rises with a twining stalk eight or ten feet high, garnished with heart-shaped leaves, divided into three lobes which end in sharp points; these are woolly, and stand upon long foot-stalks; the flowers come out on long foot-stalks, each sustaining two flowers of a very deep blue colour, from whence it has been titled Anil or Indigo. This is one of the most beautiful flowers of this genus, and is undoubtedly a distinct species, though some have supposed it to be only a variety of the fourth sort: the leaves of this has three deeply divided lobes, and those of the fourth sort are entire. This sort is annual, and must be propagated in the same manner as the fifth. It flowers all the latter part of summer, and, in good seasons, the seeds ripen very well in the open air.

The seventh sort is that whose roots are eaten, and is generally called *Spanish* Potatoe; these roots are annually imported from *Spain* and *Portugal*, where they are greatly cultivated for the table, but they are too tender to thrive well in the open air in *England*; they are cultivated by the roots in the same way as the common Potatoe, but require much more room; for these send out many trailing stalks, which extend six or eight feet every way, and at their joints send out roots, which, in warm countries, grow to be large tubers, so that from a single root planted, forty or fifty large roots are produced. This is sometimes propagated by way of curiosity in *England*, but the roots should be planted on a hot-bed in the spring, and if the plants are kept covered in bad weather with glasses, they will produce flowers, and some small roots will be produced from the joints of the stalks; but if they are exposed to the open air, they seldom grow to be of any size.

The eighth sort grows naturally at *La Vera Cruz*, in *New Spain*. This rises with a strong winding stalk, to the height of twenty feet, dividing into several smaller, which fasten themselves about any of the neighbouring trees and shrubs;

and are garnished with leaves in shape of a hand, having seven lobes, which are spear-shaped, and deeply cut on their borders, ending in sharp points. The flowers are single on each foot-stalk, which are very long. The empalement of the flower is large, spreading open, and is divided deeply into five parts. The flowers are large, of a purple colour, and are succeeded by large roundish seed vessels, having three cells, in each of which is lodged a single seed.

This plant is tender, so the seeds should be sown on a hot-bed in the spring, and when the plants are fit to remove, they must be transplanted each into a separate pot, and plunged into a moderate hot-bed, observing to shade them from the sun till they have taken new root; then they should have a large share of air admitted to them every day, to prevent their drawing weak. When the plants are grown too tall to remain in the hot-bed, they must be shifted into larger pots, and placed in the bark stove, where, if they are allowed room, they will rise to a great height, and produce flowers, but it rarely produces seeds in *England*.

The ninth sort is an annual plant; it grows naturally near *Carthagera*, in *New Spain*. This rises with a twining slender stalk, ten or twelve feet high, garnished with arrow-pointed leaves, whose ears at the base are rounded. The flowers are produced in small clusters, standing on long foot-stalks; these are yellow, and are succeeded by three-cornered seed vessels, having three cells, in each of which are lodged two seeds.

This plant is annual, and too tender to thrive in the open air in *England*, so the seeds should be sown on a hot-bed in the spring, and the plants may be afterward treated in the same way as the eighth sort, with which management they will flower, and produce ripe seeds.

The seeds of the tenth sort were sent me from *Jamaica*. This is an annual plant, rising with slender, twining stalks, eight or nine feet high, garnished with heart-shaped leaves, which are downy. The flowers stand many together at the end of strong foot-stalks; they are purple, and are succeeded by roundish seed vessels with three cells, containing three small seeds.

This sort requires the same treatment as the eighth, being too tender to thrive in this country in the open air.

The eleventh sort was sent me from the island of *Barbuda*. This is an annual plant, which rises with twining stalks seven or eight feet high, garnished with oblong, oval, smooth leaves. The flowers come out at every joint on slender long foot-stalks, each supporting a large purple flower, whose empalement is cut almost to the bottom, in ten parts. The seeds and capsule are like those of the other species. This is a tender plant, so must be treated in the same manner as the eighth sort.

The twelfth sort grows naturally at *Carthagera*, in *New Spain*. This is a perennial plant, which rises with strong winding stalks, to the height of fourteen or sixteen feet, garnished with leaves divided into five lobes, standing upon short foot-stalks; the flowers stand upon long foot-stalks, each sustaining two purple flowers. The stalks, leaves, and every part of the plant, is closely covered with pungent stinging hairs of a light brown colour. This sort is tender, so must be treated in the same manner as the eighth.

The thirteenth sort grows naturally about *Tolu*, in *New Spain*. This hath a ligneous stalk covered with a purple bark, which twines about the trees, and rises to the height of thirty feet or more, garnished with leaves which are deeply divided into five sharp-pointed lobes. The flowers stand upon long thick foot-stalks, which have a knee in the middle; they are very large, of a purple colour, and are succeeded by round seed vessels, as large as a middling Apple, divided into three cells, each containing two very large smooth seeds.

This plant is too tender to thrive in the open air in *England*, so must be treated in the same manner as the eighth sort, but it grows too tall for the stoves here. I have had these plants upward of twenty feet high, which have sent out many side branches, extending so wide on every side, as to cover most of the neighbouring plants, so that I was obliged to remove them into a cooler situation, where they would not thrive.

The fourteenth sort grows naturally on the sea shores in most of the islands in the *West-Indies*, where the stalks trail on the ground, which are garnished with oval leaves, indented at the top. The flowers are large, of a purple colour, and are produced by threes, on very long foot-stalks; these are succeeded by large oval seed vessels, with three cells, each containing a single seed; this hath a perennial stalk, which spreads to a great distance, but is too tender to thrive in the open air in *England*, so must be treated in the same manner as the eighth sort, and may be continued two or three years in a warm stove; but it is apt to spread too far for a small stove, so that where there is not great room, it is not worthy of culture.

The fifteenth sort grows naturally in *Jamaica*; this rises with slender winding stalks, eight or ten feet high; the leaves of these are shaped a little like those of the common great white *Convolvulus*, but the foot-stalks, which are pretty long, do each sustain many purple flowers, growing in bunches. The seed vessels of this sort are three-cornered, and have three cells, each containing a single seed.

The sixteenth sort hath been long preserved in several curious gardens in *England*. It grows naturally in the *Canary* islands; this hath a strong fibrous root, from which arise several twining woody stalks, and where they have support, will grow more than twenty feet high, garnished with oblong heart-shaped leaves, which are soft and hairy. The flowers are produced from the wings of the leaves, several standing upon one foot-stalk; they are for the most part of a pale blue, but there is a variety of it with white flowers. It flowers in *June*, *July*, and *August*, and sometimes ripens seeds here; but as the plants are easily propagated by layers, and also from cuttings, so the seeds are not so much regarded, nor indeed will those plants which are raised by layers or cuttings, produce seeds, though those which come from seeds seldom fail. It may be propagated by laying down of the young shoots in the spring, which generally put out roots in three or four months; then they may be taken from the old plants, and each planted in a separate pot, and placed in the shade till they have taken new root, after which they may be placed with other hardy green-house plants till autumn, when they should be removed into the green-house, and afterward treated in the same way as *Myrtles*, and other green-house plants. If the tender cuttings of this are planted during any of the summer months, and plunged into a moderate hot-bed, shading them from the sun, they will take root, and afterward should be treated as the layers.

The seventeenth sort is an annual plant; this rises with a very slender twining stalk, four or five feet high, garnished with triangular leaves, which are pointed. The flowers grow in clusters, sitting close to the stalks, which are blue, and are succeeded by seeds like those of the fourth sort. This sort will not ripen seeds in *England*, unless the plants are brought forward on a hot-bed in the spring, and afterward placed in a glass case, where they may be defended from cold.

The eighteenth sort grows naturally in *Jamaica*. This is one of the most beautiful species of this genus, the flowers being very large, and of a fine Rose colour. It rises with a winding stalk, seven or eight feet high, garnished with heart-shaped leaves, ending in long points, sitting upon very long foot-stalks.

foot-stalks. The flowers also have long foot-stalks, each supporting two flowers, whose empalement is divided deeply into five parts; the seeds of this are large, and covered with a fine down. This is an annual plant, which is too tender to thrive in the open air in this country, so the seeds should be sown on a hot-bed in the spring, and the plants afterward treated in the same manner as is directed for the eighth sort.

The nineteenth sort grows naturally near the sea, at *Campeachy*. It hath strong, smooth, winding stalks, which send out roots at their joints, garnished with arrow-pointed leaves, whose ears (or lobes) are obtuse; the flowers are large, of a sulphur colour, and sit upon very long foot-stalks, which proceed from the side of the stalks, each supporting one flower, with a large swelling empalement; they are succeeded by large, smooth, oval capsules, having three cells, each including one large smooth seed. This is a perennial plant, whose stalks extend to a great distance, and put out roots at the joints, whereby it propagates in plenty, but it is too tender to thrive in *England*, unless it is preserved in a warm stove, where it requires more room, than can well be allowed to one plant. It must be treated in the same manner as the eighth sort.

The twentieth sort grows naturally in *Africa*; this rises with a slender winding stalk, five or six feet high, garnished with heart-shaped arrow-pointed leaves; the flowers stand on long slender foot-stalks, they are white, with purple bottoms. This may be treated in the same manner as the common great *Convolvulus*.

The twenty-first sort grows naturally in *Spain* and *Italy*. It is an annual plant, which rises about two feet high, with slender twining stalks, garnished with oval leaves. The flowers are small, and of a bluish colour; each foot-stalk supporting one flower, of little beauty, so is not often cultivated in gardens. If the seeds of this sort are permitted to scatter, the plants will rise in the spring, and require no other culture but to keep them clean from weeds; or if the seeds are sown in the spring, where the plants are to remain, they will flower in *June*, and the seeds will ripen in *August*.

The twenty-second sort grows naturally in *Sicily*, and also in the islands of the *Archipelago*; this hath a perennial root, which sends out many slender stiff stalks, twisting themselves round the neighbouring plants, and grow five or six feet high, garnished with leaves, which are divided into five or seven narrow lobes, and are soft like fatten, standing on short foot-stalks. The flowers are produced from the side of the stalks, upon long foot-stalks, which sustain two flowers of a pale Rose colour, with five stripes of a deeper red. This sort creeps at the root, so seldom produces seeds in *England*, but is propagated by the shoots taken from the old plants; the best time for parting and transplanting these plants, is about the beginning of *May*, when they may be taken out of the green-house, and exposed in the open air; but the young plants which are separated from the old ones, should be placed under a frame, and shaded from the sun till they have taken new root, after which they must be gradually hardened to bear the open air; but in autumn they must be placed in the green-house, and may be treated in the same way as the *Canary Convolvulus* beforementioned.

The twenty-third sort hath some appearance of the twenty-second, and hath been supposed to be the same species by some writers, but as I have cultivated both many years, and never have found either of them alter, so I make no doubt of their being distinct plants. This hath a perennial root like the former, which sends out many weak twining stalks, rising three or four feet high, twisting about the plants which stand near it, or about each other, and if they have no other support, fall to the ground; they are garnished

with leaves of different forms, some are shaped almost like those of *Betony*, being slightly cut on their edges, others are almost heart-shaped, and are deeply cut on the sides, and some are cut to the midrib; they have a shining appearance like fatten, and are soft to the touch, standing on short foot-stalks. The flowers are produced on the opposite side from the leaves, having very long foot-stalks, each sustaining two flowers of a pale Rose colour, very like those of the former species. It hath a perennial root, which sends out offsets, by which it is propagated in *England*, in the same manner as the last mentioned, and the plants must be treated in the same way.

The twenty-fourth sort grows naturally in *Portugal*, but hath been long cultivated in the flower gardens in *England* for ornament; this is usually titled *Convolvulus minor*, by the seedsmen and gardeners. It is an annual plant, which hath several thick herbaceous stalks, growing about two feet long, which do not twine like the other sorts, but decline toward the ground, upon which many of the lower branches lie prostrate; they are garnished with spear-shaped leaves, which sit close to the branches; the foot-stalks of the flowers come out just above the leaves at the same joint, and on the same side of the stalks, and are about two inches long, each sustaining one large open bell-shaped flower, which in some is of a fine blue colour, with a white bottom; in others they are pure white, and some are beautifully variegated with both colours. The white flowers are succeeded by white seeds, and the blue by dark coloured seeds, and this difference is pretty constant in both; but those plants with variegated flowers, have frequently plain flowers of both colours, intermixed with the striped; therefore the only method to continue the variegated sort, is to pull off the plain flowers when they appear, never suffering any of them to remain for seed.

This sort is propagated by seeds, which should be sown on the borders of the flower garden, where they are designed to remain, and when the plants come up, if the seeds grow, there should be but one or two left in each place. After which they will require no other culture, but to keep them clean from weeds.

The twenty-fifth sort grows naturally in *Italy* and *Sicily*; this hath a perennial root, which runs deep in the ground, from which arise two or three upright branching stalks, two or three feet high, garnished with narrow leaves about two inches long, which sit close to the stalks; the foot-stalks of the flower proceed from the same place; these are four or five inches long, each sustaining four or five flowers, of a pale Rose colour, which spread open almost flat. It flowers in *July* and *August*, and the stalks decay in autumn; but the roots will last several years, and if they are in a dry soil and warm situation, will abide through the winters very well without covering, and may be propagated by layers.

The twenty-sixth sort hath a perennial creeping root, from which arise several short branching stalks, about four inches high, garnished with spear-shaped silky leaves; the flowers are produced on the side, and at the top of the stalks, in small clusters, sitting close together; they are much smaller than those of the former sort, but are of a deeper Rose colour: it seldom produces seeds in *England*, but the roots propagate in plenty; it may be transplanted either in the spring or autumn. This is by some supposed to be the same as the last mentioned sort, but whoever has cultivated them, can have no doubt of their being different species.

The twenty-seventh sort grows naturally in *Italy*, *Sicily*, and the islands of the *Archipelago*; it rises with upright shrubby stalks about three feet high, closely garnished with blunt, spear-shaped, silky leaves, which are placed on every side the stalks; they are near two inches long, and a quarter broad

broad, rounding at their ends. The flowers are produced in clusters at the top of the stalks, sitting very close; they are of a pale Rose colour, and come out in *June* and *July*, but do not perfect seeds in *England*. This plant will live in the open air in mild winters, if it is planted in a light soil and a warm situation, but in hard winters it is sometimes destroyed; therefore some of the plants should be kept in pots, and sheltered under a common frame in winter, where they may enjoy the free air in mild weather, and be protected from the frost, and in summer placed abroad with other hardy exotick plants, where its fine silky leaves will make a pretty appearance. It may be propagated by laying down the branches, and also by cuttings.

The twenty eighth sort grows naturally in *Candia*, and several of the islands in the *Archipelago*; this hath a perennial root, which sends up several erect branching stalks about two feet high, which are garnished with very narrow-pointed leaves, sitting close to the stalks, which are hoary. The flowers come out singly on the side of the stalks, sitting very close to them, having scarce any foot-stalks; these are of a very pale bluish colour, and spread open almost to the bottom. This sort is propagated in the same manner as the twenty-fifth, and the plants require the same treatment.

The twenty-ninth sort grows naturally in both *Indies*; this is an annual plant, which sends out several weak stalks from the root, inclining to the ground, which are garnished with oval leaves, sitting close to the stalks; they are about the size of Chickweed leaves, but are hairy, and are placed alternate on the branches, the flowers are small, of a light blue, two growing upon each foot-stalk, they are succeeded by small round capsules divided into three cells, which contain the seeds.

This sort is very tender, so the seeds should be sown on a hot-bed in the spring, and when the plants are fit to remove, they should be each planted into a separate small pot, and plunged into a hot-bed, observing to screen them from the sun till they have taken fresh root; after which, they must be treated in the same manner as the other tender sorts before mentioned.

The thirtieth sort is used in medicine; this is styled *Soldanella*, and *Brassica marina*; it grows naturally on the sea beaches in many parts of *England*, but cannot be long preserved in a garden. It hath many small white stringy roots, which spread wide, and send out several weak trailing branches, which twine about the neighbouring plants, like the common Bindweed, garnished with kidney-shaped leaves, about the size of those of the lesser Celandine, standing upon long foot-stalks, and are placed alternate. The flowers are produced on the side of the branches, at each joint. These are shaped like those of the first sort, and are of a reddish purple colour; they appear in *July*, and are succeeded by round capsules having three cells, each containing one black seed; every part of the plant abounds with a milky juice.

The thirty-first sort grows naturally in the island of *Ceylon*; this is a perennial plant, having thick fleshy roots, which spread far in the ground, and abound with a milky juice, which flows out when the roots are broken or wounded, and soon hardens into a resinous substance, when exposed to the sun and air. From the root shoots forth many twining branches, which twist about each other, or the neighbouring plants, like the common Bindweed. They are garnished with heart-shaped leaves, which are soft to the touch, like those of the Marsh-mallow. The flowers are produced at the joints on the side of the stalks, several standing together on the same foot-stalk; they are white, and shaped like those of the common great Bindweed, and are succeeded by round capsules, having three cells, which contain two seeds in each.

The roots of this plant, which are used in medicine, are brought to us from *India*; it is titled Turpethum, or Turbith, in the shops.

This plant is tender, so will not live in the open air in *England*. It is propagated by seeds, which must be sown on a hot-bed, and, when the plants are fit to remove, they should be each planted in a separate pot, and plunged into a hot-bed of tanners bark, and screened from the sun till they have taken root, and afterward must be treated in the same manner as hath been directed for the eighth sort.

The thirty-second sort is the Jalap which is used in medicine. This grows naturally at *Haleppo*, in the *Spanish West-Indies*, situated between *La Vera Cruz* and *Mexico*. The root of this plant hath been long used in medicine, but it was not certainly known from what plant it was produced. The old title of this was *Mechoacana nigra*, but Father *Plumier* asserted, that it was the root of one species of *Marvel of Peru*; from whence *Tournefort* was induced to constitute a genus of that plant, under the title of *Jalapa*. But Mr. *Ray*, from better information, put it among the *Convolvuli*, and titled it, *Convolvulus Americanus*, *Jalapium dictus*. This was, by the late Dr. *Houssoun*, fully ascertained, who brought some of the roots of this plant from the *Spanish West-Indies* to *Jamaica*, where he planted them, with a design of cultivating the plants for use in that island, where they flourished, during his abode there: but, soon after he left the country, the person to whose care he committed them was so careless, as to suffer hogs to root them out of the ground, and destroy them, so that there was no remains of them left when he returned there; nor have I heard of this plant being introduced into any of the *British* islands since.

This hath a large root, of an oval form, which is full of a milky juice, from which come out many herbaceous twining stalks, rising eight or ten feet high, garnished with variable leaves, some of them being heart-shaped, others angular, and some oblong and pointed; they are smooth, and stand upon long foot-stalks; and from a drawing of the plant, made by a *Spaniard*, in the country where it grows naturally, who gave it to Dr. *Houssoun*, and is now in my possession, the flowers are shaped like those of the common Great Bindweed, each foot-stalk supporting one flower: but, as it is only a pencil drawing, so the colour is not expressed, therefore I can give no farther account of it.

As this plant is a native of a warm country, so it will not thrive in *England*, unless it is preserved in a warm stove: therefore the seeds must be sown on a hot-bed, and the plants put into pots, and plunged into a hot-bed of tanners bark, and treated in the same manner as the eighth sort, with this difference only, that, as this hath large, fleshy, succulent roots, so they should have but little water given them, especially in winter, lest it cause them to rot.

CONYZA. *Lin. Gen. Plant.* 854. Flea-bane.

The Characters are,

It hath a compound flower, made up of many hermaphrodite florets, which compose the disk; and female half florets, which form the rays; the hermaphrodite florets are funnel-shaped, and cut into five parts at the brim, and have each five short hairy stamina; in the bottom of each floret is situated a germen. The female half florets, or rays, are funnel-shaped, and cut into three parts at the top; these have a germen. The hermaphrodite and female florets are both succeeded by one oblong seed, crowned with down, sitting upon a plain receptacle, and are included in the empalement.

The Species are,

1. CONYZA foliis lanceolatis acutis, caule annuo corymbofo. *Hort. Cliff.* 405. Common greater Flea-bane.

2. *CONYZA foliis ovato oblongis, amplexicaulibus.* Hort. Cliff. 405. Pyrenean Flea-bane with a Primrose leaf.

3. *CONYZA foliis ovatis tomentosis, floribus confertis, pedunculis lateralibus terminalibusque.* Hort. Cliff. 405. Shrubby Flea-bane of Crete, with soft woolly leaves, which are very white.

4. *CONYZA foliis hastatis scabris, caule erecto ramoso, perenni, floribus corymbosis.* Yellow tree-like Flea-bane, with a trifid leaf.

The first sort grows naturally upon dry places, in several parts of *England*, so is seldom allowed a place in gardens. This is a biennial plant, which decays soon after the seeds are ripe; it hath several large oblong pointed leaves, growing near the ground, which are hairy; between these the stalks come out, which rise more than two feet high, and divide upward into several branches, which are garnished with smaller oblong leaves, standing alternate; at the ends of the stalks the flowers are produced in round bunches, which are of a dirty yellow colour; these are succeeded by oblong seeds, crowned with down.

The second sort grows naturally on the mountains in *Italy*, and is preserved in botanick gardens for the sake of variety: it hath a perennial root, but an annual stalk. From a thick fibrous root, arise many upright stalks, garnished with oblong oval leaves, which are rough, and embrace the stalks with their base; these have appendages running along the stalk, from one to the other, whereby the stalk is winged. The upper part of the stalks divide into many smaller branches, garnished with leaves of the same form as the other, but smaller, standing alternate. The branches are terminated by yellow flowers, growing in round bunches, and are succeeded by oblong seeds, crowned with down. This is propagated by seeds, which may be sown on a bed of light earth in the spring, and, when the plants come up, they should be thinned where they are too near, and kept clean from weeds; the following autumn they may be transplanted where they are designed to remain, and require no other care but to keep them clean from weeds.

The third grows naturally in *Crete*. This hath a short shrubby stalk, which in this country seldom rises more than six inches high, dividing into several short branches, which are closely garnished with oval woolly leaves, which are very white; from these branches arise the flower-stalks, which are woolly, and about nine inches high; these are garnished with small oval white leaves, placed alternate. The flowers are produced at the sides and end of the stalk, sometimes but one, at other times two, and sometimes three flowers standing on the same foot-stalk: they are of a dirty yellow colour, and rarely are succeeded by seeds in this country: so the plant is propagated here by slips, which, if taken from the old plants in *June*, and planted on an east-aspected border, and covered with hand glasses, will take root in six or eight weeks; when they have taken root, they should be gradually exposed to the open air. In autumn these should be carefully taken up, preserving the earth to their roots; some of them may be planted in pots, that they may be sheltered under a frame in the winter; and the others may be planted in a warm border of dry, poor earth, where they will endure the cold of our ordinary winters very well, and continue many years.

The fourth sort grows naturally in *Jamaica*. This is titled, by Sir *Hans Sloane*, *Virga aurea major, sc. Herba Doria folio sinuato hirsuto.* Cat. Jam. 125. It rises with a shrubby stalk, seven or eight feet high, dividing into several branches, which are cloathed with rough leaves, shaped like the point of a halbert, about four inches long. The flowers are produced in roundish bunches, at the extremity of the branches; they are yellow, and stand close together. These are succeeded by oblong seeds, crowned with down.

This plant is too tender to thrive in the open air in this country, therefore the seeds must be sown upon a hot-bed, and, when the plants are fit to remove, they must be each transplanted into a separate small pot, and plunged into a hot-bed, observing to screen them from the sun till they have taken new root; then they must have free air admitted to them every day, in proportion to the warmth of the season. As the plants advance in strength, so they must have a greater share of air; and, if the season is warm, they may be exposed to the open air for a few weeks in the heat of the summer, provided they are placed in a warm situation; but if the nights prove cold, or much wet should fall, they must be removed into shelter. If these plants are placed in a moderate stove in winter, they will thrive better than in greater heat; and in summer they should have a large share of air. With this management I have had the plants flower well, though they have not perfected seeds here.

COPAIBA, the Balsam of Capevi Tree.

The Characters are,

It hath a flower consisting of five leaves, which expands in form of a rose; it hath five short stamina. The germen is fixed in the centre of the flower, which afterward becomes a pod, containing one or two seeds, which are surrounded with a pulp of a yellow colour.

We know but one sort of this tree, which is,

COPAIBA folio subrotundo, flore rubro. The Balsam of Capevi, with a roundish leaf and a red flower.

This tree grows near a village called *Ayapel*, in the province of *Antiochi*, in the *Spanish West-Indies*, which is about ten days journey from *Carthagena*. There are great numbers of these trees in the woods about this village, which grow to the height of fifty or sixty feet. Some of these trees do not yield any of the balsam; those which do, are distinguished by a ridge which runs along their trunks. These trees are wounded in their center, and they place Calabash shells, or some other vessels, to the wounded part, to receive the balsam, which will all flow out in a short time. One of these trees will yield five or six gallons of balsam: but, though these trees will thrive well after being tapped, yet they never afford any more balsam.

The seeds of this tree were brought from the country of their growth by Mr. *Robert Millar*, surgeon, who sowed a part of them in *Jamaica*, which he informed me had succeeded very well: so that there were hopes to have had these trees propagated in great plenty, in a few years, in some of the *English* colonies; but the slothfulness of the inhabitants suffered them to perish, as they have the *Cinnamon* tree, and some other useful plants, which have been carried thither by curious persons.

There are not, at present, any of these trees in *Europe*, that I can learn: for those seeds which were sent over to *England*, were all destroyed by insects in their passage, so that not one succeeded in the several places where they were sown.

CORALLODENDRON. See *Erythrina*.

CORCHORUS. *Lin. Gen. Plant.* 596. *Tourn. Inst.* 259. *Tab.* 135. Jews Mallow.

The Characters are,

The flower hath five oblong blunt petals; it hath many hairy stamina, which are shorter than the petals; in the center is situated an oblong furrowed germen, which afterward becomes a cylindrical pod, having five cells, which are filled with angular-pointed seeds.

The Species are,

1. *CORCHORUS capsalis oblongis, ventricosus, foliorum infimis serraturis setaceis, reflexis.* *Lin. Flor. Zeyl.* 213. Common Jews Mallow.

2. *CORCHORUS-*

2. *CORCHORUS foliis cordatis, serratis, capsulis oblongis, ventricosis, sulcatis.* Jews Mallow, with heart-shaped sawed leaves, and oblong, swelling, furrowed capsules.

3. *CORCHORUS capsulis subrotundis, depressis, rugosis.* Flor. Zeyl. 214. Jews Mallow with roundish depressed capsules, which are rough.

4. *CORCHORUS foliis ovato-cordatis crenatis, capsulis tetragonis, apicibus reflexis.* Jews Mallow with a yellow flower, and fruit like a Clove.

5. *CORCHORUS foliis lineari-lanceolatis, serratis, capsulis linearibus, compressis, bivalvibus.* American Jews Mallow, with narrower leaves and fruit.

The first species, *Rawolf* says, is sown in great plenty about *Aleppo*, as a pot-herb, the *Jews* boiling the leaves of this plant to eat with their meat. This he supposes to be the *Olus Judaicum* of *Avicenna*, and the *Corchorum* of *Pliny*.

This plant grows in the *East* and *West-Indies*, from both which places I have several times received the seeds. In the *East-Indies* the herb is used in the same manner as in the *Levant*, as I have been informed; but I do not hear that it is used by the inhabitants of *America*.

This is an annual plant, which rises about two feet high, dividing into several branches, garnished with leaves of different sizes and forms; some are spear-shaped, others are oval, and some almost heart-shaped; they are of a deep green, and slightly indented on their edges, having near their base two bristly segments, which are reflexed. They have very long slender foot-stalks, especially those which grow on the lower part of the branches. The flowers sit close on the opposite side of the branches to the leaves, coming out singly: they are composed of five small yellow petals, and a great number of stamina surrounding the oblong germen, which is situated in the center of the flower, and afterward turns to a rough swelling capsule, two inches long, ending in a point, opening in four cells, which are filled with angular greenish seeds.

The second sort grows naturally in several islands of the *West-Indies*. This is also an annual plant, which rises with a strong herbaceous stalk, two feet high, divided upward into two or three branches, which are garnished with heart-shaped leaves, sawed on their edges, standing upon long foot-stalks; and between these are several leaves, nearly of the same form, sitting close to the branches. The flowers come out singly on the side of the branches, as the other, which are shaped like them, and are succeeded by longer swelling pods, which are rough, and have four longitudinal furrows; these open into four parts at the top, and contain four rows of angular seeds.

The third sort grows naturally in both *Indies*. This is also an annual plant, which rises with a slender herbaceous stalk, about three feet high, sending out several weak branches, which are garnished at each joint by one leaf of an oblong heart-shape, ending in a long acute point, and are sawed on their edges, standing upon short foot-stalks, but have no small leaves between. The flowers come out singly on the side of the branches, to which they sit very close; they are smaller than those of the former sorts, and are succeeded by short roundish seed vessels, which are rough, and flatted at the top, having six cells, filled with small angular seeds.

The fourth sort is also a native of both *Indies*. It is an annual plant, which rises about two feet high, dividing into small branches, garnished with oval heart-shaped leaves, crenated on their edges. The flowers of this are very small, of a pale yellow, and are succeeded by swelling, rough, four-cornered seed vessels, about an inch long, flatted at the top, where there are four horns, which are reflexed; so that these have some resemblance in shape to the Clove.

The seeds of the fifth sort were sent me from *Cartbagen*, where the plant grows naturally. This rises about three feet high, sending out several weak side branches, garnished with long narrow leaves, which are sawed on their edges, sitting close to the branches. The flowers are small, of a pale yellow, and come out on the side of the branches. These are succeeded by very narrow compressed pods, near two inches long, opening with two valves, and filled with small angular seeds.

All these plants are too tender to thrive in *England* in the open air; therefore their seeds must be sown on a hot-bed in the spring, and, when the plants are come up fit to remove, they should be transplanted on a fresh hot-bed, to bring the plants forward. After the plants are rooted in the new hot-bed, they must have free air admitted to them every day, for they must not be drawn up weak; and, when they have obtained strength, they should be transplanted each into a separate pot, and plunged into a hot-bed, observing to shade them from the sun till they have taken root; in *June* they should be gradually inured to the open air: part of them may be shaken out of the pots, and planted in a warm border, where, if the season proves warm, they will flower, and perfect their seeds; but, as these will sometimes fail, so it will be proper to put one or two plants of each sort into pots, which should be placed in a glass case, where they may be screened from bad weather, and from these good seeds may always be obtained.

CORDIA. Plum. Nov. Gen. 13. Tab. 14. Sebesten.

The Characters are,

The flower hath one funnel-shaped petal, whose tube is the length of the empalement; the top is divided into four, five, or six parts. It hath five stamina, and in the center a roundish pointed germen, which afterwards becomes a dry berry, which is globular and pointed, fastened to the empalement, inclosing a furrowed nut with two cells.

The Species are,

1. *CORDIA foliis oblongo ovatis, repandis, scabris.* Lin. Sp. Plant. 190. *Cordia* with oblong, oval, rough leaves, turning backward.

2. *CORDIA foliis subovatis serrato dentatis.* Hort. Cliff. 63. The cultivated Sebesten.

3. *CORDIA foliis ovatis, integerrimis.* Lin. Sp. Plant. 191. *Cordia* with oval entire leaves.

The first sort grows naturally in several islands in the *West-Indies*, where it rises with many shrubby stalks, eight or nine feet high, which are garnished toward the top with oblong, oval, rough leaves, standing alternate, on short foot-stalks; they are of a deep green on their upper side. The flowers terminate the branches, growing in large clusters upon branching foot-stalks, some sustaining one, others two, and some have three flowers, which are large, funnel-shaped, having long tubes, which spread open at the top, where it is divided into five obtuse segments: they are of a beautiful scarlet, so make a fine appearance.

The second sort is, by most botanists, believed to be the *Myxa* of *Cæsalpinus*, which is the true Sebesten of the shops; the fruit of which was formerly used in medicine, but of late years has been seldom brought to *England*. This is called *Affyrian Plumb*, from the country where it naturally grows; it rises to the height of our common *Plumb* trees in its native country, but is very rare in *Europe* at present.

The third sort was discovered by *Father Plumier*, in some of the *French* islands in *America*. This sort grows to the height of eighteen or twenty feet, in the natural places where it is found wild. It hath winged leaves, which are large, entire, and smooth; but it hath not yet flowered in *England*, so I can give no farther account of it.

These plants, being natives of warm countries, are too tender to live through the winter in *England*, unless they

are preserved in a stove. They are all propagated by seeds, which must be procured from the countries of their natural growth. These must be sown in small pots, which should be plunged into a good hot-bed of tanners bark in the spring; if the seeds are fresh and good, the plants will begin to appear in six weeks or two months after. These must be brought forward in the hot-bed, by being treated as other tender exotick plants, observing frequently to water them, as they are aquatick plants; in summer they should be gradually hardened, and as they obtain strength, will become more hardy; but, during the two first winters, it will be proper to plunge them into the tan bed in the stove, but, when they begin to have woody stems, they may be placed on shelves, in a dry stove, where, if they are kept in a moderate degree of heat, they may be preserved very well (especially the first sort) which is somewhat hardier than the others.

These plants produce very fine flowers, especially the first sort, which has large tufts of scarlet flowers, produced at the extremity of the branches, after the same manner as the Oleander, or Rose bay; but these flowers are much larger, and of a finer colour.

A small piece of the wood of this tree, being put on a pan of lighted coals, will send forth a most agreeable odour, which will perfume a whole house.

COREOPSIS. *Lin. Gen. Pl.* 879. Tickseed.

The Characters are,

The common empalement of the flower is double; the disk of the flower is composed of many hermaphrodite florets, which are tubular; these have each five hairy stamina; in their center is situated a compressed germen, with two horns, which afterward becomes a single orbicular seed. The border, or rays, is composed of eight female florets, which are tongue-shaped, indented in five parts; these have no stamina, but a germen like the other, and are abortive.

The Species are,

1. COREOPSIS *foliis lanceolatis, ferratis, alternis, petiolatis decurrentibus.* *Hort. Upsal.* 270. Tickseed with spear-shaped, sawed leaves, placed alternate, and are decurrent, and have foot-stalks.

2. COREOPSIS *foliis linearibus, integerrimis.* *Gron. Virg.* 131. Tickseed with very narrow entire leaves.

3. COREOPSIS *foliis lanceolatis, integerrimis.* *Lin. Sp. Pl.* 908. Tickseed with spear-shaped leaves, which are entire.

4. COREOPSIS *foliis decomposito-pinnatis, linearibus.* *Lin. Sp. Pl.* 907. Tickseed with decomposed, winged, narrow leaves.

5. COREOPSIS *foliis subternatis, integerrimis.* *Hort. Upsal.* 269. Tickseed with leaves growing by threes, which are entire.

The first sort grows naturally in most parts of North America. This hath a perennial root, and an annual stalk; the stalks are strong, herbaceous, and rise to the height of eight or ten feet, garnished with spear-shaped leaves, sawed on their edges, which are from three to four inches long, and one broad in the middle, placed alternate on every side the stalks, with a border, or wing, running from one to the other, the whole length of the stalk. The flowers grow at the top of the stalks, forming a sort of corymbus, each foot-stalk sustaining one, two, or three yellow flowers, shaped like Sun-flowers, but much smaller. It is a very hardy plant, and may be propagated in plenty, by parting of the roots in autumn, when the stalks begin to decay. It will thrive in almost every soil and situation.

The second sort is a plant of humbler growth, seldom rising above two feet high. The stalks grow erect, and the leaves are very long, narrow, entire, and rough. The flowers are produced at the extremity of the shoots, which are of a fine yellow colour, having a dark purple middle,

and are of long duration. The plants commonly begin to flower the middle of July, and continue till October, and, if the season proves favourable, some flowers will continue till November, which makes it merit a place in every good garden. The seeds of this sort have been frequently sent to England from Maryland, where the plants grow wild; but they are biennial plants with us, their roots having as yet continued but two years; nor do they perfect their seeds in England, so that at present the plants are very rare in the English gardens.

The third sort is an annual plant. The seeds of this were brought from Carolina by Mr. Catesby, in the year 1726. It hath an upright stalk, garnished with smooth, narrow, spear-shaped leaves, placed opposite, which are entire; from the wings of the leaves come out the foot-stalks of the flowers, which stand opposite, and are erect; the lower part of these have one or two pair of very narrow leaves, but the upper is naked, and terminated by one large yellow flower, whose border, or rays, are deeply cut into several segments; these are succeeded by flat winged seeds, which, when ripe, roll up; the naked foot-stalks of these flowers are more than a foot long. This must be sown upon a gentle hot-bed in the spring, and, when the plants are fit to transplant, they should be each planted into a separate small pot, and plunged into a fresh hot-bed, to bring them forward; and in June they should be inured, by degrees, to the open air, and afterward some of them may be shaken out of the pots, and planted in a warm border, where, if the season is good, they will flower in the middle of July, and ripen their seeds the beginning of September.

The fourth sort hath a perennial root, which sends up many stiff angular stalks, which rise upward of three feet high, garnished at each joint with decomposed winged leaves, standing opposite; these are very narrow, and entire. The branches also come out by pairs opposite, as do also the foot-stalks of the flowers, which are long, slender, and each terminated by a single flower, of a bright yellow, the rays, or border, being oval and entire; the disk, or middle, is of a dark purple colour. This grows naturally in Maryland and Philadelphia. It is propagated by parting of the roots, in the same manner as the first sort, and delights in a light loamy earth, and a sunny exposure.

The fifth sort hath a perennial root, and an annual stalk. This grows naturally in many parts of North America. The stalks of this are strong, round, and smooth, rising six or seven feet high, and are garnished at each joint with some trifoliate leaves, which stand opposite. The flowers are produced in bunches at the top of the stalks, standing upon long foot-stalks; they are of a pale yellow, with a dark purple disk. This sort is propagated by parting of the roots, in the same manner as the first, but requires a better soil and position.

CORIANDRUM. *Lin. Gen. Plant.* 318. Coriander.

The Characters are,

It is a plant with an umbellated flower; the proper empalement is divided into five parts; the rays of the principal umbel are difform; the hermaphrodite flowers, which form the disk, have five equal heart-shaped petals; they have each five stamina. The germen, which is situated under the flower, afterward becomes a spherical fruit, divided into two parts, each having a hemispherical concave seed.

The Species are,

1. CORIANDRUM *fructibus globosis.* *Hort. Cliff.* 100. Great Coriander.

2. CORIANDRUM *fructibus didymis.* *Hort. Cliff.* 100. Smaller testiculated Coriander.

The first of these species is the most common kind, which is cultivated in the European gardens and fields for the seeds, which are used in medicine. The second sort is less com-

mon than the first, and is seldom found but in botanick gardens in these parts of *Europe*. These plants grow naturally in the south of *France*, in *Spain* and *Italy*; but the first sort has been long cultivated in the gardens and fields, though at present there is not near so much of it sown in *England* as was some years past.

They are propagated by sowing their seeds in the autumn, in an open situation, in a bed of good fresh earth, and, when the plants are come up, they should be hoed out to about four inches distance every way, clearing them from weeds; by which management these plants will grow strong, and produce a greater quantity of good seeds. The first sort was formerly cultivated in the gardens as a salad herb.

CORIARIA. *Lin. Gen. Plant.* 458. Myrtle-leaved Sumach, *vulgo*.

The Characters are,

It is male and female in different plants; the male flowers have five leaves, which are joined to the empalement, and have ten slender stamina; the female flowers have the same number of petals; and in the center are placed five pointals, which turn to a berry, inclosing five kidney-shaped seeds.

The Species are,

1. **CORIARIA foliis ovato oblongis.** *Hort. Upsal.* 299. Male Myrtle-leaved Sumach.

2. **CORIARIA vulgaris fœmina.** *Lin. Hort. Cliff.* Female Myrtle-leaved Sumach.

The sort with male flowers is the most common in *England*, the other is very rarely seen in any of the gardens. These grow wild, in great plenty, about *Montpelier* in *France*, where it is used for tanning of leather; and, from this use, has been titled by the botanists, *Rhus coriariorum*, i. e. Tan-ners Sumach.

These shrubs seldom grow more than three or four feet high, and, as they creep at the root, they send forth many stems, whereby they form a thicket, so may be planted to fill up vacancies in wilderness quarters; but they are improper for small gardens, where they will take up too much room, and, as there is no great beauty in the flowers, they are only admitted for variety.

It may be propagated plentifully from the suckers, which are produced from the creeping roots in great abundance; these should be taken off in autumn, and planted into a nursery, to form good roots, where they may continue one or two years, and then must be removed to the places where they are to remain.

CORINDUM. See *Cardiospermum*.

CORIS. *Lin. Gen. Plant.* 216. We have no English name for this plant.

The Characters are,

The flower hath one ringent petal, whose tube is the length of the empalement, spread open at the top, where it is divided into five oblong segments; it hath five bristly stamina. In the center is situated a round germen; the empalement afterward becomes a globular capsule, having five valves, inclosing several small oval seeds.

We have but one Species of this plant, *viz.*

CORIS. *Hort. Cliff.* 68. Blue maritime Coris.

There are two other varieties of this plant, one with a red, and the other a white flower; but these are only accidental varieties, arising from the same seeds.

These plants grow wild about *Montpelier*, and in most places in the south of *France*; they seldom grow above six inches high, and spread near the surface of the ground, like heath; and in *June*, when they are full of flowers, they make a very pretty appearance.

They may be propagated by sowing of their seeds on a bed of fresh earth, and, when the plants are about an inch high, they should be transplanted, some of them into pots,

that they may be sheltered in winter, and the others into a warm border, where they will endure the cold of our ordinary winters very well, but in severe frosts they are generally destroyed: for which reason, it will be proper to have some plants of each sort in pots, which may be put under a common hot-bed frame in winter, where they may be covered in frosty weather, but, when it is mild, they should have a great share of free air. These plants rarely producing ripe seeds in *England*, should be increased from slips and cuttings, which will take root if planted in *August*, on a very gentle hot-bed, and shaded from the sun, and duly watered.

CORISPERMUM. *Lin. Gen. Plant.* 12. Tickseed.

The Characters are,

The flower hath no empalement; it hath two compressed incurved petals; it hath one, two, or three stamina, and a compressed pointed germen, which afterward becomes one oval compressed seed, with an acute border.

The Species are,

1. **CORISPERMUM floribus lateralibus.** *Hort. Upsal.* 2. Tickseed with flowers on the side of the stalks.

2. **CORISPERMUM spicis squarrosis.** *Hort. Upsal.* 3. Tickseed with rough spikes.

These plants are preserved in botanick gardens for the sake of variety, but they have no beauty, so are seldom cultivated in other gardens.

The first sort is an annual plant, which, if suffered to scatter its seeds, the ground will be plentifully stocked with the plants, which will require no other care, but to prevent the weeds from over growing them.

The second will not grow but in marshy places, where there is standing water; over the surface of which this plant will soon extend, when once it is established.

CORK-TREE. See *Quercus*.

CORN-FLAG. See *Gladiolus*.

CORN-MARIGOLD. See *Chrysanthemum*.

CORN-SALLAD. See *Valerianella*.

CORNUS. *Lin. Gen. Plant.* 139. The Cornelian Cherry.

The Characters are,

It hath many flowers, which are included in one common, four-leaved, coloured involucre; the flowers have four plain petals, and four erect stamina, which are longer than the petals; the round germen situated below the empalement, afterward becomes an oval, or roundish berry, inclosing a nut with two cells, having an oblong kernel.

The Species are,

1. **CORNUS arborea, cymis nudis.** *it. W-goth. Lin. Sp. Plant.* 117. Female Dogwood.

2. **CORNUS arborea, umbellis involucre æquantibus.** *Hort. Cliff.* 38. Male Cornel, or Cornelian Cherry tree.

3. **CORNUS arborea, involucre maximo, foliolis obversè cordatis.** *Hort. Cliff.* 38. Male *Virginia* Dogwood, with flowers collected into a corymbus.

4. **CORNUS arborea, foliis lanceolatis, acutis, nervosis, floribus corymbosis terminalibus.** Female *Virginia* Dogwood, with a narrower leaf.

5. **CORNUS arborea foliis oblongo ovatis, nervosis, infernè albis, floribus corymbosis terminalibus.** Wild *Tartarian* Dogwood, with a white fruit.

6. **CORNUS herbacea ramis binis.** *Fl. Lapp.* 55. Low herbaceous Dogwood, called Dwarf Honeyfuckle.

The first of these trees is very common in the hedges in most parts of *England*, and is seldom preserved in gardens. This tree is called *Virga sanguinea*, from the young shoots being of a fine red colour in winter.

The second sort was formerly very common in the *English* gardens, where it was propagated for its fruit, which by many people was preserved to make tarts. Of this there are two or three varieties, which differ in the colour of their

their fruit; but that with the red fruit is the most common in *England*.

As the fruit of this tree is not at present much esteemed, the nursery-men about *London* propagate it only as a flowering shrub, and is by some people valued for coming so early to flower: for, if the season is mild, the flowers will appear by the beginning of *February*; and though there is no great beauty in the flowers, yet as they are generally produced in plenty, at a season when few other flowers appear, a few plants of them may be admitted for variety. The fruit of this tree is seldom ripe before *September*.

The third sort is found growing naturally in all the northern parts of *America*. This will grow to the same height with our common female Dogberry, and make a much better appearance. It is now very common in the nurseries, where it is known by the name of *Virginia Dogwood*. This is well garnished with leaves, which are larger than either of the other sorts, but is not so plentiful of flowers, nor do the plants produce berries in *England*, though the shrubs are as hardy as the other.

The sixth sort grows upon *Cheviot* hills in *Northumberland*, and also upon the *Alps*, and other mountainous places in the northern countries, but is very difficult to preserve in gardens. The only method is, to remove the plants from the places of their natural growth, with good balls of earth to their roots, and plant them in a moist shady situation, where they are not annoyed by the roots of other plants. In such a situation they may be preserved two or three years, but it rarely happens that they will continue longer.

All the sorts of Dogwood may be propagated by their seeds, which, if sown in autumn soon after they are ripe, will most of them come up the following spring; but, if the seeds are not sown in autumn, they will lie a year in the ground before the plants will appear; and, when the season proves dry, they will sometimes remain two years in the ground: therefore the place should not be disturbed where these seeds are sown under two years, if the plants should not come up sooner. When the plants are come up, they should be duly watered in dry weather, and kept clean from weeds, and, the autumn following, they may be removed, and planted in beds in the nursery, where they may remain two years, by which time they will be fit to transplant where they are to remain for good.

They are also propagated by suckers, and laying down of the branches. Most of the sorts produce plenty of suckers, especially when they are planted on a moist soil, which may be taken off from the old plants in autumn, and planted into a nursery for a year or two, and then may be transplanted into the places where they are to remain; but those plants which are propagated by suckers, rarely have so good roots as those which are propagated by layers.

CORNUTIA. *Plum. Nov. Gen.* 17. *Lin. Gen. Plant.* 684.

The Characters are,

The flower has one petal, having a cylindrical tube, which is divided into four parts at the top; it hath four stamina; two of these are longer than the tube, the other are shorter; in the center is situated the roundish germen, which afterward becomes a globular berry, sitting upon the empalient, inclosing several kidney-shaped seeds.

We have but one Species of this plant,

CORNUTIA. *Hort. Cliff.* 319. Cornutia with a blue pyramidal flower and hoary leaves.

This plant is found in plenty in several of the islands in the *West-Indies*, at *Campeachy*, and at *La Vera Cruz*. It grows to the height of ten or twelve feet, with rude branches; the leaves are placed opposite. The flowers are produced in spikes, at the end of the branches, which are of a fine blue colour; these usually appear in au-

turn, and sometimes will remain in beauty for two months or more.

It is propagated either by seeds or cuttings. The seeds should be sown early in the spring on a hot-bed, and, when the plants are come up, they should be transplanted each into a separate halfpenny pot, and plunged into a hot-bed of tanners bark, observing to shade them until they have taken root; when the plants have filled these pots with their roots, they should be shifted into others of a larger size, and plunged into a hot-bed again, where they should be continued till *October*, when they must be removed into the bark stove, and plunged into the tan, for otherwise it will be very difficult to preserve them through the winter: but a moderate share of heat will agree better with them than a very warm stove. The third year from seed these plants will flower, when they will make a very fine appearance in the stove; but they never perfect their seeds in *England*.

The cuttings should be planted into pots, and plunged into a bark bed, observing to shade and water them; they will take root, and must be afterwards treated as the seedling plants.

CORONA IMPERIALIS. See *Fritillaria*.

CORONA SOLIS. See *Helianthus*.

CORONILLA. Jointed-podded *Colutea*.

The Characters are,

It hath a butterfly flower, with nine stamina, which are united, and one standing single, terminated by small summits; in the center is situated an oblong taper germen, which afterward becomes a taper-jointed pod, inclosing oblong seeds.

The Species are,

1. CORONILLA fruticosa, foliolis emarginatis, extimo minore. Shrubby maritime Coronilla, with a sea-green leaf.

2. CORONILLA fruticosa foliolis undenis, extimo majore. *Lin. Sp. Plant.* 743. Shrubby silvery Coronilla of *Crete*.

3. CORONILLA fruticosa stipulis subrotundis. *Lin. Sp. Plant.* 742. Shrubby Spanish Coronilla.

4. CORONILLA fruticosa enneaphylla, foliolis emarginatis, stipulis majoribus subrotundis. Coronilla with thicker pods and seeds.

5. CORONILLA foliolis plurimis, ovatis, caule suffruticoso declinato, pedunculis longioribus. Smallest Coronilla.

6. CORONILLA herbacea, leguminibus erectis, teretibus, torosis, numerosis, foliis glabris. *Hort. Cliff.* 363. Herbaceous Coronilla, with a various coloured flower.

7. CORONILLA herbacea, leguminibus quinis, erectis, teretibus, articulatis. *Prod. Leyd.* 387. Herbaceous Coronilla of *Crete*, with a small purplish flower.

The first sort is an humble shrub, which seldom rises more than two feet high, with a shrubby branching stalk, garnished closely with winged leaves, each being generally composed of five pair of small leaves, or lobes, terminated by an odd one; these are narrow at their base, and broad at the top, and of a sea-green colour. The flowers are produced on slender foot-stalks from the wings of the leaves, on the upper part of the branches, several standing together in a roundish bunch; they are of the butterfly, or Pea-bloom kind, of a bright yellow colour, having a very strong odour, which to some persons is agreeable, but to others the contrary.

This plant is propagated by sowing the seeds in the spring, either upon a gentle hot-bed, or on a warm border of ight earth; when the plants are come up about two inches high, they should be transplanted either into pots, or in a bed of fresh earth, at about four or five inches distance every way, where they may remain until they have obtained strength enough to plant out for good, which should be either into pots filled with good fresh earth, or in a warm-situated border; in which, if the winter is not too severe,

they will abide very well, provided they are in a dry soil.

The second sort is a shrub of the same size with the first, from which it differs in the number of small leaves, or lobes, on each midrib, these having nine or eleven; they are of a silver colour, but the flowers and pods are the same as the former, and the plants requires the same treatment.

The third sort is a shrubby plant, which will rise five feet high, but the stalks are weak, so must be supported; these are garnished with many winged leaves, composed of small oval lobes, placed along the midrib by pairs, ending in an odd one. The flowers stand upon long slender foot-stalks, which arise from the ends of the branches; they are yellow, and grow together in close bunches. This sort, if sheltered from hard frosts, will flower all the winter.

This is a perennial plant, which is propagated by seeds; they may be sown on a bed of light earth in April, and, when the plants are fit to transplant, they should be planted in a warm border near a wall, a pale, or reed hedge, observing to shade them from the sun till they have taken fresh root; after they are well rooted, they will require no other culture but to keep them clean from weeds, and to support their branches, otherwise they will fall on the ground; the next year they will flower, and if they are on a dry soil, and in a warm situation, they will continue many years.

The fourth sort is nearly like the first, but hath fewer pinnæ on each midrib; the flowers are larger, and have little scent; the pods and seeds are much larger, and the plants are not quite so hardy. It requires the same treatment as the first; but in winter the plants should be sheltered, otherwise hard frosts will destroy them.

The fifth sort is a low trailing plant, with shrubby stalks, which spread near the ground, and are garnished with winged leaves, composed of many pair of small leaves placed along the midrib, terminated by an odd one; these are oval, and of a bright green; the flowers stand upon long foot-stalks, in close bunches; they are yellow, and without scent. This is propagated by seeds, in the same manner as the other sorts, and requires the same treatment.

The sixth sort dies to the ground every winter, but rises again the succeeding spring; the shoots rise to the height of five or six feet, where they have support, otherwise they trail on the ground, and are garnished with winged leaves, composed of several oblong small pinnæ, which are sometimes placed by pairs, and at other times are alternate, ending in a single one; they are of a deep green. The flowers come out on long foot-stalks from the wings of the leaves, many growing together in round bunches; they are variable, from a deep to a light purple, mixed with white, and are succeeded by slender pods, from two to three inches long, standing erect. The roots of this plant creep very far under ground, by which the plant increases greatly; which, when permitted to remain unmoved for two or three years, will spread and overbear whatever plants grow near it; for which reason the roots should be confined, and should be planted at a distance from any other plants: they will grow in almost any soil and situation, but thrive best in a warm sunny exposure, in which the flowers will also be much fairer, and in greater quantities. This plant was formerly cultivated to feed cattle.

The seventh sort hath an herbaceous stalk, which rises two feet high, garnished with winged leaves, composed of six pair of small leaves, placed along the midrib, which is terminated by an odd one; these are larger than those of the sixth sort, and broader at the top. The foot-stalks of the flowers come out from the the sides of the stalks, but are shorter than those of the sixth sort, and sustain smaller

heads of flowers, which are succeeded by taper-jointed pods, near two inches long.

This is an annual plant, which grows naturally in the *Archipelago*, from whence *Tournefort* sent the seeds to the royal garden at *Paris*. The seeds of this sort should be sown on a bed of light earth in the spring, where the plants are designed to remain, and, when the plants come up, they should be thinned where they are too close, and afterward kept clean from weeds, which is all the culture they will require: in *June* they will flower, and the seeds ripen in autumn.

CORONOPUS. See *Plantago*.

CORTUSA. *Lin. Gen. Plant.* 181. Bear's-ear Sanicle.

The Characters are,

The flower hath one wheel-shaped petal, cut into five parts at the brim, having five prominent tubercles at the base; it hath five short obtuse stamina; in the center is fixed an oval germen, which afterward becomes an oval, oblong, pointed capsule, having two longitudinal furrows, and one cell, opening with two valves, and filled with small oblong seeds.

The Species are,

1. CORTUSA *calycibus corollâ brevioribus*. *Lin. Sp. Plant.* 144. Bear's-ear Sanicle with an empalement shorter than the petal.

2. CORTUSA *calycibus corollam excedentibus*. *Amæn. Acad.* 2. p. 340. Bear's-ear Sanicle with an empalement longer than the petal.

The first sort grows naturally on the *Alps*, the mountains in *Austria*, and in *Siberia*. This plant sends out many oblong smooth leaves, which are a little indented on the edges, and form a sort of head, like the *Auricula*. The foot-stalks of the flowers come out in the center of the leaves; these rise about four inches high, and support an umbel of flowers, each sitting on a slender, separate, short foot-stalk; they are of a flesh colour, and spread open like those of *Auricula*; this plant is with great difficulty kept in a garden; the only method by which I could ever preserve it, has been by planting the plants in pots, covering the earth with moss, and placing them in a shady situation, where they were duly watered in dry weather; in this place they constantly remained both summer and winter, for the cold will not destroy them; the earth for this plant should be light, and not rich. As this very rarely produces any seeds in *England*, the only method to propagate it is, by parting the roots in the same manner as is practised for *Auriculas*; the best time for this is about *Michaelmas*, soon after which the leaves decay.

The second sort is very like the first, but the flowers are much less, and their empalements are larger; this grows naturally in *Siberia*, but is with great difficulty kept in a garden.

CORYLUS. *Lin. Gen. Plant.* 953. The Hazel, or Nut Tree.

The Characters are,

It hath male and female flowers growing at remote distances on the same tree. The male flowers are produced in long scaly katkins, having no petals, but eight short stamina fastened to the side of the scale; the female flowers are included in the future bud, sitting close to the branches; these have no petals, but a small round germen occupies the center; which afterward becomes an oval nut, shaved at the base, and compressed at the top, ending in a point.

The Species are,

1. CORYLUS *stipulis ovatis obtusis*. *Hort. Cliff.* 448. Wild Hazel Nut.

2. CORYLUS *stipulis oblongis, obtusis, ramis erectioribus*. The Filbert.

3. CORYLUS *stipulis linearibus acutis*. *Hort. Cliff.* 448. Byzantine Nut.

The first of these trees is common in many woods in *England*, from whence the fruit is gathered in plenty, and brought to the *London* markets by the country people. This is seldom planted in gardens; it delights to grow on a moist strong soil, and may be plentifully increased by suckers from the old plants, or by laying down their branches, which, in one year's time, will take sufficient root for transplanting; and these will be much handsomer, and better rooted plants, than suckers, and will greatly outgrow them, especially while young.

The second sort is by many supposed to be only a semi-nal variety from the first, which hath been improved by culture; but this is very doubtful, for I have several times propagated both from the nuts, but never have found them vary from one to the other, though they have altered in the size and colour of their fruit, from the sorts which were sown; but as the shrubs of this grow more erect than those of the other, and the stipulæ are different in their shape, so I have enumerated it as a distinct sort; of this there are the red and white Filberts, both which are so well known, as to need no description.

The third sort grows naturally near *Constantinople*; the nuts of this are large, roundish, and in shape like those of the common Hazel, but are more than twice their size; the cups in which the nuts grow are very large, so as almost to cover the nut, and is deeply cut at the brim. This sort is not common in *England*, but I take those large nuts, which are annually imported from *Barcelona* in *Spain*, to be of the same kind, the nuts being so like, as not to be distinguished when out of their cups; and those of the *Spanish* sort come over naked, so I cannot with certainty say how they essentially differ.

All these sorts may be propagated by layers or sowing their nuts in *February*, which, in order to preserve them good, should be kept in sand in a moist cellar, where the vermin cannot come at them to destroy them; nor should the external air be excluded from them, which would occasion their growing mouldy.

COSTUS. *Lin. Gen. Plant.* 3.

The Characters are,

It hath a simple spadix and spathe, with a small empalement, divided into three parts, sitting on the germen; the flower hath three concave petals, which are erect and equal, with a large oblong nectarium of one leaf, having two lips; the upper is shorter, and turns to a stamen, this is fastened to the upper lip of the nectarium; the germen is situated within the receptacle of the flower, and afterward becomes a roundish capsule with three cells, containing several triangular seeds.

We have but one sort of this plant, viz.

COSTUS. *Hort. Cliff.* 2. *Arabian Costus.*

This hath a fleshy jointed root, like that of Ginger, which propagates under the surface as that doth; from which arise many round taper herbaceous stalks, garnished with oblong smooth leaves, embracing them like those of the Reed; these stalks rise two feet high, and out of the center, the club, or head of flowers is produced, which is two inches long, the thickness of a man's finger, and blunt at the top, composed of several leafy scales, out of which the flowers come; these have but one thin white petal, which is of short duration, seldom continuing longer than one day before it fades, and is never succeeded by seeds in this country. The time of its flowering is uncertain, for sometimes it flowers late in the winter, and at other times it has flowered in summer, so is not constant to any season in *England*.

This is propagated by parting of the roots; the best time for doing this is in the spring, before the roots put out new stalks; the roots must not be divided too small, because that will prevent their flowering; they should be planted in pots, and plunged into the tan bed in the stove, where they

should constantly remain, and may be treated in the same manner as the Ginger.

The roots of this plant were formerly imported from *India*, and were much used in medicine; but of late years they have not been regarded, the roots of Ginger being generally substituted for these.

COTINUS. See Rhus.

COTONEA MALUS. See Cydonia.

COTONEASTER. See Mespilus.

COTULA. *Lin. Gen. Plant.* 868. Mayweed.

The Characters are,

It hath a flower composed of hermaphrodite florets in the disk, and female half florets, which form the rays, included in one common convex empalement. The hermaphrodite florets are tubular, cut into four unequal parts at the top, and have four small stamina, with a germen in the center, which becomes one small oval angular seed; the female half florets have an oval compressed germen, but have no stamina, and are succeeded by single heart-shaped seeds, plain on one side, and convex on the other.

The Species are,

1. COTULA foliis pinnato-multifidis, corollis radio destitutis. *Hort. Cliff.* 417. Yellow Chamomile with heads having no rays.

2. COTULA receptaculis subtus inflatis, turbinatis, *Hort. Cliff.* 417. African Mayweed with an elegant empalement.

3. COTULA foliis lanceolato-linearibus, amplexicaulibus pinnatifidis. *Hort. Cliff.* 417. Smaller foreign Corn Marigold without rays, having the appearance of naked Chamomile.

The first sort grows naturally in *Spain*, *Italy*, and the *Archipelago*; this is an annual plant, which rises with a branching stalk, half a foot high, garnished with leaves which are finely divided like those of Chamomile; the flowers are produced singly at the end of the branches, which are very like those of the naked Chamomile, but the heads rise higher in the middle like a pyramid. If the seeds of this sort are permitted to scatter, the plant will come up in the spring, and require no other care, but to keep them clean from weeds, and thin the plants where they are too close.

The second sort grows naturally at the *Cape of Good Hope*; this is an annual plant, sending out many branching stalks from the root, which spread on the ground, garnished with very fine divided leaves, covered with a lanugo, or cotton; the flowers are produced singly upon long foot-stalks, arising from the side of the branches; these have a narrow border of white rays, with a pale yellow disk: this sort must be raised on a moderate hot bed in the spring, and when the plants have obtained strength, they may be transplanted into a warm border, where they will ripen their seeds very well.

The third sort is an annual plant, which sends out trailing stalks about six inches long, garnished with succulent leaves, in shape like those of Buckhorn Plantain; the flowers grow from the divisions of the stalks, upon short weak foot-stalks, being destitute of rays; they are of a sulphur colour. If the seeds of this sort are sown on a warm border, where the plants are to remain, they will require no other culture, but to keep them clean from weeds; the flowers of the two last sorts stand erect when they first appear, but so soon as the florets are impregnated, and their colour changes, the foot-stalks become very flaccid toward the top, and the flowers hang downward; but when the seeds are ripe, the foot-stalks become stiff, and the heads stand erect for the wind to disperse the seeds.

COTYLEDON. *Lin. Gen. Plant.* 512. Navelwort.

The Characters are,

The flower hath one petal, which is funnel-shaped, cut into five parts at the brim; it hath five germina, which have each a squamous concave nectarium at the base, and ten erect stamina; the germen afterward become so many oblong swelling capsules, opening.

opening longitudinally with one valve, and filled with small seeds.

The Species are,

1. *COTYLEDON foliis cuculatis, serrato dentatis, alternis, caule ramoso, floribus erectis.* Lin. Sp. Plant. 429. Greater Navelwort, or *Umbilicus Veneris*.

2. *COTYLEDON foliis oblongis spinoso mucronatis, caule spicato.* Lin. Sp. Plant. 429. Navelwort with oblong pointed leaves, ending with a spine, and a spiked stalk.

3. *COTYLEDON foliis ovalibus, crenatis, caule spicato.* Lin. Sp. Plant. 429. Navelwort of Crete with an oblong fringed leaf.

4. *COTYLEDON foliis semiglobosis.* Hort. Cliff. 176. Navelwort with semiglobular leaves; or Navelwort of the Cape, with a semiglobular leaf.

5. *COTYLEDON foliis subrotundis, planis integerrimis.* Hort. Cliff. 176. Shrubby African hoary Navelwort, with roundish leaves.

6. *COTYLEDON caule ramosissimo, foliis rotundis, planis, marginibus purpureis.* Navelwort with a very branching stalk, and round, plain, hoary leaves, with purple edges.

7. *COTYLEDON caule ramoso, succulento, foliis obversè ovatis, emarginatis, marginibus purpureis.* Navelwort with a branching, succulent stalk, and obverse, oval leaves, which are indented at the top, and have purple borders.

8. *COTYLEDON caule ramoso, succulento, foliis ovatis planis, acuminatis oppositis semiamplexicaulibus.* Navelwort with a succulent, branching stalk, and oval, plain, pointed leaves, growing opposite, and half embracing the stalk.

9. *COTYLEDON caule ramoso, foliis longis, succulentissimis, supernè sulcatis infernè convexis, floribus cernuis.* Shrubby African Navelwort, with long, narrow leaves, and a yellowish flower.

10. *COTYLEDON foliis laciniatis, floribus quadrifidis.* Hort. Cliff. 175. Navelwort with cut leaves, and four pointed flowers.

The first sort, which is that used in medicine, grows upon old walls and buildings in divers parts of England, particularly in *Shropshire* and *Somersetshire*, in both which counties it greatly abounds upon old buildings, and on rocky places; but is not often found wild near London, nor often cultivated in gardens; this hath many round succulent leaves, whose foot-stalks are placed almost in the center, so as to resemble a target. These are alternately sawed on their edges; the upper surface of the leaves are hollowed in the middle, where the foot-stalks are joined on the lower side, so as to resemble a navel, from whence the plant was titled Navelwort. From between the leaves arise the foot-stalks of the flowers, which in some places grow near three feet high, and in others no more than six inches, their lower part being garnished with leaves; and their upper part with flowers, which stand close to the side of the branches, and grow erect; they are of a whitish yellow colour. It requires a dry rubbishy soil, and to have a shady position: it is a biennial plant, so that after it hath perfected seed, the plant decays; but if the seeds are scattered on walls, and old buildings, as soon as it is ripe, or if the seeds are permitted to fall on such places, the plants will come up, and thrive much better than when they are sown in the ground; and when once the plants are established upon an old wall or building, they will sow their seeds, and maintain their place, better than when cultivated with more care.

The second sort grows naturally in *Siberia*. It is a low plant, in shape like the first, but the leaves are longer and terminate in soft spines. The flower-stalks rise eight inches high, and support four or five whitish flowers, which are cut at the brim into five parts. This sort requires a very shady situation; for if it is exposed to the sun in summer, the plants will soon decay. It is propagated like the other, and requires a pretty strong soil.

The third sort grows naturally in the *Levant*; this hath a fibrous root, from which is produced a single upright succulent stalk, garnished with oblong, thick succulent leaves placed alternate, which are sawed on their edges. The upper part of the stalk is garnished with purplish flowers, growing in a loose spike, two or three being joined on the same foot-stalk, which is very short. It is a biennial plant, which decays soon after the seeds are ripe. If this sort is sown upon a wall, it will thrive better than in the ground, and be less liable to suffer by frost; so that where the seeds scatter themselves in such situations, the plants thrive better than when they are cultivated.

The fourth sort grows naturally at the *Cape of Good Hope*. This hath a thick succulent stalk, which rarely rises above a span high, dividing into many branches, garnished with thick short succulent leaves, which are very convex on their under side, but plain on their upper, not more than half an inch long, and a quarter broad, of a grayish colour, spotted over with small green spots, and sit close to the branches. The foot-stalks of the flower rise from the top of the branches, and are six inches long, naked, and support five or six flowers, which come out alternate from the side, sitting very close to the stalks; they are tubular, and cut into five parts at the top, they are greenish with purple tips.

The fifth sort grows naturally upon dry gravelly spots at the *Cape of Good Hope*. It hath a thick succulent stalk, which by age becomes ligneous, and rises three or four feet high, sending out crooked branches, which grow irregular, garnished with thick fleshy succulent leaves, about two inches long and near as wide toward the top; they are narrow at the base, and rounded at the top, of a sea green colour with a purple edge, which is frequently irregularly indented. The flowers grow upon thick succulent foot-stalks, which arise from the end of the branches, and are near a foot long, naked, and supporting eight or ten flowers, growing in an irregular umbel at the top; these are of a pale yellow colour, having long tubes which hang downward, cut into five parts at the brim, which turn backward; the stamina and style being longer than the tube of the flower, hanging downward.

The sixth sort is also a native of the *Cape of Good Hope*; this hath a short, thick, succulent stalk, which rarely rises more than a foot high, branching out on every side, so as to spread over the pots in which they are planted. These become woody by age, and are closely garnished with thick round leaves of a grayish colour with purple borders. They are plain on their upper side, but convex on their under, very fleshy, of an herbaceous colour within, and full of moisture. This sort hath not flowered in *England*, so far as I can learn. It is undoubtedly a different sort from the former, although they have been supposed to be the same by some writers.

The seventh sort is somewhat like the sixth, but the stalks rise higher; the leaves are much larger, and shaped more like those of the fifth, but are spotted on their upper side with great numbers of dark green spots; they have a deep border of purple on their edges, and sit close to the branches. This hath not as yet flowered in *England*.

The eighth sort hath been of late years introduced from the *Cape of Good Hope*, where it grows naturally. This rises with a succulent stalk near three feet high, which divides into many branches, growing erect, garnished with oval, succulent leaves, placed by pairs opposite; they are of a lively green, and end in points, and half embrace the stalks with their base. This sort hath not as yet produced any flowers in *England*.

The ninth sort grows on rocky places at the *Cape of Good Hope*. This hath a short, greenish, succulent stalk, which seldom rises more than a span high, dividing into several irregular branches, garnished with thick, succulent leaves,
four

four inches long, and half an inch broad, and as much in thickness, having a broad concave furrow on their upper side, running almost their whole length, and are convex on their under side, of a bright green with a purple tip. The foot-stalks of the flowers are produced at the end of the branches, which rise a foot high, having here and there an oblong pointed leaf, growing on their side. The flowers stand upon short foot-stalks, which branch out from the principal stem; these are yellow, having pretty long tubes, which are cut at the top into five parts, and are reflexed backward. The flowers of this sort hang downward, and the stamina are longer than the tube of the flower; the reflexed parts of the petal are tipped with purple.

The tenth sort grows naturally in the warm parts of *Africa*, so is much more tender than either of the other sorts; this rises with an upright stem about a foot high, which is jointed and succulent, garnished with broad leaves, which are deeply cut on their edges; they are of a grayish colour, placed opposite, and almost embrace the stalks with their base. The foot-stalks of the flowers arise from the end of the branches, which are about six inches long, sustaining seven or eight small flowers of a deep yellow colour, which are divided into four parts almost to the bottom. The stamina of these flowers, are not longer than the short tube.

This sort requires a warm stove to preserve it through the winter in *England*, nor should it be exposed abroad in summer; for if it receives much wet, the stalks are very subject to rot, so that it should constantly remain either in the stove, or in summer be placed in an airy glass case, with other tender succulent plants, where they may have free air in warm weather, and be screened from cold and wet; but in autumn they must be removed into the stove, where they should be kept in a moderate temperature of warmth. This is propagated by cuttings, which should be taken off in summer, and planted into small pots, and plunged into a moderate hot-bed, and when they have taken root, they should be removed into the stove.

The other *African* kinds are all of them propagated by planting cuttings in any of the summer months, which should be laid in a dry place for a fortnight or more after they are taken from the plant, before they are planted; for these abound with juice, which will certainly rot the cuttings, if they are not suffered to lie out of the ground, so long as that the wounded part may heal over, and the great redundancy of sap evaporate. The soil in which these plants thrive best, is one third fresh light earth from a pasture, one third sand, and the other third part lime rubbish; these should be well mixed, and laid in a heap six or eight months before it is used, turning it over five or six times, that the parts may the better incorporate; and before it is used it will be proper to pass it through a screen, to separate the large stones, clods, &c. therefrom.

In about a month or six weeks after planting, these cuttings will be rooted, when they must be inured to bear the open air by degrees; first drawing the pots out of the tan, and setting them on the top, then raise the glasses very high in the day time; and in about three weeks after remove the pots into a green-house, and there harden them for another week; after which they may be exposed to the open air in a well defended place, observing not to set them into a place too much exposed to the sun, until they have been inured to the open air for some time.

In this place the plants may remain until the beginning of *October*; at which time you should remove them into the conservatory, placing them as near the windows as possible at first, letting them have as much free open air as the season will permit, by keeping the windows open whenever the weather is good: and now you must begin to abate your

waterings, giving it to them sparingly; but you should not suffer their leaves to shrink for want of moisture, which is another extreme some people run into for want of a little observation.

The best method to treat these plants is, to place them in an open, airy, dry glass case, among *Ficoides's* and *African* Houseleeks, where they may enjoy as much of the sunshine as possible, and have a free dry open air; for if they are placed in a common green-house amongst shrubby plants, which perspire freely, it will fill the house with a damp air, which these succulent plants are apt to imbibe; and thereby becoming too replete with moisture, often cast their leaves.

COURBARIL. See *Hymenæa*.

COWSLIP. See *Primula*.

CRAB-TREE. See *Malus*.

CRAMBE. *Lin. Gen. Pl.* 739. Sea Cabbage.

The Characters are,

The flower hath four petals, placed in form of a cross; it hath six stamina, two of which are the length of the empalement, the other four are longer. The petals have honey glands on their inside, which are longer than the stamina. It hath an oblong germen, which afterward becomes a round dry capsule, with one cell, enclosing one roundish seed.

The Species are,

1. CRAMBE *foliis cauleque glabris. Fl. Suec.* 570. Sea Cabbage with smooth stalks and leaves.

2. CRAMBE *foliis profunde laciniatis, caule erecto, ramoso.* Sea Cabbage with leaves deeply cut, and an upright branching stalk.

3. CRAMBE *foliis scabris, caule glabro. Lin. Sp. Pl.* 671. Sea Cabbage with rough leaves, and a smooth stalk.

4. CRAMBE *foliis cauleque scabris. Hort. Upsal.* 193. Sea Cabbage with rough stalks and leaves.

5. CRAMBE *foliis laciniatis, laciniis oppositis, integerrimis, foliis cauleque glabris.* Sea Cabbage with cut leaves, whose jags are opposite and entire, and smooth stalks and leaves.

The first sort sends out many broad leaves, which are jagged and furbelowed on their sides, of a grayish colour, spreading on the ground; between these arise a thick smooth foot-stalk about one foot high, which spreads out into many branches, having at each joint one leaf of the same form of those below, but much less: these foot-stalks subdivide again into many smaller, which are garnished with white flowers growing in a loose spike, composed of four concave petals placed in form of a cross; these are succeeded by round dry seed vessels, about the size of large Pease, having a single seed in each. The roots of this sort creep under ground, whereby it propagates very fast.

The seeds of the second sort were sent me from *Petersburgh*. This hath a perennial root, which sends out many oblong smooth leaves, which are pointed, and irregularly cut on their sides, into acute segments almost to the midrib; they are very smooth, and of a sea-green colour; between these arise the stalk, which grows three feet high, garnished below by oblong pointed leaves, which are acutely indented on their edges. The stalks branch out into many smaller, and subdivide again into less, which are garnished with loose spikes of white flowers like those of the first sort, which are succeeded by seeds of the same form. This differs greatly from the first, in the shape of its leaves, which are longer, ending in points, and the segments do the same, whereas those of the other are blunt, and not half so deeply cut. The stalks rise more than twice the height of the first, branch out more, and the branches grow more erect. And these differences are constant, where the plants grow in the same soil.

The third sort grows naturally in the *East*. This hath a perennial root, from which arise many leaves in the spring,

spring, which are alternately divided to the midrib, and these divisions are again alternately cut on their edges into many points, so that they have the appearance of winged leaves, and are of a grayish colour. The stalks rise about two feet high, and divide into many branches, which are terminated by loose panicles of small white flowers placed in form of a cross, which are succeeded by small round capsules, each containing a single seed.

The fourth sort is an annual plant, which grows naturally in *Spain* and *Italy*. This rises with a very branching stalk near three feet high, garnished with roundish heart-shaped leaves indented on their edges, standing upon long foot-stalks; the branches subdivide into many slender ones, which end in long loose spikes of small white flowers, and are succeeded by small round dry seed vessels, which contain a single seed. The leaves and stalks of this sort are rough.

The fifth sort hath a perennial root; this grows naturally in the *Levant*. The leaves of this are more than a foot long, and are almost triangular, but are deeply cut on the sides, into opposite segments which terminate in points. They are smooth and of a sea-green colour, spreading near the ground. The stalks rise more than two feet high, branching upward into many smaller, which are naked below, but end in loose spikes of whitish yellow flowers which are small, and are succeeded by small round seed vessels inclosing a single seed.

The first of these species is found wild upon sea shores in divers parts of *England*; but particularly in *Suffex* and *Dorsetshire* in great plenty, where the inhabitants gather it in the spring to eat, preferring it to any of the Cabbage kind; as it generally grows upon the gravelly shore, where the tide flows over it, so the inhabitants observe where the gravel is thrust up by the roots of this plant; they open the gravel, and cut the shoots before they come out, and are exposed to the open air, whereby the shoots appear as if they were blanched; and when they are cut so young, they are very tender and sweet; but if they are suffered to grow till they are green, they become tough and bitter.

This plant may be propagated in a garden, by sowing the seed soon after it is ripe, in a sandy or gravelly soil, where it will thrive exceedingly, and increase greatly by its creeping roots, which will soon overspread a large spot of ground, if encouraged; but the heads will not be fit to cut, until the plants have had one years growth; and in order to have it good, the bed in which the plants grow, should at *Michaëlnas* be covered over with sand or gravel about four or five inches thick, which will allow a proper depth for the shoots to be cut before they appear above ground; and if this is repeated every autumn, in the same manner as is practised in earthing of *Asparagus* beds, the plants will require no other culture.

The other sorts are only preserved in curious gardens of plants for variety, but are not of any use or beauty. The perennial sorts may be propagated in the same manner as the first.

CRANE'S-BILL. See *Geranium*.

CRANIOLARIA. *Lin. Gen. Plant.* 670. *Martynia. Housf. Gen.*

The Characters are,

The flower hath a permanent empalement, composed of four short narrow leaves and a swollen hood, which is cut longitudinally on the side. The flower hath one petal which is unequal, having a very long tube, whose brim is divided into two lips. It hath four stamina, two of which are the length of the tube, and two are shorter. At the bottom of the tube is situated an oval germen, which afterward becomes an oval leathery fruit, pointed at both ends, opening with two valves, inclosing a depressed, woody nut, pointed at both ends and recurved, having two or three furrows, so as to resemble a skull opening in two parts.

The Species are,

1. CRANIOLARIA *foliis cordatis, angulatis. Lin. Sp. Plant.* 618. Craniolaria with heart-shaped, angular leaves.
2. CRANIOLARIA *foliis lanceolatis, dentatis. Lin. Sp. Pl.* 618: Craniolaria with spear-shaped, indented leaves.

The first sort was discovered in the neighbourhood of *Carthagera* in *New Spain*. This is an annual plant, which rises with a branching stalk about two feet high; the branches come out opposite, which are hairy and viscous; the leaves also are placed opposite upon very long foot-stalks; these are of different shapes, some of them are divided into five lobes, others into three, and some are almost heart-shaped, ending in acute points; they are hairy and clammy. The flowers are produced from the side, and also at the end of the branches, standing on short foot-stalks, having an inflated sheath or cover, out of which the tube of the flower arises, which is seven or eight inches long, and very slender, but at the top is divided into two lips, the under being large, and divided into three broad segments, the middle being larger than the other two; the upper lip is roundish and entire; the flowers are succeeded by oblong fruit, having a thick dry skin, which opens lengthways, inclosing a hard furrowed nut, with two recurved horns. This is an annual plant, whose seeds must be sown on a hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a separate small pot, and plunged into a moderate hot-bed, carefully shading them from the sun, till they have taken new root; after which they should have free air admitted to them, to prevent their drawing up weak, and treated in the same manner as other tender exotic plants, being too tender to thrive in the open air in *England*; so that when they are grown too large to remain under the frames, they should be removed into the bark stove, and plunged into the tan bed, where they will flower, and with good management they often perfect their seeds in *England*. But the seeds of this plant should remain on till they drop, otherwise they will not grow; for the outer covers of these seeds split open and drop off, like those of the *Almond*, before the seeds are fully ripened.

The second sort grows naturally at the *Hawannah*, and in some of the other islands in *America*. This rises with a shrubby stalk to the height of ten or twelve feet, dividing upward into a few branches, which are garnished with spear-shaped leaves, cut on their edges; these are soft and hairy. The flowers are produced from the side of the branches, growing several together on the same foot-stalk; they are shaped like those of the *Foxglove*, of a greenish yellow colour, with brown spots on the inside; the flowers have a swelling tube which is recurved, and the brim is slightly divided into five unequal segments.

This sort is propagated by seeds, which must be sown on a hot-bed in the spring, and when the plants are fit to remove, they should be each planted into a separate small pot, and plunged into a fresh hot-bed, where they must be shaded from the sun till they have taken fresh root; then they must have air admitted to them daily. In autumn they must be removed into the bark stove, and plunged into the tan bed; during the winter season the plants should not have much water, and may be treated in the same manner as other tender plants from those countries.

CRASSULA. *Dillen. Hort. Elth.* 114. Lesser Orpine Live-ever.

The Characters are,

The flower consists of five narrow petals, which are joined at their base, but are reflexed, and spread open at the brim: in the bottom of the tube are situated five nectaria, and five stamina situated round these. At the bottom of the tube are placed five oblong, pointed germina; after the flower is past, these become five capsules, opening lengthways, and filled with small seeds.

The

The Species are,

1. *CRASSULA foliis planis cartilagineo-ciliatis, basi connatis vaginantibus.* Vir. Cliff. 26. Shrubby African Navelwort, with umbels of scarlet flowers.

2. *CRASSULA foliis lanceolato-subulatis sessilibus connatis, canaliculatis subtus convexis.* Hort. Cliff. 116. Tallest Crassula with perfoliate leaves.

3. *CRASSULA foliis oppositis, obtusè ovatis, integerrimis, hinc angustioribus.* Hort. Cliff. 496. Crassula with an Orpine leaf.

4. *CRASSULA foliis oppositis, oblongis, planiusculis, distinctis, ciliatis.* Hort. Cliff. 496. Crassula with leaves like Orpine placed crossways.

5. *CRASSULA foliis oppositis, patentibus, scabris.* Lin. Sp. Plant. 283. Shrubby African Navelwort, with narrow, rough, pointed leaves, and a greenish flower.

6. *CRASSULA foliis subulatis, radicans, caule nudo.* Hort. Cliff. 116. Crassula with a long Onion-like leaf.

7. *CRASSULA caule flaccido, foliis connatis, cordatis, succulentibus, floribus confertis terminalibus.* Lesser Orpine with a weak stalk growing through the leaves, which are heart-shaped and succulent, and flowers growing in clusters at the end of the branches.

8. *CRASSULA foliis longis, teretibus, alternis, caule fruticoso, ramofo.* Lesser Orpine with long, taper leaves, placed alternate, and a branching, shrubby stalk.

9. *CRASSULA caule flaccido, prolifero, determinatè-foliofo, foliis patentissimis, imbricatis.* Hort. Cliff. 496. African Rock Housleek, with leaves like the common sort, spreading like a Rose.

10. *CRASSULA caule flaccido repente, foliis oppositis.* Lin. Sp. Pl. 283. Creeping Crassula with the appearance of Purslane.

11. *CRASSULA foliis obverse-ovatis, oppositis, caule fruticoso, succulento.* Tree-like Crassula with the appearance of Purslane.

The first sort hath a round reddish stalk which is jointed, rising about three feet high, which divides upward into many irregular branches, garnished with oblong, plain leaves placed opposite, having a gristly border, set with small silver hairs; they closely embrace the stalks with their base, and form a sort of sheath or cover to it. The flowers terminate the branches in close umbels, sitting very close at the top of the branches; these are funnel-shaped, having pretty long tubes cut at the top into five parts which spread open; they are of a fine scarlet colour, and stand erect. This is propagated by cuttings during any of the summer months; which should be taken off three weeks before they are planted, and laid in a dry place that the wounded part may heal over; then they should be each planted in a small pot, and plunged into a moderate hot-bed, giving them but little water; in about six weeks these will have put out roots, when they should be gradually inured to the open air, into which they should be removed, placing them in a sheltered situation, where they may remain till autumn; when they must be removed into a dry airy glass case, where they may enjoy the sun as much as possible, and be screened from the wet and cold. In warm dry weather during the summer months, while they are abroad, these plants should be gently watered two or three times a week, but in winter they should have very little given them. These plants require no artificial heat in winter, but they must be secured from frost and wet.

The second sort will rise with an upright stalk ten or twelve feet high, if it is not broken or injured, but it will require support; for the stalks being slender, and the leaves very weighty, they are very subject to break, especially if they are exposed to the wind. The leaves of this plant are about three inches long, they are hollowed on the upper side, and have a convex ridge on their lower, and are

placed opposite, furrounding the stalks with their base and alternately cross each other. They are very thick succulent, and of a pale green colour, ending in acute points; at the top of the stalk the flowers are produced in large clusters, which are of a whitish herbaceous colour, having short tubes, cut into five parts at the brim, which spread open. The stalk which sustains the flowers is pretty thick and succulent, generally turning first downward, and then upward again, almost in the form of a syphon. This sort is propagated by cuttings in the same manner as the first, and the plants require the same treatment.

The third sort rises with a weak succulent stalk about two feet high, sending out many irregular branches, garnished with oblong, oval, thick leaves, plain on their upper side, but convex below, of a deep green, and their borders set with a few silvery hairs. The stalk which supports the flowers rises from the top of the branches, and is from four to six inches long, putting out several side branches, which grow erect; these are terminated by large clusters of small greenish flowers.

This is propagated by cuttings in the same manner as the two former, but being pretty hardy, should not be so tenderly treated; for if the cuttings of this are planted in a border of light earth, they will put out roots, and may afterward be taken up and potted.

The fifth sort hath a very weak succulent stalk, which rises about a foot and an half high, dividing upward into small branches, garnished with thin rough leaves, which are flat, near two inches long, and a quarter broad at their base, gradually narrowing to a point; they are rough, placed opposite, and embrace the stalks with their base. The flowers come out in small clusters at the end of the branches, which are small, and of an herbaceous colour, so make no figure. This may be propagated by cuttings, which may be treated in the same manner as the fourth sort.

The sixth sort never rises with a stalk, but the leaves come out close to the ground, forming a sort of head; they are taper and succulent, ending in points, and frequently put out roots: out of the center of the heads arise the flower-stalk, which grows about six inches high, and branches into two or three smaller upward, each being terminated by clusters of greenish flowers, which make no great appearance.

This is propagated by taking off the heads, or side offsets, which should be laid to dry three or four days before they are planted, then they may be treated in the same manner as the other hardier sorts before-mentioned.

The seventh sort hath been lately introduced from the *Cape of Good Hope*; this hath very slender stalks, which are reddish, and full of joints; they trail upon the ground, unless they are supported, and are closely garnished with thick, succulent, heart-shaped leaves, placed opposite, which are closely joined at their base, so that the stalks run through them; they are of a grayish colour; the stalks are divided, and grow about eight or nine inches long, terminated by clusters of small white flowers, sitting very close to the top of the stalks. It is propagated by cuttings in the same manner as the other hardier sorts, and may be treated in the same way.

The eighth sort rises with a shrubby stalk four or five feet high, dividing into many branches, which at first are taper and succulent, but by age become ligneous; these are garnished with very slender, taper, succulent leaves, which are near three inches long, flaccid, and generally turning downward, especially in winter, when they are in the house; but it hath not as yet flowered here. This is equally hardy with the former sorts, and takes easily from cuttings, so may be treated in the same way.

The ninth sort is a low plant, with the appearance of Housleek, having open spreading heads, very like those of

some sorts of Housleek; these grow on the ends of very slender trailing stalks, which are produced in plenty on every side the parent plant, in like manner as the childing Marigold. The flower stalks arise from the center of these heads, which are naked, about four inches long, and are terminated by close clusters of herbaceous flowers. This plant propagates very fast by the side heads, which come out from the parent plant, and frequently put out roots as they trail on the ground, so may be taken off and potted, during any of the summer months; it is equally hardy with the former sorts, so the plants may be treated in the same way.

The tenth sort hath very slender, trailing, succulent stalks, of a reddish colour, which put out roots at the joints as they lie upon the ground. The stalks and leaves of this sort have the appearance of Purslane, and trail upon the ground like Chickweed. The flowers are produced in small clusters at the end of the branches; these are white, with a blush of purple at their brim. This sort is easily propagated by its trailing branches, and the plants require the same treatment as the other hardy sorts, but is of short duration.

The eleventh sort rises with a very thick, strong, succulent stalk, to the height of five feet, sending out branches on every side, so as to form a kind of pyramid, the lower branches being extended to a great length, and the other diminishing gradually to the top; these are of a red, or a purplish colour, and very succulent: they are garnished with roundish succulent leaves, very like those of Purslane, from whence the gardeners have titled it the Purslane tree.

This sort hath not flowered in *England*, though it has been many years in the gardens, so that we are not sure if it is properly ranged in this genus; but from the outward appearance it seems to be nearly allied to some of the other species, on which account *Dr. Dillenius* has placed it here.

It is propagated with great facility by cuttings, which may be planted during any of the summer months, but these should be laid to dry for some days before they are planted, that the wounded part may be healed over, otherwise they will rot. This is somewhat tenderer than the four sorts last mentioned, so must be placed in a warm glass case in winter, where it may enjoy the full sun, and should have very little water during that season; in summer the plants should be placed abroad in a sheltered situation, and in warm weather will require to be refreshed with water twice a week, but as the stalks are very succulent, so too much wet at any season is very hurtful to these plants.

All the hardy sorts of *Crassula*, may be treated in the same way as the *Ficoides*, and other hardier kinds of succulent plants, with this difference only, not to give them so much water; but the first, second, and eleventh sorts require to be placed in a warm dry glass case in winter, and must not be so long exposed abroad in the summer, as the other species, and should have but little water, especially in the winter.

CRATÆGUS. *Tourn. Inst. R. H.* 633. The Wild Service.

The Characters are,

The flower hath five roundish concave petals, and many stamina, which are inserted in the empalement. The germen is situated under the flower, which afterward becomes an oval, or roundish umbilicated berry, inclosing two oblong hard seeds.

The Species are,

1. CRATÆGUS foliis ovatis inæqualiter serratis, subtus tomentosis. *Hort. Cliff.* 187. Cratægus with a roundish sawed leaf, white on the under side, commonly called *Aria Theophrasti*, and in some countries the white Beam, or white Leaf tree.

2. CRATÆGUS foliis cordatis septangulis, lobis infimis divaricatis. *Lin. Sp. Pl.* 476. Wild, or Maple-leaved Service.

3. CRATÆGUS foliis oblongo-ovatis serratis, utrinque virentibus. Cratægus with an oblong sawed leaf, green on both sides.

4. CRATÆGUS foliis oblongo-ovatis, crenatis, subtus argenteis. *Virginia* Cratægus with an *Arbutus* leaf.

The first sort grows naturally on the chalky hills in *Kent*, *Surry*, and *Suffex*, and in some other parts of *England*; it grows to the height of thirty or forty feet, with a large trunk, and divides upward into many branches; the young shoots have a brown bark, covered over with a meally down; these are garnished with oval leaves between two and three inches long, and one and an half broad in the middle, of a light green on their upper side, but very white on their under, having many prominent transverse veins, running from the midrib to the border, where they are unequally sawed. The flowers are produced at the end of the branches in bunches, their foot-stalks being meally, as are also the empalements of the flowers, which are cut into five obtuse segments, that are reflexed. The flowers have five short petals, which spread open, and are like those of the Pear tree, having a great number of stamina of the same length with the petals, terminated by oval summits. The germen, which is situated below the flowers, afterward becomes an oval fruit, crowned with the empalement of the flower, having one cell, in which is inclosed three or four seeds. It flowers in *May*, and the fruit ripens in autumn.

This tree may be propagated by seeds, which should be sown soon after they are ripe; for if they kept out of the ground till the spring, they remain at least one year in the ground before the plants appear. When the plants come up, they may be treated in the same manner as the *Haws*, but they should by no means be headed, or cut down; when these plants are upon a poor chalky soil, they make great progress, and the wood is very white and hard, so has been often used for making cogs for mills, and many other purposes where hard tough timber is wanted.

It may also be propagated by layers in the same manner as the *Lime tree* and *Elm*, but these should be laid in the young wood, and they are two years before they have sufficient roots to transplant.

The tree will take by grafting, or budding upon *Pear* stocks very well, and *Pears* will take by grafting on these trees, so that there is a nearer affinity between the *Cratægus* and the *Pear*, than there is between either of these and the *Mespilus*; for although both these will sometimes take upon the *Mespilus*, yet neither of them thrive so well, or last so long, when grafted, or budded upon those stocks, as they do upon each other.

The second sort grows naturally in many parts of *England*, and is chiefly found upon strong soils; it formerly grew in great plenty in *Cane Wood*, near *Hampstead*, and lately there were some young trees growing in *Bishops Wood*, near the same place; this rises to the height of forty or fifty feet, with a large trunk. The young branches are covered with a purplish bark, garnished with leaves placed alternately, standing on pretty long foot-stalks, which are cut into many acute angles, like those of the *Maple tree*; they are near four inches long, and three broad in the middle, having several smaller indentures toward the top; of a bright green on their upper side, but a little woolly on their under. The flowers are produced in large bunches toward the end of the branches, they are white, and shaped like those of the *Pear tree*, but smaller, and stand upon longer foot-stalks; and are succeeded by roundish compressed fruit, which are shaped like large *Haws*, and ripen late in autumn, and if kept till they are soft, in the same way as *Medlars*, they have an agreeable acid flavour. The fruit of this tree is annually sold in the *London* markets in autumn.

The third sort grows naturally upon mount *Baldus*, and on other mountainous parts of *Italy*; it rises with a woody trunk about twenty feet high, dividing into many branches closely garnished with oblong sawed leaves, standing alternate on very short foot-stalks; they are about three inches long, and one and an half broad, and are slightly sawed on their edges, of a deep green on both sides. The flowers are produced at the end of the branches in small bunches, which have rarely more than four or five in each; they are white, and much smaller than those of the former sorts; and are succeeded by fruit about the size of the common Haw, which is of a dark brown colour when ripe.

This sort may be propagated in the same manner as the first, but requires a strong deep soil, otherwise it will not thrive. It is very hardy in respect to cold, but at present is very rare in *England*.

The fourth sort grows naturally in most parts of *North America*; this seldom rises more than five or six feet high, it hath generally many shrubby stalks arising from the same root, garnished with leaves placed alternate, standing on very short foot-stalks; they are about two inches long, and one broad, ending in a point, of a deep green on their upper side, and a little woolly on their under, of a yellowish white colour; these leaves in autumn change to purple, some time before they fall off. The flowers are produced in small bunches at the end, and also from the side of the branches; they are small, white, and shaped like those of the former sorts, but the petals are narrower, and are succeeded by small fruit, shaped like those of the common Haw, which turn red in autumn, and when fully ripe are of a dark brown colour.

This sort may be propagated by seeds, which should be sown in autumn, in the same manner as hath been directed for the first sort; but as these seeds are frequently brought from *America*, and do not arrive here till spring, so they may be buried in the ground the first summer, and taken up and sown in the autumn, as is frequently practised with Haws; and when the plants have grown one year in the place where they were sown, they may be transplanted, and treated in the same way as the other sorts.

This is generally planted among flowering shrubs of the same growth, where it will add to the variety.

CRATEVA. *Lin. Gen. Plant.* 528. Garlick Pear.

The Characters are,

The flower hath four oval petals, which are narrow at their base, and broad at the top. It hath many bristly stamina, which are longer than the petals, and a long incurved style, upon which sits the oval germen, which afterward becomes a large fleshy globular fruit with one cell, including many kidney-shaped seeds.

The Species are,

1. CRATEVA *inermis*. *Flor. Zeyl.* 211. Smooth Crateva, or Garlick Pear.

2. CRATEVA *spinosa*. *Flor. Zeyl.* 212. Prickly Crateva.

The first sort grows naturally in both *Indies*, where it has a very large trunk, which rises to the height of thirty feet, or upward, covered with a dark green bark, and forms a large head: the branches are garnished with trifoliate leaves, standing on pretty long foot-stalks; the middle lobe, which is much larger than either of the other, is oval, about five inches long, and two and a half broad in the middle; the two side lobes are oblique, and turn at both ends toward the middle, so that their mid-rib is not parallel to the sides, these two end in acute points; they are smooth, of a light green on the upper side, but pale on their under. The flowers are produced at the ends of the branches, standing upon long foot-stalks; their empalements are of one leaf, which are cut into four segments almost to the bottom; the flower hath four oblong petals, which spread open, and are

reflexed, having many long slender stamina, which are connected at their base, but spread open above, and are terminated by oblong purple summits; these surround a slender long style, upon which is situated the oval germen, which is crowned by an obtuse stigma; the germen afterward becomes a round fruit, about the size of an Orange, having an hard brown shell, or cover, inclosing a mealy pulp, filled with kidney-shaped seeds. This fruit hath a strong smell of Garlick, which is communicated to the animals that feed on it.

This is propagated by seeds, which must be sown on a hot-bed in the spring, and when the plants come up, they must be treated in the same manner as hath been directed for the *Annona*, to which article the reader is desired to turn for the culture.

The second sort grows naturally in *India*, where it becomes a very large tree, sending out many long branches, garnished with trifoliate leaves, which are oblong, entire, and end in acute points; between these the branches are armed with long sharp thorns, which come out by pairs, and spread asunder; the flowers are produced in small clusters from the side of the branches, five or seven standing upon a common branching foot-stalk; these have each five acute petals, which are reflexed, and many stamina which stand round a single style of the same length; the petals are green on the outside, and whitish within, and have a grateful odour. After the flower is past, the germen swells to a large fruit, the size of an Orange, having a hard shell, which incloses a fleshy viscous pulp, of a yellowish colour, having many oblong plain seeds situated within it; the pulp of this fruit hath an agreeable flavour when ripe, so is frequently eaten in *India*, where they serve up the fruit, mixed with sugar and Orange, in their deserts, and is esteemed a great delicacy.

This sort is propagated by seeds, and requires the same treatment as the former.

CREPIS. *Lin. Gen. Plant.* 819. Bastard Hawkweed.

The Characters are,

It hath a flower composed of many hermaphrodite florets, which are included in a double empalement; these florets are of one leaf, uniform, tongue-shaped, and are indented at the top in five parts, and have each five short hairy stamina; the germen is situated in the center of the florets, which afterward becomes an oblong seed, crowned with a long feathery down, which sits upon little foot-stalks.

The Species are,

1. CREPIS *foliis amplexicaulibus, lanceolatis, omnibus dentatis: radicalibus sinuatis*. *Vir. Cliff.* 79. Hawkweed with a Dandelion leaf, and a soft red flower.

2. CREPIS *foliis pinnatis angulatis, petiolatis, dentatis*. *Prod. Leyd.* 126. Hawkweed with hairy wild Succory leaves, smelling like Castor.

3. CREPIS *involveris calyce longioribus incurvatis, foliis lanceolatis dentatis*. Greater Spanish Hawkweed, with flowers black in the middle.

4. CREPIS *foliis amplexicaulibus, oblongis acuminatis inferioribus supernè, summis infernè, denticulatis*. *Hort. Upsal.* 238. Alpine Hawkweed with a Viper's Grass leaf.

There are several other species of this genus, some of which grow naturally in *England*, and others are weeds in divers parts of *Europe*, so are rarely admitted into gardens, therefore I shall not enumerate them here.

The first sort grows naturally in *Apulia*, but is now commonly cultivated in the *English* gardens for ornament; it is an annual plant, which perishes after it hath ripened seeds; this hath many spear-shaped leaves which spread on the ground, and are deeply jagged on their sides; between them arise the branching stalks, which grow a foot and a half high, garnished with oblong leaves deeply indented on their

edges, embracing the stalks with their base; the stalks are each terminated by one large radiated flower, of a soft red colour, composed of many half florets, which are succeeded by oblong seeds crowned with a feathery down.

The seeds of this plant should be sown in the spring on the borders of the flower-garden where they are designed to remain, so that if six or eight seeds are sown in each patch, when the plants come up they may be reduced to three or four; and if these are kept clean from weeds, they will require no other culture. If the seeds are sown in autumn, or permitted to scatter, the plants will come up and live through the winter without shelter, and these will flower early in the spring.

The second sort grows naturally in the south of *France* and in *Italy*; this is a biennial plant, and sometimes, when it is in poor ground, it will continue longer; this hath a thick tap root which strikes deep into the ground, sending out many small fibres; the lower leaves are from four to five inches long, and about a quarter of an inch broad, having several deep jags on their edges; from the same root arise four or five stalks, which grow about nine or ten inches high; the lower part of these are garnished with leaves of the same form with those at the root, but are smaller, and more jagged; the upper part of the stalks are naked, and terminated by one flower of a gold colour, inclining to copper, composed of many florets which are included in a single empalement; the flowers are succeeded by oblong narrow seeds, crowned with a feathery down; the whole plant, when bruised, emits a strong odour of Castor.

It is propagated by seeds in the same manner as the first sort, but as this continues longer, so the seeds need not be annually sown: the plant will require no other culture but to keep them clean from weeds.

The third sort is an annual plant, which grows naturally in *Spain*, but is now frequently propagated in the flower-gardens for ornament; this puts out leaves near the root, which are nine inches long, and almost two broad in the middle, of a light green colour, and a little jagged on their edges; the stalks rise a foot and a half high, and are garnished with leaves of the same form as those at bottom, but are smaller; the flowers are produced at the end of the branches, these have a double empalement, composed of many long, very narrow leaves; the outer series are reflected downward, and turn upward again, and are inflexed at their extremities; the flowers are composed of many florets, which spread regularly in form of rays, situated over each other like scales of fish; the bottom or middle is black, so make a pretty appearance in a garden: this plant requires the same culture as the first, and is equally hardy, so that where the seeds are permitted to scatter, the plants will come up without care.

The fourth sort grows naturally on the *Alps*; this is also an annual plant, which sends out many leaves near the root five inches long, and almost two broad at their base; the upper part of these are slightly indented, but their lower are entire; the stalks are strong, upright, rising two feet high, and are terminated by pale white flowers, inclosed in a strong hairy empalement; this requires the same culture as the first, and the seeds will scatter about the garden, so that if the plants are not destroyed, they will maintain themselves without any care.

CRESCENTIA. *Lin. Gen. Plant.* 680.— Calabash tree.

The Characters are,

The flower hath one petal, which is irregular, having a curved gibbous tube; it hath an empalement of one leaf, cut into two obtuse segments, which are concave; it hath four stamina, two of which are the length of the petal, the other are shorter, and an oval germen, which afterward becomes an oval or bottle-shaped fruit, with a hard shell inclosing many flat heart-shaped seeds.

The Species are,

1. *CRESCENTIA foliis lanceolatis, utrinque attenuatis. Hort. Cliff.* 327. Calabash tree with oblong narrow leaves, and a large oval fruit.

2. *CRESCENTIA foliis oblongo-ovatis, fructu rotundo, cortice fragili.* Broad-leaved Calabash tree, whose fruit hath a tender shell.

The first sort grows naturally in *Jamaica*, and in all the *Leeward Islands*; this hath a thick trunk, covered with a whitish bark, which rises from twenty to thirty feet high, and at the top divides into many branches, forming a large regular head, garnished with leaves which come out irregularly, sometimes single, and at others many arise from the same knot; they are near six inches long, and one and a half broad in the middle, of a lucid green, and have very short foot-stalks; the flowers are produced from the side of the large branches, and sometimes from the trunk, standing upon long foot-stalks; they have but one petal, which is irregular, having an incurved tube, which is divided at the brim into two irregular segments, which turn backward; these are of a greenish yellow colour, striped and spotted with brown; they have four slender stamina of the same colour with the petal, which are of unequal lengths, two being full as long as the petal, and the other are much shorter, terminated by oblong summits, divided in the middle, which lie prostrate on the stamina. From the lower part of the tube arises a long slender foot-stalk, supporting the oval germen, which afterward turns to a large fruit, of different forms and size; they are often spherical, sometimes they are oval, and at other times they have a contracted neck like a bottle, and are so large, as when the pulp and seeds are cleaned out, the shells will contain three pints or two quarts of liquid. These fruit or shells are covered with a thin skin of a greenish yellow when ripe, which is peeled off; and under this is a hard ligneous shell, inclosing a pale yellowish soft pulp, of a tart unfavoury flavour, surrounding a great number of flat heart-shaped seeds.

The shells of this fruit are cleaned of their pulp, and the outer skin taken off by the inhabitants of the islands, and are dried; then they use them for drinking-cups, some of which are tipped with silver, and to the necks they fasten handles; and some of the long small fruit are formed into the shape of spoons or ladles, and are used as such; the round ones are cut through the middle, and are used as cups for chocolate. In short, they convert these shells into many sorts of furniture, which is the principal use made of the fruit, for the pulp is seldom eaten.

The second sort seldom rises more than fifteen or twenty feet high, with an upright trunk, covered with a white smooth bark, sending out many lateral branches at the top, garnished with leaves three inches in length, and one and a quarter broad, ranged alternately on the branches, sitting upon short foot-stalks, of a deeper green than those of the first sort, and their edges are entire; the flowers come out from the side of the large branches and the trunk; they are smaller, and of a deeper yellow colour than those of the first; the fruit of this is sometimes round, at others oval, some being much larger than the other; the shells of this fruit are thin and very brittle, so are unfit for any purposes to which those of the former are employed: the wood of this tree is hard and very white, so might be useful, were it not for the plenty of other sorts, which abound in many of the islands.

These trees are too tender to live abroad in *England*, so require a warm stove to be preserved here; they are easily propagated by seeds, which, when fully ripe, should be brought over in the fruit; for when the seeds are taken out of the pulp abroad, and sent over hither, if they are long in their passage, they will lose their growing quality before they

they arrive; the seeds must be sown on a good hot-bed in the spring, and when the plants are fit to remove, they should be each planted into a small half-penny pot, and plunged into a hot-bed of tanners bark, observing to shade them from the sun till they have taken fresh root; then they must be treated in the same manner as other tender plants which are natives of the same countries, keeping them in the tan bed of the bark stove, and should have but little water in winter; in summer they will require to be gently watered two or three times a week, according to the warmth of the season, and should have a large share of air admitted to them; these plants may also be propagated by cuttings.

CRESS, the garden. See Nasturtium.

CRESS, the Indian. See Tropæolum.

CRESS, the water. } See Sifymbrium.

CRESS, the winter. }

CRINUM. Lin. Gen. Plant. 366. Asphodel Lilly.

The Characters are,

The flower hath one petal, which is funnel-shaped, deeply cut at the top into six parts, which are reflexed; it hath six long stamina, which are inserted in the tube of the petal, spreading open; the germen is situated in the bottom of the flower, which afterward becomes an oval capsule with three cells, each containing one oval seed; the flowers are included in a two-leaved sheath.

The Species are,

1. CRINUM foliis sublancoelatis planis, corollis obtusis. Lin. Sp. Plant. 292. African tuberous Crinum, with a blue umbellated flower.

2. CRINUM foliis carinatis. Flor. Zeyl. 127. Crinum with keel-shaped leaves.

3. CRINUM corollarum apicibus introrsum unguiculatis. Lin. Sp. Plant. 292. Crinum with ever-green leaves, and many white flowers.

4. CRINUM foliis carinatis, basi angustioribus, floribus profundè dissectis. Crinum with keel-shaped leaves which are narrower at their base, and flowers deeply cut.

The first sort grows naturally at the Cape of Good Hope; the root of this plant is composed of many thick fleshy fibres, diverging from the same head, which strike deep into the ground; from the same head arises a cluster of leaves surrounding each other with their base, so as to form a kind of herbaceous stalk, about three inches high, from which the leaves spread only two ways, appearing flat the other two. The flower-stalk arises by the side of these leaves, which is round, hollow, and rises upward of three feet high, terminated by a large head of flowers, included in a kind of sheath, which splits into two parts, and is reflexed; the flowers stand each upon a foot-stalk about one inch long; they are tubulous, of one petal, which is cut almost to the bottom into six oblong blunt segments, which are waved on their edges; in the center is situated an oval three cornered germen, supporting a long style, which is attended by six stamina, two of the same length, two somewhat shorter, and the two which rest upon the lower segments are the shortest; the flowers are of a bright blue colour, and grow in large bunches, so make a fine appearance; they begin to flower in September, and frequently continue in beauty till Christmas, which renders them more valuable.

It is propagated by offsets which come out from the side of the plants; they may be taken off the latter end of June, at which time they are in their greatest state of rest; when the plants should be turned out of the pots, and the earth carefully cleared away from the roots; then the fibres of the offsets should be separated from those of the old roots, and the offsets may be taken from the old plants, being careful not to break their heads; but where they adhere so closely to the old plant, as not to be so separated, they must be cut off with

a knife, taking great care not to wound or break the roots of either the offsets or the parent plant. When these are parted, they should be planted each into a separate pot, and placed in a shady situation, where they may enjoy the morning sun, giving them a little water twice a week, if the weather proves dry; but they must not have too much wet, especially at this season, when they are almost inactive, for as the roots are fleshy and succulent, so they are apt to rot with great moisture. In about five weeks time the offsets will have put out new roots, when the pots may be removed to a more sunny situation, and then they may have a little more water, which will strengthen their flowering; but it must not be given them too liberally, for the reasons before given. In September they will put out their flower-stalks, and toward the end of that month the flowers will open, when, if the weather should be very wet or cold, they should be removed under shelter, to prevent the flowers from being injured; but they should have as much free air as possible, otherwise the flowers will be pale coloured and weak. Toward the end of October they should be removed into the green-house, and placed where they may enjoy as much free air as possible, and not be over-hung by other plants; in the winter they may have a little water once a week or oftener in mild weather, but in frost they should be kept dry; it should not have any artificial warmth in winter, and must be placed in the open air in summer.

The second sort hath large bulbous roots, which send out many large fleshy fibres, which have bulbs formed at their ends; the leaves are near three feet long, hollow on their upper side, and closely fold over each other at their base; the outer leaves generally turn downward at the top; they are of a deep green: the flower-stalks arise on one side the leaves, which are thick, succulent, and hollow in the middle, and a little compressed on two sides; these grow two feet high or more, and are of the same colour with the leaves; these are terminated by large umbels of flowers, which hath a sort of sheath or cover, which splits lengthways, and is reflexed back to the stalk, where it dries and remains; the flowers have narrow tubes near four inches long, which are deeply cut into six long segments, which are reflexed back almost to the tube; in the center arises the style, attended by six long stamina, which stand out beyond the petal, and are terminated by oblong prostrate summits of a yellow colour. After the flowers are past, the germen, which is situated at the bottom of the tube, becomes a large roundish three cornered capsule, having three cells, two of which are generally abortive, and the third hath one or two irregular bulbs, which if planted produce young plants.

The third sort hath broader leaves than the second, which are plain, and not hollowed on their upper side, but they are shorter and of a lighter green; these embrace each other at their base; by the side of these arise the flower stalk, which is compressed and hollow, rising about three feet high, terminated by large umbels of white flowers, like those of the former sort, but the segments of the petal are broader and not so much reflexed.

The fourth sort hath roots like those of the second; the leaves of this are narrower at their base, and are stained with purple on their under side; the flower-stalks are purple, and grow to the same height as those of the second; the flowers are in shape like them, but the tube is purple, and the segments have a purple stripe running through them; the stamina also are purple, which renders this more beautiful than either of the other sorts, and these differences are constant in all the plants which rise from seeds, so there can be no doubt of its being a distinct sort.

These three sorts grow naturally in both Indies, so are tender, therefore must be kept in a stove, otherwise they will

will not thrive in *England*. They are easily propagated by offsets, which the roots put out in plenty, or by the bulbs which succeed the flowers, and ripen perfectly here. These must be planted in pots, and plunged into the tan bed in the stove, where the plants will make greater progress, and flower oftener, than when they are placed on shelves; though in the latter way they will succeed very well, provided they are kept in a good temperature of heat. The roots should be transplanted in the spring, and all the offsets taken off, otherwise they will fill the pots, and starve the old plants; they must be frequently refreshed with water, but it must not be given them too plentifully, especially in winter.

CRITHMUM. *Lin. Gen. Plant.* 303. Samphire.

The Characters are,

It is a plant with an umbelliferous flower; the general umbel is uniform; the flowers have five oval inflexed petals, which are almost equal, and five stamina the length of the petals; the germen is situated under the flower, which afterward becomes an oval compressed fruit, dividing into two parts, each having one compressed, elliptical, furrowed seed.

The Species are,

1. CRITHMUM *foliolis lanceolatis carnosis*. *Hort. Cliff.* 98. Samphire with spear-shaped, fleshy leaves.

2. CRITHMUM *foliolis lateralibus bis trifidis*. *Hort. Cliff.* 98. Pyrenean Parsley, with the appearance of scorching Carrot.

The first sort grows upon the rocks by the sea side, in many parts of *England*. This hath a root composed of many strong fibres, which penetrate deep into the crevices of the rocks, sending up several fleshy succulent stalks, which rise about two feet high, garnished with winged leaves, composed of three or five divisions, each of which hath three or five small, thick, succulent leaves, near half an inch long; the foot-stalks of the leaves embrace the stalks at their base. The flowers are produced in circular umbels at the top of the stalks; these are of a yellow colour, composed of five petals, which are near equal in size, and afterward are succeeded by seeds like those of Fennel, but are larger. This herb is pickled, and esteemed very comfortable to the stomach, and is very agreeable to the palate; it provokes urine gently, removes the obstructions of the viscera, and creates an appetite. It is gathered on the rocks, where it grows naturally; but the people who supply the markets with it seldom bring the right herb, but, instead of it, they bring a species of Aster, which is called Golden Samphire, of a different flavour from the true, nor has it any of its virtues.

This plant is with difficulty propagated in gardens, nor will it grow so vigorous with any culture, as it does upon rocks; but if the plants are planted on a moist gravelly soil, they will thrive tolerably well, and may be preserved some years: it may be propagated either by seeds or parting of the roots.

The second sort is by *Tournefort* ranged in his genus of *Apium*. This grows naturally on the *Pyrenean* mountains; it is a biennial plant, which doth not flower till the second year, and perishes soon after the seeds are ripe. There are two or three varieties of this plant, which differ in their outer appearance; one of these is titled by *Mr. Ray*, *Apium montanum* *sive*, *petræum album*. This is of humbler growth than the other; the small leaves are broader, and not so much cut on their edges, and are of a paler green: these plants are preserved in a few gardens for the sake of variety. They are propagated by seeds, which should be sown where they are designed to remain, and will require no other culture but to keep them clean from weeds, and thin them where they are too close.

CRISTA PAVONIS. See Poinciana.

CROCUS. *Lin. Gen. Plant.* 53. Saffron.

The Characters are,

The flower hath one petal, which is deeply cut into six oblong equal segments, and three stamina, which are shorter than the petal; the roundish germen is situated at the bottom of the tube, which afterward becomes a roundish fruit with three cells, filled with roundish seeds.

The Species are,

1. CROCUS *spathâ univalvi radicali*, *corollæ tubo longissimo*. *Lin. Sp. Plant.* 36. Cultivated Saffron.

2. CROCUS *spathâ univalvi pedunculato*, *corollæ tubo brevissimo*. Rush-leaved autumnal Crocus, with a large purplish flower.

3. CROCUS *spathâ bivalvi radicali*, *floribus sessilibus*. Broad-leaved spring Crocus with a variable yellow flower, commonly called Bishop's Crocus.

4. CROCUS *spathâ biflorâ corollæ tubo tenuissimo*. Ordinary, spring, striped Crocus.

There are great variety of these flowers cultivated in gardens, but, as most of them are only feminal variations, so I have not enumerated them here; those which are here mentioned I think must be allowed to be specifically different, since they do not vary to each other.

The first sort is the plant which produces the Saffron, which is a well known drug. This hath a roundish bulbous root, as large as a small Nutmeg, which is a little compressed at the bottom, and is covered with a coarse, brown, netted skin; from the upper part of the root come out the flowers, which, together with the young leaves, whose tops just appear, are closely wrapped about by a thin spatha, or sheath, which parts within the ground, and opens on one side. The tube of the flower is very long, arising immediately from the bulb, without any foot-stalk, and at the top is divided into six oval obtuse segments, which are equal, and of a purple blue colour. In the bottom of the tube is situated a roundish germen, supporting a slender style, which is not more than half the length of the petal, crowned with three oblong golden stigmas (which is the Saffron;) these spread asunder each way; the style is attended by three stamina, whose base are inserted in the tube of the petal, and rise to the height of the style, where they are terminated by arrow-pointed summits. This plant flowers in *October*, and the leaves keep growing all the winter, but it never produces any seeds here.

The second sort grows naturally on the *Alps* and *Helvetican* mountains. This hath a smaller bulbous root than the first, which is more compressed; the flowers appear about the same season with the former, but they rise with a short foot-stalk, having a short spatha, or sheath, just below the flower, which covers it before it expands; the tube of the flower is very short, the petal being divided almost to the bottom, and the segments terminate in acute points; the stamina and style are short, and the leaves of the plant are very narrow. There is a variety of this with a sky blue flower.

The third sort hath a pretty large, compressed, bulbous root, covered with a light brown netted skin, from which arise four or five leaves, like those of the other vernal Crocuses, of a purplish dark colour on their lower parts; from between these come out one or two flowers, of a deep yellow colour, sitting close between the young leaves, never rising above two inches high; these have an agreeable odour: the outer segments of the petal are marked with three black streaks, or stripes, running lengthways from the bottom to the top of the segment; they are narrower than the inner segments: from the double arrangement of these segments, some have called it a double flower. Out of the center of the tube arises a slender style, crowned by a golden stigma, which is broad, flat, and is attended by three slender stamina

stamina of the same length, terminated by yellow summits. After the flower is past, the germen pushes out of the ground, and swells to a roundish three-cornered seed vessel, which opens in three parts, and is filled with roundish brown seeds. This is one of the earliest Crocuses of the spring.

The fourth sort rises with a few very narrow leaves, which are, together with the flower-buds, closely wrapped round by a spatha, or sheath, out of which arise two flowers, one of which hath a longer tube than the other, but these are very slender, and do not rise much above the spatha; there the petal enlarges, and is divided into six obtuse segments, which are of equal size; they are of a dirty white on their outside, with three or four purple stripes in each; the inside of the petal is of a purer white; the stamina and style are nearly the same as those of the former sort. This is one of the earliest sorts which flower in the spring.

The varieties of the autumnal Crocus are,

1. The sweet-smelling autumnal Crocus, whose flowers come before the leaves. *C. B.* This is our second sort.
2. The autumnal mountain Crocus. *C. B.* This hath a paler blue flower.
3. The many-flowering, bluish, autumnal Crocus. *C. B.* This hath many sky blue flowers.
4. The small-flowering autumnal Crocus. *C. B.* This hath a small deep blue flower.

The varieties of the spring Crocus are,

1. Broad-leaved, purple, variegated spring Crocus. *C. B.* This hath broad leaves, and a deep blue flower striped.
2. Broad-leaved Crocus of the spring with a purple flower. *C. B.* This hath a plain purple flower.
3. Broad-leaved spring Crocus with a violet-coloured flower. *C. B.* This hath a large deep blue flower.
4. Spring Crocus with a white flower and purple bottom. *C. B.*
5. Broad-leaved, white, variegated spring Crocus. *C. B.*
6. Broad-leaved spring Crocus, with many purple violet flowers, striped with white. *C. B.*
7. Broad-leaved spring Crocus with an ash-coloured flower.
8. Broad-leaved spring Crocus with a large yellow flower. *C. B.*
9. Broad-leaved spring Crocus with a smaller and paler yellow flower. *C. B.*
10. Broad-leaved spring Crocus with smaller yellow flowers striped with black.
11. Narrow-leaved spring Crocus with a smaller brimstone-coloured flower.
12. Narrow-leaved spring Crocus with a small white flower.

All these varieties of Crocuses are very hardy, and will increase exceedingly by their roots, especially if they are suffered to remain two or three years unremoved; they will grow in almost any soil or situation, and are very great ornaments to a garden early in the spring of the year, before many other flowers appear. They are commonly planted near the edges of borders, on the sides of walks; in doing of which, there should be care taken to plant such sorts in the same line as flower at the same time, and are of an equal growth, otherwise the lines will seem imperfect. When the roots lose their fibres and leaves, they may then be taken up, and kept dry until the beginning of *September*, observing to keep them from vermin, for the mice are very fond of them. In planting these roots (after having drawn a line upon the border) holes are made with a dibble, about two inches deep, or more, according to the lightness of the soil, and two inches distance from each other, in which must be placed the roots, with the bud uppermost; then with a rake fill up the holes in such a manner, as that the upper part of the root may be covered

an inch or more, being careful not to leave any of the holes open; for this will entice the mice to them, which, when once they have found out, will destroy all your roots, if they are not prevented.

This is the way in which these flowers are commonly disposed in gardens: but the better way is, to plant them six or eight near each other in bunches, between small shrubs, or on the borders of the flower-garden, where, if the varieties of these flowers are planted in different patches, and properly intermixed, they will make a much better appearance than when they are disposed in the old method of strait edgings.

The autumnal Crocuses are not so great increasers as those of the spring, nor do they produce seeds in our climate, so that they are less common in the gardens, except the true Saffron, which is propagated for use in great plenty, in many parts of *England*. These may be taken up every third year, as was directed for the spring Crocuses, but should not be kept out of the ground longer than the beginning of *August*, for they commonly produce their flowers in the beginning of *October*; so that if they remain too long out of the ground, they will not produce their flowers so strong, nor in such plenty, as when they are planted early.

CROTOLARIA. *Lin. Gen. Plant.* 771.

The Characters are,

The flower is of the butterfly kind; the standard is large, heart-shaped, and pointed; the wings are oval, and half the length of the standard; the keel is pointed, and as long as the wings; it hath ten stamina, which are united, and an oblong reflexed germen, that after-ward becomes a short turgid pod, with one cell, opening with two valves, and filled with kidney-shaped seeds.

The Species are,

1. CROTOLARIA foliis simplicibus ovatis, stipulis semicordatis, ramis tetragonis. *Flor. Zeyl.* 277. Asiatick Crotolaria with a single-warted leaf and blue flower.
 2. CROTOLARIA foliis simplicibus lanceolatis pilosis, petiolis decurrentibus. American Crotolaria with a winged stalk, hairy leaves, and yellow flowers disposed in loose spikes.
 3. CROTOLARIA foliis oblongo-ovatis hirsutis sessilibus, stipulis acutis pedunculis longioribus. Smaller, hairy, herbaceous, American Crotolaria, with an arrow-shaped stalk.
 4. CROTOLARIA foliis simplicibus, lineari-lanceolatis hirsutis, petiolis decurrentibus, caule fruticoso. Shrubby hairy Crotolaria with a yellow flower, winged branches, and pointed leaves.
 5. CROTOLARIA foliis simplicibus lanceolatis, villosis, argenteis, sessilibus, siliquis pendulis. Asiatick Crotolaria with a silvery, hairy leaf, a yellow flower, and hanging pods disposed in a spike.
 6. CROTOLARIA foliis cordato-ovatis perfoliatis. *Lin. Sp. Plant.* 714. Crotolaria with a Thorough-wax leaf.
 7. CROTOLARIA foliis simplicibus, oblongis cuneiformibus retusis. *Flor. Zeyl.* 276. Asiatick Crotolaria with yellow flowers, and a single heart-shaped leaf.
 8. CROTOLARIA foliis simplicibus ovatis villosis, petiolis simplicissimis, ramis teretibus. *Hort. Cliff.* 357. African Crotolaria with a Storax-tree leaf.
 9. CROTOLARIA foliis ovatis sessilibus, ramis angulatis hirsutis, floribus lateralibus simplicissimis. Crotolaria with oval leaves fitting close to the branches, which are angular and hairy, and single flowers proceeding from the sides of the branches.
- The first sort grows naturally in *India*. This is an annual plant, which hath an herbaceous four-cornered stalk, rising about two feet high, dividing into three or four branches, that have four acute angles, garnished with oval, warted leaves, of a pale green colour, standing on very short foot-stalks. The flowers are produced in spikes at the end of the branches,

branches, which are of the butterfly shape, and of a light blue colour; these are succeeded by short turgid pods, that inclose one row of kidney-shaped seeds.

The second sort grows naturally at *La Vera Cruz* in *New Spain*. This rises with a compressed winged stalk near three feet high, putting out several side branches, garnished with spear-shaped leaves near three inches long, and one broad, covered with soft hairs, sitting close to the branches, alternately; from the foot-stalks of each there runs a border or leafy wing, along both sides of the branches; the flowers are produced in loose spikes at the end of the branches, which are of a pale yellow colour, the standard being stretched out a considerable length beyond the wings. These are succeeded by short turgid pods, which, when ripe, are of a deep blue, having one row of small kidney-shaped seeds, which are of a greenish brown colour.

The third sort grows in *South Carolina*, and in several parts of *America*; this is an annual plant, which rises with a slender stalk a foot and an half high, dividing into three or four spreading branches, garnished with oblong oval leaves sitting close. The upper part of the branches have two leafy borders or wings, running from one leaf to the other, but the lower part of the branches have none; the foot-stalks of the flowers arise from the side of the stalk; they are very slender, and sustain one or two pale yellow flowers at their top, which are not more than half so large as the former sort, and are succeeded by very short turgid pods, in which are inclosed three or four smooth kidney-shaped seeds.

The fourth sort grows naturally in *Jamaica*. It rises with a shrubby taper stalk near four feet high, sending out many side branches which are very slender, ligneous, and covered with a light brown bark; they are garnished with very narrow spear-shaped leaves, which are hairy, and sit close to the branches; the younger shoots have a leafy border or wing on two sides, but the old branches have none; the flowers are produced near the end of the branches, three or four growing alternate on a loose spike, they are of a dirty yellow, and small; the pods which succeed them are about an inch long, very turgid, and of a dark blue when ripe.

The seeds of the fifth sort were brought me from the coast of *Malabar*. This rises with an angular stalk near four feet high, dividing upward into three or four branches, garnished with narrow spear-shaped leaves, placed alternately on very short foot stalks, and are pretty closely covered with soft mealy hairs. The flowers are produced at the end of the branches, in loose spikes; they are large, of a deep yellow colour, and the style stands out beyond the standard. The flowers are succeeded by large turgid pods, containing one row of large kidney-shaped seeds.

This plant is annual in *England*, but by the lower part of the stalk growing woody, it appears to be of longer duration in the country where it naturally grows, though it will not live through the winter here; for if the plants are placed in a stove, the heat is too great for them; and in a green-house, they are very subject to mouldiness in damp weather. I have sown the seeds of this in the full ground, where the plants have grown upward of three feet high, and have flowered very well, but no pods were formed on these; and when they have been treated tenderly, the plants have grown much larger, and produced a greater number of flowers, but these have not been succeeded by seeds. The only way which I could ever obtain any seeds, was by raising the plants in pots upon hot-beds, and the beginning of *July*, turning them out of the pots into the full ground on a very warm border under a wall, in which situation they flowered very well, and a few pods of seeds were ripened.

The sixth sort grows naturally in *South Carolina*, at a

great distance from the *English* settlements. By the description sent me with the seeds, it grows with a shrubby stalk four or five feet high, but the plants which were raised here, perished at the approach of winter, so that they only flowered, without producing any pods.

The seventh sort rises with an herbaceous stalk near three feet high, dividing into several branches, garnished with oblong leaves, which are narrow at their base, but gradually widen to the top, where they are rounded and indented in the middle in the shape of a heart; they are of a pale green, and smooth. The flowers are produced in spikes at the end of the branches, they are pretty large, and of a yellow colour. This grows naturally in the island of *Ceylon*, and is an annual plant, perishing soon after it perfects seeds.

The eighth sort grows naturally at the *Cape of Good Hope*. This rises with a shrubby stalk about five feet high, dividing into several branches, garnished with roundish leaves sitting close; they are of a hoary green, and soft to the touch, the branches are taper and smooth; the flowers are produced at the end of the branches in loose spikes; they are about the size of those of the first sort, and of a fine blue colour.

The ninth sort grows at *Campeachy*; this rises with a taper upright stalk near three feet high, dividing upward into several erect branches, garnished with oval, spear-shaped leaves, of a pale green colour; the flowers are produced singly from the side of the branches, which are of a bright yellow, and are succeeded by short turgid pods, having one row of kidney-shaped seeds.

As most of these plants are annual, so they require to be brought forward in the spring, otherwise the summers are too short for them to perfect seeds in *England*; so that unless the seeds are sown upon a good hot-bed in the spring, and the plants afterward carefully managed, they will not flower well here; for in general, the summers in this country are not very favourable for these tender plants. Therefore in order to have the annual sorts in perfection, there should be a low glass case erected about five or six feet high, which should be made with glasses to open or slide down on every side, as should also the top on both sides, having sliding glasses, that the plants may have sun and air on every side; in this there should be a pit for tanners bark to make a hot-bed, in which may be placed these and other curious tender annual plants, where the sun will constantly shine on them, so long as he makes his appearance above the horizon; and here they may have plenty of free air admitted at all times, when the weather is warm, so may be brought to great perfection, and hereby good seeds may be annually obtained.

These plants naturally grow on sandy light soils, so they should always be planted in such, and the pots in which they are planted, must not be too large, for in such they will not thrive; so that after they have filled the small pots with their roots in which they were first planted, they should be shaken out of those, and put into penny pots, which will be large enough for all the annual kinds. The waterings of these plants should be performed with caution, for too great moisture will rot the fibres of their roots; so that in summer, if they are gently watered three or four times a week in hot weather, it will be sufficient.

CROTON. *Lin. Gen. Pl.* 960. Bastard Ricinus.

The Characters are,

It hath male and female flowers in the same plant; the flowers have five petals, those of the male being no larger than the leaves of the empalement; and have five nectarious glands, which are fixed to the receptacle; they have ten or fifteen stamina, which are joined at their base. The female flowers have a roundish germen, with three reflexed styles. The germen afterward be-

comes a roundish three-cornered capsule, with three cells, each containing a single seed.

The Species are,

1. *CROTON foliis rhombeis repandis, capsulis pendulis caule herbaceo.* Hort. Upsal. 290. Bastard Ricinus, from which the Turnfol of the French is made.

2. *CROTON foliis ovato-lanceolatis, minimè serratis, caule herbaceo hirsuto, floribus alaribus pedunculis longioribus.* Marsh Bastard Ricinus, with oblong sawed leaves, and a prickly fruit.

3. *CROTON foliis inermi-serratis, inferioribus quinquelobis, superioribus trilobis.* Hort. Cliff. 445. Herbaceous Bastard Ricinus, with trifid, or quinquefid sawed leaves.

4. *CROTON tetraphyllum, foliis lanceolatis, acuminatis, subtus cæsiis, caule herbaceo ramoso.* Dwarf Bastard Ricinus, with oblong pointed leaves, gray on their under side, and an herbaceous stalk.

5. *CROTON foliis lanceolatis glabris, caule fruticoso, floribus alaribus & terminalibus.* Shrubby Bastard Ricinus, with a Laurel leaf, and a very large green empalement to the flower.

6. *CROTON foliis cordatis, acuminatis, subtus tomentosis, floribus alaribus sessilibus, caule fruticoso.* Bastard Ricinus, with hairy leaves like those of Poplar.

7. *CROTON foliis lineari-lanceolatis, glabris, subtus argenteis, caule fruticoso, floribus spicatis terminalibus.* Bastard shrubby Ricinus, with narrow leaves, which are whitish on their under side, commonly called wild, or Spanish Rosemary, in Jamaica.

8. *CROTON foliis oblongo-cordatis tomentosis, caule fruticoso ramoso, floribus spicatis terminalibus.* Shrubby American Bastard Ricinus, with a Marshmallow leaf.

9. *CROTON foliis ovatis tomentosis, integris, serratis.* Hort. Cliff. 444. Dwarf Ricinus, with roundish sawed leaves, silvery on their under side, and flowers and fruit growing in clusters.

The first sort grows naturally in the south of France; this is an annual plant, which rises with an herbaceous branching stalk, about nine inches high, garnished with irregular, or rhomboidal figured leaves, which are near two inches long, and one inch and a quarter broad, standing upon slender foot-stalks. The flowers are produced in short spikes from the side of the stalks, the upper part of the spike is composed of male flowers; having many stamina, which coalesce at the bottom; the lower hath female flowers, which have each a roundish three-cornered germen, which afterward becomes a roundish capsule with three lobes, having three cells, each including one roundish seed.

The seeds of this plant should be sown in the autumn, on a border of light earth, in a warm situation, where they are designed to remain, and when the plants come up, they should be thinned where they are too close, leaving them six inches asunder, after this they will require no other care but to keep them clean from weeds. If the summer proves favourable, the plants will flower in July, and in very warm autumns they sometimes perfect their seeds in England.

The second sort was discovered by the late Dr. Houstoun, at La Vera Cruz; this is also an annual plant, which grows naturally in low marshy grounds, where it hath a very different appearance from what it puts on when sown upon dry land; those of the watery places have broad flat stalks, and leaves three inches long, which are scarce a quarter of an inch broad; they are rough, and but little indented on their edges, but those plants upon dry ground have oval leaves three inches long, and upwards of two inches broad, which are sawed on their edges. The flowers are produced at the wings of the leaves, in short loose spikes, having four or five herbaceous male flowers at the top of each, and three or four female flowers at bottom, which are succeeded by roundish capsules with three lobes, covered with a prickly husk, with three cells, each inclosing a single seed.

The third sort was discovered by the same gentleman, at the same place as the former; this is an annual plant, which rises with a taper herbaceous stalk, a foot and an half high, dividing into several branches, garnished with smooth leaves, standing upon very long foot-stalks, which are for the most part placed opposite; the lower leaves are divided deeply into five oblong lobes, and the upper into three, which are slightly sawed on their edges, and end in acute points. The flowers are produced in loose spikes at the end of the branches, those on the upper part being male, and the lower female, they are of a whitish herbaceous colour; the female flowers are succeeded by oblong capsules, having three lobes, which open in three parts, having three cells, each containing one oblong seed.

The fourth sort grows naturally at the Havannah. This is an annual plant, which rarely grows more than nine inches high, dividing into two or three branches; the lower parts of the branches are garnished with four leaves placed in form of a cross, two of which are three inches long, and one inch broad near their base, ending in acute points; these stand opposite, and the other two leaves between these are about two inches long, and a quarter of an inch broad; they are of a light green on their upper side, and of a gray or Ash-colour on their under. The flowers are produced in long loose spikes at the top of the stalks; the upper part of these spikes have male, and the lower female flowers, of an herbaceous colour; the female flowers are succeeded by round capsules with three cells, each containing one roundish seed.

The fifth sort grows naturally in Jamaica. It rises with a shrubby stalk to the height of seven or eight feet, covered with an Ash-coloured bark, dividing into many slender branches upward, which are naked below, but toward their upper part are garnished with smooth spear-shaped leaves, about two inches and an half long, and three quarters of an inch broad, standing on pretty long foot-stalks; the flowers are produced in short spikes at the end of the branches, in the same manner as the former; they are of an herbaceous colour, and inclosed in large green empalements.

The sixth sort grows in Jamaica. This rises with a shrubby stalk seven or eight feet high, sending out many irregular branches, covered with an Ash-coloured bark, garnished with heart-shaped leaves, near four inches long, and two inches broad, ending in acute points; they are of a light green on their upper side, but woolly on their under, standing on slender foot-stalks, sometimes single, and at others, two or three arise from the same joint. The flowers are produced in short spikes from the side of the branches, they are of a whitish green colour, and the female flowers are succeeded by capsules, having three cells, each including a single seed.

The seventh sort grows naturally in Jamaica. This rises with a shrubby stalk about six or seven feet high, sending out many side branches, which are covered with a smooth bark, of a pale yellow colour, garnished closely with narrow stiff leaves, near three inches long, and about one eighth of an inch broad, of a light green on their upper side, but the under side is the same colour as the bark. Between the branches arise a long loose spike of whitish green flowers. The whole plant hath an aromattick odour when rubbed. The upper part of the spike hath male flowers, the lower female; the seeds grow in roundish capsules having three cells, each including a single seed.

The eighth sort grows naturally in Jamaica. This rises with a shrubby stalk six or seven feet high, dividing into several branches, whose bark is covered with a yellowish down, and are garnished with long heart-shaped leaves, ending in acute points, standing on long foot-stalks, covered on both sides with a woolly down of the same colour as the branches. The flowers are produced on long close spikes at the end of the branches; the male flowers, which

are situated on the upper part of the spikes, have white flowers of one leaf, divided into five parts almost to the bottom. The female flowers, on the lower part of the spikes, have large woolly empalements, and are succeeded by round capsules with three cells, each including a single seed.

The ninth sort grows naturally at *Campeachy*. This is an annual plant, which rises with an herbaceous stalk two feet and an half high, dividing into several small branches, garnished with oval woolly leaves, near three inches long, and two and an half broad in the middle. The flowers are produced at the extremity of the branches, in short close spikes or clusters, sitting close between the leaves; they are small, of a whitish green colour; the female flowers are succeeded by small round capsules, inclosed by the woolly empalement; they have three cells, but seldom more than one of them contains seeds, which must be gathered as soon as they are ripe, otherwise they will scatter.

All these plants, except the first, are natives of warm countries, so will not thrive in *England*, unless they are tenderly treated. They are propagated by seeds; those which are annual perfect their seeds in *England*, but the shrubby sorts very rarely arrive to that perfection. The seeds must be sown on a hot-bed early in the spring, and when the plants are fit to remove, they should be each transplanted into a small pot, and plunged into a moderate hot-bed of tanners bark, where they should be shaded from the sun till they have taken fresh root; then they must have air admitted to them daily, in proportion to the warmth of the season. After the plants are grown too tall to remain in the frames, they should be removed, either into the stove, or a glass case, where there is a hot-bed of tanners bark, into which the pots should be plunged, and there the annual sorts will flower and perfect their seeds; but the shrubby kinds must be removed into the bark stove in the autumn, and during the winter season they should have but little water.

As the perennial sorts retain their leaves all the year, so they make a pretty variety in winter, when they are intermixed with other plants, whose leaves are of different forms and colours from these.

CROWN IMPERIAL. See *Ptellium*.

CRUCIANELLA. *Lin. Gen. Plant.* 118. Petty Madder.

The Characters are,

The flower hath one petal, with a slender cylindrical tube, longer than the empalement, cut into four parts at the brim. It hath four stamina situated in the mouth of the tube. It hath a compressed germen, situated at the bottom of the tube, which afterward becomes two twin capsules, each containing one oblong seed.

The Species are,

1. CRUCIANELLA *erecha*, foliis senis linearibus. *Hort. Ups.* 27. Petty Madder with a narrower leaf.

2. CRUCIANELLA *procumbens*, foliis quaternis lanceolatis, floribus spicatis. *Hort. Upsal.* Broad-leaved Petty Madder.

3. CRUCIANELLA *procumbens*, foliis quaternis, floribus subverticillatis. *Lin. Sp. Pl.* 109. Maritime Petty Madder.

The first sort grows naturally in the south of *France* and *Italy*; it is an annual plant, which rises with several upright stalks a foot high, which have six or seven very narrow linear leaves, placed in whorls at each joint. The flowers grow in close spikes at the top and from the side of the branches; these are small, white, and not longer than the empalement, so make no great appearance.

The second sort grows in the islands of the *Archipelago*, and also about *Montpelier*; this is also an annual plant, sending out several branching stalks from the root, which lie prostrate, and are garnished with four spear-shaped leaves at each joint. The flowers are produced in long spikes at the extremity of the branches; they are very small, so make no appearance.

The third sort is like the second in the appearance of its leaves and stalks, but the flowers grow on the side of the stalks, almost in whorls, and make little appearance. This grows naturally on the borders of the sea, in the south of *France* and *Italy*.

These three sorts are preserved in some gardens for the sake of variety: if the seeds are sown on a bed of light earth in the spring, where they are designed to remain, they will require no other culture, but to thin them where they are too close, and keep them clean from weeds; or if the seeds are permitted to scatter, the plants will come up in the spring, and require no other treatment; they are all annual plants.

CRUCIATA. See *Valantia*.

CRUPINA BULGARUM. See *Serratula*.

CUCUBALUS. *Lin. Gen. Plant.* 502. Berry-bearing Chickweed.

The Characters are,

The flower hath five petals, with tails as long as the empalement, but spread open at the top, and ten stamina, five of which are alternately inserted in the tail of the petals. In the center is situated the oblong germen, supporting three styles. The empalement afterward becomes a pointed close capsule with three cells, opening at top in five parts, and filled with many roundish seeds.

The Species are,

1. CUCUBALUS *calycibus campanulatis, petalis distantibus, fructu colorato, ramis divaricatis.* *Lin. Sp. Pl.* 414. Climbing Berry-bearing Chickweed.

2. CUCUBALUS *caulibus erectis glabris, calycibus subglobosis, staminibus corollâ longioribus.* Wild Lychnis, or white Behen of the shops, commonly called Spattling Poppy.

3. CUCUBALUS *calycibus subglobosis, caule ramoso patulo, foliis linearibus acutis.* Wild Lychnis or Spattling Poppy, with narrower pointed leaves.

4. CUCUBALUS *calycibus subglobosis glabris reticulato-venosis, capsulis trilocularibus corollis subnudis.* *Flor. Suec.* 360. Swedish Lychnis with a leaf and appearance of white Behen, having a large empalement, called Gumsepungar.

5. CUCUBALUS *caulibus procumbentibus, calycibus amplissimis nervosis, foliis lanceolatis.* English Sea Lychnis.

6. CUCUBALUS *caulibus procumbentibus, calycibus amplissimis reticulato-venosis, floribus pentagynis.* English Sea Lychnis with larger leaves

7. CUCUBALUS *foliis obovatis carnosiss.* *Prod. Leyd.* 448. Rocky maritime Lychnis with an Orpine leaf.

8. CUCUBALUS *floribus lateralibus decumbentibus, caule indiviso, foliis basi reflexis.* *Lin. Sp. Pl.* 414. Greater perennial Night-flowering Lychnis of *Dover*.

9. CUCUBALUS *foliis quaternis.* *Hort. Upsal.* 110. Lychnis with smooth Gentian leaves, four at each joint embracing the stalk, and a large fringed flower.

10. CUCUBALUS *calycibus striatis acutis petalis bipartitis, caule paniculato, foliis linearibus.* Narrow-leaved, sweet-scented, Night-flowering Lychnis.

11. CUCUBALUS *floribus dioicis, petalis setaceis indivisis.* *Hort. Cliff.* 272. Viscous Lychnis with a mossy flower.

12. CUCUBALUS *acaulis.* *Flor. Lapp.* 184. Alpine Dwarf Lychnis with a grassy flower, or Alpine Moss with a flower of Lychnis.

13. CUCUBALUS *petalis bipartitis, floribus paniculatis, staminibus longis, foliis lanceolatis acutis.* Tallest Lychnis with the appearance of Wild Campion.

The first sort grows naturally in *France*, *Germany*, and *Italy*, in shady places, and is seldom kept in gardens, unless for the sake of variety; it sends out many climbing stalks, which grow four or five feet high, where they meet with support, otherwise they trail on the ground; these stalks send out side branches by pairs, opposite, at each joint; the leaves are like those of Chickweed, and are placed

placed opposite. The flowers come out single at the end of the branches, which have large inflated empalements; they consist of five petals, which are white, and are placed at a distance from each other; these are succeeded by oval berries, which, when ripe, are black and full of juice, inclosing several flat shining seeds. This hath a perennial creeping root, whereby it is apt to multiply too fast in gardens. It delights in shade, and will thrive in almost any soil.

The second sort grows naturally in most parts of *England*, where it is generally called Spattling Poppy. This stands in the catalogue of medicinal plants, under the title of *Beben album*; the roots of it are sometimes used, and are accounted cordial, cephalick, and alexipharmick. It hath a perennial root, which strikes deep into the ground, so that they are not easily destroyed by the plough, therefore it is frequently seen growing in bunches among Corn. It is a rambling weed, so is never cultivated. There are two varieties of this, one with smooth, the other hath hairy leaves.

The third sort grows naturally on the *Alps*; this differs from the former, in having much longer and narrower leaves, and the stalks being more divided and spreading, nor do the roots creep under ground like those of the former. These differences are constant from seeds.

The fourth sort grows naturally in *Sweden*, and some other northern countries, where it passes for the common sort, but is certainly a distinct species, and I have been informed has been found growing naturally in *England*. The stalks of this are much larger, the leaves longer and more pointed; the empalement of the flower is curiously veined like net work, of a purplish colour, whereas that of the common sort is plain. These differences are lasting, when the plants are cultivated in a garden.

The fifth sort grows naturally on the borders of the sea, in many parts of *England*. This is by some supposed to be the same as the second sort, from which it greatly differs; the stalks of this are weak, and trail upon the ground; the leaves are shorter, those upon the stalks are much broader, and the empalement of the flowers are netted with purple veins like the *Swedish* sort before-mentioned.

The sixth sort was found growing naturally in some parts of *England*. This differs from the last, in having much longer trailing stalks, and larger leaves; the petals of the flowers are more than twice the size of those, and the flowers have five styles. These differences are lasting. All these sorts have perennial roots, and multiply too fast in gardens, therefore are never admitted but into botanick gardens for variety.

The seventh sort was discovered by *Tournefort* in the *Levant*. This puts out many oval, thick, succulent leaves near the ground, out of the middle of which arises an upright stalk about fifteen inches high, the lower part of which is garnished with leaves of the same form and consistence as Orpine, but smaller; they are placed opposite; the upper part of the stalk divides into two smaller, on which stand a few small herbaceous flowers at each joint. The plant is biennial, generally perishing when it has produced seeds; but unless it is sown upon dry rubbish, in a warm situation, the plants will not live through the winter in *England*; for when they are in good ground, they grow large, and are so replete with moisture, as to be affected by the first frost in the autumn; but where they have grown upon an old wall, I have known them escape, when all those were killed which grew in the ground.

The eighth sort grows naturally upon the cliffs near *Dover*. This hath a perennial root, from which arises single stalks about a foot high, garnished with long narrow leaves placed opposite; the flowers are produced from the side of the stalks, each foot-stalk sustaining three flowers; the foot-

stalks come out by pairs; the empalement of the flower is long and striped, the flowers are of a pale red.

The ninth sort grows naturally in *Virginia*, and several other parts of *North America*. This hath a perennial root, from which arise two or three slender upright stalks about three feet high, garnished with four leaves at each joint, placed in form of a cross; they are smooth, of a deep green, about an inch and an half long, and half an inch broad, terminating in acute points; the joints of the upper part of the stalk are garnished with white fringed flowers, standing single upon pretty long foot-stalks, which come out by pairs opposite.

The tenth sort grows naturally in *Spain* and *Italy*. This is a perennial plant, which rises with an upright branching stalk a foot and an half high, garnished with very narrow leaves placed opposite; the upper part of the stalk is very branching; the flowers stand upon long naked foot-stalks, each supporting three or four flowers, which have long tubes, with striped empalements; the petals are large, and deeply divided at the top; they are of a pale bluish colour. The flowers are closed all day, but when the sun leaves them they expand, and then they have a very agreeable scent. This sort may be propagated by seeds, which should be sown in the spring, upon a bed of light earth; and when the plants are fit to remove, they should be planted in a nursery bed, at about four inches distance, where they may remain till autumn, when they may be planted in the borders of the flower garden, where they are designed to remain. The following summer these will produce their flowers, and ripen their seeds in the autumn; but the roots will continue several years, provided they are not planted in rich ground, where they are very subject to rot in winter.

The eleventh sort grows naturally in *Austria*, *Silesia*, and *Italy*. This sort is male and female in different plants; it hath a thick, fleshy, perennial root, which strikes deep into the ground, sending out many oblong leaves, narrow at their base; from between these arise the stalks, which in the male plants often grow four feet high, but those of the female plants are seldom above three; the stalks are garnished with narrow leaves placed opposite; at the joints there exudes a viscous clammy juice, which sticks to the fingers when handled; and the small insects which settle upon those parts of the stalks, are thereby fastened so as not to get loose again. The flowers of the male plants, are produced in loose spikes from the joints of the stalk in clusters; these are small, of a greenish colour, and have each ten stamina. The female plants have three or four flowers growing upon each foot-stalk, which arise from the side of the stalk. These are succeeded by oval seed vessels, containing many small seeds. This is propagated by seeds, which should be sown where the plants are designed to remain; for as they send out long tap roots, so they do not bear transplanting, unless it is performed while the plants are young.

The twelfth sort grows naturally on the *Alps*, and also upon some hills in the north of *England* and *Wales*. This is a very low plant, with small leaves, which spread on the ground, and have the appearance of Moss; the flowers are small, erect, and rarely rise more than half an inch high; they are of a dirty white colour, and appear in *May*. This is a perennial plant, which will not thrive but in a moist soil and a shady situation.

The thirteenth sort grows naturally in *Italy* and *Sicily*. This is a perennial plant, with large thick roots, sending out many long spear-shaped leaves; between these arise round viscous stalks, which grow four or five feet high, garnished at each joint by two long narrow leaves ending in acute points. The stalks branch out into many divisions; the foot-stalks of the flowers arise from each joint by pairs; each

each of these sustain three or four flowers of an herbaceous colour, whose petals are divided into two parts. This is propagated by seeds in the same manner as the eleventh.

CUCUMIS. *Lin. Gen. Pl.* 969. Cucumber.

The Characters are,

It hath male and female flowers on the same plant. The flowers are bell-shaped, of one petal, which adheres to the empalement, and is cut into five oval rough segments. The male flowers have three short stamina, which are inserted in the empalement. The female flowers have no stamina, but have three small pointed filaments without summits. The germen is situated under the flower, which afterward becomes an oblong fleshy fruit with three cells, including many oval flat pointed seeds.

The Species are,

1. CUCUMIS *foliorum angulis rectis, pomis oblongis scabris.* *Hort. Cliff.* 451. The common Garden Cucumber.

2. CUCUMIS *foliorum angulis rectis, pomis longissimis scabris.* The long Turkey Cucumber.

3. CUCUMIS *foliis rotundato-angulatis, pomis acutangulis.* *Lin. Sp. Pl.* 1011. Round-leaved Egyptian Cucumber, called Chate.

The first sort is the Cucumber which is generally cultivated for the table, and is so well known as to need no description.

The second sort is the long Turkey Cucumber, which is also pretty well known in *England*. The stalks and leaves of this sort are much larger than those of the common sort. The fruit is generally twice the length, and hath a smooth rind; this is undoubtedly different from the common sort. There are green and white fruit of this, and also of the common sort, which differ but little except in their colour. The white is less watery than the green, so is generally better esteemed.

The third sort here enumerated, is rarely cultivated, but in botanick gardens for the sake of variety, the fruit being very indifferent, and the plants being tender, require a good heat to bring them to perfection in *England*; these plants ramble very far, so must have much room.

The common sort is cultivated in three different seasons: the first of which is on hot-beds under garden frames, for early fruit; the second is under bell or hand glasses, for the middle crop; and the third is in the common ground, for a late crop, or to pickle.

I shall begin with giving directions for raising Cucumbers early, which is what most gentlemen's gardeners have an emulation to exceed each other in; and some have been at the pains and expence to have ripe fruit in every month of the year, which is rather a curiosity than real advantage; but as there are many persons, who yet value themselves on their skill in raising early Cucumbers, so we may probably be censured as being deficient in what they call an essential part of gardening, should we omit the method practised for raising these fruit early in the year; therefore shall proceed to give such directions, which, if carefully attended to, will not fail of success.

Those persons who are very desirous to be early with their Cucumbers, generally sow their seeds before *Christmas*, but the generality of gardeners commonly put their seeds into the hot-bed about *Christmas*; but where persons have the conveniency of a stove for raising these plants, it is attended with less trouble than a common hot-bed, and is a much surer method, because the plants will have a much greater share of air than under frames; therefore when there is this convenience, the seeds may be sown in small pots, and plunged into the tan bed, in the warmest part of the stove. The seeds should be at least three or four years old, but if it is more, provided it will grow, it will be the better. When the plants are up, and begin to put out their rough leaf, there should be a sufficient number of small pots filled

with good earth, and plunged into the bark bed, that the earth may be warmed to receive the plants, which should be pricked into these pots, two plants in each; but when they have taken root and are safe, one of the worst should be drawn out, being careful not to disturb the roots of that which is left. In the management of these plants there must be great care taken, not to give them too much water, and it will be very proper to put the water into the stove some hours before it is used, that the cold may be taken off, but there must be caution used, not to make it too warm, for that will destroy the plants; they must also be guarded from the moisture which frequently drops from the glasses of the stove, which is very hurtful to these plants while young; then there should be a proper quantity of new dung prepared for making a hot-bed to receive them; this must be in proportion to the quantity of holes or plants intended: for a middling family six or nine lights of Cucumbers will be sufficient, and for a large family double the quantity. The dung should be new, and not too full of straw; it should be well mixed together, and thrown in a heap, mixing some sea coal ashes with it; after it hath lain in a heap a few days, and has fermented, it should be carefully turned over and mixed, laying it up again in a heap; and if there is a great share of straw in it, there may be a necessity for turning it over a third time after having lain a few days; this will rot the straw and mix it thoroughly with the dung, so there will be less danger of its burning when the bed is made, which should be done when the dung is in proper order. The place where the hot-bed is made should be well sheltered with Reed hedges, and the ground should be dry; then there should be a trench made in the ground, of a proper length and breadth, and a foot deep at least, into which the dung should be wheeled and carefully stirred up and mixed, so that no part of it should be left unseparated; for where there is not this care taken, the bed will settle unequally; there should also be great care taken, to beat the dung down close in every part of the bed alike; when the bed is made, the frames and glasses should be put upon it to keep out the rain, but there should be no earth laid upon the dung, till two or three days after, that the steam of the dung may have time to evaporate: if there should be any danger of the bed burning, it will be proper to lay some short old dung, or some neats dung, over the top of the hot dung about two inches thick, which will keep down the heat, and prevent the earth from being burnt. The usual quantity of dung allowed for making of the beds at this season, is one good cart load to each light: in about three days, the bed will be in a proper temperature of heat to receive the plants; at which time the dung should be covered over with dry earth about two inches thick, and in the middle of the bed it should be a foot thick. This should be laid upon the dung two or three days before the plants are removed into the bed, that the earth may be properly warmed; then the plants should be carefully shaken out of the pots, preserving all the earth to their roots, and placed on the top of the earth in the middle of the bed. Two of these plants will be sufficient for each light, and these should be placed at about seven or eight inches asunder, but not all their roots together, as is too often practised. When the plants are thus situated in the bed, the earth which was laid a foot thick in the middle of the bed, should be drawn up round the ball which remained to the roots of the plants, into which the roots will soon strike; there should always be a magazine of good earth laid under cover to keep it dry, for the earthing of these beds, for if it is taken up wet, it will chill the beds, and also occasion great damps in the bed, therefore it is quite necessary to have a sufficient quantity of earth prepared long before it is used. When the plants are thus settled, they must have proper air and

and water, according to the weather, being careful not to admit too much cold air, or give too much water; the glasses should also be well covered with mats every night, to keep up the warmth of the bed, and some fresh earth should be put into the bed at different times, which should be laid at some distance from the roots of the plants, till it is warmed, and then should be drawn up round the heap of earth in which the plants grow: this should be raised to the full height of the former ball, that the roots of the plants may more easily strike into it; by this method of supplying the earth, the whole surface of the beds will be covered a foot deep with earth, which will be of great service to the roots of the plants; for where the earth is very shallow, the leaves of the plants will always hang in the heat of the day, unless they are shaded; and the plants will require more water to keep them alive, than is proper to give them; therefore, it will be found much the better way to allow a proper depth of earth to the beds: by thus gradually applying the earth it will be fresh, and much better for the roots of the plants, than that which has been long upon the bed, and has been too much moistened by the steam arising from the dung.

If the heat of the bed should decline, there should be some hot dung laid round the side of the bed to renew the heat; for if that should fail at the time that the fruit appears, they will fall off and perish, therefore this must be carefully regarded; and when the plants have put out side branches (which the gardeners call runners) they should be properly placed, and pegged down with small forked sticks to prevent their rising up to the glasses, and also from crossing and entangling with each other; so that when they are properly directed at first, there will be no necessity of twisting and tumbling the plants afterward, which is always hurtful to them.

When the earth of the bed is laid the full thickness, it will be necessary to raise the frames, otherwise the glasses will be too close to the plants; but when this is done, there must be care taken to stop the earth very close round the sides of the frame, to prevent the cold air from entering under them. The watering of the plants and admitting fresh air to them must be diligently attended to, otherwise the plants will be soon destroyed, for a little neglect either of admitting air, or letting in too much, or by over watering, or starving the plants, will very soon destroy them past recovery.

When the fruit appears upon the plants, there will also appear many male flowers on different parts of the plant; these may at first sight be distinguished, for the female flowers have the young fruit situated under them, but the male have none, but have three stamina in their center, with their summits, which are loaded with a golden powder; this is designed to impregnate the female flowers; and when the plants are fully exposed to the open air, the soft breezes of wind convey this farina or male powder from the male to the female flowers; but in the frames, where the air is frequently too much excluded at this season, the fruit often drops off for want of it: and I have often observed that bees which have crept into the frames when the glasses have been raised to admit the air, have supplied the want of those gentle breezes of wind, by carrying the farina of the male flowers on their hind legs into the female flowers, where a sufficient quantity of it has been left to impregnate them. These insects have taught the gardeners a method to supply the want of free air, which is so necessary for the performance of this in the natural way; this is done by carefully gathering the male flowers, at the time when this farina is fully formed, and carrying them to the female flowers, turning them down over them, and with the nail of one finger gently striking the outside of the male, so as to cause the powder on the summits to scatter into the female flowers,

and this is found sufficient to impregnate them; so that by practising this method, the gardeners have now arrived at a much greater certainty than formerly to procure an early crop of Cucumbers and Melons; and by this method the florists have arrived to greater certainty of procuring new varieties of flowers from seeds, which is done by the mixing of the farina of different flowers into each other.

When the fruit of the Cucumbers are thus fairly set, if the bed is of a proper temperature of warmth, they will soon swell and become fit for use; so all that is necessary to be observed, is to water the plants properly, which should be done, by sprinkling the water all over the bed, for the roots of the plants will extend themselves to the side of the beds; therefore those who are inclined to continue these plants as long as possible in vigour, should add a sufficient thickness of dung and earth all round the sides of the beds, so as to enlarge them to near double their first width; this will supply nourishment to the roots of the plants, whereby they may be continued fruitful great part of the summer; whereas, when this is not practised, the roots of the plants, when they have reached the side of the beds, are dried by the wind and sun, so that the plants languish and decay long before their time.

Those gardeners, who are fond of producing early Cucumbers, generally leave two or three of their early fruit, which are situated upon the main stem of the plant near the root for seed, which, when fully ripe, they carefully save to a proper age for sowing, and by this method they find a great improvement is made of the seed; and this they always use for their early crops only, for the succeeding crops do not deserve so much care and attention.

I have here only mentioned the method of raising the young Cucumber plants in stoves, for as these conveniences are now pretty generally made in the curious kitchen gardens in most parts of *England*, so this method may be more universally practised; but in such gardens where there are no stoves, the seeds should be sown upon a well prepared hot-bed; and here it will be the best way to sow the seeds in small halfpenny pots, because these may be easily removed from one bed to another if the heat should decline, or, on the contrary, if the heat should be too great, the pots may be raised up, which will prevent the seed or the young plants from being injured thereby. When the plants are come up, as was before directed, there should be a fresh hot-bed prepared, with a sufficient number of halfpenny pots plunged therein ready to receive the plants, which must be planted into them in the same manner as before directed; and the after-management of the plants, must be nearly the same; but as the steam of the hot-bed frequently occasions great damps, so there must be great care to turn and wipe the glasses frequently, to prevent the condensed moisture falling on the plants, which is very destructive to them. There must also be great attention to the admitting fresh air at all proper times, as also to be careful in keeping the bed to a proper temperature of heat; for as there is a want of fire to warm the air, so that must be supplied by the heat of dung; afterward these plants must be ridged out, in the same manner as before directed.

About the middle of *March*, or a little later, according to the carliness of the season, you must put in your seeds for the second crop, which may be sown either under a bell glass, or in the upper side of your early hot-bed; and when the plants are come up, they should be pricked upon another moderate hot-bed, which should be covered with bell or hand glasses, placed as close as possible to each other; the plants should be set about two inches distance from each other, observing to shade them until they have taken root. This is to be understood of such places where a great quantity of plants are required, which is constantly the case in

the kitchen gardens near *London*; but where it is only for the supply of a family, there may be plants enough raised on the upper side of the beds where the first crop is growing: you must raise the glasses on the opposite side from the wind, to give air to the plants every day when the weather is warm, which will greatly strengthen them; you must also water them as you shall find they require it, but this must be done sparingly while the plants are young.

About the middle of *April* the plants will be strong enough to ridge out, you must therefore be provided with a heap of new dung, in proportion to the quantity of holes you intend to plant, allowing one load to five or six holes. When your dung is fit for use, you must dig a trench about two feet four inches wide, and in length just as you please, or the place will allow; and if the soil be dry, it should be ten inches deep, but if wet, very little in the ground, levelling the earth in the bottom; then put in your dung, observing to stir and mix every part of it as was directed for the first hot-beds, laying it close and even.

When this is done, you must cover the ridge over with earth about four inches thick, laying the earth the same thickness round the sides, raising hills in the middle at three feet and an half asunder; then you must set the glasses upon the hills, leaving them close down about twenty-four hours, in which time the earth in the hills will be warmed sufficiently to receive the plants; then with your hand stir up the earth, making it a little hollow in the middle in form of a basin; into each of which you should plant four plants, observing to water and shade them until they have taken root; after which time you must be careful to give them air by raising the glasses on the opposite side to the wind, in proportion to the heat of the weather, but you must only raise the glasses in the middle of the day, until the plants fill the glasses, at which time you should raise the glasses with a forked stick on the south side in height proportionable to the growth of the plants, that they may not be scorched by the sun; this also will harden and prepare the plants to endure the open air, but you should not expose them too soon thereto, for it often happens, that there are morning frosts in *May*, which are many times destructive to these plants when exposed thereto; it is therefore the surest method to preserve them under the glasses, as long as they can be kept without prejudice to the plants; and if the glasses are raised with three bricks, they may be kept a great while without danger.

Towards the latter end of *May*, when the weather appears settled and warm, you should turn the plants down gently out of the glasses, but do not perform this in a very dry hot sunny day, but rather when there is a cloudy sky, and an appearance of rain; in doing of this raise the glasses either upon three bricks, or three forked sticks, whereby they may stand secure at about four or five inches high from the ground, that the plants may lie under them without bruising; nor should you take the glasses quite away till the latter end of *June*, or the beginning of *July*, for these will preserve the moisture much longer to their roots than if they were quite exposed to the open air; about three weeks after you have turned the plants out of the glasses, they will have made a considerable progress, especially if the weather has been favourable, at which time you should dig up the spaces of ground between the ridges, laying it up to the sides of the bed, that the roots of the plant may strike into it; then lay out the runners of the vines in exact order, and be careful in this work not to disturb the vines too much, nor to bruise or break the leaves. After this there will be no farther care needful, but only to keep them clear from weeds, and to water them as often as they shall require, which they will soon shew, by the hanging of their greater leaves. The ridges thus managed, will continue to produce

large quantities of fruit from *June* until the latter end of *August*.

From these ridges people commonly preserve their Cucumbers for seed, by making choice of one or two of the fairest fruit upon each hole, situated near the root of the plant; but those persons who value themselves upon producing Cucumbers very early, commonly leave three or four Cucumbers of the first produce of their earliest crop, when the fruit is fair; and the seeds of these early fruit, are generally preferred to any other for the first crop. These should remain upon the vines until the seeds are perfectly ripe; and when you gather them from the vines, it will be proper to set the fruit in a row upright against a hedge or wall, where they may remain until the outer cover begins to decay; at which time you should cut them open, and scrape out the seeds, together with the pulp, into a tub, which should be afterwards covered with a board, to prevent filth from getting amongst the pulp. In this tub it should be suffered to remain eight or ten days, observing to stir it well with a stick to the bottom every day, in order to rot the pulp, that it may be easily separated from the seeds; then pour some water into the tub, stirring it well about, which will raise the scum to the top, but the seeds will settle to the bottom; so that by two or three times pouring in water, and afterwards straining it off from the seeds, they will be perfectly cleared from the pulp; then they should be spread upon a mat, which should be exposed to the open air three or four days, until they are perfectly dry, when they may be put up in bags, and hung up in a dry place, where vermin cannot come to them, where they will keep good for several years, but are generally preferred when three or four years old, as being apt to produce less vigorous, but more fruitful plants.

I shall, in the next place, proceed to give directions for managing Cucumbers for the last crop, or what are generally called picklers.

The season for sowing these is in the beginning of *June*, when the weather is settled. The ground where these are commonly sown by the *London* gardeners, is between the wide rows of Cauliflowers, which are four feet and an half asunder. In these rows they dig up square holes at about three feet and an half distance from each other, breaking the earth well with a spade, and afterwards smoothing and hollowing it in the form of a basin with their hands; then they put eight or nine seeds into the middle of each hole, covering them over with earth about half an inch thick; if the weather is very dry, they water the holes gently in a day or two after the seeds are sown, in order to facilitate their vegetation.

In five or six days, if the weather is good, the plants will begin to thrust their heads above ground; at which time they are careful to keep off the sparrows, which are very fond of the young tender heads of these plants; and, if they are not prevented, will pinch them off, and thereby destroy the whole crop: but as it is not above a week that the plants are in this danger, it will be no great trouble to look after them during that time; for when the plants have expanded their seed leaves, the sparrows will not meddle with them.

There must also be care taken to water them gently, as the season may require; and when the third or rough leaf of the plants begin to appear, all the weakest plants should be drawn out, leaving only four of the most promising and best situated in each hole, stirring the earth round about them with a small hoe to destroy the weeds, and raise the earth about the shanks of the plants, putting a little earth between them, pressing it gently down with the hand, that the plants may be thereby separated from each other to a greater distance; then they give them a little water (if the weather

weather is dry) to settle the earth about them, which must be afterwards repeated as often as it shall be necessary, still being careful to keep the ground clear from weeds.

When the Cauliflowers are quite drawn off the ground from between the Cucumbers, they hoe and clean the ground, drawing the earth up round each hole of Cucumbers in form of a basin, the better to contain the water when it is given them; then lay out the plants in exact order as they are to run, so that they may not interfere with each other; then lay a little earth between the plants left, pressing it down gently with the hand, the better to spread them each way, giving them a little water to settle the earth about them, repeating it as often as the season shall require. The plants, thus managed, will begin to produce fruit toward the latter end of *July*, or the beginning of *August*, when they either gather them young for pickling, or suffer them to grow for large fruit.

The quantity of holes necessary for a family, is about fifty or sixty; for if there are fewer, they will not produce enough at one gathering to make it worth the trouble and expence of pickling, without keeping them too long in the house, for there are rarely more than two hundred fit to gather at each time from fifty holes; but this may be done twice a week during the whole season, which commonly lasts five weeks; so that from fifty holes may be reasonably expected about two thousand in the season, which, if they are taken small, will not be too many for a private family. And if so many are not wanted, they may be left to grow to a proper size for eating.

CUCUMIS AGRESTIS. See Momordica.

CUCURBITA. *Lin. Gen. Plant.* 968. The Gourd.

The Characters are,

It hath male and female flowers in the same plant. The male flowers have three stamina, which are connected at their extremity, but are distinct at their base. The female flowers have a large germen, situated under them, supporting a conical trifid style, which afterward becomes a large fleshy fruit, having three soft membranaceous cells which are distinct, inclosing two rows of seeds which are bordered.

The Species are,

1. CUCURBITA foliis subangulatis tomentosis, basi subtus biglandulosis, pomis lignosis. *Lin. Sp. Plant.* 1010. Long Gourd, with a soft leaf and white flower, commonly called the Long Gourd.

2. CUCURBITA foliis lobatis, pomis lævibus. *Lin. Sp. Pl.* 1010. Greater round Gourd, with a yellow flower and rough leaf, commonly called Pompion, or Pumpkin.

3. CUCURBITA foliis lobatis, pomis nodoso-verrucosis. *Lin. Sp. Pl.* 1010. Warty Gourd.

4. CUCURBITA foliis lobatis, caule erecto, pomis depresso-nodosis. *Lin. Sp. Plant.* 1010. Melopepo having a shield-shaped fruit, commonly called Squash.

The first sort is sometimes propagated in the *English* gardens by way of curiosity, for the fruit is very rarely eaten here; though, if they are gathered when they are young, while the skins are tender, and boiled, they have an agreeable flavour. In the eastern countries these fruit are very commonly cultivated and sold in the markets for the table, and are a great part of the food of the common people, from *June* to *October*.

This sort doth not vary like most of the others, but always produces the same shaped fruit; the plants of this extend to a great length, if the season proves warm and favourable, and will then produce ripe fruit; but in cold summers, the fruit seldom grows to half its usual size. I have measured some of these fruit when growing, which were six feet long, and a foot and an half round; the plants were near twenty feet in length: the stalks of this, and also the leaves, are covered with fine soft hairy down;

the flowers are large, white, and stand upon long foot stalks, being reflexed at their brim; the fruit is generally incurved and crooked, and when ripe, is of a pale yellow colour. The rind of this fruit becomes hard, so that if the seeds and pulp are taken out, and the shell dried, it will contain water; and in those countries where they are much cultivated, are used for many purposes.

The second sort, which is commonly known by the title of Pumpkin, is frequently cultivated by the country people in *England*, who plant them upon their dunghills, where the plants run over them, and spread to a great distance; and when the seasons are favourable, they will produce plenty of large fruit; these they usually suffer to grow to maturity, then they cut out a hole on one side, and take the seeds out of the pulp as clean as possible, after which they fill the shell with Apples sliced, which they mix with the pulp of the fruit, and some add a little sugar and spice to it; then bake it in an oven, and eat it in the same manner as baked Apples; but this is a strong food, and only fit for those who labour hard, and can easily digest it.

Both these may be propagated by sowing their seeds in *April*, on a hot-bed; and the plants transplanted on another moderate bed, where they should be brought up hardily, and have a great deal of air to strengthen them; and when they have got four or five leaves, they should be transplanted into holes made upon an old dunghill, or some such place, allowing them a great deal of room to run, for some of the sorts will spread to a great distance.

There are several varieties of this fruit, which differ in their form and size; but as these are annually varying from seeds, so I have omitted the mentioning them, for they seldom continue to produce the same kinds of fruit three years together.

The third sort is very common in most parts of *America*, where it is cultivated as a culinary fruit; of this sort there are also several varieties, which differ in their form and size; some of these are flat, others round; some are shaped like a bottle, and others are oblong, their outer cover or rind being white, when ripe, and covered with large protuberances or warts. The fruit are commonly gathered when they are half grown, and boiled by the inhabitants of *America* to eat as a sauce with their meat.

The fourth sort is also very common in *North America*, where it is cultivated for the same purposes as the third. This very often grows with a strong bushy erect stalk, without putting out runners from the side, as the other sorts, but frequently varies; for after it has been cultivated a few years in the same garden, the plants will become trailing like the others, and extend their branches to a great distance.

CUIETE. See Crescentia.

CUMINOIDES. See Lagoecia.

CUMINUM. *Lin. Gen. Pl.* 313. Cumin.

The Characters are,

It hath an umbelliferous flower; the involucre is longer than the umbel. The great umbel is uniform; the flowers have five unequal petals, whose borders are inflexed, and five single stamina, with a large germen situated under the flower, supporting two small styles, which afterward becomes an oval striated fruit, composed of two oval seeds, which are convex and furrowed on one side, and plain on the other.

We have but one Species of this genus,

CUMINUM. *Lin. Mat. Med.* 139. Cumin.

This plant is annual, perishing soon after the seeds are ripe; it seldom rises more than nine or ten inches high, in the warm countries where it is cultivated; but I have never seen it grow more than four in *England*, where I have sometimes had the plants come so far as to flower very well, but never to produce seeds. The leaves of this plant are divided

vided into long narrow segments, like those of Fennel, but much smaller; they are of a deep green, and generally turn backward at their extremity; the flowers grow in small umbels at the top of the stalks; they are composed of five unequal petals, which are of a pale bluish colour, and are succeeded by long channelled aromack seeds.

This plant is propagated for sale in the island of *Malta*, where it is called *Cumino aigro*, i. e. hot Cumin. But Anise, which they also propagate in no less quantity, they call *Cumino dulce*, i. e. sweet Cumin. So that many of the old botanists were mistaken, when they made two species of Cumin, viz. *acer* and *dulce*.

If the seeds of this plant are sown in small pots, and plunged into a very moderate hot-bed to bring up the plants, and these after having been gradually inured to the open air, turned out of the pots, and planted in a warm border of good earth, preserving the balls of earth to their roots, the plants will flower pretty well, and by thus bringing of the plants forward in the spring, they may perfect their seeds in warm seasons.

CUNILA. See Sideritis.

CUNONIA. *Buttn. Cun. tab. 1.*

The Characters are,

The flowers grow alternate in an imbricated spike, each having a spathe or sheath; they have one ringent petal, with a short slender tube, which is dilated at the chaps and compressed on the sides; the upper lip is arched, stretched out beyond the alæ or wings. It hath three slender stamina, which are situated in the upper lip, and a slender style, which is shorter than the stamina, crowned by three cylindrical stigmas. The germen, which is situated below the flower, becomes an oblong capsule with three cells, filled with compressed seeds.

We have but one Species of this genus at present in the English gardens, which is,

CUNONIA floribus sessilibus, spatibus maximis. *Buttn. Cun. 211. tab. 1.* Cunonia with flowers sitting close to the stalk, and very large spathe or sheaths.

This plant grows naturally at the *Cape of Good Hope*. It hath a compressed bulbous root, somewhat like that of Corn Flag, covered with a brown skin: from this arise several narrow sword-shaped leaves, about nine inches long, and a quarter of an inch broad, terminating in acute points; these have one longitudinal midrib which is prominent, and two longitudinal veins running parallel on each side; they are of a sea-green colour. In spring the stalk rises from between the leaves, which is round, strong, and jointed; at each joint is situated a single leaf, which almost embraces the stalk, which rises near a foot and an half high, and is generally curved two opposite ways; the upper part of the stalk is terminated by a loose spike of flowers, coming out of large spathe or sheaths, composed of two oblong concave leaves, terminating in acute points: these are at their first appearance placed *imbricatim* over each other, but as the stalk increases in length, so these are separated; from between these two leaves comes out the flower, which having a slender Saffron-coloured tube near half an inch long, which is then enlarged where the petal is divided, and the upper segment is extended two inches in length, being arched over the stamina and style. This is narrow as far as to the extent of the wings, but above them is enlarged and spread open, half an inch in length, and is concave, covering the summits and stigmas, which are extended to that length; the two wings are also narrow at their base, but are enlarged upward in the same manner, ending in concave obtuse points, which are compressed together, and cover the stamina and style. This flower is of a beautiful soft scarlet colour, so makes a fine appearance about the latter end of *April*, or beginning of *May*, which is the season of its flowering. After the flowers decay, the germen becomes an

oval smooth capsule opening in three cells, which are filled with flat bordered seeds.

This plant is easily propagated by offsets, which it sends out in great plenty, or by sowing of the seeds, which should be sown in pots about the middle of *August*, and placed in a situation where they may enjoy the morning sun; in *September* the pots may be removed to a warmer situation, and in *October* they must be placed under a frame, where they may be protected from frost and hard rains, but in mild weather enjoy the free air. The plants will appear in *October*, and continue growing all the winter, and in *June* their leaves will decay; then they may be taken up, and planted in halfpenny pots. As this plant is a native at the *Cape of Good Hope*, so it is too tender to live through the winter in *England* without shelter from frost; the best way to have this and other bulbous-rooted flowers from the same country in perfection, is to build a frame of a proper depth, to allow room for the stalks of their flowers to rise to their usual height under the glasses, and make a bed of good fresh earth two feet deep, into which the roots should be planted; and here they may be protected from frost, and in mild weather fully exposed to the open air, so will thrive and flower much better than when they are placed in a green-house in winter. But where such a frame is wanting, the roots should be planted in pots, and sheltered in winter under a common hot-bed frame, that they may always have free air in mild weather. These seedling plants must be sheltered in the same manner as the old roots in winter, and the third year they will flower.

CUPRESSUS. *Lin. Gen. Pl. 958.* The Cypress tree.

The Characters are,

It hath male and female flowers on the same plant; the male flowers are formed into oval katkins, in which the flowers are placed thinly; they have no petals nor stamina, but have four summits which adhere to the bottom of the scales. The female flowers are formed in a roundish cone, each containing eight or ten flowers; the germen is scarce visible, but afterward becomes a globular cone, opening in angular target-shaped scales, under which are situated angular seeds.

The Species are,

1. CUPRESSUS foliis imbricatis, ramis erectioribus. Female or common upright Cypress.

2. CUPRESSUS foliis imbricatis acutis, ramis horizontalibus. Male spreading Cypress.

3. CUPRESSUS foliis imbricatis, apicibus aculeatis, ramis dependentibus. Portugal spreading Cypress with a smaller fruit.

4. CUPRESSUS foliis distichis patentibus. *Hort. Cliff. 409.* Virginia Cypress which sheds its leaves, commonly called Deciduous Cypress.

5. CUPRESSUS foliis imbricatis, frondibus ancipitibus. *Lin. Sp. Plant. 1003.* Dwarf Maryland Cypress with a small blue fruit.

6. CUPRESSUS foliis linearibus simplicibus cruciatim positis. Cypress with narrow, single leaves, placed crossways.

The first of these trees is very common in most of the old gardens in *England*, but at present is not so much in request as formerly, though it is not without its advantages; nor should it be entirely rejected, although some persons are of that opinion; for it is of great beauty to wildernesses, or clumps of evergreens, and where they are properly disposed they have much beauty; for they are one of the principal ornaments of the *Italian villas*.

The second sort is the largest growing tree, and is the most common timber in the *Levant*: this, if planted upon a warm sandy gravelly soil, will prosper wonderfully; and though the plants of this sort are not so finely shaped as the first, yet they greatly recompense for that defect, by its vigorous growth, and strength in resisting all weathers. Besides,

sides, the wood of this tree is very valuable, when grown to a size fit for planks; which I am convinced it will do, in as short space as Oaks, if properly cultivated for that purpose; since there are many places in *England* where the soil is of a sandy or gravelly nature, so seldom produces any trees worth cultivating. Now, in such places these would thrive wonderfully, and greatly add to the pleasure of the owner, while growing, and afterward render as much profit to his successors, as perhaps the best plantation of Oaks; especially should the timber prove as good here, as in the islands of the *Archipelago*, which I see no reason to doubt of; for we find it was so gainful a commodity in the island of *Candia*, that the plantations were called *Dos Filiae*; the felling of one of them being reckoned a daughter's portion.

The timber of this tree is said to resist the worm, moth, and all putrefaction, and also to last many hundred years. The coffins were made of this material, in which *Thucydides* tells us the *Athenians* used to bury their heroes.

The fourth sort is a native of *America*, where it grows in watery places, rising to a prodigious height, and is of a wonderful bulk: I have been informed, that there are trees of this kind in *South Carolina* which are upwards of seventy feet high, and several fathoms in circumference, which trees grow constantly in the water; therefore they may probably be of singular advantage to plant in such swampy or wet soils, where few other trees will grow, especially of the resinous kind.

These trees are all propagated from seeds, which should be sown early in the spring in pots or boxes, which, if placed in a very moderate hot-bed will bring up the plants soon; or if the seeds are sown upon a moderate hot-bed, and the beds covered with mats, they will come up much sooner, and with greater certainty, than when they are sown in the cold ground.

In these pots, boxes, or this bed, the young plants may remain one year, by which time they will have strength enough to be transplanted, either into boxes, or a warm border; for while the plants are young, they are tender, so should be covered in severe frost with mats to prevent their being injured thereby. The best season for removing them is in the beginning of *April*, when the drying easterly winds of *March* are over; and, if possible, choose a cloudy day, when it is inclinable to rain; and in taking them out of the seed bed or pots preserve the roots as entire as possible, and, if you can, some earth to each plant; having prepared the border by carefully digging and cleansing it from all noxious weeds, you must lay it level. Then draw the lines where the plants are to be planted, at one foot asunder, row from row, and the cross lines at six inches distance in the rows; the plants must be set exactly in the squares, closing the earth to their roots, and water them well to settle the earth to them; which should be repeated in dry weather twice a week, until the plants have taken fresh root.

These plants may remain in the borders two years, according to the progress they make, but if you intend to let them remain longer, you should take up every other tree in the rows, and transplant them out; for otherwise their roots will be matted together, so that it will render it difficult to transplant them, and also endanger their future growth. These plants should by no means be let stand too long in the nursery, before they are transplanted out for good; because they rarely grow when their roots are much cut, for the roots of the *Cypress* are apt to extend out in length, so it is one of the most difficult trees to remove when grown large; therefore most curious persons choose to plant the young plants into small pots, when they first take them out of the border; and so train them up in pots two or three years,

until they are fit to plant out, where they are to stand for good; and, by this management, they are secure of all the plants; and these may be shaken out of the pots at any time of the year without danger, and planted with their whole ball of earth, which is likewise a great advantage. When they are planted out for good (if they are designed for timber,) they should be planted about ten or twelve feet distance every way. When they are planted, you must settle the earth close to their roots, as before, laying a little mulch upon the surface of the ground about their stems, to prevent the sun and wind from entering the earth to dry their fibres; and water them well, to settle the ground to their roots; which must also be repeated (if the weather be dry) until they have taken root; after which time, they will require little more care than to keep them clear from weeds.

The first, which is the most common sort in *England*, seldom produces good seeds in this country; it is therefore the best way to have the cones brought over entire from the south parts of *France* or *Italy*, where they ripen perfectly well, and take the seeds out just before you sow them, for they will keep much better in the cones than if they are taken out. The method to get the seeds out is to expose the cones to a gentle heat, which will cause them to open, and easily emit their seeds.

The second sort grows naturally in the *Levant*, for what has passed under this title in many places here, is only a variety of the common sort, whose branches grow much looser, and not so upright as the first; but the cones taken from these trees, and the seeds sown, have frequently produced plants of both varieties; but the spreading *Cypress* extends its branches much more horizontally, and the plants raised from the seeds do not vary, so that it is certainly a distinct species. This grows to be a large timber tree in the *Levant*, and in *Italy* there are some of a considerable size.

The *Virginian* kind may also be propagated in as great plenty; for the cones of this may be easily procured from *Carolina* or *Virginia*, in both which places they grow in great abundance; and the seeds will rise as easily as any of the other sorts, and the plants are equally as hardy. As this tree grows in places where the water commonly covers the surface of the ground three or four feet, so it may be a very great improvement to our boggy soils, were they planted with them. It may also be propagated by cuttings, which should be planted in a bed of moist earth, in the spring; before the trees begin to shoot.

The third sort is, at present, pretty rare in the *English* gardens, though of late years there have been many plants raised in the nurseries; but this sort is not quite so hardy as the common *Cypress*, for the plants are frequently killed or greatly injured in severe winters; and in the hard frost in 1740, there were few trees in *England* of this kind, which were not entirely killed. There are great plenty of these trees growing at a place called *Busaco*, near *Coimbra* in *Portugal*, where this tree is called the Cedar of *Busaco*; and there it grows to be a timber tree, so that from thence the seeds may be easily procured.

But its natural place of growth is at *Goa*, from whence it was first brought to *Portugal*, where it has succeeded, and been propagated; formerly there were some trees of this sort growing in the bishop of *London's* garden at *Fulham*, where it passed under the title of Cedar of *Goa*, by which it was sent from thence to the *Leyden* garden under that name.

The fifth sort is a native of *North America*, where it grows to a considerable height, and affords an useful timber to the inhabitants for many purposes. This sort is extremely worth cultivating in *England*; for as it grows in a much colder country, there is no danger of its thriving well

in the open air in *England*; and being an ever-green of regular growth, will add to the variety in wilderness quarters, or other plantations of ever-green trees.

The branches of this tree are garnished with flat ever-green leaves, resembling those of the *Arbor Vitæ*; and the cones are no larger than Juniper berries, from which they are not easily distinguished at a little distance; but upon closely viewing, they are easily distinguished to be perfect cones, having many cells, like those of the common Cypress. If these trees are planted in a moist strong soil, they make very great progress; and may, in such situations, become profitable for timber; but however this tree may succeed for timber, yet it will be a great ornament to large plantations of ever-green trees, especially in such places where there is naturally a proper soil for them; because, in such situations, there are not many sorts of ever-green trees which thrive so well, especially in cold places; and by increasing the number of sorts of these ever-greens, we add to the beauty of our gardens and plantations.

The sixth sort grows naturally at the *Cape of Good Hope*, and by the accounts which I received with the seeds, the cones of the tree are black when ripe. The young plants which I have raised from seeds have loose spreading branches, which are closely garnished with narrow strait leaves, which come out opposite, and are alternately crossing each other; these are one inch long, of a light green colour; and continue in verdure all the year. These plants being young, are too tender to thrive in the open air in *England* as yet, but when they have obtained more strength, it is very probable they may do well in warm situations.

CURCUMA. *Lin. Gen. Plant.* 6. Turmerick.

The Characters are,

The flowers have spathæ, which are single and drop off; they have one petal with a narrow tube, which is cut at the brim into three segments; and an oval-pointed nectarium of one leaf, inserted in the sinus of the largest segment; it hath five stamina, four of which are barren, and one is fruitful, which is situated within the nectarium. It hath a roundish germen situated under the flower, which afterward becomes a roundish capsule having three cells, which are filled with roundish seeds.

The Species are,

1. CURCUMA foliis lanceolato-ovatis, nervis lateralibus rarissimis. *Lin. Sp. Pl.* 2. Turmerick with a round root.

2. CURCUMA foliis lanceolatis nervis lateralibus numerosissimis. *Lin. Sp. Pl.* 2. Turmerick with a long root.

The first sort hath a fleshy jointed root, somewhat like that of Ginger, but rounder; which sends up several spear-shaped oval leaves, which rise upwards of a foot high, with one longitudinal midrib, and a few transverse nerves running to the sides; they are of a sea-green colour; from between these arise the flower-stalk, supporting a loose spike of flowers of a pale yellowish colour, inclosed in several different spathæ or sheaths, which drop off. These flowers are never succeeded by seeds in the gardens here.

The second sort hath long fleshy roots of a deep yellow colour, which spread under the surface of the ground, like those of Ginger; they are about the thickness of a man's finger, having many round knotty circles, from which arise four or five large spear-shaped leaves, standing upon long foot-stalks; they have a thick longitudinal midrib, from which a numerous quantity of veins are extended to the sides. The flowers grow in loose scaly spikes on the top of the foot-stalks, which arise from the larger knobs of the roots, and grow about a foot high; they are of a yellowish red colour, and shaped somewhat like those of the *Indian Reed*.

These plants grow naturally in *India*, from whence the roots are brought to *Europe* for use. They are very tender, so will not live in this country, unless they are placed in a warm stove. They are propagated by parting of their roots;

the best time for removing and parting these roots is in the spring, before they put out new leaves, for the leaves of these plants decay in autumn, and the roots remain inactive till the spring, when they put out fresh leaves; these roots should be planted in pots, which should be constantly kept plunged in a bark-bed in the stove. In the summer season, when the plants are in a growing state, they will require to be frequently refreshed with water, but it should not be given to them in large quantities; they should also have a large share of air admitted to them in warm weather; but when the leaves are decayed they should have very little wet, and must be kept in a warm temperature of air, otherwise they will perish.

CURRENT-TREE. See Ribes.

CURURU. See Paullinia.

CUSTARD-APPLE. See Anona.

CYANUS. See Centaurea.

CYCLAMEN. *Lin. Gen. Plant.* 184. Sowbread.

The Characters are,

The flower hath one petal with a globular tube; the upper part is divided into five large segments which are reflexed; it hath five small stamina situated within the tube of the petal; it hath a roundish germen supporting a slender style, which afterward becomes a globular fruit with one cell, opening in five parts at the top, inclosing many oval angular seeds.

The Species are,

1. CYCLAMEN foliis hastato-cordatis angulatis. Sowbread with an Ivy leaf.

2. CYCLAMEN foliis orbiculato-cordatis, infernè purpurascens. Round-leaved Sowbread, with a purple under side.

3. CYCLAMEN foliis cordatis serratis. This is the heart-shaped Spring, or *Persian Cyclamen*.

4. CYCLAMEN foliis cordatis angulosis integris. Winter and spring flowering Sowbread, with a large angular leaf, and a white flower purple at the bottom, called *Persian Cyclamen*.

5. CYCLAMEN radice inæquali, foliis orbiculatis. Sowbread with a root the size of a Chestnut.

6. CYCLAMEN foliis orbiculatis planis, pediculis brevibus floribus minoribus. Winter Cyclamen with orbicular leaves, red on their under side, and a purplish flower; or the *Coum* of the herbalists.

The first sort is the most common in the *English* gardens; this grows naturally in *Austria*, *Italy*, and other parts of *Europe*, so will thrive in the open air in *England*, and is never hurt by the frost; it hath a large, orbicular, compressed root, from which arise a great number of angular heart-shaped leaves upon single foot-stalks, which are six or seven inches long, marked with an angular circle of black in their middle: the flowers appear before the leaves, rising immediately from the root; they appear in *August* and *September*, and soon after the leaves come out, and continue growing all the winter and spring till *May*, when they begin to decay; after the flowers are fallen, the foot-stalks twist up like a screw, inclosing the germen in the center, and lay down close to the surface of the ground between the leaves, which serve as a protection to the seed; this germen becomes a round fleshy seed vessel, with one cell, inclosing several angular seeds, which ripen in *June*, and should be sown in *August*. There are two varieties of this, one with a white and the other with a purplish flower, which appear at the same time.

The second sort flowers in autumn; this is at present rare in *England*; the leaves of this sort are large, orbicular, heart-shaped at their base, and of a purple colour on their under side; the leaves and flowers of this come up from the root at the same time; the flowers are of a purplish colour, and their bottoms are of a deep red; it flowers late in the autumn, and requires protection from the frost in winter.

The

The third sort hath stiff heart-shaped leaves, which are sawed on their edges, and have strong fleshy foot-stalks of a purple colour; the flowers rise with single foot-stalks from the root; these are pure white, with a bright purple bottom; the petal is divided into nine segments to the bottom, which are twisted and reflexed backward like the other sorts; this flowers in *March* and *April*, and the seeds ripen in *August*.

The fourth sort is commonly called the *Persian* Cyclamen; this hath large, angular, heart-shaped leaves; which are veined and marbled with white on their upper side, and stand upon pretty long foot-stalks; the flowers are large, of a pale purple colour, with a bright red or purple bottom; these appear in *March* and *April*, and the seeds ripen in *August*.

The fifth sort hath a small irregular root, not larger than a nutmeg; the leaves are orbicular and small; the flowers are of a flesh colour, small, and have purple bottoms; they appear in the spring, but rarely produce seeds in *England*.

The sixth sort is not so tender as the four last-mentioned, so may be planted in warm borders, where, if they are covered in hard frost, they will thrive and flower very well; it hath plain orbicular leaves, which have shorter and weaker foot-stalks than either of the other; their under sides are very red in the beginning of the winter, but that colour goes off in the spring; their upper sides are smooth, of a lucid green, and spread open flat, whereas the other sorts are hollowed, and reflexed at their base; the flowers are of a very bright purple colour, and appear in the middle of winter, at a time when there are few other flowers, which renders the plants more valuable; the seeds of this sort ripen in the end of *June*.

There are some other varieties of this plant, which chiefly differ in the colour of their flowers, particularly among the *Persian* kind, of which there is one with an entire white flower, which smells very sweet; but as these are accidental variations, so I have not enumerated them, those which are here mentioned being undoubtedly distinct species.

All the sorts are propagated by seeds, which should be sown soon after they are ripe in boxes or pots, and covered about half an inch deep, placing them where they may have only the morning sun till the beginning of *September*, when they may be removed to a warmer exposure. Those of the first sort may be plunged into the ground, close to a south wall, a pale or Reed-hedge in *October*, where, if it should be very severe frost, it will be proper to cover them either with mats or Pease haulm; but in common winters they will not require any. The pots or tubs, in which the *Persian* kinds are sown, should then be placed under a common hot-bed frame, where they may be protected from frost and hard rains; but in mild weather, the glasses may be taken off every day to admit fresh air to them; those of the *Persian* kinds will come up early in the spring, and continue green till *June*, when they will begin to decay; then they should be removed to an east aspect, where they will have only the morning sun; in which situation they may remain till the middle of *August*, during which time they should have very little water, as the roots are then in an inactive state, when much wet will rot them; in the beginning of *October* there should be some fresh earth spread over the tubs or pots, and then they should be removed again into shelter in the same manner as before; and the following summer they must be managed also in the same way till their leaves decay, when they should be carefully taken up, and those of the first sort planted in a warm border at four or five inches distance; but the other sorts must be planted in pots or tubs, to be sheltered in winter.

The third, fourth, and fifth sorts, are more impatient of cold and wet than the three other; these must constantly be preserved in pots, and sheltered in winter either under common hot-bed frames, or in an airy glass-case, where they

may enjoy as much free open-air as possible, in mild weather; for if they are crowded under other plants, and are kept too close, they are very subject to mould and rot; nor should they have much water in winter, which is also very injurious to them; but whenever they want water, it should be given them sparingly. In summer these plants may be exposed to the open air, when their green leaves will decay, at which time you should remove them to a place where they may have the morning sun until eleven o'clock; but during the time that the roots are destitute of leaves, they should have very little water given them, because at that season they are not capable of discharging the moisture; when their leaves are decayed; it is the proper season to transplant the roots, or to fresh earth them; and as the autumn comes on, that the heat decreases, they may be removed into places more exposed to the sun, where they may remain until *October* before they need be sheltered.

Toward *Christmas*, if the roots are in good health, the sixth sort will begin to flower, and continue producing fresh flowers until the middle of *February*; these will be succeeded by the *Persian* sorts, which continue till *May*; but if you intend to have good seeds, the pots of these sorts should be placed so as to receive a great share of fresh air; for if their flowers are drawn up weak, they seldom produce good seeds. The seeds are ripe about *July*, when they should be immediately sown in pots or cases of good light undunged earth; which should be sheltered in winter under a frame, and exposed in summer in the same manner as is directed for the older roots. When they are two years old, they should be taken up, and each root planted in a small separate pot, in which they may remain two years; then they should be removed into pots a size larger, to give them room, and in about four or five years time they will begin to flower, when they must be put into larger pots.

Several of these sorts have been planted under warm walls in the full ground, where, in mild winters they have succeeded very well, but in severe frost they have been destroyed; therefore, whenever these roots are planted in an open border, there should be common hot-bed frames placed over them in winter, or some other covering, that they may be screened from frost: and when they are thus managed, the plants will produce more flowers, and those will be much fairer, than what are produced from the roots in the pots, and from these there may always be good seeds expected. Therefore, such persons who are curious in flowers, should have a border framed over on purpose for these; and the *Guernsey* and *Belladonna* Lilies, with some other of the curious bulbous-rooted flowers; in which borders there may be many of these curious flowers cultivated, to more advantage than in any other method now practised.

CYDONIA. *Tourn. Inst. R. H.* 632. The Quince tree.

The Characters are,

The flower is composed of five large roundish concave petals, which are inserted in the permanent empalement. The germen is situated under the flower; it hath five slender styles, with twenty stamina. The germen afterward becomes a pyramidal or roundish fruit, which is fleshy and divided into five cells, in which are lodged several hard kernels or seeds.

The Species are,

1. CYDONIA foliis oblongo-ovatis subtus tomentosis, pomis oblongis basi productis. Quince tree with oblong oval leaves, woolly on their under side, and an oblong fruit lengthened at their base; commonly called the Pear Quince.
2. CYDONIA foliis ovatis, subtus tomentosis, pomis rotundioribus. Quince tree with oval leaves, woolly on their under side, and a rounder fruit; commonly called the Apple Quince.
3. CYDONIA foliis obverse-ovatis subtus tomentosis. Quince tree with obverse oval leaves, woolly on their under side, commonly called the Portugal Quince.

The *Portugal Quince* is the most valuable, the pulp of it turning to a fine purple when stewed or baked, and becomes much softer and less austere than the others, so is much better for making of marmalade.

All the sorts are easily propagated, either by layers, suckers, or cuttings, which must be planted in a moist soil. Those raised from suckers, are seldom so well rooted as those which are obtained from cuttings or layers; and are subject to produce suckers again in greater plenty, which is not so proper for fruit bearing trees. The cuttings should be planted early in the autumn, on a moist border. The second year after they should be removed into a nursery at three feet distance row from row, and one foot asunder in the rows, where they must be managed as was directed for Apples. In two years time these trees will be fit to transplant, where they are to remain for good; which should be either by the side of a ditch, river, or some other moist place, where they will produce a greater plenty, and much larger fruit than in a dry soil; though those in the dry soil will be better tasted, and earlier ripe. The trees require very little pruning; the chief thing to be observed is, to keep their stems clear from suckers, and cut off such branches as cross each other; likewise all upright luxuriant shoots from the middle of the tree should be taken entirely out, that the head may not be too much crowded with wood, which is of ill consequence to all sorts of fruit trees. If they are propagated by budding, or grafting upon stocks raised by cuttings, to multiply the best sorts, the trees so raised will bear fruit much sooner and be more fruitful, than those which come from suckers or layers,

Quince stocks are also in great esteem for to graft and bud Pears on; which on a moist soil will greatly improve some sorts, especially those designed for walls and espaliers: for the trees upon these stocks do not shoot so vigorously as those upon free stocks, and therefore may be kept in less compass, and are sooner disposed to bear fruit: but hard winter fruits do not succeed so well upon these stocks, their fruit being very subject to crack, and are commonly stony, especially all the breaking Pears, but more especially if they are planted in dry ground; therefore these stocks are only proper for the melting Pears, and for a moist soil. The best stocks are those which are raised from cuttings or layers.

As the Pear will take upon the Quince by grafting or budding, and so *vice versa*, we may conclude there is a near alliance between them; but as neither of these will take upon the Apple, nor that upon either of these, so we should separate them under different genera, as will be farther mentioned under the article *MALUS*.

CYNANCHUM. *Lin. Gen. Pl.* 268. Bastard Dogsbane.

The Characters are,

The flower hath one petal, which is spread open, plain, and divided into five parts; the nectarium, which is situated in the center of the flower, is erect, cylindrical, and the length of the petal. It hath five stamina, which are parallel to the nectarium, and an oblong bifid germen; the empalement becomes a capsule with two oblong pointed pods, which open longitudinally, and are filled with seeds lying over each other imbricatum, crowned with long down.

The Species are,

1. *CYNANCHUM caule volubili herbaceo, foliis cordato-oblongis glabris. Hort. Cliff.* 79. *Montpelier Periploca* with acute-pointed leaves, commonly called *Montpelier Scammony*.

2. *CYNANCHUM caule volubili herbaceo, foliis reniformi-cordatis acutis. Hort. Cliff.* 79. *Montpelier Periploca* with rounder leaves, or round-leaved *Montpelier Scammony*.

3. *CYNANCHUM caule volubili infernè suberoso fisso, foliis cordatis acuminatis. Hort. Cliff.* 79. *Carolina Periploca* with a smaller starry flower.

4. *CYNANCHUM caule volubili fruticoso, infernè suberoso fisso, foliis ovato-cordatis. Hort. Cliff.* 79. *Periploca* with a climbing stalk, a Citron leaf, and a large fruit.

5. *CYNANCHUM caule erecto divaricato, foliis cordatis glabris. Hort. Cliff.* 79. Upright Dogsbane with a roundish leaf.

6. *CYNANCHUM caule volubili fruticoso, foliis cordatis acutis asperis, floribus lateralibus.* Climbing Dogsbane with heart-shaped rough leaves, and large, yellow, spreading flowers.

7. *CYNANCHUM caule scandente, foliis cordatis acuminatis glabris.* Dogsbane of *Bithynia* climbing to the tallest trees, having a roundish leaf.

The first and second sorts grow naturally at *Montpelier*; they have perennial creeping roots, but annual stalks, which twist themselves like Hops, round whatever plants are near them, and rise to the height of six or eight feet; the first of these has oblong, heart-shaped, smooth leaves, ending in acute points, placed by pairs on long foot-stalks; the flowers come out in small bunches from the wings; they are of a dirty white colour, divided into five acute segments, which spread open in form of a star. They appear in *June* and *July*, but are not succeeded by any seed vessels in *England*, which may be occasioned by their roots creeping so far under ground.

The second sort differs from the first in the shape of its leaves, which are broader and rounder at their base. The roots of this sort are very thick, running deep into the ground, so that where this plant hath gotten possession of the ground it is not easily extirpated. Both these plants abound with a milky juice like the Spurge, which issues out where-ever they are broken; and this milky juice when concreted, has been frequently sold for Scammony.

These plants propagate too fast by their creeping roots, when they are admitted into gardens, so few people care to preserve them: the roots may be transplanted any time after their stalks decay.

The third sort grows naturally in *Carolina*; this is a perennial plant with twining hairy stalks, which, if supported, will rise six or seven feet high; the lower part of the stalks are covered with a thick fungous bark, somewhat like cork, which is full of fissures; the stalks are slender, and garnished at each joint with two oblong, heart-shaped, pointed leaves, standing on long hairy foot-stalks. The flowers are produced in small bunches at the wings of the leaves, which are star-shaped and green when they first appear, and afterward fade to a worn-out purple colour.

This plant will live in the open air in *England*, if it is planted in a dry soil and warm situation. It may be propagated by laying down some of the young shoots about *Midsummer*, which, if they are now and then refreshed with water, will put out roots, so may be transplanted in autumn, where they are designed to remain. The roots of this plant should be covered in winter with some rotten tan to keep out the frost, otherwise in severe winters they are liable to be destroyed.

The fourth sort grows naturally in *Jamaica*. This rises with a twining stalk to the height of twenty feet or upward, provided it hath support; the lower part of the stalks are covered with a thick fungous bark, full of fissures, which gape open; the leaves are oblong and smooth, and placed by pairs, standing upon long foot-stalks: the flowers are produced from the wings of the leaves in small bunches, they are star-shaped, and of a yellowish green colour, but are not succeeded by pods in *England*.

This is tender, so will not thrive in this country unless it is placed in a warm stove, and requires the same treatment as other tender plants from the same country. It is propagated by laying down of the young shoots, which in three or four months will put out roots, and may then be transplanted into pots, and plunged into the tan bed in the bark stove, where the plants should continue all the year.

The fifth sort grows naturally in *Syria*; this is a perennial plant, which rises with slender upright stalks about three feet

feet high, which are garnished with broad, smooth, heart-shaped leaves, ending in points, placed opposite; the flowers come out from the wings of the leaves in small bunches, standing on branching foot-stalks; these are small and white, greatly resembling those of the common white *Afclepias*, or Swallow-wort, and are succeeded by oblong taper pods, filled with flat seeds crowned with down, but these rarely ripen in this country.

It is propagated by parting of the root; the best time for doing of this or transplanting of the roots, is in the Spring, before they shoot: it requires a warm situation, otherwise it will not live abroad in *England*.

The sixth sort grows naturally at *La Vera Cruz* in *New Spain*; this hath a shrubby twining stalk, which twists about any prop that is near it, and rises to the height of twenty feet or upward; the stalks are very slender, and are armed with small stinging hairs, and garnished with broad heart-shaped leaves, which end in acute points, placed by pairs at each joint, and have slender foot-stalks; they are covered with rough hairs on their under side; the flowers are produced in small clusters, sitting close to the side of the stalks; they are pretty large, yellow, and star-shaped, spreading open to the bottom; and are succeeded by long swelling pods, filled with flat seeds lying *imbricatim*, which are crowned with long down.

This sort is tender, so requires the same treatment as the fourth, and is propagated the same way.

The seventh sort grows naturally in *Bithynia*. This rises with a pretty strong stalk, which fastens itself to any neighbouring tree, and mounts up to the top, garnished with broad, heart-shaped, smooth leaves, standing upon long foot-stalks; they are generally placed opposite, but sometimes there are three leaves arising from the same joint, one of which hath a much longer foot-stalk than the other two. The flowers come out from the wings of the leaves, standing upon pretty long branching foot-stalks; they are star-shaped, and of a pale yellowish colour.

This sort must be planted in a warm situation, otherwise it will not live through the winter in *England*. It requires the same treatment as the fifth sort, but may be propagated by laying down the young shoots in the same manner as the fourth sort.

CYNARA. *Lin. Gen. Plant.* 835. Artichoke.

The Characters are,

It hath a compound flower, made up of many hermaphrodite florets, included in one common scaly empalement. The florets are tubulous, equal, and uniform, divided at the top into five narrow segments. They have five short hairy stamina. At the bottom of each is situated an oval germen, which afterwards becomes a single, oblong, compressed, four-cornered seed, crowned with long hairy down.

The Species are,

1. CYNARA foliis subspinosis, pinnatis indivisisque, calycinis squamis ovatis. *Lin. Sp. Plant.* 827. The green or French Artichoke.

2. CYNARA foliis pinnatis inermibus, calycinis squamis obtusis emarginatis. The Globe Artichoke.

3. CYNARA foliis spinosis, omnibus pinnatifidis, calycinis squamis ovatis. *Lin. Sp. Pl.* 827. The Cardoon.

4. CYNARA foliis spinosis, pinnatifidis, subtus tomentosis, calycibus squamis subulatis. *Lin. Sp. Pl.* 828. Wild Artichoke of Spain.

The first sort is commonly known here by the title of French Artichoke, being the sort which is most commonly cultivated in *France*. The leaves of this sort are terminated by short spines, the head is oval, and the scales do not turn inward at the top, like those of the Globe Artichoke, they are also of a green colour; the bottoms of these are not near so thick of flesh as those of the Globe, and have a perfumed taste, which to many persons is very disagreeable,

so it is very seldom cultivated in the gardens near *London*, where the Globe or Red Artichoke is the only sort in esteem. The leaves of this are not prickly; the head is globular, a little compressed at the top; the scales lie close over each other, and their ends turn inward, so as to closely cover the middle.

The culture of these having been fully treated under the article ARTICHOKE, the reader is desired to turn to that, to avoid repetition.

The Chardoon, or Cardoon, is propagated in the kitchen gardens to supply the markets; this is annually raised from seeds, which should be sown upon a bed of light earth in *March*; and when the plants come up, they should be thinned where are too close; and if the plants are wanted, those which are drawn out may be transplanted into a bed at about three or four inches distance, where they should remain till they are fit to transplant out for good. In *June* they must be transplanted out, on a moist rich spot of ground at about four feet asunder every way; the ground should be well dug before they are planted, and the plants should be well watered until they have taken new root, after which the ground must be kept clean from weeds, to encourage the growth of the plants; and as they advance in height, there should be some earth drawn up about each; and when they are fully grown, their leaves should be closely tied up with a hay band, and the earth drawn up in hills about each plant, almost to their tops, being careful to keep the earth from falling between the leaves, which may occasion the rotting of the plants. This earth should be smoothed over the surface that the wet may run off, and not fall into the center of the plants. In about five or six weeks after the plants have been thus earthed, they will be blanched enough for use; so that if a succession of them are wanted for the table, there should be but few plants earthed up at the same time, but every week or ten days, there may be a part of them earthed, in proportion to the quantity desired.

Toward the middle or latter end of *November*, if the frost should be severe, it will be proper to cover the tops of those plants which remain with Pease haulm, or straw, to prevent the frost from penetrating to the tender leaves, which frequently pinches them where there is not some covering; but this should be taken off again in mild weather; if this care is taken, the plants may be preserved for use all the winter.

The fourth sort grows naturally in *Spain*, and also on the African shore, and is preserved in gardens for the sake of variety; this is very like the third sort, but the stems of the leaves are much smaller, and do not grow more than half so high. The heads of this have some resemblance to those of the French Artichoke, but have no meat, or fleshy substance in their bottoms; this may be planted in the same manner as the third sort, at about three or four feet apart, and will require no other treatment, than the keeping them clean from weeds; the second year they will flower, and, if the season proves dry, they will ripen their seeds.

CYNOGLOSSUM. *Lin. Gen. Pl.* 168. Hounds Tongue.

The Characters are,

It hath a funnel-shaped flower of one leaf, with a long tube. It hath five short stamina, in the chaps of the petal. At the bottom of the tube are situated four germen; the empalement afterwards becomes four capsules, inclosing four oval seeds.

The Species are,

1. CYNOGLOSSUM staminibus corolla brevioribus, foliis lanceolatis tomentosis sessilibus. *Lin. Sp. Plant.* 134. Common Greater Hounds Tongue.

2. CYNOGLOSSUM staminibus corollam aequantibus. *Hort. Upsal.* 33. Greatest Mountain Hounds Tongue.

3. CYNOGLOSSUM foliis oblongis tomentosis, amplexicaulis, caule ramoso, spicis florum longissimis sparsis. Broad-leaved stinking Hounds Tongue of *Crete*.

4. CYNOGLOSSUM

4. *CYNOGLOSSUM corollis calyce duplo longioribus foliis lanceolatis. Prod. Leyd. 406.* Hounds Tongue of Crete, with a narrow silvery leaf.

5. *CYNOGLOSSUM caule ramoso hirsuto, foliis lanceolatis asperis, floribus sparsis.* Virginia Hounds Tongue with a very small white flower.

6. *CYNOGLOSSUM caule erecto ramoso, foliis lanceolatis scabris sessilibus, spicis florum longissimis.* Taller Portugal Navelwort with a Hounds Tongue leaf.

7. *CYNOGLOSSUM foliis lineari-lanceolatis glabris. Hort. Cliff. 47.* Portugal Navelwort with a Flax leaf, commonly called Venus Navelwort.

8. *CYNOGLOSSUM repens, foliis radicalibus cordatis. Hort. Cliff. 47.* Low Spring Navelwort with a Comtry leaf.

The first sort grows naturally by the side of hedges and foot-ways in most parts of England, so is seldom admitted into gardens; the roots of this sort are used in medicine, which are gathered by the herb-folks in the fields. The leaves of this plant have a strong odour, like that of mice in a trap.

The second sort grows naturally on the *Apeunine* mountains; the leaves of this sort are much larger, the petal of the flower is shorter, and the plants grow taller than those of the first, and come earlier to flower in the spring; this is equally hardy with the common sort, and where the seeds are permitted to scatter, there will be plenty of the plants arise without care.

The third sort grows naturally in *Andalusia*; this hath a tall branching stalk, garnished with oblong woolly leaves, which embrace the stalk with their base. The flowers are produced in loose spikes, which come out from the side of the stalk, and are from six to eight inches long, and are thinly placed on one side; they are blue, striped with red. The seeds ripen in autumn, soon after which the root decays.

The fourth sort grows naturally in *Spain*, and also in the island of *Crete*. This rises with an upright stalk, little more than a foot high, garnished with long, narrow, silvery leaves, having no foot-stalks. The flowers are produced from the side, and at the top of the stalks, which are but thinly dispersed on the side, but at the top of the stalk are in small clusters; they are of a deep purple colour, and much longer than the empalement; these are succeeded by four broad buckler-shaped seeds, which are rough.

The fifth sort grows naturally in *Virginia*, and in other northern parts of *America*; this rises with an upright branching stalk, near four feet high. The stalks and leaves are covered with rough hairs; the branches are spread out on every side, and are but thinly garnished with leaves, from three to near four inches in length, and little more than one inch broad in the middle, gradually lessening to both ends; they have very short foot-stalks, and are placed alternate; the flowers grow scatteringly toward the end of the branches; these are small, white, and are succeeded by four small seeds, which ripen in autumn.

The sixth sort grows naturally in *Portugal*, but the seventh sort hath been long cultivated in the gardens for ornament, by the title of *Venus Navelwort*, but of late years that has been lost in *England*; and the sixth sort is now generally sown in the gardens, the seeds of which are sold by the seedsmen under that title; this is a much larger plant than the other, so makes a finer appearance. The leaves of the sixth sort are broad at their base, and are gradually narrowed to the end; they are slightly covered with hairs. The stalks grow nine or ten inches high, and divide into many branches, each being terminated by a long loose spike of white flowers, standing on separate foot-stalks; and are succeeded by four umbilicated seeds, from whence it had the title of *Navelwort*.

The seventh sort seldom rises more than five or six inches high; the stalks do not branch near so much as those of the sixth. The leaves are very narrow and long, of a grayish colour, and smooth. The flowers grow in short loose panicles at the end of the branches; these are white, but smaller than those of the other sort, and are succeeded by seeds of the same form.

These are both annual plants, which have been commonly sown in gardens, with other low annual flowers, to adorn the borders of the flower garden; but these should be sown in autumn, for those which are sown in the spring often fail, especially in dry seasons; and the autumnal plants always grow much larger, than those which arise from the spring sowing, and come to flower earlier in the year. The seeds should be sown where the plants are designed to remain, for they do not bear transplanting, unless it is performed while they are young. The plants require no other culture, but to be thinned where they are too close, and kept clean from weeds.

The eighth sort is a low perennial plant, which grows naturally in the woods of *Spain* and *Portugal*, where it usually flowers about *Christmas*. It hath trailing branches, which put out roots from their joints, whereby it propagates very fast. The leaves are heart-shaped, of a bright green colour, and stand upon long slender foot-stalks. The flowers grow in loose panicles, which arise from the divisions of the stalk; they are shaped like those of *Borage*, but are smaller, and of a lively blue colour; they appear in *March* and *April*, and in a cool shady situation continue great part of *May*, but are rarely succeeded by seeds; but the plants propagate themselves so fast by their trailing branches, as to render the cultivation of them by seeds unnecessary. It delights in a moist cool situation.

CYPRIPEDIUM. Lin. Gen. Pl. 906. Ladies Slipper.

The Characters are,

It hath a simple spadix. The germen sits under the flower, which is covered with a sheath. The flowers have four or five narrow spear-shaped petals, which expand. The nectarium, which is situated between the petals, is swollen and hollow, in shape of a shoe, or slipper. It hath two short stamina. Below the flower is fixed a slender contorted germen, which afterward becomes an oval blunt capsule with three corners, having three valves, and one cell, filled with small seeds.

The Species are,

1. *CYPRIPEDIUM radicibus fibrosis, foliis ovato-lanceolatis caulinis. Aët. Upsal. 1740.* Our Ladies Slipper.

2. *CYPRIPEDIUM scapo unifloro, foliis oblongis glabris, petalis angustis acuminatis.* Yellow Ladies Slipper.

3. *CYPRIPEDIUM foliis oblongo-ovatis venosis hirsutis, flore maximo.* Ladies Slipper with a larger flower.

The first sort grows naturally in some shady woods in the north of *England*. I found it in the park of *Borough Hall*, in *Lancashire*, the seat of the late *Robert Fenwick, Esq.* It hath a root composed of many fleshy fibres, from which arise two, three, or more stalks, in proportion to the strength of the root; these grow nine or ten inches high, garnished with oval spear-shaped leaves, having a few longitudinal veins; in the bosom of one of the upper leaves, is inclosed the flower-bud, which is supported by a slender foot-stalk, which generally turns a little on one side. The flower hath four dark purple petals, placed in form of a cross, which spread wide open. In the center is situated the large hollow nectarium, almost as large as a bird's egg, shaped like a wooden shoe, of a pale yellowish colour, with a few brown streaks; the opening is covered with two ears; the upper one is tender, white, and spotted with purple; the lower is thick, and of an herbaceous colour.

The second sort grows naturally in *Virginia*, and other parts of *North America*; this hath longer and smoother leaves than

than the former. The two side petals of the flower are long, narrow, and terminate in acute points, and are wreathed, or undulated on their sides. The nectarium is oblong, and narrower than in the first sort, and is yellow, spotted with brownish red. The stalks rise near a foot and an half high.

The third sort grows naturally in *America*, where the inhabitants call it Moccasin flower; this rises a foot and an half high. The leaves are of an oblong oval form, and are deeply veined. The flower is large, of a reddish brown colour, marked with a few purple veins.

All these sorts are with difficulty preserved in gardens; they must be planted in a loamy soil, and in a situation where they may have the morning sun only. They must be procured from the places where they naturally grow, for they cannot be propagated in gardens. The roots should be seldom removed, for transplanting them prevents their flowering.

CYSTICAPNOS. See *Fumaria*.

CYTISO GENISTA. See *Spartium*.

CYTISUS. *Lin. Gen. Pl.* 785. Base Tree Trefoil.

The Characters are,

It hath a butterfly flower. The standard of the flower is rising, oval, and reflexed on the sides. The wings are obtuse, erect, and the length of the standard. The keel is bellied and acute. It hath ten stamina, nine joined, and one standing separate, and an oblong germen, which after-ward becomes an oblong blunt pod, filled with kidney-shaped flat seeds.

The Species are,

1. *CYTISUS foliis oblongo-ovatis, racemis brevioribus pendulis, caule arboreo*. Broad-leaved Cytisus of the Alps, with pendulous bunches of flowers, commonly called Laburnum.

2. *CYTISUS foliis ovato-lanceolatis, racemis longioribus pendulis, caule fruticoso*. Narrow-leaved Cytisus of the Alps, with longer pendulous bunches of flowers, commonly called long-spiked Laburnum.

3. *CYTISUS racemis simplicibus erectis, foliis ovato-oblongis*. *Hort. Cliff.* 354. Blackish smooth Cytisus.

4. *CYTISUS villosus, foliolis cuneiformibus perennantibus, caulibus ramosissimis, racemis terminalibus*. Ever-green hoary Cytisus of the Canary islands.

5. *CYTISUS racemis erectis, calycibus bractea triplici unctis, foliis floralibus sessilibus*. *Lin. Sp. Pl.* 739. Smooth Cytisus with roundish leaves, and very short foot-stalks, commonly called by gardeners, *Cytisus secundus Clusii*.

6. *CYTISUS hirsutus, foliolis ovatis, floribus lateralibus, caule erecto fruticoso*. Hairy Cytisus, commonly called Ever-green Cytisus of *Naples*.

7. *CYTISUS floribus subsessilibus, foliis tomentosus, caulibus herbaceis*. *Lin. Sp. Pl.* 740. Low silvery Cytisus with narrow leaves.

8. *CYTISUS floribus capitatis, ramis decumbentibus*. *Prod. Leyd.* 376. Low Cytisus, with the under side of the leaves and pods covered with a soft down.

9. *CYTISUS floribus lateralibus, foliis hirsutis, caule erecto striato*. *Sauv. Monsp.* 161. Cytisus of *Montpelier* with a Medick leaf, and hairy pods collected in thick bunches.

10. *CYTISUS ramis humifusis albidis, floribus capitatis terminalibus, foliolis ovalibus glabris aggestis*. *Sauv. Monsp.* 190. Hoary narrow-leaved Cytisus with complicated leaves.

11. *CYTISUS caule erecto fruticoso, ramis foliolis ovatis glabris, floribus capitatis terminalibus*. Cytisus with a shrubby, erect, branching stalk, oval smooth leaves, and flowers collected in heads terminating the branches; or the *Siberian* Cytisus.

12. *CYTISUS floribus capitatis, foliolis ovato-oblongis, caule fruticoso*. Cytisus with flowers collected in heads, oblong oval leaves, and a shrubby stalk; commonly called *Tartarian* Cytisus.

13. *CYTISUS caule erecto fruticoso, foliolis cuneiformibus*

emarginatis, floribus simplicibus alaribus. Cytisus with a shrubby erect stalk, wedge-shaped leaves, which are indented, and single flowers growing on the sides of the branches.

14. *CYTISUS foliis lanceolato-linearibus tomentosus, floribus spicatis alaribus pedunculis longissimis*. Hairy narrow-leaved *African* Cytisus.

15. *CYTISUS racemis lateralibus strictis, ramis angulatis, foliolis cuneiformibus*. *Lin. Sp. Plant.* 740. *Ethiopian* Cytisus, with smaller, roundish, hoary leaves, and a small yellow flower.

16. *CYTISUS racemis axillaribus erectis, foliolis sublancoelatis tomentosus, intermedio longius petiolato*. *Flor. Zeyl.* 357. Tree Cytisus with eatable fruit, commonly called Pigeon Pea in *America*.

The first sort is the common broad-leaved Laburnum, which was formerly in greater plenty in the *English* gardens than at present; for since the second sort hath been introduced, it hath almost turned this out; the spikes of flowers being much longer, they make a finer appearance when they are in flower, which has occasioned their being more generally cultivated; but the first grows to be the largest tree, and the wood of it is very hard, of a fine colour, and will polish very well; it approaches near to green Ebony. In *England*, there are few of these trees which have been suffered to stand long enough to arrive to any considerable size; for as they have been only considered as an ornamental tree, so the frequent alterations which most of the gardens in *England* have undergone, have occasioned their being rooted out, where-ever they were growing; but in some of the old gardens in *Scotland*, where they have been permitted to stand, there are large trees of this kind, which are fit to cut down for the use of the timber. They grow very fast, and are extremely hardy, so may be well worth propagating upon poor shallow soils, and in exposed situations. His grace the duke of *Queensberry* sowed a great quantity of the seeds of this tree, upon the side of the downs, at his seat near *Amesbury*, in *Wiltshire*, where the situation was very much exposed, and the soil so shallow, as that few trees would grow there; yet in this place the young trees were twelve feet high in four years growth, so became a shelter to the other plantations, for which purpose they were designed; but the hares and rabbits are great enemies to these trees, by barking them in winter, so that where these trees are cultivated, they should be fenced from these animals.

Both the sorts are easily propagated by seeds, which the trees produce in great plenty; if these are sown upon a common bed of earth in *March*, the plants will appear by the middle, or end of *April*, and will require no other care but to be kept clean from weeds, during the following summer; and if the plants are too close together, they may be transplanted the autumn following, either into a nursery where they may grow a year or two to get strength, or into the places where they are designed to remain; but where people would cultivate them for their wood, it will be the best way to sow the seeds upon the spot where they are intended to grow, because these trees send out long thick fleshy roots to a great distance, which will penetrate gravel or rocks, and if the roots are cut or broken, it greatly retards their growth; therefore when they are not sown upon the intended spot, they should be transplanted thither young, otherwise they will not grow to near the size; though where they are only designed for ornament, the removing the plants twice will stop their growth, and cause them to be more productive of flowers; but all trees intended for timber, are much better sown on the ground, where they are to remain, than if they are transplanted.

If the seeds of these trees are permitted to scatter in winter, the plants will rise in great plenty the following spring, so that a few trees will soon supply any person with a sufficient number of the plants.

If the first sort comes to be considered as a useful wood, which there is no reason to doubt it may be, it may be planted in large clumps in parks, where they will be very ornamental; and I am certain, from long experience, that this tree will thrive upon many soils, and in such situations as few other trees will make any progress; the objection to fencing is the same here, as for any other trees, for wherever plantations are made, if they are not well secured from animals, they will not answer the design of the planters.

The second sort differs from the first, in having narrower leaves, longer bunches of flowers, and the trees do not grow so large and strong; this difference I find is constant from seed. There is another sort mentioned by *Tournefort*, with shorter bunches of flowers than either of these, one tree of which kind I thought I had found in a garden; the bunches of the flowers upon this tree were close and almost round, but I sowed the seeds of it, and the plants proved to be only the common sort.

The third sort grows naturally in *Austria*, *Italy*, and *Spain*, and at present is pretty rare in the *English* gardens; it was formerly in some of the curious gardens here, but had been long lost, till a few years ago, when I procured the seeds from abroad.

This shrub seldom rises more than three or four feet high in *England*; it naturally puts out many lateral branches near the ground, which spread out on every side, so as to form a low shrubby bush, and is with difficulty raised to a stem: the branches are very slender, and their ends are frequently killed if the winter is severe; these are garnished with oblong oval leaves, growing by threes on each foot-stalk; they are equal in size, and of a dark green colour; the branches grow erect, and are terminated by spikes of yellow flowers, about four or five inches long, standing upright; and as all the branches are thus terminated, so when the shrubs are in flower, they make a fine appearance; it flowers in *July*, after most of the other sorts are past. This is propagated by seeds, which should be sown on a bed of light earth in *March*. In the beginning of *May* the plants will appear, when they must be carefully weeded. In autumn the bed should be arched over with hoops, that in frosty weather the plants may be covered with mats, to prevent their tender shoots from being killed; for as these young plants are apt to continue growing later in the autumn, than those which are become woody, so they are much more susceptible of cold; therefore where there is not some care taken to cover them, if the winter should prove severe, many of them may be entirely destroyed. The spring following, after the danger of hard frost is over, the plants should be carefully taken up, and planted out at the distance of one foot, row from row, and six inches asunder in the rows; this should be in a sheltered situation: as these plants do not shoot till late in the spring, so they need not be transplanted before the beginning of *April*, and if the season should then prove warm and dry, it will be proper to give the plants some water to settle the earth to their roots. After they have taken new root, they will require no farther care, but to keep them constantly clean from weeds: in this nursery the plants may remain two years, by which time they will have acquired strength enough to be transplanted where they are to remain.

The fourth sort grows naturally in the *Canary* islands. This is too tender to live through the winter in the open air here, but requires the shelter of a green-house, and will thrive in such places where *Myrtles* and *Amomum Plinii* do well. It is a very bushy shrub, which rises with rough pliable stalks to the height of eight or ten feet, sending out many slender hairy branches, which are very closely garnished with small wedge-shaped leaves, placed by threes on each foot-stalk: they are of a dark green, and very hairy; the branches are terminated by close bunches of bright yellow flowers, which

are frequently succeeded by short hairy seed pods, which ripen in *August*.

It is propagated by seeds, which should be sown upon a very temperate hot-bed in *March*, which will bring up the plants in a short time; then they may be transplanted, each into a small halfpenny pot, filled with light earth, and plunged into a moderate hot-bed, just to forward their taking fresh root; after which they should be inured gradually to the open air, and the middle or latter end of *May*, they should be placed abroad in a sheltered situation, and afterward treated in the same way, as other hardy kinds of green-house plants.

The fifth sort grows naturally in the south of *France*, in *Spain* and *Italy*, but has been long cultivated in the nursery gardens, as an ornamental flowering shrub, by the title of *Cytisus secundus Clusii*, which is a great mistake, for the tenth species here enumerated is the second of *Clusius*. This rises with a woody stalk, putting out many branches covered with a brownish bark, and garnished by obverse, oval, small leaves, growing by threes on very short foot-stalks. The flowers are produced in close short spikes at the end of the branches; they are of a bright yellow colour, and appear in *June*; these are succeeded by short broad pods, which contain one row of kidney-shaped seeds, which ripen in *August*. These shrubs will rise to the height of seven or eight feet, and become very bushy; they are very hardy, so will thrive in any situation, and upon almost any soil, which is not too wet.

The sixth sort hath a soft shrubby stalk, dividing into many branches, which grow erect, and rise to the height of eight or ten feet; the stalks and leaves of this are very hairy, the leaves are oval, growing three upon each foot-stalk; the flowers come out from the side of the branches, in short bunches; they are of a pale yellow, and are succeeded by long, narrow, hairy pods, with one row of kidney-shaped seeds.

This sort, of late years, has been much cultivated in the nursery gardens near *London*, by the title of ever-green *Cytisus* of *Naples*; but as in severe frost these shrubs are sometimes killed, so they are not proper for every situation, therefore should only be planted on a dry soil, and in warm situations; they are also very difficult to remove, when grown to any size, for they shoot long roots deep into the ground, and when these are cut or broken, the plants seldom survive it. This may be propagated in the same manner as hath been directed for the third sort.

The seventh sort grows naturally in the south of *France*, and in *Italy*. This is a low perennial plant, which puts out several weak stalks from the root, which spread on the ground, and are from six to eight inches long, garnished with small silvery leaves growing by threes; the flowers are produced at the end of the branches, two or three growing together upon short foot-stalks; they are of a pale yellow colour; but unless the season proves very warm, they do not produce seeds in *England*. It is propagated by seeds, which should be sown in the spring, in a warm border, where the plants are to remain; for as they have commonly one downright root, so they seldom live if they are transplanted. The plants require no other culture, but to keep them clean from weeds, and the second year they will flower.

The eighth sort grows naturally in *Sicily*, *Italy*, and *Spain*; this is a perennial plant, from whose downright root, proceed several weak branches, which trail upon the ground, and extend to the length of eight or ten inches; garnished with oblong leaves, placed by threes upon pretty long foot-stalks; they are hoary on their under side; but smooth above; the flowers are collected in heads at the ends of the stalks, having a cluster of leaves under them; they are of a deep yellow colour, and in warm seasons they

they are succeeded by flat woolly pods, containing one row of small kidney-shaped seeds. This plant is propagated by seeds, which should be sown where they are to remain, and treated in the same manner as the seventh sort.

The ninth sort grows naturally about *Montpelier*; this rises with an upright stalk four or five feet high, sending out many side branches, which are streaked or furrowed, and garnished with oval hairy leaves; the flowers are produced in short spikes on the side of the branches, which are of a bright yellow, and are succeeded by hairy pods, which ripen in autumn. This may be propagated in the same manner as the third sort.

The tenth sort grows naturally about *Montpelier*; this is a perennial plant, with a strong downright root, sending out many tough ligneous branches, which spread flat on the ground, and extend to a foot and an half in length, covered with a white bark, and garnished with very small Trefoil leaves; the flowers are produced at the extremity of the branches in clusters; they are but small, and of a deep yellow inclining to an Orange colour, and in very warm seasons are succeeded by short pods, containing three or four kidney-shaped seeds in each. This sort is propagated in the same manner as the seventh.

The eleventh sort came from *Siberia*; this is a low shrub, which seldom rises more than three feet high in *England*, sending out side branches, garnished by oval smooth leaves, having pretty long foot-stalks; the flowers are produced in clusters or heads at the end of the branches; they are of a bright yellow, and appear the end of *March*, or the beginning of *April*, but are seldom succeeded by pods in *England*. This is propagated by seeds as the other sorts, but requires a cool situation; for the plants are subject to shoot upon the first mild weather in *February*, and so are often cut down by the frosts in *March*, which sometimes kills the shoots down to the old wood.

The twelfth sort grows naturally in *Tartary*. This hath a weak shrubby stalk, which rises near four feet high, covered with a green bark, and closely garnished by oblong oval leaves, which are hoary; the flowers are produced in close heads at the end of the branches, having a cluster of leaves under them; they are of a bright yellow colour, and are sometimes succeeded by short woolly pods, containing three or four small kidney-shaped seeds in each. This is propagated by seeds, which should be sown early in the spring, on a border of strong ground exposed to the east; for if they are sown where they have full sun, the plants will not thrive. It requires a cold situation and a pretty strong soil, otherwise it will not thrive.

The thirteenth sort grows naturally about *Algiers*. This rises with a soft shrubby stalk to the height of eight or ten feet, with many slender branches, garnished with small

wedge-shaped leaves, indented at the top, and of a dark green colour; the flowers come out single from the side of the branches, they are large and of a bright yellow colour, and are sometimes succeeded by pods containing three or four kidney-shaped seeds, which ripen in autumn. This sort is too tender to live in the open air through the winter in *England*, therefore the plants must be treated in the same way as those of the fourth sort; it is propagated by seeds in the same manner.

The fourteenth sort grows naturally in *Africa*; this rises with weak stalks about five feet high, which send out a few side branches, garnished by narrow, spear-shaped, Trefoil, woolly leaves, standing on long foot-stalks; the flowers grow in close spikes, upon long naked foot-stalks, which arise from the wings of the leaves; they are small, of a deep yellow colour, but do not produce seeds here. This requires the same treatment as the former sort.

The fifteenth sort grows naturally at the *Cape of Good Hope*; this hath a weak shrubby stalk near six feet high, sending out weak angular branches, like those of the common Broom, garnished by wedge-shaped small leaves growing by threes. The flowers come out in small slender bunches from the side of the stalks; they are small and of a pale yellow colour, but are rarely succeeded by seeds here. This must be propagated and treated in the same manner as the fourth sort.

The sixteenth sort grows naturally in the islands of *America*; it rises with a shrubby stalk eight or ten feet high, garnished by spear-shaped woolly leaves, placed by threes on each pedicle; that in the middle having a distinct foot-stalk, the two side lobes growing close to the principal foot-stalk. The flowers come out from the side of the branches, sometimes single, at other times in clusters; they are of a deep yellow colour, and about the size of those of the common Laburnum, and are succeeded by hairy pods about three inches long, which are sickle-shaped, ending with a long acute point; the seeds are roundish, a little inclined to a kidney shape, and are esteemed an excellent food for pigeons in *America*, from whence it had the title of Pigeon Pea.

This plant grows only in very warm countries, so cannot be preserved in *England*, unless it is placed in a warm stove. It rises easily from seeds in a hot-bed, and will grow three or four feet high the first year, provided they have a proper heat, and the second year they will produce flowers and seeds. The plants must be placed in the bark bed in the stove, and treated in the same manner as other tender plants from the same countries: they should have but little water in winter, and in the summer should have a large share of free air admitted to them in warm weather.

D A M

D AFFODIL. See Narcissus.

DAISIES. See Bellis.

DALECHAMPIA. Lin. Gen. Plant. 1022.

The Characters are,

It hath male and female flowers on the same plant; the male flowers have no petals, but many stamina. The female flowers have a roundish three-cornered germen, which afterward becomes a round three-cornered capsule, having three cells, each containing one roundish seed.

We have but one Species of this in England, viz.

DALECHAMPIA foliis trilobis glabris, floribus axillaribus caule volubili. Delachampia, with smooth trifoliate leaves, flowers growing from the sides of the branches, and a twining stalk.

This plant grows naturally in Jamaica. From the root composed of many fibres, arise several weak twining stalks, which fasten themselves to the neighbouring plants, and mount up to a considerable height; they are garnished at each joint by one trifoliate leaf, or more properly by a leaf divided into three lobes, for these are joined together at their base, which are smooth; the two side lobes are oblique to the midrib. The flowers are produced from the side of the stalks, three or four growing upon each foot-stalk; some of these are male, and others female; they are of an herbaceous colour, and small, so make no appearance; they have each a double involucre, made up of two orders of leaves, which are narrow, and armed with small bristly hairs, which sting the hands of those who unwarily touch them; the flowers are succeeded by roundish capsules, having three prominent lobes which are smooth, each inclosing a single seed.

This plant is propagated by seeds, which must be sown early in the spring on a hot-bed; and when the plants are three inches high, they should be carefully transplanted, each into a separate small pot, and plunged into a hot-bed of tanners bark, being careful to screen them from the sun, until they have taken new root; after which, they should have a great share of fresh air in warm weather. When the plants have grown so large as to fill these pots with their roots, they should be removed into larger, and placed in the bark bed in the stove; where they must be supported either with stakes, or a trellis, round which they will twine, and rise to the height of eight or ten feet.

The plants must be kept constantly in the stove, for they are too tender to bear the open air in this country, even in the summer season; therefore they should be placed with tender Convolvuluses, and other twining plants, near the back of the stove, where a support should be made for them; in summer they will flower, and in warm seasons will perfect their seeds in this country. These plants do not continue longer than one year, so that young plants should be raised annually to preserve the kind.

DAMASONIUM. Star-headed Water Plantain.

The Characters are,

It hath a flower composed of three petals, included in a three-leaved empalement, with a star-shaped fruit, which is full of oblong seeds.

D A P

The Species are,

1. DAMASONIUM stellatum. Lugd. Star-headed Water Plantain.

2. DAMASONIUM Americanum maximum, plantaginis folio, flore flavescente, fructu globofo. Plum. Greatest American Water Plantain, with a Plantain leaf, a yellowish flower, and a globular fruit.

The first of these plants is a native of England; it grows commonly in standing waters, which are not very deep. It is sometimes used in medicine, but never cultivated in gardens, so must be gathered for use in the places of its growth.

The second sort grows in Jamaica, Barbadoes, and several other places in the warm parts of America, where it is generally found in stagnating waters, and other swampy places; so that it would be difficult to preserve this plant in England, for it will not live in the open air, and requires a bog to make it thrive; but as it is a plant of no great beauty or use, it is not worth the trouble of cultivating in this country.

DANDELION. See Leontodon.

DAPHNE. Lin. Gen. Plant. 436. Spurge Laurel, or Mezereon.

The Characters are,

The flower hath no empalement; it is of one petal, cut into four parts at the top; it hath eight short stamina. The oval germen is situated at the bottom of the tube, which afterward becomes a roundish berry with one cell, inclosing one roundish fleshy seed.

The Species are,

1. DAPHNE racemis axillaribus, foliis lanceolatis glabris. Lin. Sp. Plant. 357. Male Laureola, commonly called Spurge Laurel.

2. DAPHNE floribus sessilibus ternis caulinis, foliis lanceolatis deciduis. Lin. Sp. Plant. 357. Thymelæa, with a deciduous Bay leaf, commonly called Mezereon.

3. DAPHNE floribus sessilibus axillaribus, foliis lanceolatis, caulibus simplicissimis. Lin. Sp. Plant. 356. Thymelæa, with smooth Milkwort leaves.

4. DAPHNE floribus sessilibus aggregatis axillaribus, foliis ovatis utrinque pubescentibus nervosis. Lin. Sp. Pl. 356. Thymelæa, with soft, white, fatty leaves, commonly called Tarton-raire.

5. DAPHNE floribus sessilibus aggregatis lateralibus, foliis lanceolatis obtusiusculis subtus tomentosis. Lin. Sp. Pl. 356. Alpine Chamelæa, with obtuse leaves hoary on their under side.

6. DAPHNE floribus congestis terminalibus sessilibus, foliis lanceolatis nudis. Lin. Sp. Plant. 357. This is the Cneorum. Matth. Hist. 46.

7. DAPHNE paniculâ terminali, foliis lineari lanceolatis acuminatis. Lin. Sp. Pl. 357. Thymelæa, with Flax leaves.

8. DAPHNE floribus terminalibus pedunculatis, foliis sparsis linearibus patentibus mucronatis. Lin. Sp. Plant. 358. Thymelæa, with a woolly head, and many small pointed leaves.

The first sort grows in the woods in many parts of England, and is commonly known by the title of Spurge Laurel; of late years there are poor people, who get the young plants out of the woods, and carry them about London to sell

fell in the spring. This is a low ever-green shrub, which rises with several stalks from the root, to the height of three feet, which are garnished with thick spear-shaped leaves, sitting pretty close to the branches, and are of a lucid green; between these, toward the upper part of the stalks, come out the flowers in small clusters, of a yellowish green colour, and appear soon after *Christmas*, if the season is not very severe; these are succeeded by oval berries, which are green till *June*, when they ripen and turn black, soon after which they fall off. The whole plant is of a hot caustick taste, burning and inflaming the mouth and throat. The leaves continue green all the year, which renders the plants ornamental in winter; and as they will thrive under tall trees, so are very proper to fill up the spaces in plantations.

The second sort grows naturally in *Germany*, and of late there hath been a discovery made of its growing in *England*, in some woods near *Andover*, from whence a great number of plants have been taken. This is a very ornamental shrub in gardens; the flowers come out very early in the spring, before others make their appearance. There are two distinct sorts of this, one with a white flower, which is succeeded by yellow berries, the other with Peach-coloured flowers and red berries. These are by some supposed to be accidental varieties arising from the same seeds, but I have several times raised these plants from seeds, and always found the plants come up the same, as those from which the seeds were taken, so they may be called different species. There is a variety of the Peach-coloured *Mezercon*, with flowers of a much deeper colour than the common, but these I have always found to vary in their colours when raised from seeds.

This shrub grows to the height of five or six feet, with a strong woody stalk, putting out many woody branches, so as to form a regular head; the flowers come out very early in the spring, before the leaves appear, growing in clusters all round the shoots of the former year; there are commonly three flowers produced from each knot or joint, standing on the same short foot-stalk, which have short swelling tubes divided into four parts at the top, which spread open; they have a very fragrant odour, so that where there are plenty of the shrubs growing together, they perfume the air to a considerable distance round them. After the flowers are past, the leaves come out, which are smooth, spear-shaped, and placed without order; they are about two inches long, and three quarters broad in the middle, gradually lessening to both ends; the flowers are succeeded by oval berries, which ripen in *June*; those of the Peach-coloured flowers are red, and those of the white yellow.

This is propagated by seeds, which should be sown on a border exposed to the east, soon after the berries are ripe; for if they are not sown till spring, they often miscarry, or at least remain a year in the ground, before the plants appear; whereas those which are sown in *August*, will many of them grow the following spring. When the plants come up, they will require no other care but to keep them clean from weeds, and may continue in the seed bed two summers, especially if they do not make great progress the first year; then at *Michaelmas*, when the leaves are shedding, they should be carefully taken up so as not to break or tear their roots, and planted into a nursery at about sixteen inches row from row, and eight inches asunder in the row. In this nursery they may remain two years, by which time they will be fit to remove to the places where they are designed to remain for good; the best time to transplant these shrubs is in autumn, for as the plants begin to vegetate very early in the spring, so it is not proper to transplant them at that season. The plants grow best in a light earth which is dry, for in cold wet land they become mossy, and make little progress.

Although the berries of this tree are so very acrid, as to burn the mouth and throat of those who may incautiously

taste them, yet the birds greedily devour them, as soon as they begin to ripen; so that unless the shrubs are covered with nets to preserve the berries, they will all be destroyed before they are fit to gather.

The third sort grows naturally in *Spain*, *Italy*, and the south of *France*, where it rises to the height of three or four feet, with a single stalk covered with a light coloured bark; the flowers come out in clusters on the sides of the stalks, which are of an herbaceous colour, so make but little appearance; they appear early in the spring, and are succeeded by small berries which are yellowish when ripe.

The fourth sort grows naturally in the south of *France*; this is a low shrubby plant, which sends out several weak stalks from the root, about a foot long, which spread about irregularly; they seldom become woody in *England*, but are tough and stringy, covered with a light bark; the leaves are small, of an oval form, and are very soft, white, and shining like fatten; these sit pretty close to the stalks; between these the flowers come out in thick clusters from the side of the stalks, they are white, and are succeeded by roundish berries having one hard seed. This flowers here in *June*, but doth not produce ripe seeds.

The fifth sort grows in the mountains near *Geneva*, and in other parts of *Italy*, where it rises about three feet high; the flowers of this come out in clusters from the side of the branches, early in the spring. The leaves are spear-shaped, ending in blunt points, and are hoary on their under side. The flowers are succeeded by small roundish berries, which turn red when ripe.

The sixth sort grows naturally on the *Alps*, as also upon the mountains of *Verona*. This is a very humble shrub, seldom growing more than one foot high with ligneous stalks, garnished with narrow spear-shaped leaves, which are placed round the stalks without order; the branches are terminated by small clusters of purple flowers which stand erect, having no foot-stalks; the tubes of these flowers are longer and narrower than those of the *Mezereon*, and the mouth is cut into four acute parts which are erect. The flowers emit a pleasant odour; they appear early in the spring, but do not produce seeds here.

The seventh sort grows naturally about *Montpelier*. This hath a shrubby stalk, about two feet high, dividing into many smaller branches, closely garnished with narrow spear-shaped leaves, ending in acute points; the ends of the branches are terminated by panicles of flowers, which are much smaller than those of the *Mezereon*, having swelling tubes, which are contracted at the mouth.

The eighth sort grows naturally at the *Cape of Good Hope*. This shrub rises to the height of five or six feet, dividing into several branches which grow erect, and are covered with white bark, and closely garnished with small narrow leaves, which come out on every side of the branches without order. The tops of the branches are terminated by woolly heads, out of which the flowers come in small clusters; they are white, having oblong tubes, which are divided into four obtuse segments at the mouth, which spread open.

The third, fourth, and seventh sorts are hardy, so will live through the winters in *England* in the open air, provided they are in a dry soil. The fifth and sixth sorts are as hardy as the common *Mezereon*, so are not in danger of being hurt by frost in *England*, but these are very difficult to keep in gardens, because neither of them will bear to be transplanted. I have several times raised the plants from seeds, which have succeeded well in the places where they were sown, but whenever they were removed, they certainly died, though performed at different seasons, and with the greatest care, and the same has happened to every other person who has raised any of these plants; and some of

my correspondents have assured me, they have frequently attempted to remove these plants from their natural places of growth, into their gardens, and have chosen plants of all sizes, from the youngest seedlings to the oldest plants, yet have never succeeded in it. Therefore those who are desirous to have these plants in their gardens, must procure their seeds, which should be immediately sown where they are designed to remain. The third, fourth, and seventh sorts, should be on a warm dry border, where, if there is a foundation of lime rubbish or chalk, under the surface of the ground, the plants will thrive better and continue much longer, than in good ground; all the culture they require, is to keep the place clean from weeds, for the less the ground is stirred near their roots, the better the plants will thrive; for they naturally grow on poor shallow land, and out of crevices of rocks, so the nearer the soil approaches to this, the more likely the plants will be to succeed.

The fifth and sixth sorts may have a cooler situation; if these are sown where they may have only the morning sun, they will thrive better than in a warmer situation, and the ground near the roots of these should not be disturbed; therefore in the choice of the situation, there should be regard had to this, not to sow them near other plants, which may require transplanting, or to have the ground dug or loosened. The seeds of these plants should be put up in wet Moss, if they are to be sent to any considerable distance, and should be sown as soon as they arrive.

The eighth sort grows naturally at the *Cape of Good Hope*, so will not live abroad through the winter in *England*, but requires a good green-house to preserve it. This plant is very difficult to keep or propagate in gardens.

DATISCA. *Lin. Gen. Pl.* 1003. Bastard Hemp.

The Characters are,

They have male and female flowers in different plants; the male flowers have a five-leaved empalement, but no petals, with ten summits. The female flowers have no petals, but empalements like the male, with an oblong perovious germen, and three styles, an oblong triangular capsule, with three valves, filled with small seeds adhering to the three sides of the capsule.

The Species are,

1. DATISCA *caule laevi. Lin. Sp. Pl.* 1037. Datisca with a smooth stalk.

2. DATISCA *caule hirsuto. Lin. Sp. Plant.* 1037. Datisca with a rough stalk.

The first sort grows naturally in *Crete*. It hath a perennial root, from which arise several herbaceous stalks, five feet high, garnished with winged leaves placed alternately, composed of three pair of lobes terminated by an odd one; they are deeply sawed on their edges, and of a light green colour. The flowers come out in long loose spikes from the side of the stalks at the wings of the leaves, but having no petals, make but a poor appearance. The summits of the male flowers being pretty long, and of a bright yellow colour, are the only visible parts of the flowers to be discerned at any distance.

The flowers on the female plants are succeeded by oblong three-cornered capsules filled with small seeds, which adhere to the three valves.

This sort may be propagated by parting the roots, which should be done in autumn, when the stalks decay (which is the best time to transplant the roots) but they must not be parted too small; they may be planted in any open beds, where they are not under the drip of trees, and will require no other culture, but to keep them clean from weeds.

The second sort grows naturally in *Canada*, and other parts of *North America*. This differs from the former, in having hairy stalks, which grow taller; the leaves are larger, and do not stand so near each other upon the stalks. It is equally hardy with the first sort, and may be propa-

gated in the same manner, but should have a more shady situation and a moister soil.

DATURA. *Lin. Gen. Plant.* 218. Thorn Apple.

The Characters are,

The flower hath one funnel-shaped petal, with a long cylindrical tube, which is pentangular, each angle being pointed; it hath five stamina, and an oval germen, which afterward becomes an oval capsule with four cells, which are filled with kidney shaped seeds adhering to the partition.

The Species are,

1. DATURA *fructu rotundo erecto, pericarpio spinoso.* Thorn Apple with a round prickly fruit, and a single white flower.

2. DATURA *fructu ovali erecto, pericarpio spinoso.* Thorn Apple with an oblong prickly fruit, and a Violet-coloured flower.

3. DATURA *caule tomentoso, calycibus bifidis cylindricis, floribus decangularibus, fructibus rotundis nutantibus.* Thorn Apple with a Henbane leaf, a flower wholly white, and a round hanging fruit set with harmless prickles.

4. DATURA *fructu rotundo nutante, pericarpio spinoso, spinis robustioribus.* Thorn Apple with strong spines.

5. DATURA *fructu oblongo, erecto, pericarpio spinoso, caule altissimo.* Thorn Apple with an oblong prickly fruit, and a white flower, commonly called *American Thorn Apple*.

6. DATURA *fructu rotundo nutante, pericarpio carnosio tuberculoso.* *Egyptian Thorn Apple* with a double flower, white on the inside, and Violet-coloured on the outside.

The sorts here enumerated are undoubtedly distinct species, though some have supposed part of them to be only feminal variations, but these also never vary from one sort to another; all the difference which any of them have ever shewn, has been in the double flowers becoming single; for which reason I have only mentioned one with double flowers, which sometimes changes to single, at other times they are with double and treble tubes, stretched out beyond each other like those Primroses called *Hose in Hose*. There is also a double flower of the third sort, which is much esteemed by the curious, but this frequently degenerates to single, so is not to be mentioned as a distinct species.

The first sort here enumerated, is the most common sort of Thorn Apple, and was probably first introduced from *Italy* or *Spain*, where it naturally grows; but it is now become so common about *London*, and near other great towns in *England*, as to appear like a native plant; for there are few gardens or dunghills without this plant in summer, though it is only near such places, where the plants may have been cultivated in the gardens; for where-ever any of these plants are permitted to feed, they will furnish a supply of the plants for some years to come, as they produce a vast quantity of seeds, some of which will lie years in the ground, and when they are turned up to the air will vegetate.

This sort seldom grows much more than two feet high, dividing into many strong, irregular, hollow branches, garnished with large, smooth, angular leaves, which when handled emit a foetid odour. The flowers come out first from the divisions of the branches, and afterward near their extremities; they have long swelling tubes, which are dilated at the top into large pentagonal brims, each angle ending in a long point or ligula; and are succeeded by large roundish seed vessels, covered with large thorns, and are divided by four furrows, to which adhere the partitions, which separate the four cells, filled with black kidney-shaped seeds. The seeds ripen in autumn, which, if permitted to scatter, will fill the ground about them with plants the following years.

The second sort grows naturally in many parts of *America*, the islands of the *West-Indies*, and also in some of the northern parts of *America*. It rises with a purple strong stalk to the height of five or six feet, dividing into many strong branches, garnished with leaves-shaped somewhat like those of the former

former sort, but larger, and have a greater number of angles and laciniae on their edges; the flowers have longer and narrower tubes, of a purple colour; the fruit is also much longer, and these differences are permanent. This is equally hardy with the former, and if the seeds are permitted to scatter, the plants will become troublesome weeds.

The third sort hath a strong woolly stem, which rises three feet high; the leaves of this sort are woolly and almost entire, having only two or three slight indentures on their edges: the flowers have very long tubes, which spread out very broad at the brim, and is divided into ten obtuse angles; they are of a pure white above, but the tubes have a tincture of green within. They are succeeded by roundish fruit, closely covered with long soft thorns, and are divided into four cells as the other, but the seeds of this are of a light brown colour when ripe.

This plant is not so hardy as the others, so the seeds must be sown upon a gentle hot-bed in the spring, and the plants must be afterward treated in the same manner as the Marvel of Peru, and other of the hardier kinds of annual plants, so may be transplanted into the full ground the latter end of May. They will flower in July, and the seeds will ripen in autumn.

The fourth sort is of humbler growth, seldom rising more than a foot and a half high, spreading out into many branches, garnished with leaves somewhat like those of the first sort, but smaller, and stand upon longer foot-stalks; the flowers are like those of the first sort, but smaller; the fruit is round, and armed with very strong sharp thorns. The seeds of this are black when ripe.

This sort is too tender to be sown in the full ground in England, so the plants should be raised on a hot-bed, and afterward transplanted into borders as the former sort.

The fifth sort grows naturally in North America; this resembles the first sort while young, but afterward greatly differs from it; the stalks of this rise five feet high, are very smooth, of a light lucid green, as are also the leaves; the flowers are longer, and have a greater resemblance to those of the second sort. These differences have always continued for above thirty years, where it has been cultivated in the gardens. It is equally hardy with the first, so will propagate itself in plenty, where it remains to ripen seeds.

The sixth sort grows naturally in Egypt, and also in India; this rises with a fine polished purple stalk, four feet high, dividing into several branches, garnished with large, smooth, sinuated leaves, standing upon pretty long foot-stalks. The flowers are produced at the divisions of the branches, and have large swelling tubes; which expand very broad at the top, where their brims turn backward. The flowers are of a beautiful purple on their outside, and a fatiny white within; some of these are single, others have two or three flowers standing one within another. They have an agreeable odour at first, but if long smelt to, become less agreeable, and are narcotick. If these plants are brought forward upon a hot-bed in the spring, and in June planted out on a warm border of rich earth, they will flower very finely in July and August; but unless they are covered with glasses, the seeds seldom ripen well in England. The fruit of this sort is round, and grows nodding downward; the seed vessel is thick and fleshy, as are also the intermediate partitions which divide the cells. The outside of the fruit is covered with blunt protuberances, and the seeds are of a bright brown colour when ripe.

DAUCUS. Lin. Gen. Pl. 296. The Carrot.

The Characters are,

It hath an umbelliferous flower. The flowers are all hermaphrodite, and have five heart-shaped petals, which turn inward; they have each five hairy stamina. The germen sits under the flower, which afterward becomes a roundish striated fruit, covered with stinging bristly hairs.

The Species are,

1. DAUCUS *seminibus hispidis, radice tenuiore servido*. Common wild Carrot.

2. DAUCUS *seminibus hispidis, radice carnofo esculento*. Manured Carrot, with an Orange-coloured root, commonly called Orange Carrot.

3. DAUCUS *radiis involucris planis, laciniis recurvis*. Prod. Leyd. 97. Shining Maritime Carrot.

4. DAUCUS *seminibus nudis*. Hort. Cliff. 89. Gingidium with an oblong umbel.

The first sort is the common wild Carrot, which grows by the side of fields, and in pasture grounds in many parts of England. The plants of this sort do not differ greatly in appearance from the Garden Carrot, which has led some persons into an opinion of their being the same plant, but those who have attempted to cultivate the wild sort, are fully convinced of their being distinct. The seeds of this sort are used in medicine, and are esteemed good to bring away gravel; it is an excellent diuretic, but instead of these seeds, the shops are usually supplied with old seeds of the Garden Carrot; when they have lost their vegetative quality, the seedsmen then sell them to druggists for medicinal use, when they cannot vend them to gardeners; but certainly all seeds which are too old to grow, can have little medicinal virtue remaining in them.

There are some varieties of the Garden Carrot, differing in the colour of their roots, which variations may be continued, where there is proper care taken not to mix the different sorts together, when they are left for seed; but the Orange Carrot is generally esteemed in London, so the yellow, the purple, and the white Carrots are seldom cultivated.

The second sort is commonly cultivated in gardens for the kitchen; and the different varieties of it are, in some places, esteemed, though in London the Orange Carrot is preferred to all the other.

Carrots are propagated at three different seasons, or sometimes oftener, where people are fond of having them young. The first season for sowing the seeds is soon after Christmas, if the weather is open, which should be in warm borders, near walls, pales, or hedges, but not immediately close thereto; but a border of Lettuce, or other young Sallad herbs, of about a foot wide, should be next the wall, &c. for if the Carrots are sown close to the wall, &c. they would draw up weak, without growing to have tolerable roots.

Carrots delight in a deep, warm, light, sandy soil, which should be dug two spades deep, that the roots may the better run down; for if they meet with any obstruction, they are very apt to grow forked, and shoot out lateral roots, but especially where the ground is too much dunged the same year that the seeds are sown, which will also occasion their being worm-eaten; but where there may be a necessity for dunging it the same year as the Carrots are sown, the dung should be well rotted, and thinly spread over the ground; and in the digging of it into the ground, great care should be taken to disperse it through the different parts, and not to bury it in heaps. Where the ground is inclinable to bind, there cannot be too much care taken to break and divide the parts; therefore in digging the land for Carrots, there should never be large spits taken, but they must be very thin, and the clods well broken; which, if not attended to by the master, is seldom properly performed by workmen, who are too apt to hurry over their work, if they are not well observed.

The ground when dug should be laid level and even, otherwise when the seeds are sown and the ground is raked over, part of the seeds will be buried too deep, and others will be in danger of being drawn up into heaps; so the plants will come up in bunches, and other parts of

the ground be naked, which should always be carefully avoided.

As these seeds have a great quantity of small forked hairs upon their borders, by which they closely adhere, so they are difficult to sow even, not to come up in patches; therefore they should be well rubbed with both hands, to separate them before they are sown; a calm day should be chosen to sow them, for if the wind blows, it will be impossible to sow the seeds equal; for as they are very light, they will be blown into heaps. When the seed is sown, the ground should be trodden pretty close, to bury them, then rake the ground level.

When the plants are come up, and have got four leaves, the ground should be hoed with a small hoe about three inches wide, cutting down all young weeds, and separating the plants to three or four inches distance each way, that they may get strength; and in about three weeks or a month after, when the weeds begin to grow again, the ground should be hoed over a second time, when there should be care taken not to leave two Carrots close to each other, and also to separate them to a greater distance, cutting down all weeds, and slightly stirring the surface of the ground in every place, the better to prevent young weeds from springing, as also to facilitate the growth of the Carrots.

In about five or six weeks after, you must hoe them a third time, to clear them from weeds as before; and now the Carrots should be separated to the distance they are to remain, which must be proportioned to the size they are intended to grow: if they are to be drawn while young, four or five inches asunder will be sufficient; but if they are to grow large before they are pulled up, they should be left eight or ten inches distant every way.

The second season for sowing these seeds is in *February*, on warm beds situated near the shelter of a wall, pale, or hedge; but those which are intended for the open large quarters, should not be sown before the beginning of *March*, nor should you sow any later than the end of the same month; for those which are sown in *April* or *May*, will run up to seed before their roots have any bulk, especially if the weather should prove hot and dry.

In *July* you may sow again for an autumnal crop, and at the end of *August* you may sow some to stand through the winter; by which method you will have early Carrots in *March*, before the spring sowing will be fit to draw; but these are seldom so well tasted, and are often very tough and sticky. However, as young Carrots are generally expected early in the spring, so most people sow some at this season; but these should be sown on warm borders and upon dry land, otherwise they are seldom good. Many people mix other sorts of feeds with these, as Leek, Onion, Parsnep, Radish, &c. especially in the kitchen gardens near *London*; but this method is not good, for, if there is a full crop of any one of these plants, there can be no room for anything else amongst them, so that what is got by the one is lost by another.

The covetousness of some gardeners will not permit them to cut out their Carrots to a proper distance when they hoe them, so that by leaving them close, they draw each other up weak; and if part of them are drawn while young, those which are left never recover their strength afterward so perfectly, as to grow near the size of those, which are properly thinned at their first hoeing.

This root has been long cultivated in gardens for the table, but has not till of late years been cultivated in the fields for cattle, nor has it been practised as yet, but in few parts in *England*; it is therefore greatly to be wished, that the culture of this root was extended to every part of *England*, where the soil is proper for the purpose; for there is scarce any root yet known, which more deserves it, being a very hearty good food for most sorts of animals. One acre of

Carrots, if well planted, will fatten a greater number of sheep, or bullocks, than three acres of Turneps, and the flesh of these animals will be firmer and better tasted. Horses are extremely fond of these roots, and for hogs there is not any better food. I have also known these roots cultivated for feeding of deer in parks; which has proved of excellent use in hard winters, when there has been a scarcity of other food; at which time, great numbers of deer have perished in some parks for want; and those which have escaped, have been so much reduced, as not to recover their flesh till very late the following summer; whereas those fed with Carrots have been kept in good condition all the winter, and upon the growth of the Grass in the spring, have been fat early in the season, which is an advantage, especially where the Grass is generally backward in its growth.

There is also an advantage in the cultivation of this root beyond that of the Turnep, because the crop is not so liable to fail; for as the Carrots are sown in the spring, the plants generally come up well; and unless the months of *June* and *July* prove very bad, there is no danger of the crop succeeding, whereas Turneps are frequently destroyed by the flies' at their first coming up; and in dry autumns they are attacked by caterpillars, which in a short time devour whole fields, but Carrots are not liable to such accidents: therefore every farmer who has a stock of cattle or sheep, should always have a supply of these roots, if he has land proper for the purpose, which must be light, and of a proper depth to admit of the roots running down.

In preparing of the land for Carrots in the open field, if it has not been in tillage before, it should be ploughed early in autumn, and then ploughed across again before winter, laying it up in ridges to mellow by the frost; and if the ground is poor, there should be some rotten dung spread over it in winter, which should be ploughed in about the end of *January*; then in *March*, the ground should be ploughed again to receive the seeds; in the doing of which, some farmers have two ploughs, one following the other in the same furrow, so that the ground is loosened a foot and an half deep or more: others have men with spades following the plough in the furrows, turning up a spit of earth from the bottom, which they lay upon the top, levelling it smooth and breaking the clods; the latter method is attended with a little more expence, but is much to be preferred to the first; because in this way the clods are more broken, and the surface of the ground is laid much even.

If the land has been in tillage before, it will require but three ploughings; the first just before winter, when it should be laid in high ridges for the reasons before given; the second cross ploughing should be in *January*, after which, if it is well harrowed to break the clods, it will be of great service; the last time must be in *March* to receive the seeds; this should be performed in the manner before mentioned: after this third ploughing, if there remain great clods of earth unbroken, it will be proper to harrow it well before the seeds are sown. One pound and an half of seed will be sufficient for an acre of land, but as they are apt to adhere together, so it renders them more difficult to sow than most other seeds; therefore some mix a quantity of dry sand with their seeds, rubbing them well together, so as to separate the Carrot seeds from each other, which is a good method. After the seeds are sown, they must be gently harrowed in to bury them; and when the plants come up, they should be hoed in the manner before directed, with this caution, to leave the plants at a greater distance.

But in order to preserve Carrots for use all the winter and spring, they should, about the beginning of *November*, when the green leaves are decayed, be dugged up, and laid in sand in a dry place, where the frost cannot come to them, taking them out from time to time as there is occasion for them.

The third sort grows naturally about *Montpelier*; this hath smoother stalks than the common Carrot, the segments of the leaves are broader, and of a lucid green; the umbels of flowers are larger, and not so regular.

The fourth sort is an annual plant, which grows naturally in *Spain* and *Italy*; it rises with an upright channelled stalk three feet high, garnished with smooth leaves, which are divided into many fine segments like those of Fennel; the stalks branch out upward, and each branch is terminated by a large umbel, composed of many small ones; the involucre is shorter than the umbel, and each of the leaves which compose it is trifid: the foot-stalks which sustain the small umbels (or rays) are long and stiff; these are by the *Spaniards* used for picking their teeth, from whence the plant had the title of *Visnaga*, or Pick-tooth. The seeds of this plant should be sown in autumn, for those which are sown in the spring frequently fail, or at least remain in the ground till the following year before they grow; the plants require no other culture but to keep them clean from weeds, and thin them where they are too close.

DAUCUS CRETICUS. See *Athamanta*.

D'AYENA. *Monier*.

This genus of plants receives its title from *Monseigneur Le Duc D'Ayen*, who is a great lover and promoter of the science of botany, and has a noble garden at *St. Germain's*, which is well stored with rare plants from many different parts of the world.

The Characters are,

The flowers arise from the wings of the stalk; they have a five-leaved empalement, and five heart-shaped petals. It hath five stamens inserted in a short nectarium, and a five-cornered germen, situated at the bottom of the nectarium, which afterward becomes a roundish five-cornered capsule, having five cells, each having one kidney-shaped seed.

We have but one Species of this genus, viz.

D'AYENA *inermis, foliis oblongo-cordatis, marginibus dentatis, floribus axillaribus*. Smooth D'AYENA, with oblong heart-shaped leaves indented on their edges, and flowers growing from the sides of the stalks.

This plant grows naturally in *Peru*; it hath a weak ligneous stalk a foot high, which divides into several slender horizontal branches, garnished with oblong heart-shaped leaves, which are slightly indented on their edges, standing upon pretty long foot-stalks; they are of a lucid green, and end in acute points. At the base of each foot-stalk, from the side of the branches, come out the flowers, two, three, or four, arising from the same point, each standing upon a separate slender foot-stalk, and have much resemblance to malvaceous flowers; they have a five-cornered germen at the bottom of the nectarium, which afterward becomes a roundish five-cornered capsule, having five cells, in each of these is lodged one kidney-shaped seed. The flowers are tubulous, and spread open at the top; they are purple, and continue in succession on the same plants, from *July* to the winter.

It is propagated by seeds, which should be sown upon a moderate hot-bed early in the spring; and when the plants have four leaves, they should be transplanted on a fresh hot-bed to bring them forward; part of them may be planted in small pots, and the others may be planted on the bed: those in the pots should be plunged into a hot-bed of tanners bark, and shaded till they have taken new root, then they must have free air admitted to them every day, in proportion to the warmth of the season. These plants should continue all the summer in the hot-bed, where they must have a good share of air, for those which are exposed to the open air will not thrive; and if they are too much drawn, they do not flower well, nor will they perfect their seeds, unless they are brought forward in the spring, and sheltered in summer.

DAY-LILY. See *Hemerocalis*.

DELPHINIUM. *Lin. Gen. Pl. 602*. Larkspur, or Larkheel.

The Characters are,

The flower is composed of five unequal petals; the upper petal is extended at the hinder part, into a tubular obtuse tail. It has a bifid nectarium situated in the center of the petals, and many small stamens, with three oval germen, which afterward become so many capsules joined together.

The Species are,

1. DELPHINIUM *nectariis monophyllis, caule subdiviso*. *Hort. Cliff. 217*. Corn Larkspur.

2. DELPHINIUM *nectariis monophyllis, caule ramoso, foliis multifidis linearibus*. Garden Larkspur, with a larger, single, blue flower, commonly called branching Larkspur.

3. DELPHINIUM *nectariis monophyllis, caule simplici*. *Hort. Cliff. 213*. Upright or unbranched Larkspur.

4. DELPHINIUM *nectariis diphyllis, capsulis solitariis, foliis multipartitis obtusis*. *Hort. Cliff. 213*. Broad-leaved Larkspur with a small flower.

5. DELPHINIUM *nectariis diphyllis, labellis bifidis, apice barbatis, foliis incis, caule erecto*. *Hort. Upsal. 151*. Perennial, hairy, Mountain Larkspur, with a Monkhood leaf, commonly called Bee Larkspur.

6. DELPHINIUM *nectariis diphyllis, labellis integris, floribus subsolitariis, foliis compositis linearimultipartitis*. *Hort. Upsal. 150*. Dwarf, narrow-leaved, perennial Larkspur, with an azure flower.

7. DELPHINIUM *nectariis diphyllis, labellis integris, floribus spicatis, foliis palmatis multifidis glabris*. Siberian Larkspur.

8. DELPHINIUM *villosum, nectariis diphyllis, labellis bifidis, foliis palmatis multifidis*. American perennial Larkspur.

9. DELPHINIUM *caule erecto simplici, foliis quinquelobatis, incis, glabris*. Smooth Portugal Larkspur, with a Monkhood leaf.

10. DELPHINIUM *nectariis diphyllis, foliis palmatis, lobis integris*. *Hort. Cliff. 213*. Larkspur with a Plane tree leaf, called Staveacre.

The several varieties of the Garden Larkspur are not here enumerated, but as the gardeners distinguish the Garden Larkspurs into those which are branched, and such as have upright stalks; which difference is permanent, so I shall just mention the varieties of both sorts. And first of the branched Larkspur, there are of the following colours, with single and double flowers.

Blue, purple, white, flesh, Ash, and Rose colours; and some have flowers beautifully variegated, with two or three of these different colours.

The upright or unbranched Larkspur, produces a greater variety of colours than the branched, and the flowers are larger and fuller than those; but the principal colours run nearly the same with those of the other, though many of the colours are deeper, and there are more different shades of these colours in the flowers of this sort.

The first sort grows naturally amongst the Wheat in *Cambridgehire*, and some other parts of *England*, where the flowers are of two colours, viz. blue and white.

The branching Larkspur, which is the second sort, comes later to flower than the upright, and has a very branching stalk; the branches come out horizontally from the side of the stalks, but afterward turn that part on which the spike of flowers grow upward, so as to make an angle; the leaves are long and finely divided, the flowers are placed thinner in the spikes than those of the upright sort; they are large, and some of them very double and of various colours.

The third sort hath upright stalks, which scarce put out any branches; the spikes of flowers grow erect, and the flowers are placed very close together, so that they make a fine appearance. These plants flower in *July* and *August*, and

and are very great ornaments to the borders of the flower-garden.

The plants are annual, so are every year propagated by seeds, which should be sown in the autumn in the places where the plants are designed to remain; but to continue a succession of these flowers, there should be some seeds sown in the spring. Where the seeds are sown on the borders of the flower-garden for ornament, it should be in small patches in the middle of the borders, at proper distances; in each of these patches may be scattered a few seeds, covering them over about a quarter of an inch with earth; in the spring, the plants may be thinned, leaving three or four of the upright sort in each patch to stand for flowering; but of the branching sort, not more than two, because these require room; after this the plants will require no farther care but to keep them clean from weeds, and when they begin to flower should be supported, to prevent their being broken by wind, especially if they are not in a sheltered situation. If the seeds are well chosen, there will be very few ordinary flowers among them; and if there are seeds of the different coloured flowers sown in each patch, they will make a pleasing variety: but the upright sort should never be mixed in the same patches with the branching, because they do not flower at the same time.

In order to preserve the two sorts fine without degenerating to single or bad colours, there should be a bed of each sort sown in autumn, in some separate part of the garden, where the plants should be properly thinned, and kept clean from weeds, till they begin to shew their flowers, when they should be carefully looked over every other day, to pull out all those plants, whose flowers are not very double or of good colours; for if these are permitted to stand among the others till their farina has impregnated them, it will certainly cause them to degenerate; so that those persons who are contented with only marking their good flowers for seed, and suffer the others to stand for seed among them, will always find themselves disappointed: therefore those who propose to have their flowers in perfection, should never gather the seeds of such as grew in the borders of the flower-garden; because there it will be almost impossible to preserve them so true, as when they are in beds at a distance from all other kinds.

When the seed vessels turn brown, they must be carefully watched, to gather them before they open and discharge the seeds; so that those which are situated on the lower part of the stalk, will open long before those on the upper part are ripe, for which reason the pods should from time to time be gathered as they ripen.

The fourth sort grows naturally in *Sicily* and *Spain*. This hath a very branching stalk, which rises about two feet high; the lower leaves are divided into many broad obtuse segments, but those which are upon the stalks are generally single; the flowers grow scatteringly toward the upper part of the branches, they are small and of a deep blue colour; these are succeeded by very small seed vessels, which are sometimes single, and at others double, and very rarely three together, as in the common sorts. This is an annual plant, whose seeds should be sown in autumn, and the plants treated as the common sort; it hath little beauty, and is only kept in some gardens for the sake of variety.

The fifth sort hath a perennial root, which sends out several upright stalks in the spring, rising five or six feet high, garnished with leaves which are divided into many broad segments, in form of a spreading hand; these segments are cut at their extremities into several acute points; they are hairy, and stand upon long foot-stalks; the flowers terminate the stalks, growing in long spikes; they are of a light blue, covered toward their hinder part with a mealy down.

The sixth sort grows naturally in *Siberia*. This hath a perennial root, which puts out two or three branching stalks, which rise a foot and an half high, garnished at each joint with leaves composed of many narrow segments, which terminate with several acute points; they are smooth, and of a light green colour; the flowers come out toward the upper part of the stalks singly, each standing upon a long naked foot-stalk; they are large, and of a fine azure colour.

The seventh sort grows naturally in *Siberia*. This is a perennial plant, which rises with many strong branching stalks, seven or eight feet high; the upper part of the stalks are of a fine purple colour, and are garnished with hand-shaped leaves, which are divided into four or five broad lobes, ending with many acute points; they are smooth, and stand upon long foot-stalks; the flowers terminate the stalks, growing in long spikes; they are of a fine blue colour, with a large bearded nectarium, having two lips; of a dark colour, resembling at a small distance the body of a bee, from whence some have titled this and also the fifth sort, Bee Larkspur.

The eighth sort grows naturally in *North America*. This is a perennial plant, which resembles the seventh, but the segments of the leaves are broader, the flowers are much smaller, and of a paler blue, and grow in longer spikes; the leaves of this are woolly, and the stalks seldom grow so tall; these differences are constant in the plants raised from seed.

The ninth sort grows naturally in *Portugal*. This rises with an upright unbranched stalk, about three feet high, garnished with smooth leaves divided into five obtuse lobes, which are cut on their edges into obtuse segments. The flowers are produced in short spikes at the extremity of the stalk; they are of a fine bright blue colour, and do not expand so broad as those of the former sorts.

All these perennial Larkspurs are propagated by seeds, which, if sown in autumn, will more certainly succeed, than those which are sown in the spring; when the plants come up, they should be kept clean from weeds, and where they are too close together, part of them should be drawn out, to allow room for others to grow till the following autumn, when they must be planted where they are to remain; the following summer they will flower, and the roots will continue many years growing in magnitude, so will produce a greater number of flower-stalks.

The tenth sort is an annual plant, which grows naturally in the *Levant*, as also in *Calabria*; this rises with a strong hairy stalk three feet high, garnished with hand-shaped hairy leaves, composed of five or seven oblong lobes, which have frequently one or two acute indentures on their sides; the flowers form a loose spike at the upper part of the stalk, each standing on a long foot-stalk; they are of a pale blue or purple colour, and have a two-leaved nectarium. This is propagated by seeds, which should be sown in autumn, for those sown in the spring never grow the same year. The seeds should be sown where the plants are to remain, and require no other treatment than the common Larkspur.

DENS CANIS. See *Erythronium*.

DENS LEONIS. See *Leontodon*.

DENTARIA. *Lin. Gen. Pl.* 726. Toothwort.

The Characters are,

The flower hath four obtuse petals placed in form of a cross, and six stamina, four of which are as long as the empalement, the other two are shorter. In the center is situated an oblong germen, which after-ward becomes a long taper pod with two cells, divided by an intermediate partition, opening with two valves, including many roundish seeds.

The Species are,

1. DENTARIA *foliis quinatis, foliolis acuminatis serratis*. Five-leaved Toothwort with sawed leaves.
2. DENTARIA *foliis inferioribus pinnatis, summis simplicibus*. Hort. Cliff. 335. Seven-leaved bulb-bearing Toothwort.
3. DENTARIA *foliis ternis ternatis*. Lin. Sp. Plant. 653. Three-leaved Toothwort.
4. DENTARIA *foliis summis digitatis*. Lin. Sp. Plant. 654. Five-leaved Toothwort with rough leaves.

The first sort rises with a strong stalk a foot and an half high, garnished with a leaf at each joint, composed of five lobes, which are four inches long, and near two broad, deeply sawed on their edges; they are smooth, and stand on long foot-stalks; the flowers grow in loose spikes at the top of the stalks; they are small, of a bluish colour, and are succeeded by long taper pods filled with small roundish seeds. It grows in the shady woods in the south of France and Italy.

The second sort rises with slender stalks about a foot high; the leaves at the bottom have seven lobes, those a little above five, others but three, and at the upper part of the stalk they are single: the flowers grow in clusters at the top of the stalk; these have four obtuse purple petals, and are succeeded by taper pods filled with roundish seeds.

The third sort rises with an upright stalk a foot high; the leaves are composed of nine lobes, three growing together, so that one leaf has three times three; the flowers grow in small bunches on the top of the stalks, and are succeeded by small taper pods filled with roundish seeds.

The fourth sort rises a foot and an half high; the lower leaves of this are composed of seven lobes, and those on the upper part of the stalk have five, they are rough and hairy: the flowers grow in loose spikes on the top of the stalks; they are white, and are succeeded by taper pods like the other sorts.

These plants grow on the mountains in Italy, and in the woods of Austria. The second sort is found wild in some parts of England, but particularly near Harefield, in Hertfordshire. This produces bulbs on the side of the stalks, where the leaves are set on, which, if planted, will grow and produce plants. The plants are propagated by seeds, or parting their roots; the seeds should be sown soon after they are ripe, in a light soil and a shady situation: in the spring the plants may be taken up where they grow too close, and transplanted out in the like soil and situation; where, after they have taken root, they will require no farther care, but to keep them clear from weeds: the second year they will produce flowers, and sometimes perfect their seeds.

The best time to transplant the roots is in October, when they should be planted in a moist soil and a shady situation; for they will not live in a dry soil, or when they are exposed to the sun.

DIANTHERA. Lin. Gen. Plant. 37.

The Characters are,

The flower is of the grinning kind, with a short tube; it hath two stamina, one of which hath a twin summit, the other is a little taller, and an oblong germen. The empalement afterward becomes a capsule with two cells, which open with an elasticity, casting a single flat seed out of each cell.

The Species are,

1. DIANTHERA *spicis solitariis*. Lin. Syst. Dianthera with a single spike.
2. DIANTHERA *spicis filiformibus venticillatis, inferioribus umbellatis*. Lin. Syst. Dianthera with whorled spikes, and umbels below.

The first sort grows naturally in Virginia, and other parts of North America. This is a low herbaceous plant with a

perennial root, which sends out upright stalks a foot high, garnished with long narrow leaves of an aromattick odour, standing close to the stalks; from the side of the stalks the foot-stalks of the flowers are produced, sustaining small spikes of flowers.

This plant is very difficult to preserve in this country, for although it is hardy enough to live in the open air in England, yet it is very subject to rot in winter; and if it is placed under shelter, it is apt to draw up weak, and soon after decay, so that at present the plants are rare in this country.

The second sort grows naturally in Jamaica; it has hairy stalks near a foot high, garnished with narrow leaves placed opposite. The flowers are produced in slender spikes, which on the lower part of the stalk is placed in whorls, but at the top they come out without order; the flowers are of a pale purple colour, and being small make no appearance.

It may be propagated by seeds, which must be sown upon a hot-bed, and when the plants are fit to remove, they must be planted in pots, and plunged into a fresh hot-bed; they must be kept in the stove, and treated like other tender plants from the same country.

DIANTHUS. Lin. Gen. Plant. 500. Clove Gillyflower, Carnation and Pink.

The Characters are,

The flower hath a cylindrical empalement of one leaf, scaly below, with five petals, whose tails are as long as the empalement, but their upper part is broad, plain, and spread open. It hath ten stamina. In the center is situated an oval germen, which afterward becomes a cylindrical capsule with one cell, opening in four parts at the top, filled with compressed angular seeds.

The Species are,

1. DIANTHUS *floribus solitariis, squamis calycinis lanceolatis binis, corollis crenatis*. Hort. Cliff. 164. Common narrow-leaved wild Pink.
2. DIANTHUS *caule subunifloro, corollis crenatis, squamis calycinis brevissimis, foliis subulatis*. Lin. Sp. Pl. 412. English small creeping or maiden Pink, commonly called the Matted Pink by seedsmen.
3. DIANTHUS *floribus subsolitariis, squamis calycinis lanceolatis quaternis, corollis crenatis*. Hort. Cliff. 164. Branching Pink, with a white flower having a purple circle, commonly called Mountain Pink.
4. DIANTHUS *floribus solitariis, squamis calycinis subovatis brevissimis, corollis multifidis fauce pubescentibus*. Lin. Sp. Plant. 411. Single wild Pink, with a small, pale, reddish flower.
5. DIANTHUS *floribus solitariis squamis calycinis subovatis brevissimis, corollis crenatis*. Hort. Cliff. 164. Single Garden Carnation with a large flower.
6. DIANTHUS *floribus aggregatis fasciculatis, squamis calycinis lanceolatis villosis tubum æquantibus*. Hort. Cliff. 165. Bearded wild Pink, called Deptford Pink.
7. DIANTHUS *floribus aggregatis fasciculatis, squamis calycinis linearibus, foliis lanceolatis*. Broad-leaved Garden Sweet William.
8. DIANTHUS *floribus aggregatis capitatis, squamis calycinis ovatis obtusis muticis tubum superantibus*. Lin. Sp. Pl. 410. Wild childing Sweet William.
9. DIANTHUS *floribus aggregatis capitatis, squamis calycinis lanceolatis aristatis, corollis crenatis*. Italian umbellated Mountain Pink, with flowers varying from yellow to an iron colour in the same cluster.
10. DIANTHUS *floribus solitariis, squamis calycinis subulatis patulis, tubum æquantibus, corollis crenatis*. Hort. Cliff. 164. The China Pink.
11. DIANTHUS *caulibus unifloris squamis calycinis ovatis, corollis multifidis, foliis linearibus*. Flor. Suec. 318. Dwarf wild Pink with one flower.

12. *DIANTHUS caule unifloro, corollis crenatis, squamis calycinis exterioribus tubum æquantibus, foliis linearibus obtusis.* Lin. Sp. Pl. 412. Dwarf broad-leaved Pink.

The first sort hath a short ligneous stalk, from which come out several tufted heads closely garnished with long narrow leaves, whose base lie over each other embracing the stalks; between these arise the flower-stalks, which grow about nine inches high, garnished at every joint by narrow grassy leaves placed opposite. The stalks are terminated by a single flower of a pale red colour. This is rarely admitted into gardens, the flower having little beauty.

The second sort is a low trailing plant, whose stalks lie on the ground; they grow very close together, and are garnished with short, narrow, grassy leaves of a deep green colour; the stalks are terminated by small red flowers, each standing upon a separate foot-stalk. This sort grows naturally in several parts of *England*, so is not now often cultivated in gardens, but formerly the seeds were sown to make edgings for the borders of the flower-garden by the title of Matted Pink, by which the seeds were sold in the shops.

The third sort grows naturally upon *Chidder* rocks in *Somersetshire*, and some other parts of *England*; this was formerly cultivated in the gardens, by the title of Mountain Pink. It hath a resemblance of the second sort, but the leaves are shorter, of a grayish colour; the stalks grow taller and branch more; the flowers are larger, of a white colour with a purple circle at the bottom, like that sort of Pink called Pheasant's Eye. As the flowers of this sort have no scent, the plants are seldom kept in gardens.

The fourth sort grows naturally in several parts of *England*, frequently upon old walls; it is a small single Pink of a pale red colour, so is not cultivated in gardens.

The fifth sort is a small single Carnation, which has been long cast out of all the gardens; from some one of this sort, it is supposed the fine flowers now cultivated in the gardens had their original.

The sixth sort grows naturally in several parts of *England*, and particularly in a meadow near *Deptford* in *Kent*, from whence it had the title of *Deptford* Pink. This is of the kind called Sweet William; the flowers of these grow in close clusters at the end of the branches; they are red, and have long bearded empalements. I have never observed this to vary.

The seventh sort is the common Sweet William, which has been long cultivated in the gardens for ornament, of which there are now great varieties which differ in the form and colour of their flowers, as also in the size and shape of their leaves; those which have narrow leaves were formerly titled Sweet Johns by the gardeners, and those with broad leaves were called Sweet Williams; there are some of both these sorts with double flowers, which are very ornamental plants in gardens.

The eighth sort grows naturally in the south of *France*, in *Spain* and *Italy*; this is an annual plant, which rises with an upright stalk about a foot high, garnished with narrow grassy leaves, and is terminated by a small head of pale red flowers, which are included in one common scaly empalement. These have little beauty, so the plants are seldom kept in gardens.

The ninth sort is a perennial plant, which rises with an upright stalk a foot and an half high, having long narrow leaves placed opposite at each joint, which embrace the stalk with their base; they are of a deep green colour, stiff, and end in acute points. The flowers grow in close clusters at the top of the stalks, having stiff bearded empalements; they are yellow and iron-coloured, intermixed on the same stalk, and frequently there are of both colours in the same

head. The roots will continue several years, and annually flower and seed; but the young plants of the second year, always produce the strongest flowers.

The tenth sort came originally from *China*, so it is titled the *China* Pink; the flowers of this have no scent, but there are a great variety of lively colours among them, and of late years there has been great improvements made in the double flowers of this sort, some of which are as full of petals as the double Pink, and their colours are very rich. The plants seldom grow more than eight or nine inches high, branching out on every side; the branches grow erect, and are terminated each by a single flower. They are commonly raised every year from seeds, but the roots will continue two years in dry ground.

The eleventh sort is found growing naturally upon old walls and buildings in many parts of *England*; this is a single small Pink of a sweet odour, but of a pale colour, so makes no appearance; and since the great improvement which has been made in these flowers by culture, this hath been entirely neglected.

The twelfth sort grows naturally on the *Alps*; this hath broad, short, blunt leaves; the stalks seldom rise more than four inches high, each being terminated by a single flower of a pale red colour. It is sometimes preserved in botanick gardens for the sake of variety, but is rarely admitted into other gardens.

The sorts here enumerated, are such as the botanists allow to be distinct species; and all the varieties of fine flowers, which are now cultivated in the gardens of the curious, are supposed to be only accidental variations which have been produced by culture; the number of these are greatly increased annually, in many different parts of *Europe*; so that as new varieties are obtained, the old flowers are rejected.

The plants of this genus may be properly enough divided into three sections. The first to include all the variety of Pinks, the second all the Carnations, and the third those of the Sweet William; for although these agree so nearly in their principal characters, as to be included under the same genus by the botanists, yet they never vary from one to the other, though they frequently change and vary in the colour of their flowers.

I shall proceed therefore to treat of these under their different sections: and first I shall begin with the Pink, of which there are a great variety now cultivated in the gardens; the principal of which are, the damask Pink, the white Shock, the Pheasant Eye with double and single flowers, varying greatly in their size and colour, the Cob Pink, Dobson's Pink, and Bat's Pink. The old Man's Head, and Painted Lady Pink, rather belong to the Carnation.

The damask Pink is the first which flowers of the double sorts; this hath a short stalk, the flower is not very large, and not so double as many others; the colour is of a pale purple inclining to red, but is very sweet.

The next which flowers is the white Shock, which was so called from the whiteness of its flowers, and the borders of the petals being much jagged and fringed; the scent of this is not so agreeable as that of some others.

Then comes all the different kinds of Pheasants Eye, of which there are frequently new varieties raised, which are either titled from the persons who raised them, or the places where they were raised; some of these have very large double flowers, but those which burst their pods, are not so generally esteemed.

The Cob Pink comes after these to flower; the stalks of this are much taller than those of any of the former; the flowers are very double, and of a bright red colour; these have the most agreeable odour of all the sorts, so merit a place

place in every good garden. The time of the Pinks flowering is from the latter end of *May* to the middle of *July*, and frequently that sort of Pheasant Eye, which is called Bat's Pink, will flower again in autumn.

The old Man's Head Pink, and the Painted Lady, do not flower till *July*, coming at the same season with the Carnation, to which they are more allied than the Pink. The first when it is in its proper colours, is purple and white, striped and spotted, but this frequently is of one plain colour, which is purple; this sort will continue flowering till the frost in autumn puts a stop to it, and the flowers having an agreeable scent renders them valuable. The Painted Lady is chiefly admired for the liveliness of its colour, for it is not so sweet, or of so long continuance as the other.

The common Pinks are propagated either by seeds, which is the way to obtain new varieties, or by making layers of them as is practised for Carnations, or by planting slips, which, if carefully managed, will take root very well.

If they are propagated by seeds, there should be care taken in the choice of them, and only the seeds of the best sorts saved, where persons are curious to have the finest flowers. These seeds may be sown in the spring, and the plants afterward treated in the same manner as is hereafter directed for the Carnation: with this difference only, that as the Pinks are less tender, so they may be more hardily treated. Those which are propagated by layers, must be also managed as the Carnation, for which there are full instructions hereafter given. The old Man's Head and Painted Lady Pinks are commonly propagated this way, but most of the other sorts are propagated from slips.

The best time to plant the slips of Pinks is about the end of *July*, when, if there should happen rain, it will be of great service to them; but if the weather be dry, they will require to be constantly watered every other day, until they have taken root; these should be planted in a shady border, and the ground should be dug well, and all the clods broken, and if no rain falls, it should be well soaked with water a few hours before the slips are planted; then the slips should be taken from the plants, and all their lower leaves stripped off, and planted as soon as possible after, for if they are suffered to lie long after they are taken from the plants, they will wither and spoil; these need not be planted at a greater distance than three inches square, and the ground must be closed very hard about them; then they must be well watered, and this must be repeated, as often as it is found necessary, till the cuttings have taken root; after which they will require no other care but to keep them clean from weeds till autumn, when they should be transplanted to the borders of the flower-garden where they are to remain: there are some who plant the slips of Pinks later in the season than is here directed, but these plants are never so strong nor flower so well, as those which are early planted.

We shall next proceed to the culture of the Carnation; these the florists distinguish into four classes.

The first they call Flakes; these are of two colours only, and their stripes are large, going quite through the petals.

The second are called Bizarrs; these have flowers marked or variegated with three or four different colours, in irregular spots and stripes.

The third are called Piquettes; the flowers of these have always a white ground, and are spotted (or pounced, as they call it) with scarlet, red, purple, or other colours.

The fourth are called Painted Ladies; these have their petals of a red or purple colour on their upper side, and are white underneath.

Of each of these classes there are numerous varieties, but particularly of the Piquettes, which some years ago were chiefly

in esteem with the florists, but of late years the Flakes have been in greater request than any of the other kinds. To enumerate the varieties of the principal flowers in any one of these classes, would be needless, since every country produces new flowers almost every year; so that those flowers, which, at their first raising, were greatly valued, are in two or three years become so common, as to be of little worth, especially if they are defective in any one property. Therefore (where flowers are so liable to mutability, either from the fancy of the owner, or that better kinds are yearly produced from seeds, which, with good florists, always take place of older, which are turned out of the garden to make room for them) it would be but superfluous in this place to give a list of their names, which are generally borrowed either from the names and titles of noblemen, or from the person's names, or places of abode, who raised them.

These flowers are propagated either from seeds (by which new flowers are obtained), or by layers, for the increase of those sorts which are worthy maintaining; but I shall first lay down the method of propagating them from seed, which is thus:

Having obtained some good seeds, either of your own saving, or from a friend that you can confide in, about the middle of *April*, prepare some pots or boxes (according to the quantity of seed you have to sow); these should be filled with fresh light earth mixed with rotten neats dung, which should be well incorporated together; then sow your seeds thereon (but not too thick), covering it about a quarter of an inch with the same light earth, placing the pots, or cases, so as to receive the morning sun only, till eleven of the clock, observing also to refresh the earth with water as often as it may require; in a month or five weeks the plants will come up, and if kept clear from weeds, and duly watered, will be fit to transplant about the latter end of *June*; at which time should be prepared some beds (of the same sort of earth as was directed to sow them in) in an open airy situation, in which they should be planted at the distance of three inches square, observing to water and shade them; till they have taken new root, then they must be kept clear from weeds; in these beds they may remain till the end of *August*, by which time they will have grown so large as almost to meet each other; then prepare some more beds of the like good earth (in quantity proportionable to the flowers raised), in which they should be planted at six inches distance each way, and not above four rows in each bed, for the more conveniently laying such of them as may prove worthy preserving; for in these beds they should remain to flower.

The alleys between these beds should be two feet wide, that persons may pass between the beds to weed and clean them. If the season should prove very dry at this time, they should not be transplanted till there is some rain, so that it may happen to be the middle, or latter end of *September* some years, before there is wet enough to moisten the ground for this purpose; but if there is time enough for the plants to get good root before the frost comes on, it will be sufficient. If the winter should prove severe, the beds should be arched over with hoops, that they may be covered with mats, otherwise many of the plants may be destroyed, for the good flowers are not so hardy as the ordinary ones of this genus. There will be no other culture wanting to these, but to keep them clean from weeds, and when they shoot up their stalks to flower, they must be supported by sticks to prevent their breaking. When the flowers begin to blow, they must be looked over to see which of them proffer to make good flowers; as soon as that can be discovered, all the layers upon them should be laid; those which are well marked, and blow whole without breaking their pods, should be reserved to plant in borders, to

furnish seeds; and those which burst their pods, and seem to have good properties, should be planted in pots, to try what their flowers will be, when managed according to art; and it is not till the second year of flowering, that any person can pronounce what the value of a flower will be; but in order to be well acquainted with what the florists call good properties, I shall here set them down.

1. The stem of the flower should be strong, able to support the weight of the flower without nodding down.

2. The petals of the flower should be long, broad, and stiff, and pretty easy to expand, or (as the florists term them) should be free flowerers.

3. The middle pod of the flower should not advance too high above the petals in the other part of the flower.

4. The colours should be bright, and equally marked all over the flower.

5. The flower should be very full of leaves, so as to render it, when blown, very thick and high in the middle, and the outside perfectly round.

Having made choice of such flowers as promise well, these should be marked separately for pots, and the round whole blowing flowers for borders; all single flowers, or such as are ill-coloured and not worth preserving, should be drawn out, that the good flowers may have the more air and room to grow strong; when the layers of the good flowers have taken root (which will be some time in *August*), they should be taken off and planted out; those that blow large, in pots, and the other in borders (as hath been already directed).

Of late years, the whole-blowing flowers have been much more esteemed than those large flowers which burst their pods; but especially those round flowers which have broad stripes of beautiful colours, and round Rose leaves, of which kinds there have been a great variety introduced from *France*, within these few years; but as these *French* flowers are extremely apt to degenerate to plain colours, and being much tenderer than those which are brought up in *England*, there are not such great prices given for the plants now, as was a few years past: from the present taste for these whole-blowing flowers, many of the old varieties, which had been turned out of the gardens of the florists, have been received again; and large prices have been paid of late for such flowers as some years ago were sold for one shilling a dozen, or less, which is a strong proof of the variableness of the fancies of the florists.

I shall next proceed to give some directions for propagating these by layers, and the necessary care to be taken of them to have large and fair flowers.

The best season for laying these flowers is in *July*, as soon as the shoots are strong enough for that purpose: it is performed in the following manner: after having stripped off the leaves from the lower part of the shoot intended to be laid, make choice of a strong joint about the middle of the shoot (not too near the heart of the shoot, nor in the hard part next the old plant); then with a penknife make a slit in the middle of the shoot, from the under side of the joint upward half the way or more, to the joint next above it, according to the distance of the joints; then with your knife cut the tops of the leaves, and also cut off the swelling part of the joint where the slit is made, so that the part slit may be shaped like a tongue; (when that outward skin is pared off, which, if left on, would prevent their pushing out roots); having loosened the earth round the plant, and, if need be, raised it with fresh mould, that it may be level with the shoot intended to be laid, lest by the ground being too low, by forcing down the shoot it should be split off; then make a hollow place in the earth, just where the shoot is to come, and bend the shoot gently into the earth, observing to keep the top as upright as pos-

sible, that the slit may be open; and being provided with forked sticks for that purpose, thrust one of them into the ground, so that the forked part may take hold of the layer, to keep it down in its proper place; then gently cover the shank of the layer with the same sort of earth, giving it a gentle watering, to settle the earth about it, observing to repeat the same as often as is necessary, to promote their rooting. In about five or six weeks after this, the layers will have taken root sufficient to be transplanted; then those which are intended for pots, should be each planted in a separate small pot, placing them in the shade until they have taken fresh root; after which they may be removed into a more open situation, where they may remain till the middle of *November* (if the weather continues so long good) when the pots should be put under a common frame, where they may enjoy the open air at all times when the air is mild, but screened from hard rains, snow and frost.

Where there is conveniency, the layers, which are intended for the common borders, may be planted upon a bed at about three inches asunder each way, and in winter covered with a frame, or else arched over with hoops, and in bad weather covered with mats, which will secure them till spring, when they may be taken up with balls of earth, and planted where they are designed to flower.

Those layers, which were planted in small pots in the autumn, should, in the spring, be turned out of those pots, preserving the earth to their roots, paring off the outside with the matted roots, and put into the pots they are designed to remain for good. The best compost for these flowers is as follows:

Make choice of some good upland pasture, or a common that is of an hazel earth, or light sandy loam; dig from the surface of this about eight inches deep, taking all the turf with it; let this be laid in an heap to rot and mellow for one year, turning it once a month, that it may sweeten; then mix about a third part of rotten neat's dung, or for want of that some rotten dung from a Cucumber, or a Melon bed; let this be well mixed together, and if you can get it time enough before-hand, let them lie mixed six or eight months before it is used, turning it several times, the better to incorporate their parts. But as the layers, which are made from such roots as have been forced to flower the same year, do seldom succeed so well the next, it will be a good method to plant two or three layers of each of the best kinds in a bed of fresh earth not over dunged; which plants should only be suffered to shew their flowers, that their colours may be known to be perfect in their kind; and when satisfied in that particular, the flowers should be cut off the stems, and not suffered to spend the roots in blowing, by which means the layers will be strengthened. And from some of the best plants of these, the layers should be taken for the next year's blowing, always observing to have a succession of them yearly, by which means every year a fine bloom of these flowers may be expected, supposing the season favourable. When the plants which are intended to flower, are put into the larger pots in the spring, they should be placed in a situation where they may be defended from the north wind; observing to give them gentle waterings, as the season may require.

Here they may remain till the middle, or latter end of *April*, when a stage of boards should be made to set the pots upon, which should be so ordered as to have little cisterns of water round each post, to prevent the insects from getting to the flowers in their bloom; which, if they are suffered to do, they will destroy all the flowers in a short time: the chief and most mischievous insect in this case is, the earwig, which will gnaw off all the lower parts of the petals of the flowers (which are very sweet), and thereby cause the whole flower to fall to pieces; but since the mak-

ing one of these stages is somewhat expensive, and not very easy to be understood by such as have not seen them, I shall describe a very simple one, which I have used for several years, which answers the purpose full as well as the best and most expensive one can do. First, prepare some common flat pans, about two feet over, and three inches deep, place these two and two opposite to each other, at about two feet distance, and at every eight feet in length. In each of these turn a flower-pot upside down, then lay a piece of flat timber, about two feet and an half long, and three inches thick, cross from pot to pot, the whole length of the stage; then lay the planks lengthways upon these timbers, which will hold two rows of the size for these pots which are proper for the Carnations; and when you have set the pots upon the stage, fill the flat pans with water, always observing, as it decreases in the pans, to replenish it, which will effectually guard your flowers against insects, for they do not care to swim over water; so that if by this, or any other contrivance, the passage from the ground to the stage, on which the pots are placed, is defended by a surface of water four or five inches broad, and as much in depth, will effectually prevent these vermin from getting to the flowers.

This stage should be placed in a situation open to the south east, but defended from the west winds, to which these stages must not be exposed, lest the pots should be blown down by the violence of that wind, which is often very troublesome at the season when these flowers blow; indeed they should be defended by trees at some distance, from the winds of every point; but these trees should not be too near the stage, nor by any means place them near walls, or tall buildings, for in such situations the stems of the flowers will draw up too weak. About the middle of *April*, the layers will begin to shoot up for flower; therefore there should be provided some deal sticks, about four feet and an half long, which should be thicker toward the bottom, and planed off taper at the top; these sticks should be carefully stuck into the pots as near as possible to the plant, without injuring it; then with a slender piece of bass mat, fasten the stalk of the flower to the stick to prevent its being broken; this must be often repeated as the stalk advances in height, and all the side stalks must be pulled off as they are produced, never letting more than two stalks remain upon one root, nor above one, if they are intended to blow exceeding large. Toward the beginning of *June* the flowers will most of them have attained their height, and their pods will begin to swell, and about the end some of the earliest begin to open on one side; therefore the pods must be opened in two other places, at equal angles; this must be done as soon as the pod breaks, otherwise the flower will run out on one side, and be in a short time past recovering, so as to make a complete flower. In a few days after the flowers begin to open, they must be covered with glasses which are made for that purpose, in the following manner:

Upon the top of the glass, exactly in the center, is a tin collar, or socket, about three-fourths of an inch square, for the flower-stick to come through; to this socket are soldered eight slips of lead at equal distances, which are about six inches and an half long, and spread open at the bottom about four inches asunder; into these slips of lead are fastened slips of glass, cut according to the distances of the lead, which, when they are fixed in, are bordered round the bottom with another slip of lead quite round, so that the glass hath eight angles, with the socket in the middle, and spread open at the bottom about eleven inches wide.

When the flowers are open enough to be covered with these glasses, a hole must be made with an awl through the flower-stick, exactly to the height of the under part of the pod, through which should be put a piece of small wire

about six inches long, making a ring at one end of the wire to contain the pod, into which ring should the stem of the flower be fixed, taking off all the tyings of bass; and the stem of the flower must be placed so far from the stick, as may give convenient room for the flower to expand without pressing against it; to which distance it may be fixed, turning the wire so as not to draw back through the hole; then make another hole through the stick, at a convenient distance above the flower, through which should be put a piece of wire, an inch and an half long, to support the glasses from sliding down upon the flowers, observing that the glasses are not placed so high as to admit the sun and rain under them to the flowers, nor so low as to scorch their leaves with the heat. At this time also, or a few days after, should be cut some stiff paper, cards, or some such thing, into collars about four inches over, and exactly round, cutting a hole in the middle of it about three-fourths of an inch diameter, for the bottom of the flower to be let through; then place these collars about them, to support the petals of the flower from hanging down; this collar should be placed within side the calyx of the flower, and should be supported thereby. If, as the flowers blow, one side comes out faster than the other, the pots should be turned about, to shift the other side toward the sun; and, if the weather proves very hot, the glasses should be shaded in the heat of the day with Cabbage leaves, &c. to prevent their being scorched, or forced out too soon; and, when the middle pod begins to rise, the calyx must be pulled out with a pair of nippers made for that purpose; but this should not be done too soon, lest the middle part of the flower should advance too high above the sides, which will greatly diminish the beauty of it. And when the flowers are fully blown, if they are cut off, a fresh collar of stiff paper should be put on, which should be cut exactly to the size of the flower, that it may support the petals to their full width, but not to be seen wider than the flower in any part: when this is put on, the widest leaves should be spread out, to form the outside of the flower, which although they should happen to be in the middle (as is often the case), yet by removing the other leaves they may be drawn down, and so the next longest leaves upon them again, that the whole flower may appear equally globular without any hollow parts. In the doing of this, some florists are so curious as to render an indifferent flower very handsome; and on this depends, in a great measure, the skill of the artist to produce large fine flowers.

The directions here given are chiefly for the management of those large Carnations, which require the greatest skill of the florists, to have them in perfection; but as of late years these have not been so much in esteem as formerly, and those flowers which do not break their pods have now the preference. These are generally planted in pots, and treated in the same way as the large flowers, but do not require so much trouble to blow them: all that is necessary to be done for these, is to fasten their stems up to flower-sticks to prevent their being broken, and to take off the pods which proceed from the side of the stalks, leaving only the top bud to flower, if they are intended to be large and fair; and when the flowers begin to open, if they are screened from the sun in the heat of the day, and also from wet, they will continue much longer in beauty.

The layers which are planted in the full ground, generally produce seeds better than those in pots; therefore whoever proposes to raise a supply of new flowers from seeds, must always observe to save the best of their seedling flowers for this purpose; for it is well known, that after any of these flowers have been a few years propagated by layers, they become barren, and do not seed; which is also the case with many other plants, which are propagated by slips, layers, or cuttings; so that the young plants which have

been newly obtained from seeds, are always the most productive of seeds.

I shall next proceed to the culture of that species, which is commonly known by the title of Sweet William: of this there are a great variety of different colours, which are single, and three with double flowers: some of these have narrow leaves, which were formerly titled Sweet Johns, but of late that distinction has not been made, because they are found to vary when raised from seeds.

Some of the single flowers have very rich colours, which frequently vary in those of the same bunch; there are others with fine variegated flowers, and others whose middles are of a soft red, bordered with white, which are called Painted Ladies; but where persons are desirous to preserve any of these varieties in perfection, the best flowers of each should be particularly marked, and no other permitted to stand near them, lest their farina should impregnate them, which would cause them to vary.

That which is called the Painted Lady Sweet William, is a very beautiful variety; the stalks of this do not rise so high as most of the other; the bunches of flowers are larger, and produced more in the form of an umbel, the flowers standing equal in height, make a better appearance: there are others whose stalks rise three feet high, and the flowers are of a very deep red or scarlet colour. These all flower at the same time with the Carnations, which renders them less valuable, because they have no scent.

The single kinds of these flowers are generally propagated by seeds, which must be sown the beginning of *April*, in a bed of light earth, and in *June* they will be fit to transplant out, at which time must be prepared some beds ready for them; they should be planted six inches distance every way: in these beds they may remain till *Michaelmas*, at which time they may be transplanted into the borders of the pleasure-garden. These will flower the next year in *June*, and perfect their seeds in *August*, which you should save from the best coloured flowers for a supply.

The three sorts with double flowers, are: 1. The broad-leaved sort, which hath very double flowers, of a deep purple colour inclining to blue, which bursts its pods, so that it is not so much esteemed as the others, and therefore has been less regarded, and is now almost totally banished the gardens of the curious. 2. The Double Rose Sweet William, whose flowers are of a fine deep Rose-colour, and smell sweet; this is much valued for the beauty and sweetness of its flowers; the empalement (or pods) of these flowers never burst, so the flowers remain with their petals fully expanded, and do not hang down loosely as those of the former. 3. The Mule, or Fairchild's Sweet William; it hath narrower leaves than either of the former, and is of that variety called Sweet John: this was said to have been produced from seeds of a Carnation, which had been impregnated by the farina of the Sweet William; the flowers of this are of a brighter red colour than either of the former; their bunches are not quite so large, but their flowers have an agreeable scent.

The double kinds are propagated by layers, as the Carnations, or by slips as Pinks; they love a middling soil, not too light, nor too heavy or stiff, nor too much dunged, which very often occasions their rotting: these continue flowering for a long time, and are extremely beautiful; but they are very subject to canker and rot away, especially if planted in a soil over wet or too light. These flowers when planted in pots, are very proper to adorn court-yards at the time they are in flower.

The *China* Pink is generally esteemed an annual plant, because the plants which are raised from seeds flower and produce ripe seeds the same season, so their roots are not often preserved; but where they are planted in a dry soil,

they will continue two years, and the second year will produce a greater number of flowers than the first. There are a great variety of very rich colours in these flowers, which annually vary when raised from seeds. The double flowers of this are most esteemed, though the colours of the single are more distinct and beautiful; for the multiplicity of petals in the double flowers, in a great measure hide the deep shades, which are toward the lower part of the petals.

These plants are propagated by seeds, which should be sown upon a gentle hot-bed about the beginning of *April*; this moderate heat is only intended to forward the vegetation of the seeds, therefore when the plants come up, they must have a large share of air admitted to them, to prevent their drawing up weak; and as soon as the weather will permit, they must be exposed to the open air; in about a month after, the plants will be fit to remove, when they should be carefully taken up with good roots, and planted in a bed of rich earth, at about three inches asunder, being careful to shade them from the sun till they have taken new root. The farther care is to keep them clean from weeds till the end of *May*, at which time they may be transplanted to the places where they are designed to remain for flowering, when they may be taken up with large balls of earth to their roots, so as scarcely to feel their removal, especially if it happens to rain at that time.

As these plants do not grow large, so when they are planted singly in the borders of the flower-garden, they do not make so fine an appearance, as where they are planted by themselves in beds; or if they are planted in small clumps, of six or eight roots in each, where the flowers being of different colours, set off each other to advantage.

Those who are curious in these flowers, take particular care in saving their seeds, for they never permit any single flowers to stand among their double, but pull them up as soon as they shew their flowers, and also draw out all those which are not of lively good colours; where this is observed, the flowers may be kept in great perfection; but where persons have trusty friends, who live at some distance, with whom they can exchange seeds once in two or three years, it is much better so to do, than to continue sowing seeds in the same place many years in succession, and this holds true in most sorts of seeds: but the great difficulty is to meet with an honest person of equal skill, who will be as careful in the choice of his plants for seed, as if he was to sow them himself.

DIAPENSIA. See Sanicula.

DICTAMNUS. *Lin. Gen. Plant.* 468.

The Characters are,

The flower hath five petals which are unequal, and ten stamina which are as long as the petals. In the center is situated a five-cornered germen, which afterward becomes a capsule with five cells joined together, inclosing several roundish, hard, shining seeds.

We have but one distinct Species of this genus, viz.

DICTAMNUS. *Hort. Cliff.* 161. White Dittany, commonly called Fraxinella.

There are three varieties of this plant, one with a pale red flower striped with purple, another with a white flower, and one with shorter spikes of flowers; but as I have observed them to vary when propagated by seeds, so I esteem them only seminal varieties.

This is a very ornamental plant for gardens, and as it requires very little culture, so deserves a place in all good gardens. It hath a perennial root, which strikes deep into the ground; the head annually increases in size; it sends up many stalks, in proportion to its bigness, which rise from two to three feet high, garnished with winged leaves placed alternate; they are composed of three or four pair of oblong lobes, terminated by an odd one, which are smooth
and

and stiff, sitting close to the midrib; the lobes placed on each side the midrib, are oblique, but those which terminate the leaf have their sides equal. The flowers are produced in a long, pyramidal, loose spike, or thyrse, on the top of the stalk, which is nine or ten inches long; the flowers of one sort is white, and the other of a pale red marked with red or purple stripes. The whole plant when gently rubbed, emits an odour like that of Lemon peel, but when bruised has something of a balsamick scent.

These plants are propagated by seeds, which, if sown in the autumn, soon after they are ripe, the plants will appear the following April; but when they are kept out of the ground till the spring, the seeds seldom succeed; or if they do grow, it is the following spring before the plants appear, so that a whole year is lost. When the plants come up, they must be constantly kept clean from weeds; and in the autumn, when their leaves decay, the roots should be carefully taken up, and planted in beds at six inches distance every way; these beds may be four feet broad, and the paths between them two, that there may be room enough to pass between the beds to weed them. In these beds the plants may stand two years, during which time they must be constantly kept clean from weeds; and if they thrive well, they will be strong enough to flower; so in the autumn they should be carefully taken up, and planted in the middle of the borders of the flower-garden, where they will continue thirty or forty years, producing more stems of flowers in proportion to the size of the roots. All the culture these require is to be kept clean from weeds, and the ground about them dug every winter.

DICTAMNUS CRETICUS. See Origanum.

DIERVILLA, *Tourn. Aët. R. Par.* 1706.

The Characters are,

The flower is of one leaf, cut into five parts at the top; it hath five stamina, which are equal with the petal; at the bottom of the flower is situated an oval germen, which afterward becomes a pyramidal berry, divided into four cells, which contain small round seeds.

We know but one Species of this genus at present, viz.

DIERVILLA *Acadiensis fruticosa, flore luteo. Aët. R. Par.* 1706. Shrubby Diervilla of Acadia, with a yellow flower.

This plant grows naturally in the northern parts of America; it hath woody roots which spread far in the ground, and put out shoots at a distance from the principal stalk, whereby it multiplies greatly: the stalks are ligneous, and seldom rise more than two feet high, and are garnished with oblong heart-shaped leaves, ending in acute points, which are very slightly sawed on their edges, and are placed opposite, sitting close to the stalks; the upper part of the stalk is garnished with flowers, which come out from the side, and also at the top of the stalks, two or three together sustained upon short foot-stalks: they are of a pale yellow, and being small make no great appearance.

It is easily propagated by suckers, which it sends out in plenty, and loves a moist soil and shady situation, where the cold will never injure it.

DIGITALIS. *Lin. Gen. Plant.* 676. Foxglove:

The Characters are,

The flower is bell-shaped, of one petal, with a large open tube, whose brim is slightly divided into five parts; it hath four stamina, which are inserted in the base of the petal, two being longer than the other; the germen afterward swells to an oval capsule, having two cells inclosing many small angular seeds.

The Species are,

1. DIGITALIS *calycinis foliolis ovatis acutis, corollis obtusis, labio superiore integro. Hort. Upsal.* 178. Common or purple Foxglove with a rough leaf.

2. DIGITALIS *calycinis foliolis acutis, corollis acutis, labio superiore bifido. Lesser Spanish purple Foxglove.*

3. DIGITALIS *calycinis foliolis acutis, corollis obtusis, labio superiore integro, foliis lanceolatis obtusis. Lesser yellow Foxglove, with a small flower.*

4. DIGITALIS *foliolis calycinis acutis, corollis obtusis, labio superiore trifido, foliis oblongo cordatis acutis. Greater Foxglove, with a small yellow or pale flower.*

5. DIGITALIS *foliolis calycinis linearibus, corollis acutis, labio superiore integro, foliis lanceolatis. Yellow Foxglove, with a larger yellow flower.*

6. DIGITALIS *calycinis foliolis ovatis obtusis, corollæ labio inferiore longitudine floris. Lin. Sp. Plant.* 622. Narrow-leaved Foxglove, with an iron-coloured flower.

7. DIGITALIS *calycinis foliolis lanceolatis, corollis bilabiatis acutis, caule fruticoso. Lin. Sp. Plant.* 622. Shrubby Canary Foxglove like Bearsbreech, with a golden flower.

The first sort grows naturally by the side of hedges and in shady woods in most parts of England, so is rarely cultivated in gardens; it is a biennial plant, which the first year produces a great tuft of oblong rough leaves; the second year it shoots up a strong herbaceous stalk, which rises from three to five feet high, garnished with leaves of the same form as the lower, but they gradually lessen upward; the flowers grow in a long loose thyrse, standing only on one side of the stalk; they are large, tubulous, and shaped like a thimble, of a purple colour, with several white spots on the under lip; these are succeeded by oval capsules with two cells, which are filled with dark brown seeds: whoever has a mind to cultivate it, should sow the seeds in autumn, for those which are sown in the spring seldom succeed.

There is a variety of this with a white flower, which is found growing naturally in some parts of England, which differs from this only in the colour of the flower; but this difference is premanent.

The second sort grows naturally in Spain; this seldom rises much more than a foot high; the lower leaves are ten inches long, and three broad in the middle; they are soft, woolly, and roughly veined on their under side; the stalks are garnished with leaves of the same shape, but smaller; the upper part of the stalk hath a short thyrse of purple flowers, like those of the common sort, but smaller, and the segments of the petal are acute: this plant retains its difference when cultivated in gardens.

The third sort hath very long obtuse leaves near the root; the stalk is small, and rises from two to three feet high, the lower part being pretty closely garnished with smooth leaves, about three inches long and one broad, ending in obtuse points: the upper part of the stalk, for ten inches in length, is adorned with small yellow flowers, which are closely ranged on one side, having a few very small acute leaves placed between them, which are situated on the opposite side of the stalk; the upper lip of the flower is entire, and the petal is obtuse.

The fourth sort differs from the third in having shorter leaves, which end in acute points, and no indentures on their edges; the flowers are larger, and the upper lip is divided into three parts.

The fifth sort hath long, smooth, veined leaves at the bottom; the stalk is strong, and rises two feet and a half high, garnished with leaves which are five inches long, one and a half broad, ending in acute points; these have many longitudinal veins, and are slightly sawed on their edges; the upper part of the stalk is adorned with large yellow flowers, nearly of the size of those of the common sort, the brim having acute points, and the upper lip entire.

The sixth sort hath narrow smooth leaves, which are entire; the stalk rises five or six feet high; the lower part of the stalk is garnished with very narrow small leaves; the flowers terminate the stalk, growing in a long spike, with very few leaves between them, and those very small; the

empalement is divided into four obtuse parts, the lower lip extending much longer than the upper; the flowers are of an iron colour; there is a variety of this with broader leaves.

The seventh sort grows naturally in the *Canary Islands*; this plant hath a shrubby stalk, which rises to the height of five or six feet, dividing into several branches, garnished with rough spear-shaped leaves near five inches long, and one and a half broad in the middle, with a few short serratures on their edges; they are placed alternately on the branches; each of the branches is terminated by a loose spike of flowers, about six inches in length; the empalement is cut into five acute segments almost to the bottom; the upper lip is long and entire, this is arched, and immediately under it the stamina and style are situated; the lower lip is obtuse, and indented at the top; there are two acute segments on the side, which compose the chaps of the flower; two of the stamina are longer than the other; in the bottom of the flower is situated the germen, supporting a slender style, crowned by an oval stigma; the germen afterward becomes an oval capsule, filled with small angular seeds.

This plant begins to flower in *May*, and there is generally a succession of flowers on the same plant, till the winter puts a stop to them, which renders the plant more valuable; it is propagated by seeds, which should be sown in pots in the autumn, soon after the seeds are ripe; these pots should be plunged into an old bed of tanners bark, whose heat is gone, and in mild weather the glasses should be drawn off to admit the air; but in hard rains and frost they must be kept on to protect the seeds from both, which frequently destroys them; in the spring the plants will come up, when they should enjoy the free air in mild weather, but must be protected from the cold: as soon as these are large enough to transplant, they should be each put into a separate small pot, and placed under the frame till they have taken new root, then they should be gradually inured to the open air. During the summer season the plants should remain abroad in a sheltered situation; but in the autumn they must be placed in a green-house, for they will not live abroad in winter: they must not be kept too warm and close in the house, for they only want protection from the frost.

All these sorts should be sown in the autumn, for if the seeds are sown in the spring they commonly fail, or at least lie a whole year in the ground before they vegetate. The plants are biennial (except the seventh sort) and perish soon after their seeds are ripe.

DIOSCOREA. *Plum. Nov. Gen. 9. tab. 26. Lin. Gen. Plant. 995.*

The Characters are,

It hath male and female flowers in different plants; the male flowers hath a perianthium cut into six parts, and have no petals, but have six short hairy stamina; the female flowers have the same perianthium, they have no petals, but have a three-cornered germen; the perianthium afterward becomes a triangular capsule with three cells, opening with three valves, containing two compressed bordered seeds in each.

The Species are,

1. DIOSCOREA *foliis cordatis alternis, caule lævi. Hort. Cliff. 459.* Climbing Dioscorea, with black Briony leaves, and fruit growing in long bunches.

2. DIOSCOREA *foliis hastato-cordatis, caule lævi, racemis longissimis.* Climbing Dioscorea, with a spear-pointed leaf, and fruit growing in long bunches.

3. DIOSCOREA *foliis cordatis rotundis, alternis, caule volubili lævi.* Climbing Dioscorea, with a roundish pointed leaf, and fruit growing in long bunches.

4. DIOSCOREA *foliis cordatis, caule alato bulbifera. Flor. Zeyl. 360.* Dioscorea with heart-shaped leaves, and a winged stalk bearing bulbs, commonly called Yam.

5. DIOSCOREA *foliis cordatis alternis oppositifque, caule lævi. Lin. Sp. Plant. 1033.* Dioscorea with heart-shaped leaves, growing alternate and opposite, and a smooth stalk.

The first sort grows naturally in most of the islands in the *West-Indies*; this hath slender climbing stalks, which fix themselves to any support near them, and rise to the height of eighteen or twenty feet, garnished with heart-shaped leaves ending in acute points, with five longitudinal veins, which arise from the foot-stalk, and diverge towards the sides, but meet again at the point of the leaves; they stand upon pretty long foot-stalks, from the base of which arise the branching spikes of flowers, which are small, and have no beauty; the female flowers are succeeded by three-cornered oblong capsules, having three cells, each containing two compressed seeds.

The second sort differs from the first in the shape of its leaves, these having two round ears at their base, but the middle extends to an acute point, like that of an halbert. The bunches of flowers are longer, and they are looser placed than those of the former sort.

The third sort hath broad, round, heart-shaped leaves, ending in acute points, having many longitudinal veins, which arise from the foot-stalk, and diverge to the side, but afterward join at the point of the leaf; the flowers come out on long loose strings, standing on short foot-stalks; the female flowers are succeeded by three-cornered oblong capsules, with three cells, having compressed bordered seeds.

The fourth sort hath triangular winged stalks, which trail upon the ground and extend to a great length; these frequently put out roots from their joints, as they lie upon the ground, whereby the plants are multiplied. The roots of this plant are eaten in many parts of both *Indies*, where the plants are much cultivated.

The fifth sort grows naturally in *Virginia*, and in other parts of *North-America*; this hath a smooth stalk, which climbs on the neighbouring plants, and rise five or six feet high, garnished with heart-shaped leaves, which are placed sometimes alternate, and at others they are opposite, and have several longitudinal veins; the flowers come out from the side of the stalk in the same manner as the other sorts, but have no beauty.

These plants may be propagated by laying their branches into the ground, which in about three months will put out roots, and may then be taken from the old plants, and planted into separate pots, which should be plunged into the tan-bed in the stove; during the winter, these plants should have but little water given them; but in summer, when they are growing vigorously, they require more; in warm weather they should have a large share of air. When the seeds of these plants are brought to *England*, they should be immediately sown in pots, and plunged in a hot-bed, where, if the seeds are fresh, the plants will come up in two months; but sometimes they remain in the ground till the following spring before the plants appear; therefore, when the plants do not come up the first season, the pots should be screened from the frost in the winter, and put into a new hot-bed in the spring, which will bring up the plants.

The fourth sort is much cultivated by the inhabitants of the islands in *America*, and is of great use to them for feeding of their negroes; and the white people make puddings of their roots, when ground to a sort of flour. This plant is supposed to have been brought from the *East* to the *West-Indies*, for it has not been discovered to grow wild in any part of *America*; but in the island of *Ceylon*, and on the coast of *Malabar*, it grows in the woods, and there are in those places a great variety of sorts.

This plant is propagated by cutting of the root into pieces, observing to preserve an eye or bud to each, as is practised in planting of potatoes; each of these being planted will grow,

grow, and produce three or four large roots: in *America* they are commonly six or eight months in the ground before the roots are taken up for use; the roots are roasted or boiled, and eaten by the inhabitants, and sometimes are made into bread.

This plant will not thrive in the open air, in the warmest time of the year, so must constantly be kept in the bark-stove.

DIOSMA. *Lin. Gen. Plant.* 241. *African Spiræa*, vulgò.

The Characters are,

The flower hath five obtuse petals, which are as long as the empalement, and five stamina, with a five-pointed hollow nectarium sitting on the germen, which afterward becomes a fruit composed of five compressed capsules, joined together, each inclosing one smooth oblong seed.

The Species are,

1. DIOSMA *foliis subulatis acutis oppositis*. *Hort. Cliff.* 71. *African Spiræa*, with leaves placed in the form of a cross.

2. DIOSMA *foliis linearibus hirsutis*. *Hort. Cliff.* 71. *Diosma* with narrow hairy leaves.

3. DIOSMA *foliis linearibus acutis glabris, subtus bifarium punctatis*. *Lin. Sp. Plant.* 198. *Diosma* with smooth, narrow, acute leaves, which are spotted on their under side.

4. DIOSMA *foliis lineari-lanceolatis subtus convexis, bifariam imbricatis*. *Lin. Sp. Plant.* 198. *African Spiræa*, with leaves like the berry-bearing Heath.

The first sort rises to the height of three or four feet; the branches are slender, and produced from the stem very irregularly; the leaves are placed crossways; the flowers are produced at the end of the branches, between the leaves: these plants continue a long time in flower, and make a fine appearance when they are intermixed with other exoticks in the open air.

The second sort makes a very handsome shrub, growing to the height of five or six feet: the stalks are of a fine coral colour; the leaves come out alternately on every side of the branches, which are narrow-pointed and hairy: the flowers are produced in small clusters at the end of the shoots, which are small and white; these are succeeded by starchy seed vessels, having five corners like those of the starchy Anise; each of these corners is a cell, having one smooth, shining, oblong, black seed: these seed vessels abound with a resin, which affords a grateful scent, as doth also the whole plant.

The third sort rises from two to three feet high, forming a bushy head; the leaves are smooth, narrow, and acute-pointed, having two or three spots on their under side; the flowers are small, of a blush colour, and come out at the end of the shoots; but this sort rarely produces seeds in *England*.

The fourth sort is of humbler growth than either of the former, seldom rising above two feet high, and spreads out into many branches; the leaves of this sort are smooth, and resemble those of the Heath; and the plant from thence had the name of *Erica Æthiopica*, &c. given to it by Dr. *Plukenet*: the flowers of this kind are produced in clusters at the end of the branches, like those of the second sort, but are smaller, and the bunches not so large.

All these plants are propagated by cuttings, which may be planted during any of the summer months in pots, and plunged into a moderate hot-bed, where they should be shaded in the day time from the sun, and frequently refreshed with water; in about two months the cuttings will have taken root, when they should be each transplanted into a small pot, and placed in a shady situation until they have taken fresh root, when they may be placed among other exotick plants, in a sheltered situation: the plants may remain abroad until the beginning of *October* or later, if the season continue favourable, for they only require to be sheltered from frost; so that in a dry airy green-house they may be preserved very well in winter, and in summer they

may be exposed to the open air, with other green-house plants.

DIOSPYROS. *Lin. Gen. Plant.* 1027. The Indian Date Plumb.

The Characters are,

It hath hermaphrodite and male flowers on separate plants; the hermaphrodite flowers have a large, obtuse, permanent empalement, divided into four parts; the flower hath one pitcher-shaped petal, cut at the brim into four segments, and eight short bristly stamina firmly joined to the empalement; in the center is situated a roundish germen, which afterward becomes a large globular berry with cells, each including one oblong, compressed, hard seed; the male flowers have the same calyx and flower, with eight short stamina, but have no germen.

The Species are,

1. DIOSPYROS *foliorum paginis discoloribus*. *Lin. Sp. Plant.* 1057. *Diospyros*, with the surface of the leaves of two colours, or the Indian Date Plumb.

2. DIOSPYROS *foliorum paginis concoloribus*. *Lin. Sp. Plant.* 1057. The Pishamin or Persimon, and by some Pitchumon Plumb.

The first sort is supposed to be a native of *Africa*, and was transplanted from thence into several parts of *Italy*, and also the south of *France*. The fruit of this tree is by some supposed to be the Lotus, which *Ulysses* and his companions were enchanted with. This is a tree of a middling growth in the warm parts of *Europe*, where it rises upward of thirty feet high; in the botanick garden at *Padua* there is one very old tree, which has been described by some of the former botanists, under the title of *Guaiacum Patavinum*. This tree produces plenty of fruit every year, from the seeds of which many plants have been raised.

The second sort is a native of *America*, but particularly in *Virginia* and *Carolina*; the seeds of this sort are frequently brought to *England*, where the trees are now become pretty common in nurseries about *London*. This rises to the height of twelve or fourteen feet, but generally divides into many irregular trunks near the ground, so that it is very rare to see a handsome tree of this sort: it produces plenty of fruit in *England*, but they never come to perfection here: in *America*, the inhabitants preserve the fruit until it be rotten (as is practised by *Medlars* in *England*) when they are esteemed a pleasant fruit.

Both sorts are propagated by seeds, which will come up very well in the open ground; but if they are sown upon a moderate hot-bed, the plants will come up much sooner, and make a greater progress; but in this case the seeds should be sown in pots or boxes of earth, and plunged into the hot-bed, because the plants will not bear transplanting till autumn, when the leaves fall off; so that when the plants are up and have made some progress, they may be inned by degrees to the open air; and in *June* they may be wholly exposed, and may remain abroad until *November*, when it will be proper to set the pots under a hot-bed frame to protect them from hard frost; which, while they are very young, may kill the tops of the plants; but they must have as much free air as possible in mild weather: the following spring, before the plants begin to shoot, they should be transplanted into a nursery, in a warm situation, where they may be trained up for two years, and then removed to the places where they are designed to remain. These are both hardy enough to resist the greatest cold of this country, after the plants have acquired strength.

DIPSACUS. *Lin. Gen. Plant.* 107. The Teazel.

The Characters are,

It hath many florets collected in one common perianthium; they have but one petal, which is tubular, cut into four parts at the top. They have four hairy stamina. The germen is situated below the flower, which afterward becomes a column-shaped seed, inclosed

closed in the common conical fruit, which is divided by long prickly partitions.

The Species are,

1. *DIPSACUS foliis sessilibus serratis, aristis fructibus erectis.* Wild. Teazel.

2. *DIPSACUS foliis connatis, aristis fructibus recurvis.* Cultivated Teazel.

3. *DIPSACUS foliis connatis sinuatis.* Lin. Sp. Plant. 97. Teazel with a lacinated leaf.

4. *DIPSACUS foliis petiolatis appendiculatis.* Hort. Upsal.
25. Wild Teazel with a smaller head, or smaller Shepherd's Rod.

The first of these plants is very common upon dry banks in most parts of *England*, and is seldom cultivated in gardens, unless for the sake of variety.

The fourth sort grows naturally in many places near *London*, and is rarely admitted into gardens.

The third sort grows naturally in *Alsace*, and is kept in botanick gardens for the sake of variety; this differs from the wild Teazel, in having the leaves deeply cut and jagged.

But it is the second sort only which is cultivated for use, which is called *Carduus Fullorum*, or *Fullonum*, being of singular use in raising the knap upon woollen cloth; for which purpose there are great quantities of this plant cultivated in the west country.

This plant is propagated by sowing the seeds in *March*, upon a soil that has been well prepared. About one peck of seed will sow an acre; for the plants should have room to grow, otherwise the heads will not be so large, nor in so great quantity. When the plants are come up, they must be hoed in the same manner as is practised for Turneps, cutting down all the weeds, and singling out the plants to about eight inches distance; and as the plants advance, and the weeds begin to grow again, they must be hoed a second time, cutting out the plants to a wider distance; for they should be, at last, left at least a foot asunder: and should be kept clear from weeds, especially the first summer; for when the plants have spread so as to cover the ground, the weeds will not so readily grow between them. The second year after sowing, the plants will shoot up heads, which will be fit to cut about the beginning of *August*; at which time they should be cut, and tied up in bunches, setting them in the sun, if the weather be fair; but if not, they must be set in rooms to dry them. The common produce is about an hundred and sixty bundles or staves upon an acre, which they sell for one shilling a stave. Some people sow Caraway and other seeds amongst their Teazels, but this is not a good method, for the one spoils the other; nor can the weeds be so well cleaned away from the Teazels.

DIRCA. Lin. Gen. 1078.

The Characters are,

The flower is tubulous, has no empalement; it has eight stamina, which are longer than the tube. The flower is succeeded by a berry with one cell, including a single seed.

There is but one sort of this genus, viz.

DIRCA. Lin. Gen. Nov. 1078. The French call it *Bois de Plomb*, i. e. Leadwood: the English in *America* call it Leatherwood, from its lightness.

This is a low shrub in this country; it seldom rises more than four or five feet high, and is very nearly allied to the Mezereon; the flowers come out early in the spring before the leaves; they are small, tubulous, and of a light herbaceous colour, so make very little appearance. The leaves are oval, smooth, and of a pale green; they fall off in the autumn; the shoots are jointed like knees.

It grows naturally in moist places in *North America*, but is at present pretty rare in the English gardens. It may be propagated by layers, but they are commonly two years

before they put out roots. It should have a moist soil and a shady situation.

DITTANY, the white. See *Dictamnus*.

DOCK. See *Rumex*.

DODARTIA. Lin. Gen. Plant. 698.

The Characters are,

The empalement is cut into five parts at top; the flower hath one petal; the upper lip is twice as long as the lower. It hath four stamina, two of which are shorter than the other. In the center is situated a round germen, which after-ward becomes a globular capsule with two cells, filled with small seeds.

The Species are,

1. *DODARTIA foliis linearibus integerrimis glabris.* Lin. Sp. Pl. 633. *Dodartia* with very narrow, smooth, entire leaves.

2. *DODARTIA foliis radicalibus oblongo-ovatis, serratis, caulibus linearibus integerrimis floribus spicatis terminalibus.* *Dodartia* with oblong, oval, sawed leaves at the bottom, those on the stalk narrow and entire, and flowers growing in spikes at the end of the stalks.

The first sort was discovered by Dr. *Tournefort* near mount *Ararat* in *Armenia*. It hath a perennial root which creeps far in the ground, and sends out stalks at a great distance from the parent plant; the stalks are firm, a little compressed, and grow a foot and an half high, sending out several side branches, garnished with long, fleshy, narrow leaves placed opposite; those on the lower part of the stalk are shorter and broader than those above, and have two or three sharp indentures on their edges. At the joints the flowers come out singly on each side the stalk, sitting close to it; they are tubulous, but divide into two lips; the upper lip is hollow like a spoon, and is divided into two parts; the lower lip is divided into three parts, the middle being the narrowest. The flower is of a deep purple colour, but is rarely succeeded by seeds in *England*. It propagates very fast by its creeping roots, so that when it is once established in a garden, it will multiply fast enough.

The second sort is a biennial plant, which perishes soon after the seeds are ripe; this sends out several oblong leaves from the root, which are narrow at their base, but increases in width upward, and are rounded at the end: between these arise the stalks which grow a foot high, their lower parts being garnished with leaves of the same form as the lower leaves, but much smaller, the upper leaves are very narrow and entire. The flowers grow in spikes at the top of the stalks, they are very small and white, but are shaped like those of the former sort.

This is propagated by seeds, which should be sown in autumn, soon after they are ripe, upon a border of light earth, where they are designed to remain. When the plants appear the following spring, they must be thinned, and kept clean from weeds, which is all the culture they require; the second year they will flower and seed, after which the plants decay; when the seeds are sown in the spring, the plants never come up the same year.

DOG'S TOOTH. See *Erythronium*.

DOG-WOOD. See *Cornus*.

DORIA. See *Solidago* and *Othonna*.

DORONICUM. Lin. Gen. Pl. 862. Leopard's Bane.

The Characters are,

It hath a flower composed of several hermaphrodite florets, which form the disk, and female florets which compose the rays; these are included in one common empalement, which hath a double series of leaves, as long as the rays. In the bottom of the hermaphrodite florets is situated the germen, which after-ward becomes a single, oval, compressed seed, crowned with hairy down. The female florets are formed like a tongue, and compose the border; these have a germen crowned by two reflexed stigmas, but have no stamina; the germen becomes a single furrowed seed without down.

The Species are,

1. *DORONICUM foliis cordatis obtusis, radicalibus petiolatis, caulinis amplexicaulibus.* *Lin. Mat. Med.* 394. Leopard's Bane with obtuse heart-shaped leaves, those from the root having foot-stalks, and those above embracing the stalks.

2. *DORONICUM foliis ovatis acutis, subdentatis, ramis alternis.* *Hort. Cliff.* 411. Leopard's Bane with oval-pointed leaves indented at bottom, and alternate branches.

3. *DORONICUM caule nudo simplicissimo unifloro.* *Hort. Cliff.* 500. Leopard's Bane with a naked single stalk having one flower.

The first sort grows naturally in *Hungary*, and upon the *Helvetian* mountains, but is frequently preserved in the *English* gardens. It hath thick fleshy roots, which divide into many knots or knees, sending out strong fleshy fibres, which penetrate deep into the ground; from these arise in the spring, a cluster of heart-shaped leaves, which are hairy, and stand upon foot-stalks; between these arise the flower-stalks, which are channelled and hairy, near three feet high, putting out one or two smaller stalks from the side, which grow erect, and are garnished with one or two heart-shaped leaves, closely embracing the stalks with their base; each stalk is terminated by one large yellow flower, composed of about twenty-four rays or female florets, long, plain, and indented in three parts at the top. In the center is situated a great number of hermaphrodite florets, which compose the disk; these are tubulous, and slightly cut at the top in five parts.

This plant multiplies very fast by its spreading roots, and if the seeds are permitted to scatter, they will produce plants where-ever they happen to fall, so that it becomes a weed where it is once established; it loves a moist soil and a shady situation.

The second sort hath oval leaves ending in acute points; these are indented on their edges toward their base, but their upper parts are entire; the stalks rise about two feet high, each is terminated by a large yellow flower like those of the former sort; the stalks of this sort have two or three leaves, which are placed alternately, and their base fits close to the stalks; these are not so hairy as those of the former sort. This grows naturally in *Portugal*, *Spain*, and *Italy*, but is equally hardy with the first, and multiplies in as great plenty; the root is perennial.

The third sort grows naturally on the *Alps* and the *Pyrenean* mountains; it hath a perennial root; the leaves are like those of the lesser Daisy, but longer, and not so broad. The flower grows upon a naked foot-stalk, which is near a foot long; the roots seldom send out more than one stalk; the rays of the flower are white, and very like those of the common Daisy; the disk of the flower is yellow, which is composed of hermaphrodite flowers.

This plant is preserved in botanick gardens for the sake of variety, but the flowers make little better appearance than those of the common Field Daisy, only they stand upon much taller foot-stalks. It must have a shady situation and a moist soil, otherwise it will not thrive in this country; it is propagated by parting of the roots, for the seeds do not ripen well in *England*.

The roots of the first sort have been sometimes used in medicine; some have commended it as an expeller of the poison of scorpions, but others reckon it to be a poison, and affirm that it will destroy wolves and dogs.

DORSTENIA. *Plum. Nov. Gen.* 29. tab. 8. *Lin. Gen. Plant.* 147. *Contrayerva.*

The Characters are,

It hath one common involucre situated vertically, upon which sit many small flowers which have no petals, but have four short stamina. In the center is situated a roundish germen, which afterward becomes a single seed, inclosed in the common fleshy receptacle.

The Species are,

1. *DORSTENIA foliis sinuatis obtusis, placentâ ovali, marginibus integris.* *Contrayerva* with obtuse sinuated leaves, and an oval placenta with entire borders.

2. *DORSTENIA foliis cordato-angulatis acutis, placentâ quadrangulari dentato.* *Contrayerva* with angular, heart-shaped, acute leaves, and a quadrangular placenta which is indented.

3. *DORSTENIA foliis palmato-angulatis, angulis acutis, placentâ oblongâ tetragono.* *Contrayerva* with angular handed leaves, whose angles are very acute, and an oblong four-cornered placenta.

The first of these plants was discovered by my late ingenious friend *Dr. William Houstoun*, near *Old La Vera Cruz* in *New Spain*. The second was found by the same gentleman, on the rocky grounds about *Campeachy*. The third sort was found in great plenty in the island of *Tobago*, by *Mr. Robert Millar*, Surgeon. But the roots of all these species are indifferently brought over, and used in medicine, and for dying.

The first sort sends out several leaves from the root, which are about four inches long, and as much in breadth, deeply lacinated into five or seven obtuse parts, standing upon long foot-stalks; they are smooth, of a deep green. The stalk which supports the placenta arises from the root, is four inches high, upon which the fleshy placenta is vertically placed; this is of an oval form about an inch long, and three quarters broad. Upon the upper surface of this, the small flowers are closely situated, the fleshy part becoming an involucre to them; these are very small, and scarce conspicuous at a distance, being of an herbaceous colour.

The second sort sends out several angular heart-shaped leaves from the root, which have foot-stalks eight or nine inches in length and very slender; the leaves are about three inches and an half long, and almost four broad at their base, the two ears having two or three angles which are acute, and the middle of the leaves are extended and end in acute points like an halbert; they are smooth and of a lucid green; the foot-stalk which sustains the placenta is nine inches long, and about half an inch square; the upper surface is closely set with small flowers like the first.

The third sort sends out leaves of different forms; some of the lower leaves are heart-shaped having a few indentures on their edges, ending in acute points, but the larger leaves are deeply cut like the fingers on a hand, into six or seven acute segments. They are five inches long, and six broad in the middle, of a deep green, and stand upon long foot-stalks. The placenta is very thick and fleshy, an inch and an half long, and three quarters broad, having four acute corners; these have a number of small flowers placed on the upper surface, like the other species.

These plants are at present very rare in *Europe*, nor was it known what the plant was, whose roots were imported, and had been long used in medicine in *England*, until the late *Dr. Houstoun* informed us: for although father *Plumier* had discovered one species of this plant, and given the name of *Dorstenia* to the genus, yet he seems not to have known, that the *Contrayerva* was the root of that plant.

It will be difficult to obtain these plants, because the seeds are seldom to be found good; nor will they grow, if they are kept long out of the ground; so that the only sure method to obtain them is, to have the roots taken up at the time when their leaves begin to decay, and planted very close in boxes of earth, which may be brought very safe to *England*, provided they are preserved from salt water, and are not over watered with fresh in their passage.

When the plants arrive, they should be each transplanted into a separate pot, and plunged into the bark stove, which should be kept of a moderate heat; they may be increased by parting their roots in the spring, before the plants put out their leaves.

DORYCNIUM. See Lotus.

DOUGLASSIA. See Volkameria.

DRABA. Dillen. Gen. Lin. Gen. Pl. 714.

The Characters are,

The flower hath four petals in form of a cross, and six stamina, four of which are as long as the empalement, the other two are much shorter. In the center is situated a bifid germen, which afterward becomes an oblong, oval, entire pod, with two cells, separated by the swelling style, which is oblique. The valves are parallel to the middle, and opens oblique, each cell containing a single seed.

The Species are,

1. DRABA scapo nudo simplici, foliis lanceolatis integerrimis. Fl. Lapp 255. Yellow hairy Alpine Madwort.
2. DRABA scapis nudis, foliis subserratis. Lin. Syst. Draba with naked stalks and cut leaves.
3. DRABA scapo nudo, foliis cuneiformibus trifidis. Lin. Syst. Least perennial Madwort of the Pyrenees with trifid leaves.
4. DRABA caule ramoso, foliis cordatis dentatis amplexicaulis. Prod. Leyd. 33. Draba with a branching stalk, and heart-shaped indented leaves embracing the stalks.
5. DRABA caule ramoso, foliis ovatis sessilibus dentatis. Lin. Sp. Pl. 643. Draba with a branching stalk, and oval indented leaves growing close to the branches.
6. DRABA foliis caulinis numerosis incanis, siliiculis obliquis. Flor. Suec. 526. Draba with many hoary leaves on the stalks, and oblique pods.

The first sort grows naturally on the Alps, and other mountainous parts of Europe. It is a very low plant, which divides into small heads, like some sorts of Houseleek, and from thence it was titled *Sedum Alpinum*, &c. or *Alpine Houseleek*. The leaves are short, narrow, and hairy; from each of these heads come out a naked flower-stalk an inch and an half high, terminated by a loose spike of yellow flowers, having four obtuse petals placed in form of a cross; when these fade, they are succeeded by heart-shaped pods, which are compressed, and inclose three or four roundish seeds.

This plant is easily propagated by parting of the heads; the best time for doing this is in autumn, because it shoots up to flower very early in the spring. It should have a moist soil and a shady situation.

The second sort is an annual plant, which grows naturally upon walls, and dry banks, in many parts of England, so is never cultivated in gardens. This flowers in April, and the seeds ripen in May.

The third sort grows naturally on the Alps, and other mountainous parts of Europe. This is a low perennial plant, which seldom rises more than two inches high; it has a shrubby stalk, which divides into many small heads like the first sort. The leaves are small, some of them are winged, having five short narrow lobes, placed on a midrib, others have but three. The flowers come out in clusters, fitting close to the leaves. They are of a bright purple colour, and appear early in the spring. This is a perennial plant, which may be propagated by parting of the heads in the same manner as the first, and requires the same treatment.

The fourth sort grows naturally in shady woods in many parts of Europe, and is but seldom kept in gardens, unless for the sake of variety. It is an annual plant, rising with an upright branching stalk, garnished with heart-shaped indented leaves, which embrace the stalks with their base. The stalks are terminated by loose spikes of white flowers,

which appear the beginning of May; in June the seeds ripen, and the plants soon after decay.

The fifth sort is an annual plant, which grows in shady woods in the northern parts of Europe. This is like the former sort, but the leaves are larger, rounder, and do not embrace the stalks; they are also hairy, and the flowers are yellow. If the seeds of this are permitted to scatter, the plants will maintain themselves, if they have a shady situation.

The sixth sort rises with an upright stalk about a foot high, the lower part being very closely garnished by oblong hoary leaves, which are indented on their edges. The upper part of the stalk puts out two or three short branches, which are almost naked of leaves, as is also the upper part of the stalk. The flowers come loosely out at the top of the stalk; they are composed of four small white petals placed in form of a cross, which are succeeded by oblong pods which are twisted, containing three or four roundish compressed seeds.

DRACO ARBOR. See Palma.

DRACO HERBA, or Tarragon. See Abrotanum.

DRACOCEPHALUM. Lin. Gen. Plant. 648. Dragon's Head.

The Characters are,

The flower hath one ringent petal, with large, oblong, inflated chaps. The upper lip is obtuse and arched, the under lip is trifid. It hath four stamina, two being shorter than the other, and a four-parted germen, which afterward becomes four oval oblong seeds, inclosed in the empalement.

The Species are,

1. DRACOCEPHALUM foliis lanceolatis serratis, floribus spicatis. Lin. Sp. American Dragon's Head.
2. DRACOCEPHALUM floribus spicatis, foliis compositis. Lin. Hort. Cliff. Three-leaved American Balm, having a strong smell, commonly called Balm of Gilead.
3. DRACOCEPHALUM floribus verticillatis, bracteis lanceolatis, serraturis capillaceis. Lin. Hort. Upsal. 166. Moldavian Balm, with a Betony leaf and blue flower.
4. DRACOCEPHALUM floribus verticillatis, bracteis serrato ciliatis orbiculatis. Lin. Hort. Upsal. Lesser eastern Moldavian Balm, with a Willow leaf and a bluish flower.
5. DRACOCEPHALUM floribus verticillatis, bracteis oblongis, serraturis spinosis, foliis subtomentosis. Hort. Upsal. 166. Eastern Moldavian Balm, with a Betony leaf and a large blue flower.
6. DRACOCEPHALUM floribus verticillatis, bracteis oblongis ovatis integerrimis, corollis majusculis nutantibus. Hort. Upsal. 167. Moldavian Balm with a Betony leaf, and larger blue pendulous flowers.
7. DRACOCEPHALUM floribus verticillatis, bracteis oblongis integerrimis, corollis vix calyce majoribus. Hort. Upsal. 167. Moldavian Balm, with a Betony leaf and very small blue flowers.
8. DRACOCEPHALUM floribus verticillatis foliis ovatis inciso-crenatis, bracteis lanceolatis integerrimis. Lin. Sp. Pl. 595. Dragon's Head with flowers growing in whorls, and oval leaves which are cut and crenated, and spear-shaped bractæ, which are entire.

The first sort is a native of North America. This sort rises with an upright four-cornered stalk, near three feet high, garnished with narrow spear-shaped leaves, fitting close to the stalk, sawed on their edges, and are placed opposite at each joint. The flowers grow in long spikes on the top of the stalks; they are of a purple colour. This is a perennial plant, which will live in the open air, but requires a moist soil, or should be duly watered in dry weather. It is propagated by parting the roots in autumn.

The second sort is a native of the Canary islands. It is usually called by the gardeners Balm of Gilead, from the strong resinous

resinous scent which the leaves emit on being rubbed. This is a perennial plant, which rises with several square stalks, to the height of three feet or more, becoming ligneous at their lower parts, garnished with compound leaves at each joint, which are placed opposite; they have three or five lobes, which are oblong, pointed, and sawed on their edges. The flowers terminate the stalks in short thick spikes; they are of a pale blue colour, and are succeeded by small angular seeds. This plant continues producing flowers most part of summer; it is usually kept in green-houses, but, in mild winters, the plants will live abroad, if they are planted in warm borders; and those plants which are kept in pots, will thrive much better when they are sheltered under a frame, than if placed in a green-house, where the plants are apt to draw up weak, for they should have as much free air as possible in mild weather, and only require to be sheltered from severe frost. This may be propagated by seeds, which, if sown in autumn, will more certainly grow, than those which are sown in the spring; if the seeds are sown in the full ground, it should be in a warm border. It may also be propagated by cuttings, which, if planted in a shady border any time in summer, will very soon take root, and furnish plenty of rooted plants.

The third sort is a native of *Moldavia*; it is an annual plant, which rises with branching stalks two feet high, garnished with oblong leaves, placed opposite, which are deeply sawed on their edges. The flowers come out in whorls round the stalks at every joint; they are blue, and are succeeded by seeds which ripen in *September*. The seeds should be sown in small patches in the spring, upon the borders where they are to remain, and when the plants come up, they should be thinned where they grow too near together, and kept clear from weeds, which is the only culture they require. Of this there is a variety with white flowers, which is pretty common in the gardens.

The fourth sort was discovered by *Dr. Tournefort* in the *Archipelago*. This rises with upright stalks about a foot high, which seldom put out branches; they are garnished with very long, narrow, entire leaves, placed opposite at each joint, where the flowers come out in whorls, almost the whole length of the stalks; they are of a pale blue, but as they are very small, so make no great appearance.

The fifth sort was also discovered by *Dr. Tournefort* in the *Levant*; this hath hoary square stalks, which rise a foot and an half high, putting out two or three side branches, garnished with hoary leaves, a little indented on their edges; they are placed opposite at their joints, just under the whorls of flowers, which sit close to the stalk; the flowers are larger than those of the other species, and are of a fine blue colour, which between the hoary leaves of the plant make a pretty appearance. It flowers and seeds about the same time with the former sorts. There is a variety of this with white flowers, the seeds of which generally produce the same coloured flowers.

The sixth sort grows naturally in *Siberia*. This is an annual plant, with many square weak stalks a foot long; these are at the bottom garnished with oval spear-shaped leaves, crenated on their edges. The upper part of the stalks have smaller leaves, which sit close at the joints, from whence come out the flowers in whorls, of a deep blue colour, and hang downward; these appear at the same time with the former, and the seeds ripen in autumn.

The seventh sort grows also in *Siberia*. It hath square stalks, which rise a foot and an half high; the lower leaves are very like those of *Betony*, and stand upon very long foot-stalks. The upper leaves are small, and sit closer to the stalks. The flowers come out in whorls at every joint; these are very small, and of a pale purple colour, so make little appearance.

The eighth sort grows naturally in *Siberia*. This is an annual plant, with a square stalk; sending out two or three small side branches from the lower part. The leaves are oval, and deeply crenated on their edges. The flowers are large, of a blue colour, and come out in whorls round the stalks, having two spear-shaped, entire, small leaves (called *bractea*) immediately under them. This sort flowers and seeds at the same time with the former.

All these sorts are propagated by seeds, which may be sown either in the spring or autumn, in the places where the plants are to remain, and will require no other treatment than the third sort.

DRACONTIUM. *Lin. Gen. Pl.* 916. Dragon.

The Characters are,

It hath a close cylindrical spadix, and a boat shaped sheath. The flowers have no empalement, but have five oval concave petals. They have an oval germen, which afterward becomes a roundish berry, inclosing several seeds.

The Species are,

1. DRACONTIUM *foliis pertusis, caule scandente. Lin. Sp. Plant.* 968. Dragon with leaves having holes, and a climbing stalk.

2. DRACONTIUM *scapo brevissimo, petiolo radicato, lacera, foliis tripartitis, laciniis pinnatifidis. Hort. Cliff.* 434. Many leaved Arum, with a rough purple stalk.

3. DRACONTIUM *foliis sagittatis, pedunculis petiolisque aculeatis. Flor. Zeyl.* 328. Dragon with arrow-pointed leaves, whose foot-stalks have spines.

4. DRACONTIUM *foliis lanceolatis. Amerit. Acad.* p. 360. Dragon with spear-shaped leaves.

The first sort grows naturally in most of the islands in the *West-Indies*. This hath trailing stalks, which put out roots at every joint, that fasten to the trunks of trees, walls, or any support which is near them, and thereby rise to the height of twenty-five or thirty feet. The leaves are placed alternately upon long foot-stalks; they are four or five inches long, and two and an half broad, and have several oblong holes in each, which on the first view appear as if eaten by insects, but they are natural to the leaves. The flowers are produced at the top of the stalk, which always swells to a much larger size in that part immediately under the flower, than in any other; these are covered with an oblong spatha (or hood) of a whitish green colour, which opens longitudinally on one side, and shews the pistil, which is closely covered with flowers, of a pale yellow, inclining to white. When this plant begins to flower, it seldom advances farther in height, so that these seldom are more than seven or eight feet high, but the leaves are much larger on these, than those of the plants which ramble much farther.

It is propagated easily by cuttings, which, if planted in pots filled with poor sandy earth, and plunged into a hot-bed, will soon put out roots, if they had none before, but there are few of the joints which are destitute of roots; the plants are tender, so will not live in the open air in *England*, therefore the pots should be placed near the walls in the hot-house, against which the plants will climb, and fasten their roots into the wall, and thereby support themselves. They should have but little water given them in the winter, but in warm weather it must be given them frequently; in the summer the free air should be admitted to them in plenty. The plants have no particular season of flowering, for they sometimes flower in autumn, and at other times in the spring, but they do not ripen their seeds in *England*.

The second sort grows naturally in several of the islands of *America*. This hath a large, knobbed, irregular root, covered with a rugged brown skin. The stalk rises about a foot high, is naked to the top, where it is garnished with a

tuft of leaves, which are divided into many parts. The stalk is smooth, of a purple colour, but is full of sharp protuberances of different colours, which shine like the body of a serpent. The spadix (or stalk) of the flower rises immediately from the root, and is seldom more than three inches high, having an oblong swelling hood at the top, which opens lengthways, shewing the short, thick, pointed pistil within, upon which the flowers are closely ranged.

This sort is tender, so requires a warm stove to preserve it in *England*. The roots must be planted in pots, and plunged into the tan bed in the stove, where they should constantly remain; in the winter they must be watered very sparingly, but in warm weather, when the plants are in vigour, they must be often refreshed, but it should not be given them in too great quantities.

The third sort grows naturally in the island of *Ceylon*, and in several parts of *India*; this hath an oblong thick root, full of joints, from which arise several leaves, shaped like those of the common Arum, but their foot-stalks are covered with rough protuberances. The stalk which supports the flower is short, and set with the like protuberances, and at the top is a hood, or spatha, about four inches long, which opens longitudinally, and exposes the pistil, which is set with flowers. This is a tender plant, and requires the same treatment as the former sort.

The fourth sort hath roots like the common Arum, from which come out several spear-shaped leaves, standing each upon a separate foot-stalk, arising immediately from the root, as those of the common Arum. This grows naturally in *Siberia*, so requires a shady situation, and will bear the greatest cold of this country.

These plants are preserved in the gardens of the curious in *England* and *Holland*, more for the sake of variety, than their beauty, for except the first sort, there is not any of them which makes much appearance; that, indeed, may be suffered to have a place against the wall of the stove, over which it will spread, and cover the nakedness of the wall, and the leaves remaining all the year, which are so remarkably perforated, make a singular appearance.

DRACUNCULUS PRATENSIS. See *Achillæa*.

DRAGON. See *Dracontium*.

DULCAMARA. See *Solanum*.

DURANTIA. *Lin. Gen. Plant.* 704.

The Characters are,

The flower is of the ringent kind, with one petal, which is erect and concave, and hath an empalement divided into five equal segments. It hath four short stamina, the two middle being a little shorter than the other. The germen, which is situated under the flower, afterward becomes a globular berry, having one cell inclosing four angular seeds.

The Species are,

1. DURANTIA spinosa. *Lin. Sp. Plant.* 637. Prickly *Durantia*.

2. DURANTIA inermis. *Lin. Sp. Plant.* 637. *Durantia* without thorns.

The first sort hath many trailing branches, which are armed with hooked thorns at every joint, and are garnished with oblong leaves, which are placed without order; the flowers come out from the side of the stalks in pretty long

bunches, like those of the common *Currant*; they are of a pale bluish colour, and are succeeded by brown berries not unlike those of the *Hawthorn*; these have one cell, and inclose four angular seeds.

The second sort hath a branching woolly stalk, which rises seven or eight feet high; the branches are garnished with oval spear-shaped leaves, sawed on their edges, of a lucid green colour, and stand opposite. The flowers are produced in long bunches at the end of the branches; these are blue, and are succeeded by pretty large, round, yellow berries, which contain four angular seeds.

These plants are natives of warm countries, so they require a stove to preserve them in winter. They are propagated by seeds, which should be sown in small pots, and plunged into a hot-bed of tanners bark; and when the plants are fit to remove, they must be planted each into a separate small pot, and plunged into a hot-bed again, observing to shade them till they have taken new root, then they must be treated in the same manner as other plants from the same country.

They may also be propagated by cuttings, which may be planted in any of the summer months; but these should be plunged into a moderate hot-bed, and shaded from the sun till they have taken root, then they may be treated in the same manner as the seedling plant.

DWARF TREES were formerly in much greater request than they are at present; for though they have some advantages to recommend them, yet the disadvantages attending them greatly over-balance; and since the introducing of *Espaliers* into the *English* gardens, Dwarf Trees have been in little esteem for the following reasons:

1. The figure of a Dwarf Tree is very often so much studied, that, in order to render the shape beautiful, little care is taken to procure fruit, which is the principal design in planting these trees.

2. The branches being spread horizontally near the surface of the ground, render it very difficult to dig or clean the ground between them.

3. Their taking up too much room in a garden (especially when they are grown to a considerable size) for nothing can be sown or planted between them.

It is also very difficult to get to the middle of these Dwarf Trees in the summer, when their leaves and fruit are on the branches, without beating off some of the fruit, and breaking the young shoots; whereas the trees on an *Espalier* can at all times be come at on each side, to tie up the new shoots, or to displace all vigorous ones, which if left on, would rob the trees of their nourishment.

Add to this, the fruit buds of many sorts of Pears and Apples are produced at the end of the former year's shoot, which must be shortened in order to keep the Dwarfs to their proper figure, so that the fruit buds are cut off, and a greater number of branches are obtained, than can be permitted to stand; so that all those sorts of fruit trees, whose branches require to be trained at full length, are very improper to train up as Dwarfs.

These evils being entirely remedied by training the trees to an *Espalier*, hath justly gained them the preference.

E.

E C H

EBENUS. *Lin. Gen. Nov.* Ebony.

The Characters are,

The empalement of the flower is slenderly indented and hairy; the flower is of the butterfly kind. It hath ten stamina. In the bottom is situated an oblong germen, which afterward becomes an oblong swelling pod, inclosing one kidney-shaped seed.

This is distinguished from *Trifolium* by the bractæ, which are situated between the flowers on the spikes.

We have but one Species of this genus, viz.

EBENUS. *Lin. Sp. Plant.* 764. Ebony.

This plant grows naturally in *Crete*, and in some of the islands of the *Archipelago*; it rises with a shrubby stalk three or four feet high, which put out several side branches, garnished with hoary leaves at each joint, composed of five narrow spear-shaped lobes, which join at their tails to the foot-stalk, and spread out like the fingers of a hand: the branches are terminated by thick spikes of large purple flowers, which are of the butterfly or Pea-bloom kind.

This is propagated by seeds, which should be sown in the autumn, for those which are sown in the spring often fail; they should be sown in pots, and placed under a frame in the winter, where they may be protected from frost; in the spring the plants will come up. When these have acquired strength enough to be removed, they should be each planted in a separate small pot, and shaded till they have taken new root; then they should be placed in a sheltered situation, where they may remain till autumn, when they must be removed into shelter, for these plants will not live in the open air through the winter; nor should they be too tenderly treated: I have found them succeed best when placed in an airy glass-case without fire in the winter, where they will have more sun and air, than in a greenhouse: during the winter season, the plants must be sparingly watered, but in the summer they will require to be often refreshed.

EBULUS. See *Sambucus*:

ECHINOMELOCACTUS. See *Cactus*.

ECHINOPHORA. *Lin. Gen. Pl.* 292. Prickly Parsnep.

The Characters are,

It hath an umbellated flower; the flowers have five unequal petals; they have each five stamina, terminated by roundish summits. Under the perianthium is situated an oblong germen within the empalement, which afterward turns to two seeds, which are inclosed in the empalement.

The Species are,

1. **E**CHINOPHORA *foliolis subulato-spinosis integerrimis. Lin. Sp. Plant.* 239. Prickly-headed Parsnep, with awl-shaped prickly leaves which are entire.

2. **E**CHINOPHORA *foliolis incisus inermibus. Lin. Sp. Plant.* 239. Prickly-headed Parsnep, with cut leaves without thorns.

These plants grow naturally on the borders of the *Mediterranean sea*; they are preserved in the gardens of botany, for the sake of variety: they have both perennial roots, which creep in the ground; the first have branching stalks, growing five or six inches high, which are garnished with short thick leaves, that terminate in two or three sharp

E C H

thorns, which are placed opposite: the flowers grow in an umbel, sitting upon a naked foot-stalk, which arises from the side of the stalk; the flowers are white, and under the umbel is situated an involucre, composed of several leaves, which terminate in sharp spines.

The second sort rises near a foot and an half high; from the principal stalk are sent out two side branches at each joint, placed opposite; the lower part is garnished with leaves, which are finely divided like those of the Carrot; the flowers grow in small umbels at the extremity of the branches, having a short prickly involucre. The seeds of these plants rarely ripen in *England*.

These plants are propagated by their creeping roots in *England*; the best time to transplant them is the beginning of *March*, a little before they shoot: the roots should be planted in a gravelly or sandy soil, and in a warm situation, or otherwise they should be covered in the winter to prevent the frost from destroying them.

ECHINOPS. *Lin. Gen. Pl.* 829. Globe Thistle.

The Characters are,

The flower hath one funnel-shaped petal, included in an imbricated empalement, divided at the top into five parts; it hath five short hairy stamina, terminated by cylindrical summits. In the bottom of the tube is situated an oblong germen, which afterward becomes an oblong oval seed narrowed at the base, but obtuse and hairy at the top.

The Species are,

1. **E**CHINOPS *calyculis unifloris, caule multifloro, foliis spinosis supra nudis. Lin. Sp. Plant.* 814. Greater Globe Thistle.

2. **E**CHINOPS *calycibus unifloris, caule unicapitato. Lin. Sp. Pl.* 815. Smaller Globe Thistle.

3. **E**CHINOPS *calycibus fasciculatis unifloris, lateralibus sterilibus, foliis pinnatifidis supra strigosis. Lin. Sp. Plant.* 815. Smaller annual Globe Thistle, with a large head.

4. **E**CHINOPS *caule unicapitato, foliis spinosis, omnibus pinnatifidis villosis, radice reptatrice. Greek Globe Thistle, whose leaves are divided into narrow segments and are woolly, with a smaller blue head.*

The first is the common Globe Thistle. This grows naturally in *Italy* and *Spain*; it hath a perennial root, from which arise many stalks that grow to the height of four or five feet, garnished with long jagged leaves, which are divided into many segments almost to the midrib, the jaggs ending in spines; they are of a dark green on their upper side, but woolly on their under; the flowers are collected in globular heads, several of these grow upon each stalk; the common sort hath blue flowers, but there is a variety of it with white.

This plant is easily propagated by seeds, which, if permitted to scatter, the plants will come up in plenty, so a few of them may be transplanted to the places where they are designed to remain to flower; they require no other culture, but to keep them clean from weeds: the second year they will flower and produce seeds, and the roots will continue two or three years after.

The second sort grows in the south of *France* and in *Italy*; this hath a perennial root, which sends up several stalks,

that

that rise two feet high, garnished with leaves, which are cut into many fine segments to the midrib, which are set with prickles, and are white on their under side: the stalks are each terminated by a globular head of flowers, which are smaller than those of the first, and of a deeper blue; there is also a variety of this with white flowers; this is propagated in the same way as the first.

The third sort grows naturally in *Spain* and *Portugal*: this is an annual plant, which rises with a stiff white stalk two or three feet high, garnished with divided leaves, ending in many points which have spines; their upper side is green, and covered with brown hairs, their under side white and woolly; the stalk is terminated by one large head of pale blue flowers; and if the season proves warm and dry, the seeds will ripen in autumn, but in wet cold years they rarely ripen here.

These seeds should be sown in the spring upon a border of light earth, where the plants are to remain; they require no other management, but to thin them where they are too close.

The fourth sort grows naturally in *Greece*; this hath a perennial creeping root, by which it multiplies fast enough; the stalks rise about two feet high, and are closely garnished with leaves which are shorter and much finer divided than either of the former sorts; these are hoary, and armed on every side with sharp thorns; the stalks are terminated by one globular head of flowers, which in some are blue and in others white: in warm seasons the seeds will ripen well in *England*, but it is easily propagated by its creeping roots; it loves a dry soil and a warm situation.

ECHIUM. *Lin. Gen. Plant.* 157. Viper's Buglofs.

The Characters are,

The flower hath one petal, with a short tube, and an erect broad brim, cut into five irregular parts, and hath naked chaps; it hath five awl-shaped stamina; in the bottom are situated four germen, which afterward become so many roundish pointed seeds, inclosed in the rough empalement.

The Species are,

1. ECHIUM caule simplici erecto, foliis caulinis lanceolatis hispidis, floribus spicatis lateralibus, staminibus corolla æquantibus. Common Viper's Buglofs.
2. ECHIUM caule simplici erecto, foliis caulinis lanceolato-linearibus hispidis, floribus lateralibus spicatis sessilibus, staminibus corollâ longioribus. This is the *English Lycopsis*.
3. ECHIUM corollis vix calycem excedentibus, marginè villosis. *Hort. Upsal.* 35. Great rough Viper's Buglofs, with a white flower.
4. ECHIUM foliis radicalibus lanceolatis amplissimis, caulinis linearibus hirsutis, corollis staminè longioribus. *Portugal Viper's Buglofs*, with a large leaf.
5. ECHIUM calycibus frutescentibus distantibus, caule prosumbente. *Lin. Hort. Upsal* 35. Broad-leaved Viper's Buglofs of *Candia*, with a red flower.
6. ECHIUM caule ramoso, aspero, foliis calloso verrucosis, staminibus corollâ longioribus. *Narrow-leaved Viper's Buglofs* of *Candia*, with a red flower.
7. ECHIUM caule fruticoso. *Hort. Cliff.* 43. Shrubby *African Viper's Buglofs*, with hairy leaves.

The first sort grows naturally in *Germany* and *Austria*; this and our common Viper's Buglofs, which is the second, have been confounded by most of the writers on botany, who have supposed they were the same plant, whereas they are very different; for the leaves of this are shorter, and much broader than those of the second; the spikes of flowers are much longer, and the stamina of the flowers are in this equal in length with the petal; whereas those of the second stand out much beyond it, which is an essential difference.

The second sort grows naturally upon chalky lands, in most parts of *England*: this is what *Lobel* titles *Lycopsis*

Anglica, and has been generally taken for the common Echium.

The third sort grows naturally in the south of *France*, and in *Italy*; this rises with an upright stalk, which is very hairy, as are also the leaves; the flowers are produced in short spikes on the side of the branches; they are small, and scarce appear above the empalements; some plants have white flowers, and others are purplish; the empalements of the flowers are very hairy, and cut into acute segments.

The fourth sort grows naturally in *Portugal* and *Spain*; the lower leaves of this are more than a foot long, and two inches broad in the middle, gradually lessening to both ends; these are covered with soft hairs. The stalks grow two feet high; the flowers are in short spikes coming from the side of the stalks; the petals of these are longer than the stamina.

The fifth sort grows naturally in *Crete*; this hath trailing hairy stalks, which grow about a foot long, and put out several side branches, garnished with hairy spear-shaped leaves fitting close to the stalks. The flowers come out on slender spikes upon long foot-stalks, which come from the wings of the leaves; they are large, of a reddish purple colour, which turns to a fine blue when they are dried; these stand at a distance from each other on the spike; it is an annual plant, which flowers in *July* and decays in autumn.

The sixth sort hath branching stalks, which grow a foot and a half long, declining toward the ground; they are covered with stinging hairs, which are wanted; the leaves are four inches long, and not more than half an inch broad; the flowers grow in loose spikes from the side of the stalks, and also at the end of the branches; they are of a reddish purple colour, but not so large as those of the former sort; and the stamina of these are longer than the petals: this is also an annual plant, which grows naturally in *Crete*.

These are all of them biennial plants, except the fifth and sixth sorts, which are annual, and are the most beautiful of all the kinds: the seeds of these must be sown every year in the places where they are designed to remain; and the plants require no other culture, but to keep them clean from weeds, and thin them where they grow too close. In *July* they flower, and their seeds ripen in five or six weeks after. The seeds of the other sorts being sown in the spring, will the second summer after produce flowers and seeds, after which they seldom continue; they all delight in a rubbishy gravelly soil, and will grow upon the tops of old walls or buildings, where, when once they have established themselves, they will drop their seeds, and thereby maintain a succession of plants without any care, and on these places they appear very beautiful.

The seventh sort grows naturally at the *Cape of Good Hope*; this rises with a shrubby stalk two or three feet high, dividing upward into several branches, which are garnished with oval leaves placed alternate, whose base fits close to the stalk; they are hairy, and of a light green colour; the flowers are produced singly between the leaves, at the end of the branches; they are of a purple colour, and in shape much like those of the fifth sort.

It is propagated by seeds, which should be sown in pots soon after they are ripe, and may be exposed to the open air till the beginning of *October*, when the pots should be placed under a frame; to guard them from frost; but in mild weather they should have the free air, to prevent the seeds from vegetating till the winter is past; for if the plants come up at that season, their stems will be weak and full of juice, and very liable to rot with damps; therefore it is much better, if the plants do not come up till toward *March*, which is the usual time of their appearing, when the seeds are not forced by warmth. When the plants are fit to remove, they should be each planted into a small pot, and placed under a frame to forward their putting out new roots;

then they should be gradually inured to bear the open air, and the latter end of *May* be placed abroad in a sheltered situation, where they may remain till the beginning of *October*, at which time they must be removed into an airy glass-case, where they may enjoy the sun, and have free air in mild weather. During the winter season these plants must be sparingly watered, for as their stems are succulent, so much moisture will cause them to rot. In the summer they should be set abroad in a sheltered situation, and treated in the same manner as other plants from the same country.

EDERA QUINQUEFOLIA. See *Vitis*.

EDGINGS. The best and most durable plant for edgings in a garden, is *Box*, which, if well planted and rightly managed, will continue in beauty several years: the best season for planting this is either in the autumn, or very early in the spring; for if you plant it late, and the season should prove hot and dry, it will be very subject to miscarry, unless great care be taken to supply it with water; the best sort for this purpose is the dwarf *Dutch Box*.

EHRETIA. *Trew. Tab. 25.* Bastard Cherry tree.

The Characters are,

The flower has one bell-shaped petal, cut into six segments, which are reflexed, and six stamina, which are longer than the petal; it has a roundish germen, which afterward becomes a succulent berry with two cells, including two stones, each having two kernels.

We know but one Species of this genus, viz.

EHRETIA. This is the *Ehretia foliis alternis oblongis acuminatis, spica florum sparsa petalis reflexis albis. Trew. Tab. 25.* It is called Bastard Cherry tree in the *West-Indies*.

This has a strong woody trunk, which in the *West-Indies* grows to the size of a middling Pear tree, covered with a gray furrowed bark, divided into many branches, garnished with oblong, acute-pointed, smooth leaves, five or six inches long, and two inches and a half broad, of a dark green colour on their upper side, placed alternate, having short foot-stalks: the flowers are produced in panicles at the end of the branches; they are small, white, and of one petal, having a bell-shaped tube, but cut into six segments to the middle, which are reflexed; these are succeeded by small, oval, succulent berries, containing one or two stones; it grows in most of the islands of the *West-Indies*.

This is usually propagated by seeds, when they can be obtained, which should be sown in pots, and plunged into a hot-bed of tan; when the plants come up they may be treated in the same way as the *Malpigbia*; to which article the reader is desired to turn, to avoid repetition; it may also be increased by layers. This plant has produced its flowers several times in the *Chelsea* garden, but it has not perfected its fruit here.

The title of this genus was given to it by the learned Dr. *Trew* of *Nuremberg*, in honour of Mr. *George Denis Ehret*, a curious botanist, who sent a drawing of the plant to the Doctor, taken from one of the plants that flowered in the *Chelsea* garden, from which he has published a curious print in his twenty-fifth table.

ELÆAGNUS. *Lin. Gen. Plant. 148.* Oleaster, or wild Olive.

The Characters are,

The flower hath a bell-shaped empalement of one leaf, which is quadrifid, rough on the outside, but coloured within; it hath no petals, but four short stamina, which are inserted in the divisions of the empalement: at the bottom is situated a roundish germen, which afterward becomes an obtuse oval fruit, with a puncture at the top, inclosing one obtuse nut.

The Species are,

1. ELÆAGNUS aculeatus, foliis lanceolatis. Prickly wild Olive, with spear-shaped leaves; or, *Saxa* broad-leaved wild Olive, with a large fruit.

2. ELÆAGNUS inermis, foliis lineari-lanceolatis. Wild Olive without thorns, and narrow spear-shaped leaves.

3. ELÆAGNUS foliis ovatis. *Prod. Leyd. 250.* Wild Olive, with oval leaves.

The first and second sorts Dr. *Tournefort* found growing naturally in the *Levant*; the first I take to be the common sort, which grows naturally in *Bobemia*, of which I saw some trees growing in the curious garden of the late Dr. *Boerhaave*, near *Leyden* in *Holland*. The leaves of this sort are not more than two inches long, and about three quarters of an inch broad in the middle; they are of a silver colour, placed alternate; at the foot-stalk of every leaf there comes out a pretty long sharp thorn, which are alternately longer: the flowers are small, the inside of the empalement is yellow, and they have a strong scent when fully open.

The second sort hath no thorns on the branches, the leaves are more than three inches long, and half an inch broad, and have a shining appearance like fatten. The flowers come out at the foot-stalks of the leaves, sometimes singly, at other times two, and frequently three at the same place; the outside of the empalement is silvery and studded, the inside of a pale yellow, having a very strong scent; this flowers in *July*, and sometimes the flowers are succeeded by fruit. This is the sort which is most commonly preserved in the *English* gardens.

These plants may be propagated by laying down the young shoots in autumn, which will take root in one year, when they may be cut off from the old trees, and either transplanted into a nursery for two or three years, to be trained up, or into the places where they are to remain. The best season for transplanting of these trees is in the beginning of *March*, or early in the autumn, provided the roots are mulched, to protect them from severe frost in winter; they should be placed where they may be screened from strong winds, for they grow very freely, and are very subject to be split down by the wind, if they are too much exposed.

The third sort grows naturally in *Ceylon*, and in some other parts of *India*. This is pretty rare at present in the *English* gardens, but some years past there were several pretty large plants of it growing in the garden at *Hampton Court*: this in *England* rises with a woody stem to the height of eight or nine feet, dividing into many crooked branches, garnished with oval silvery leaves, which have several irregular spots of a dark colour on their surface; they are placed alternately on the branches, and continue all the year. The flowers I have not seen, though some of the trees at *Hampton Court* produced flowers, but I was not so lucky as to see them.

This sort requires a warm stove to preserve it in this country, for it is too tender to live in the open air, excepting for a short time in the warmest part of summer.

ELATERIUM. See *Momordica*.

ELATINE. See *Linaria*.

ELECAMPANE. See *Inula*.

ELEPHANTOPUS. *Lin. Gen. Plant. 827.* Elephant's Foot.

The Characters are,

The flowers are collected in one common involucre, each contains four or five florets, which are tubulous, and divided into five equal parts; they have five very short hairy stamina; in the bottom is situated an oval germen, which afterward becomes a single compressed seed crowned with bristles, and sitting on a naked placenta.

The Species are,

1. ELEPHANTOPUS foliis oblongis scabris. *Hort. Cliff. 390.* Elephantopus with oblong rough leaves.

2. ELEPHANTOPUS foliis ovatis tomentosiss. *Gron. Virg. 90.* Elephantopus with oval woolly leaves.

The first sort grows naturally in both the *Indies*; this sends out many oblong rough leaves, which spread near the ground; between these, in the spring, arises a branching stalk little more than a foot high; the side branches are short, and are generally terminated by two heads of flowers, each standing upon a short foot-stalk; the heads contain a great number of hermaphrodite florets, included in a common involucre, composed of four oval leaves, ending in acute points; the florets are of a pale purple colour, but it rarely produces seeds in *England*.

The second sort grows naturally in *South Carolina*; the plants of this have frequently come up in the earth, which has been sent from thence with other plants; this hath several oval woolly leaves growing from the root, which have many transverse nerves, running from the midrib to the sides; they spread flat on the ground, and between these arise a stiff stalk about a foot high, which divides into many branches, each being terminated by two flowers, which are composed of several florets, inclosed in a four-leaved involucre; two of these leaves are alternately larger than the other: the involucre is longer than the florets, so they do but just appear within the two larger leaves; the flowers make no appearance; they appear in *July*, but the seeds never ripen in this country.

The first sort hath a perennial root, but an annual stalk. If this is planted in pots, and sheltered in the winter from frost, it may be preserved several years, and the plants will annually flower; but the second sort seldom continues longer than two years.

They are propagated by seeds, which should be sown on a hot-bed in the spring; and when the plants are come up, they must be transplanted into pots, and plunged into a hot-bed of tanners bark, observing to water and shade them until they have taken root; then they should have a large share of fresh air in warm weather, and must be frequently refreshed with water.

ELICHRYSUM. See *Gnaphalium*.

ELLISIA. *Brown. Hist. Jam.* 262.

The Characters are,

The flower has a small cylindrical empalement of one leaf, indented in five parts at the brim; it has one tubulous petal, whose brim is cut into five segments, which spread open; it has four stamina, two of which are longer than the other, and a roundish germen, which becomes a roundish berry crowned by the empalement, inclosing eight nuts, which have two cells, with one angular seed in each.

We have but one Species of this genus, viz.

ELLISIA.

This grows naturally in *Jamaica*, and some of the other islands in the *West-Indies*; it has a shrubby stalk, which divides into many slender, angular, ligneous branches, garnished with oval leaves which stand opposite; some of which are obtuse, and others end in acute points; they are sawed on their edges toward the top, and are of a light green colour when they are in the stove; but in summer, when they are exposed to the open air, they change black, and continue so till after they have been some time in the stove again. The flowers (according to *Dr. Brown's* figure) are disposed in loose spikes, which come out from the wings, and also at the end of the branches; they are white and of the ringent kind: the branches are armed at each joint with two slender erect thorns, which are situated opposite immediately above the leaves, and are unequal, one being longer than the other.

This plant is propagated by cuttings, which put out roots with great facility in any of the summer months; if they are planted in pots, and plunged into a moderate hot-bed of tan, and shaded from the sun, they will soon take root; when they begin to shoot they should have free air

admitted to them, and gradually hardened; then they should be carefully separated, and each planted in a small pot, placing them under cover till they have taken new root; when they may be removed into a warm sheltered situation, where they may remain till autumn; then they must be removed into a stove, and during the winter season should have a temperate heat, in which they will thrive best; for when they are too tenderly treated, their shoots are weak, and subject to be attacked by vermin, nor will the plants live through the winter in a green-house. In summer, they should be placed in the open air in a warm sheltered situation; with this management the plants have succeeded best.

ELM. See *Ulmus*.

EMERUS. *Tourn. Inst. R. H.* 650. Scorpion Sena, vulgò.

The Characters are,

The flower hath an empalement of one leaf, divided into five parts; the flower is of the butterfly kind; the standard is narrow, and shorter than the wings, over which it is arched; the wings are large and concave; the keel is heart-shaped and reflexed; it hath ten stamina: in the empalement is situated an oblong slender germen, which afterwards becomes a taper cylindrical pod, swelling in those parts where the seeds are lodged.

The Species are,

1. EMERUS caule fruticoso, pedunculis longioribus. Scorpion Sena with a shrubby stalk, and longer foot-stalks to the flowers.

2. EMERUS foliolis obcordatis, pedunculis brevioribus, caule fruticoso. Scorpion Sena with long heart-shaped leaves, shorter foot-stalks to the flowers, and a shrubby stalk.

3. EMERUS caule erecto, herbaceo, foliolis multijugatis, floribus singularibus, siliquis longissimis erectis. Scorpion Sena with an erect herbaceous stalk, the leaves composed of many pair of lobes, single flowers proceeding from the sides of the stalks, and very long erect pods.

The first of these shrubs is very common in all the nurseries near *London*; this rises with weak shrubby stalks to the height of eight or nine feet, dividing into many slender branches, garnished with winged leaves, composed of three pair of lobes, terminated by an odd one. The flowers come out upon long foot-stalks from the side of the branches, two or three of these foot-stalks arising from the same point, each sustaining two, three, or four yellow butterfly flowers, which are succeeded by long slender pods, swelling in those parts where the seeds are lodged; these shrubs continue long in flower, especially in cool seasons, and frequently flower again in autumn, which renders them valuable.

The second sort rises with many shrubby stalks like the first, but not more than half the height; this hath larger leaves, which are of an oblong heart-shape. The flowers are rather larger than those of the first, and stand upon shorter foot-stalks; these differences hold in the plants which are raised from seeds, therefore I think they may be allowed to stand as distinct species, though there is a great likeness at first sight in them.

These shrubs are easily propagated by laying down their tender branches, which will take root in one year, and may then be transplanted into a nursery, and managed in the same manner as other flowering shrubs.

The third sort grows naturally in the *West-Indies*, where *Plumier* first discovered it in the *French* settlements, but has since been found growing in plenty at *La Vera Cruz*, in *New Spain*, by the late *Dr. Housloun*. This plant is annual, it rises with a round herbaceous stalk three feet high, garnished at each joint with one long winged leaf, composed of about twenty pair of lobes, terminated by an odd one; the flowers come out singly from the side of the stalk, immediately above the foot-stalks of the leaves, standing upon slender foot-stalks; they are larger than those of either of the

the former sorts, and are of a pale yellow colour; these are succeeded by slender compressed pods, which are more than six inches long, having a border on each side, and swelling where each seed is lodged.

The seeds of this plant must be sown upon a hot-bed in the spring, and when the plants are fit to remove, they should be each planted into a separate small pot, and plunged into a moderate hot-bed of tanners bark, shading them from the sun until they have taken new root, then they must be treated in the same manner as other exotick plants from those warm countries. If the plants are brought forward in the spring, and kept under a deep frame in a tan-bed, or plunged into the bark-bed in the stove, when they are grown too tall to remain under common frames, they will ripen seeds in *England*, for those seeds which I received did not arrive here till *May*, and yet those plants flowered well in *August*; but the autumn proving cold, prevented their perfecting seeds, and those seeds which I reserved till the next year did not grow.

EMPETRUM. *Lin. Gen. Plant.* 977. Black-berried Heath.

The Characters are,

It hath male and female flowers on different plants; the male flowers have a three-pointed empalement, and three petals, which are narrow at their base, and three long hanging stamina; the female flowers have the same empalement and petals as the male; in the center is situated a depressed germen, with nine reflexed spreading stigmas; the germen afterward becomes a depressed round berry of one cell, inclosing nine seeds placed circularly.

We have but one Species of this genus in *England*, viz.

EMPETRUM procumbens. *Hort. Cliff.* 470. Trailing Berry-bearing Heath, Crow Berries, or Crake Berries.

This little shrub grows wild upon the mountains of *Staffordshire*, *Derbyshire*, and *Yorkshire*, and is seldom propagated in gardens, unless for variety sake; the plants should be procured from the places where they grow naturally, for the seeds remain a year in the ground before they vegetate, and afterward are very slow in their growth, so they are not worth the trouble of cultivating from seeds. If the plants are planted on a moist boggy soil in autumn, they will get roots in the winter, and will require no farther care than to clear them from weeds: as these low shrubs commonly grow upon the tops of wild mountains, where the soil is generally peaty and full of bogs, so the heath cocks feed much upon the berries of this plant; and wherever there is a plenty of these low shrubs, there are commonly many of these fowls to be found.

ENULA CAMPANA. See *Inula*.

EPHEDRA. *Lin. Gen. Plant.* 1007. Shrubby Horse Tail, *vulgò*.

The Characters are,

It hath male and female flowers in different plants; the male flowers are collected in scaly katkins, under each scale is a single flower; they have no petal, but seven stamina, which are joined in form of a column. The female flowers have a perianthium, composed of five series of leaves, which alternately lie over the divisions of the lower range; they have no petals, but two oval germen, which afterward turn to oval berries, each having two seeds.

We have but one Species of this genus in *England*, viz.

EPHEDRA pedunculis oppositis, amentis geminis. *Hort. Cliff.* 465. Shrubby Horse Tail, with opposite foot-stalks and twin katkins.

This is a low shrubby plant, which grows naturally upon the rocks by the sea in the south of *France*, in *Spain*, and *Italy*; it is also preserved in several gardens for the sake of variety, but has little beauty. This hath a low shrubby stalk, which puts out a few short branches, rising about two feet high, which have many protuberant joints, at

which come out several narrow rushy leaves, like those of the Horse Tail, which continue green all the year, but the plants rarely flower in this country.

It may be propagated by offsets, which the plants send forth in plenty, for the roots creep under ground, and put up suckers, which may be taken off to transplant in the spring; they love a pretty moist strong soil, and will endure the cold of our ordinary winters very well in the open air. Some of these plants were formerly preserved in pots, and were housed in winter; but by later experience, they are found to thrive better in the full ground.

EPHEMERUM, See *Tradescantia*.

EPIGÆA. *Lin. Gen. Plant.* 486. Trailing Arbutus.

The Characters are,

The flower hath a double empalement, the outer is composed of three, and the inner of one leaf, divided into five parts; the flower is of the salver shape; it hath ten slender stamina the length of the tube. In the center is situated a globular germen, which afterward becomes a depressed five-cornered fruit, with five cells, containing several seeds.

We know but one Species of this genus, viz.

EPIGÆA. *Lin. Gen. Plant.* 486. Trailing Arbutus.

This plant grows naturally in *North America*; it is a low plant, with a trailing shrubby stalk, which puts out roots at the joints, and when in a proper soil and situation multiplies very fast; the stalks are garnished with oblong rough leaves, which are waved on their edges; the flowers are produced at the end of the branches in loose bunches; these are white, and divided at the top into five acute segments, which spread open in form of a star.

The plants are easily propagated by their trailing stalks, which put out roots at the joints, so may be cut off from the old plant, and placed in a shady situation, and a moist soil; the best time for this is in autumn, that the plants may be well rooted before the spring. If the winter should prove severe, it will be proper to lay a few dried leaves, or some such light covering over them, which will prevent their being injured by frost; and after they are well rooted, they will require no other care but to keep them clean from weeds.

EPILOBIUM. *Lin. Gen. Plant.* 426. Willow Herb, or French Willow.

The Characters are,

The empalement of the flower is four-pointed; the flower hath four petals, and eight stamina, which are alternately shorter; under the flower is situated a long cylindrical germen, which afterward becomes a cylindrical furrowed capsule, with five cells filled with oblong seeds, crowned with down.

The Species are,

1. EPILOBIUM foliis lanceolatis integerrimis. *Lin. Hort. Cliff.* 157. Common broad-leaved Willow Herb, or French Willow.

2. EPILOBIUM foliis oppositis lanceolatis serratis. *Lin. Hort. Cliff.* 145. Hoary Willow Herb, with a large flower, commonly called Codlins and Cream.

There are several other species of this genus, some of which grow naturally in shady woods and moist places in most parts of *England*, where they are often very troublesome weeds, therefore are seldom admitted into gardens, so I shall not trouble the reader with their distinctions.

The first sort here mentioned, was formerly planted in gardens for the beauty of its flowers; but as it usually spreads far by the creeping roots, whereby it over-runs all the neighbouring plants, it has been cast out of most gardens; but it deserves to have room in some low moist places, or in great shade, where it will make a good appearance when it is in flower, and these flowers are very proper to cut for basons to adorn chimnies in the summer season. This usually grows about four feet high, with slender stiff branches,

which are beset with leaves, resembling those of the Willow, from whence it had the name of Willow Herb, or French Willow. On the upper part of the stalks the flowers are produced in long spikes, which are of a fine Peach colour; and, if the season is not very hot, they will continue near a month in beauty: this sort is found wild in divers parts of England; it is a great creeper at the root, so may be easily propagated.

There is a variety of this with white flowers, which is planted in gardens, but differs from it only in the colour of the flower; however, some persons are fond of propagating these varieties, for which reason I mentioned it here.

The second sort is found wild by the side of ditches and rivers in many parts of England; this plant grows about three feet high, and produces its flowers on the top of the stalks, but these are much less beautiful than those of the first; and the plant, being a great Rambler at the root, is never admitted into gardens. The leaves of this plant being rubbed, emit a scent like scalded apples, from whence some have given the name of Codlins and Cream to this plant.

EPIMEDIUM. *Lin. Gen. Plant.* 138. Barrenwort.

The Characters are,

The flower hath a three-leaved empalement, which falls off; it hath four obtuse petals, and four nectariums, which are cup-shaped, and as large as the petals, with four stamina, and an oblong germen, which afterward becomes an oblong pod with one cell, inclosing many oblong seeds.

This plant hath a creeping root, from which arise many stalks about nine inches high, divided at the top into three, each of which is again divided into three smaller; upon each of these stands a stiff heart-shaped leaf, ending in a point, of a pale green on the upper side, but gray on the under. A little below the first division of the stalk comes out the foot-stalk of the flower, which is near six inches long, dividing into smaller, each of these sustaining three flowers; these are composed of four leaves, placed in form of a cross; they are of a reddish colour, with yellow stripes on the border. In the center of the flower arises the style, situated upon the germen, which afterward turns to a slender pod, containing many oblong seeds, which seldom ripen with us. The roots, if planted in a good border, should be every year reduced, so as to keep them within bounds, otherwise it will spread its roots and interfere with the neighbouring plants.

EQUISETUM. Horse Tail.

There are several species of this plant, which are found in England on the sides of ditches, or in shady woods; but as they are plants which are never cultivated in gardens, I shall pass them over.

ERANTHEMUM. See Adonis.

ERICA. *Lin. Gen. Plant.* 435. Heath.

The Characters are,

The flower hath a coloured empalement of four leaves, and one swelling petal, which is quadrisid, with eight stamina fixed to the receptacle; in the bottom is situated the germen, which afterward becomes a round capsule, having four cells, which are filled with small seeds.

The Species are,

1. ERICA *antheris bicornibus inclusis, corollis inaequalibus, campanulatis mediocribus foliis oppositis sagittatis. Lin. Sp. Plant.* 352. Common smooth Heath.

2. ERICA *antheris bifidis simplicibus exsertis, corollis campanulatis longioribus, foliis quinis linearibus patentibus. Lin. Sp. Plant.* 355. Pine-leaved Heath with many flowers.

3. ERICA *antheris bicornibus inclusis, corollis ovatis racemosis, foliis ternis glabris linearibus. Lin. Sp. Plant.* 352. Dwarf Heath, with an ash-coloured bark, and Strawberry tree flower.

4. ERICA *antheris simplicibus inclusis, corollis ovatis irregu-*

laribus, floribus terno racemosis, foliis ternis ciliatis. Læf. Epist. 2. p. 9. *Lin. Sp. Plant.* 354. Heath with single sommits, oval irregular petals, triple branching flowers, and hairy leaves placed by threes.

5. ERICA *antheris bifidis exsertis, corollis globosis mediocribus, pedunculis triphyllis foliis quaternis, Lin. Sp.* 355. Shrubby African Heath.

The four first sorts grow wild upon barren uncultivated places, in divers parts of England; but notwithstanding their commonness, yet they deserve a place in small-quarters of humble flowering shrubs, where, by the beauty and long continuance of their flowers, together with the diversity of their leaves, they make an agreeable variety.

These are seldom propagated in gardens, and so not to be had from the nurseries, but may be taken up, with a ball of earth to their roots, from the natural places of their growth in autumn, and may be transplanted into the garden. The soil where they are planted should not be dunged, nor should they have any other culture than clearing them from weeds; for the less the ground is dug, the better these will thrive.

The fifth sort grows naturally at the Cape of Good Hope, and in Portugal: it hath a shrubby stalk, which rises four or five feet high, spreading into many branches, garnished with narrow smooth leaves: the flowers come out at the end of the shoots, they are of a bright purple colour, but are not succeeded by seeds in England.

This sort is preserved in some curious gardens, but is difficult to increase; it requires protection from hard frost, but in mild winters will live abroad in a warm situation.

ERICA BACCIFERA. See Empetrum.

ERIGERON. *Lin. Gen. Plant.* 855. Groundsel.

The Characters are,

It hath a compound flower, composed of many hermaphrodite florets, which form the disk, and female-half florets, which make the rays, contained in one oblong scaly empalement. The hermaphrodite florets are funnel-shaped, and have few stamina, and a small germen crowned with down, which afterward becomes a small oblong seed, crowned with long down, sitting on a naked receptacle.

The Species are,

1. ERIGERON *pedunculus unifloris lateralibus, calycibus squarrosis. Hort. Upsal.* 258. Male Fleabane of Theophrastus, and greater Fleabane of Dioscorides.

2. ERIGERON *pedunculis alternis, unifloris. Hort. Cliff.* 407. Blue acid Fleabane.

3. ERIGERON *foliis basi revolutis. Lin. Sp. Plant.* 863. Purplish Groundsel of Buenos Ayres; with under leaves like Hartshorn Plantain.

4. ERIGERON *caule floribusque paniculatis. Hort. Cliff.* 407. Annual Virginia Golden Rod.

5. ERIGERON *caule subbifloro, calyce subhirsuto. Lin. Sp. Plant.* 864. Blue Alpine Fleabane.

The first sort grows naturally in the south of France, and in Italy; it hath a perennial root, from which arise several upright stalks near three feet high, garnished with oblong, oval, hairy leaves, sitting close to the stalk; they are placed alternate; these in warm weather sweat out a clammy juice; the flowers are produced single upon pretty long foot-stalks, some arising from the side of the stalk, and others terminate it; they are yellow, and have an agreeable odour; they flower in July, and the seeds ripen in autumn.

This plant is propagated by seeds, which, if sown in autumn, will more certainly succeed, than those which are sown in the spring; it delights in a dry soil, and a sunny exposure. The second year the plants will flower and perfect their seeds, but the roots will continue some years, and annually produce their flowers and seeds.

The other four sorts are preserved in botanick gardens for the sake of variety, but are seldom admitted into gardens for pleasure. The fifth sort is a perennial plant, which grows naturally on the Alps, and may be propagated by seeds in the same manner as the first sort, but should have a shady situation and a moist soil.

The others are annual plants, which, if once admitted into a garden, and suffered to scatter their seeds, will become very troublesome weeds there.

ERINUS. *Lin. Gen. Plant.* 689.

The Characters are,

The flower hath a five-leaved empalement, and one tubulous petal, which is of the ringent kind, cut into five equal segments, is short and reflexed; it hath four stamina situated within the tube, two of which are a little longer than the other; in the bottom of the tube is situated the oval germen, which afterward becomes an oval capsule, with two cells filled with small seeds.

The Species are,

1. ERINUS *floribus racemosis*. *Lin. Sp. Plant.* 630. Erinus with branching flowers.

2. ERINUS *tomentosus, caulibus procumbentibus, floribus sessilibus axillaribus*. Woolly Erinus with trailing stalks, and flowers sitting close to their sides.

The first sort grows naturally upon the Alps and Helvetian mountains; it is a very low plant, whose leaves lie close to the ground, growing in close tufts; they are about half an inch long, and one eighth of an inch broad, sawed on their edges; between these arise the flower-stalk, which is scarce two inches high, supporting a loose bunch of purple flowers, which stand erect.

It is propagated by parting of the roots, the best time for this is in autumn; it must have a shady situation, and a loamy soil without dung, for in rich earth these plants are very subject to rot.

The second sort was sent me by the late Dr. Housloun, from La Vera Cruz, where he found it growing naturally; this sends out several trailing stalks about six inches long, which are closely garnished with small oval leaves placed on every side; they are very white and woolly, and at the joints, just above the leaves, come out the flowers, sitting very close to the stalks; they are white, and are succeeded by round capsules, having two cells filled with small seeds; this plant has great resemblance at a distance to the sea Cudweed.

The second sort is annual, so is propagated by seeds, which should be sown in pots and plunged into a moderate hot-bed, where sometimes the plants will come up in five or six weeks, and at other times the seeds do not vegetate till the following spring; this happens frequently, when the seeds have been kept long after they were gathered. When the plants are fit to remove, they should be each planted in a separate small pot, and plunged into a hot-bed of tanners bark; when they have taken new root, they should be treated in the same way as other plants from warm countries, by admitting proper air to them at all times when the weather is warm, and frequently refreshing them with water; if the plants are brought forward early in the spring, they will perfect seeds, otherwise the winter will come on before the seeds ripen.

ERIOCEPHALUS. *Dill. Hort. Elth.* 110. *Lin. Gen. Plant.* 890.

The Characters are,

It hath a radiated flower, composed of female half florets, which form the rays, and hermaphrodite florets which form the disk; the hermaphrodite flowers are funnel shaped, and cut into five parts at the brim, and have five stamina, with a naked germen; the female florets have their petals stretched out on one side like a tongue, divided at the end into three small lobes; they have no stamina, but an oval naked germen; these have one naked seed, sitting on the naked plain receptacle.

We have but one Species of this genus, viz:

ERIOCEPHALUS. *Lin. Sp. Plant.* 926. We have no proper title for this in *English*.

This plant hath a shrubby stalk, which rises from six to eight feet high, putting out many side branches, closely garnished with hairy leaves, which come out in clusters, and are divided into three or five parts, which spread open like a hand; they have a strong smell when bruised, approaching to that of the Lavender Cotton, but not quite so rank; the flowers are produced in small clusters at the extremity of the branches, standing erect, and are tubulous; the female florets which compose the rays form a hollow, in the middle of which the hermaphrodite flowers are situated which form the disk; but the plants seldom flower in this country.

It is propagated by cuttings, which may be planted any time from May to the middle of August, that there may be time for them to get good root before the winter; they should be shaded from the sun till they have taken root; then they should be removed into the open air, and placed in a sheltered situation, where they may remain till October, when they must be removed into shelter, where they may be secured from frost: in the summer, when the plants are placed in the open air, they will require to be frequently refreshed with water in hot weather.

These plants retain their leaves all the year, so they add to the variety of exoticks in the winter season.

ERUCA. *Tourn. Inst. R. H.* 226. *tab.* 111. Rocket.

The Characters are,

The flower has a four-leaved empalement; it hath four oblong petals, placed in form of a cross; it hath six stamina, four of which are a little longer than the empalement, the other two are shorter; it hath an oblong taper germen, which afterward becomes a taper cornered pod with two cells, filled with roundish seeds.

The Species are,

1. ERUCA *foliis pinnato-laciniatis, laciniis exterioribus majoribus*. Greater Garden annual Rocket, with a white striped flower.

2. ERUCA *foliis lanceolatis, pinnato-dentatis, caule nudo simplici*. Rocket with a Daisy leaf.

3. ERUCA *foliis pinnatis glabris, caule ramoso, floribus terminalibus*. Narrow-leaved perennial Rocket, with a yellow flower.

4. ERUCA *foliis dentato-pinnatifidis hirsutis, caule hispido, siliquis laevibus*. Greater wild Saffron-coloured Rocket, with a rough stalk.

5. ERUCA *foliis pinnatis, foliolis lanceolatis pinnatifidis*. *Prod. Leyd.* 342. Rocket with a Tansy leaf.

6. ERUCA *foliis sinuato-pinnatis, sessilibus, caule ramoso*. Sicilian Rocket with a Shepherd's Purse leaf.

The first sort is an annual plant, which was formerly much cultivated in the gardens as a salad herb, but at present is little known by the gardeners, for it has been long rejected on the account of its strong ungrateful smell. It stands in the list of medicinal plants, but is seldom used, though it is reckoned a provocative and a good diuretick: when it is propagated for salads the seeds should be sown in drills, in the same manner as is practised for other small salad herbs; for it must be eaten young, otherwise it will be too strong for most palates. The winter and spring seasons are the times when this herb is usually eaten, for when it is sown in the summer the plants soon run up to seed, and are then too rank for use.

The second sort grows naturally in the south of France and Italy, where it is often eaten as a salad herb; this hath many spear-shaped leaves arising from the root; the stalks are single, naked, and rise about a foot high; the flowers grow in loose bunches on the top of the stalks, which are succeeded by pods having two cells, filled with small round seeds; this is an annual plant, which may be propagated by seeds in the same manner as the former.

The third sort grows naturally about *Paris*, and in many other parts of *Europe*; the leaves of this are narrow, and regularly divided in form of a winged leaf; the stalks branch out upward, and are terminated by loose spikes of yellow flowers. This hath a perennial root and an annual stalk.

The fourth sort grows naturally upon old walls and buildings in many parts of *England*, where it continues flowering all the summer, but is rarely admitted into gardens. It is sometimes used in medicine, for which reason I have here mentioned it.

The fifth sort grows naturally about *Turin*. This hath fine divided leaves, somewhat like those of *Tansy*, but are of a hoary green colour; the stalks rise a foot and an half high, garnished with leaves of the same form, but gradually diminish in their size upward; the flowers are produced in clusters at the top of the stalks, they are small, and of a pale yellow colour, and are succeeded by slender taper pods, which contain two rows of small round seeds.

The sixth sort grows naturally in *Italy* and *Spain*; it is an annual plant, with many oblong leaves, which are smooth, and regularly sinuated on their sides, in form of a winged leaf, of a light green, having a hot biting taste; the stalks rise a foot high, they are strong, and divide into several branches, garnished with a single leaf at each joint, shaped like those below, but smaller. The flowers are produced in loose clusters at the end of the branches; they are white, and near as large as those of the *Garden Rocket*, and are succeeded by taper pods, containing two rows of round seeds.

These plants are preserved in botanick gardens for the sake of variety, so are here mentioned; that those who are inclined to cultivate them as such, may do it by sowing their seeds in an open situation. When the plants come up, they will require no other culture but to thin them, and keep them clear from weeds. They flower in *June* and *July*, and their seeds ripen in *August*.

ERUCAGO. See *Bunias*.

ERVUM. *Lin. Gen. Pl.* 784. Bitter Vetch.

The Characters are,

The flower is of the butterfly kind, having a large roundish plain standard, two obtuse wings half the length of the standard, and a shorter keel which is pointed; with ten stamina, nine joined, and one standing separate, terminated by single summits; and an oblong germen, which afterward becomes an oblong taper pod, jointed between each seed.

The Species are,

1. ERVUM *germinibus undato plicatis*. *Hort. Upsal.* 224. The true Bitter Vetch.

2. ERVUM *seminibus compressis convexis*. *Lin. Sp. Pl.* 738. Common Lentils.

3. ERVUM *pedunculis unifloris*. *Lin. Sp. Plant.* 738. Lentil with one flower upon each foot-stalk.

4. ERVUM *pedunculis subbifloris, seminibus globosis quaternis*. *Flor. Suec.* 606. Corn Vetch with single smooth pods.

5. ERVUM *pedunculis multifloris, seminibus globosis binis*. *Lin. Sp. Pl.* 738. Corn Vetch having many hairy pods.

The first sort grows naturally in *Italy* and *Spain*: it is an annual plant, which rises with angular weak stalks a foot and an half high, garnished at each joint with one winged leaf, composed of fourteen or fifteen pair of lobes, very like those of the Vetch, but narrower; the flowers come out from the side of the stalks on foot-stalks, each sustaining two pale coloured flowers, which are succeeded by short pods a little compressed, containing three or four round seeds; the pods swell at the place where each seed is lodged, so that it is called a jointed pod by many.

The second sort is the common Lentil, which is cultivated in many parts of *England*, either as fodder for cattle,

or for the seeds, which are frequently used for meagre soups. This is also an annual plant. It rises with weak stalks a foot and an half high, garnished with winged leaves at each joint, composed of several pair of narrow lobes, terminated by a tendril or clasper, which fastens to any neighbouring plant, and is thereby supported; the flowers come out three or four together upon short foot-stalks from the side of the branches; they are small, of a pale purple colour, and are succeeded by short flat pods, containing two or three seeds, which are flat, round, and a little convex in the middle. The seeds of this plant are commonly sown in *March*, where the land is dry, but in moist ground, the best time is in *April*. The usual quantity of seed allowed to an acre of land, is from one bushel and an half to two bushels. If these are sown in drills in the same manner as Peas, they will succeed better than when they are sown in broad cast: the drills should be a foot and an half asunder, to allow room for the *Dutch* hoe to clean the ground between them; for if the weeds are permitted to grow among them, they will get above the Lentils and starve them.

There is another sort of Lentil which has been cultivated of late years in *England*, by the title of *French Lentil*. This is the *Lens major* of *Caspar Baubin*, and is undoubtedly a different species from the common, being twice the size, both in plant and seed, and constantly produces the same from seeds, though they do not differ much in their characters, but this is much better worth cultivating than the other. This pulse is frequently called *Tills* in many parts of *England*.

The third sort is very like the common Lentil, but differs from it, in having but one flower on each foot-stalk, whereas the other has three or four, but in other respects is the same, so may be cultivated in the same manner.

The fourth and fifth sorts are small annual Vetches, which grow naturally among the *Wheat* and *Rye* in many parts of *England*, so are not admitted into gardens; they are only mentioned here as weeds, which may be easily rooted out of the fields, if they are cut up when they begin to flower, and not permitted to ripen their seeds; for as they have annual roots, so if they do not scatter their seeds, they may be soon destroyed.

ERVUM ORIENTALE. See *Sophora*.

ERYNGIUM. *Lin. Gen. Plant.* 287. Sea Holly, or Eryngo.

The Characters are,

It hath many small flowers sitting upon one common conical receptacle; the flowers have a five-leaved erect empalement sitting upon the germen, and form a roundish general umbel, which is uniform; each flower has five oblong petals, and five stamina, standing above the flowers. Under the empalement is situated a prickly germen, which afterward becomes an oval fruit divided in two parts, each having one oblong taper seed.

The Species are,

1. ERYNGIUM *foliis radicalibus subrotundis plicatis spinosis, capitulis pedunculatis*. *Hort. Cliff.* 87. Common Sea Holly, or Eryngo.

2. ERYNGIUM *foliis radicalibus pinnatis tripartitis*. *Hort. Cliff.* 87. Common wild Eryngo.

3. ERYNGIUM *foliis radicalibus ovalibus planis crenatis, capitulis pedunculatis*. *Hort. Cliff.* 87. Broad-leaved plain Eryngo.

4. ERYNGIUM *foliis radicalibus digitato-multifidis*. *Lin. Sp. Pl.* 233. Purple, Violet-coloured, Mountain Eryngo.

5. ERYNGIUM *foliis radicalibus rotundato-multifidis, capitulis pedunculatis*. Alpine Eryngo, with a large pale-coloured head.

6. ERYNGIUM *foliis radicalibus pinnatis, serratis spinosis, foliolis trifidis*. Oriental Eryngo with trifid leaves.

7. *ERYNGIUM foliis gladiatis serrato-spinosis, floralibus indivisis. Lin. Sp. Plant. 232.* American Sea Holly with leaves like the Aloe, lightly sawed, commonly called Rattlesnake Weed in America.

8. *ERYNGIUM foliis radicalibus oblongis incis, caule dichotomo, capitulis sessilibus. Hort. Cliff. 87.* Lesser plain Eryngo.

9. *ERYNGIUM foliis radicalibus cordatis oblongis, caulibus pinnatifidis, capitulo subcylindrico. Lin. Sp. Pl. 233.* Blue Alpine Eryngo, with heads like the Teasel.

10. *ERYNGIUM foliis gladiatis serrato-spinosis, floralibus multifidis. Lin. Sp. Pl. 232.* Stinking Eryngo, having narrow sawed leaves, commonly called Feverweed.

The first of these species grows in great plenty on the gravelly shores in divers parts of *England*, the roots of which are candied, and sent to *London* for medicinal use, and is the true Eryngo. This hath creeping roots, which spread far in the ground; the leaves are roundish, stiff, and of a gray colour, set with sharp spines on the edges. The stalks rise a foot high; they are smooth, garnished at each joint with leaves of the same form as the lower, but smaller, and embrace the stalks with their base; at the end of the branches, come out the flowers in roundish prickly heads; under each is situated a range of narrow, stiff, prickly leaves, spreading like the rays of a star; the flowers are of a pale blue colour.

This sort will grow in a garden, if the roots are planted in a gravelly soil, and produce their flowers annually; but the roots will not grow near so large and fleshy, as those which grow on the sea shore, where they are flowed by every tide with salt water. The best time to transplant the roots is in autumn, when their leaves decay; the young roots are much better to remove than the old. If they are kept clean from weeds, it is all the culture they will require.

The second sort grows naturally in several parts of *England*, where it is a very troublesome weed; for the roots spread greatly in the ground, so are not easily destroyed by the plough, therefore it is not admitted into gardens.

The third sort makes a very pretty appearance when it is in flower, especially that with blue stalks and flowers, for there is a variety of this with white flowers and stalks, though not so common. As this doth not spread at the root, but keeps within bounds, so it deserves a place in the pleasure-garden. It is propagated by seeds, which, if sown in the autumn, will more certainly succeed, than when it is sown in the spring, for the latter commonly remains in the ground a year before they vegetate; and if the seeds are sown where the plants are to remain, they will flower stronger than those which are transplanted; for as they have long downright roots, so they are frequently broken in taking out of the ground, which greatly weakens the plants. The culture they require is to thin them where they are too near, keep them clean from weeds, and dig the ground about them every spring before they shoot.

The fourth sort grows naturally upon the mountains of *Syria*, and also upon the *Apennines*. The lower leaves of this sort are divided like the fingers of a hand, into five or six segments, which are very much cut at their extremities, and have small spines; the stalk rises about two feet high, garnished with smaller and more divided leaves; the upper part of the stalk, and also the heads of flowers, are of the finest amethyst colour, so that they make a very fine appearance. This is propagated by seeds, in the same manner as the former sort.

The bottom leaves of the fifth sort are very much divided, and the extremity of the segments form an oval or circle, ending in spines; they are of a whitish gray in the middle, and green on the borders. The stalks rise about

two feet high, garnished at the joints with smaller leaves which are finely cut: the flowers terminate the stalk, they are of a light blue colour, and grow in larger heads than either of the former sorts. This grows naturally on the *Alps*; it is a perennial plant, and may be propagated by seeds in the same manner as the former.

The sixth sort was discovered by Dr. *Tournefort* in the *Levant*. This hath a perennial root; the lower leaves are regularly divided into seven or nine parts to the midrib; these segments are sawed on their edges, and end in sharp thorns. The stalks rise a foot and an half high, sending out side branches, garnished with stiff leaves, which are divided into narrower segments than the lower, terminated by three points. The flowers terminate the stalks, sitting close among the leaves, and are of a fine blue, as are also the leaves on the upper part of the stalks, so they make a pretty appearance. It is propagated in the same manner as the three former sorts, and the plants require the same treatment.

The seventh sort grows naturally in *Virginia* and *Carolina*, where it is titled Rattlesnake Weed, from its virtues of curing the bite of that venomous reptile. This hath a perennial root, from which arise several long leaves, sawed on their edges; the leaves are disposed round the root, after the same form of the Aloe or Yucca; they are of a gray colour, near a foot long, and one inch and an half broad, stiff, ending in spines. The stalk is strong, growing two feet and an half high, dividing upward into several foot-stalks, each being terminated by an oval head of flowers, shaped like those of the former sorts; they are white, with a little cast of pale blue.

This sort is propagated by seeds, which, if sown in pots and plunged into a moderate hot-bed, the plants will come up much sooner than those which are sown in the full ground, whereby the plants will be much stronger before the winter. When the plants are fit to remove, they should be each planted in a separate small pot; and if they are plunged into a moderate hot-bed, it will forward their taking root; then they must be gradually inured to bear the open air, into which they may be removed toward the latter end of *May*, and placed among other hardy exotic plants. When the plants have filled these pots with their roots, some of them may be shaken out, and planted in warm borders; the others may be put into larger pots, and in the autumn placed under a common frame, where they may be exposed to the free air in mild weather, but sheltered from severe frost: the following spring these may be turned out of the pots, and planted in a warm situation, where they will endure the cold of our ordinary winters very well; and if in severe frost they are covered with Straw, Peas haulm, or any such light covering, it will secure them from injury.

The eighth sort grows naturally in *Spain* and *Italy*; this puts out oblong plain leaves from the root, which are cut on their edges; the stalks rise a foot high, branch out into many divisions, regularly by pairs; at each of these divisions is situated a small head of flowers, sitting very close between the branches. These have no great beauty, so the plants are seldom cultivated in gardens, except for the sake of variety.

The ninth sort grows naturally on the mountains of *Helvetia* and *Italy*. The root is perennial, the lower leaves are oblong, heart-shaped, and plain; the stalks rise from two to three feet high, branching out on their side, garnished with stiff leaves, which are deeply divided, ending in many points with sharp spines; the flowers terminate the stalks, they are collected into conical heads, and are of a light blue colour, as are also the upper part of the stalks. It is propagated by seeds in the same manner as the other sorts.

The tenth sort grows naturally in the *West-Indies*, where it is much used in medicine, being accounted of great service in the cure of fevers, from whence it hath the appellation of Feverweed in those countries. The roots of this plant are composed of many small fibres, which spread near the surface; the lower leaves are six or seven inches long, narrow at their base, and enlarge upward to an inch in breadth near the top, where they are rounded off on one side like a scymitar; they are finely sawed on their edges, and are of a light green colour; the stalk rises about a foot high, spreading out into many branches, garnished with small leaves, which end in many points; the flowers are produced in small heads which sit close at every division of the stalks, and also at the end of the branches; they are of a dull white colour, so make little appearance.

As this plant is biennial, and grows naturally in hot countries, it will not thrive in *England*, but in a warm stove. It is propagated by seeds, which must be sown on a hot-bed; and when the plants are fit to remove, they should be each planted into a small pot, and plunged into the bark-bed, and afterward treated like other tender plants from the same country; the second year they will produce flowers and frequently ripen seeds, soon after which they commonly decay.

ERYSIMUM. *Lin. Gen. Plant.* 729. Hedge Mustard.

The Characters are,

The flower hath four petals placed in form of a cross, and two translucent glands situated between the stamina. It hath six stamina, four of which are the length of the empalement, the other two are shorter. It hath a narrow four-cornered germen, which afterward becomes a long, narrow, four-cornered pod with two cells, filled with small round seeds.

The Species are,

1. ERYSIMUM *siliquis spicæ adpressis.* *Hort. Cliff.* 337. Common Hedge Mustard.

2. ERYSIMUM *foliis lyratis extimo subrotundo.* *Flor. Succ.* 557. Winter Cress, with a Rocket leaf and yellow flower.

3. ERYSIMUM *foliis radicalibus lyratis, caulinis pinnato-sinuatis, floribus laxè spicatis.* Smaller early Winter Cress, with a smooth Rocket leaf.

4. ERYSIMUM *foliis radicalibus ovatis integerrimis, petiolis decurrentibus, caulinis oblongis dentatis sessilibus.* Oriental Silymbrium with the appearance of Water Cress, and a Plantain leaf.

5. ERYSIMUM *foliis cordatis.* *Hort. Cliff.* 338. Dames Violet, smelling like Garlick, commonly called Alliarina, Sauce alone, or Jack by the Hedge.

6. ERYSIMUM *foliis integris lanceolatis.* *Flor. Lapp.* 263. Gilliflower with a Dames Violet leaf.

The first sort is used in medicine; it grows naturally on the side of foot paths, and upon old walls in most parts of *England*, so is rarely cultivated in gardens; where, if it was once admitted, it would soon become a troublesome weed.

The second and third sorts also grow naturally on the banks in many parts of *England*; these were formerly eaten in winter fallads, before the *English* gardens were furnished with better plants; since when they have been rejected, for they have a rank smell, and are disagreeable to the palate.

The fourth sort is not a native of this country, but it has propagated by the scattered seeds in so plentiful a manner, in those gardens where it has been sown, as to become a troublesome weed. The lower leaves of this sort are entire, and of an oblong form; the upper leaves are oblong and indented, in which this differs from the preceding.

The fifth sort grows naturally on the sides of banks in many parts of *England*, so is not suffered to have a place in gardens. This was formerly eaten as a fallad herb by

the poorer sort of people, who gave it the title of Sauce alone. It hath a rank smell and taste of Garlick, is very biting and hot on the palate; it is frequently prescribed in medicine.

The sixth sort is sometimes found growing naturally upon old walls in some parts of *England*, particularly at *Cambridge* and *Ely*, at both which places I have observed it. This hath pretty long, hairy, soft leaves at the root; the stalks rise a foot high, their upper part being garnished with small, greenish, white flowers in loose spikes, which are succeeded by long compressed pods, hanging downward. The roots will abide several years, if they have a dry lean soil, or grow upon a wall, for in rich land they soon decay.

ERYTHRINA. *Lin. Gen. Pl.* 762. Coral Tree.

The Characters are,

The flower is of the butterfly kind, composed of five petals; the standard is spear-shaped, long, and rises upward; the two wings are scarce longer than the empalement. The keel is composed of two petals, which are no longer than the wings. It hath ten stamina which are joined below, and unequal in their length, with an awl-shaped germen, which afterward becomes a long swelling pod ending in an acute point, having one cell, filled with kidney-shaped seeds.

The Species are,

1. ERYTHRINA *foliis ternatis, caule simplicissimo inermi.* *Hort. Cliff.* 354. Low Coral Tree, with a very long spike of flowers and thick root, commonly called the *Carolina* Coral Tree.

2. ERYTHRINA *inermis, foliis ternatis, caule arborèo.* Smooth American Coral Tree.

3. ERYTHRINA *foliis ternatis, caule arborèo aculeato.* *Hort. Cliff.* 354. Prickly three-leaved American Coral Tree, with a very red flower.

4. ERYTHRINA *foliis ternatis hastatis, caule fruticoso aculeato.* Smaller three-leaved American Coral Tree, with blacker spines and seeds.

5. ERYTHRINA *foliis ternatis acutis, caule arborèo aculeato, floribus spicatis longissimis.* Three-leaved American Coral Tree, with acute-pointed leaves and scarlet seeds.

6. ERYTHRINA *foliis ternatis acutis, caule fruticoso inermi, corollis longioribus clausis.* Coral Tree without spines, having a longer closer flower.

The first sort grows naturally in *South Carolina*, from whence Mr. Catesby first sent the seeds to *England* in the year 1724. This hath a very large knotty root, which seldom rises more than a foot high, from which come out fresh roots every spring, which grow two feet high, their lower part being garnished with trifoliate leaves of a deep green colour, which are shaped like the point of an arrow; the upper part of the stalks are terminated by a long spike of scarlet flowers, composed of five petals, the upper one being much longer than the other, so that at a small distance the flowers appear to have but one petal. The pods are five or six inches long, swelling in every part where the seeds are lodged, opening in one cell, containing five or six kidney-shaped scarlet seeds.

The second sort hath a thick, irregular, woody stem, which rises about ten or twelve feet high, sending out many strong branches covered with a brown bark, garnished with trifoliate leaves standing upon long foot-stalks, the middle lobe which terminates the leaf, being much longer than the other two; they are heart-shaped, smooth, and of a deep green colour; the flowers come out at the end of the branches, in short thick close spikes, of a deep scarlet colour, and make a fine appearance. These commonly are in beauty in *May* and *June* in this country, but are not succeeded by pods here. The flowers seldom appear till the leaves drop, so that the branches are often naked at the time when the flowers are out.

The third sort chiefly differs from the second, in having its trunk, branches, and the foot-stalks of the leaves, armed with short crooked spines, the leaves and flowers being very like those of the second sort.

The fourth sort hath shrubby stalks, which divide into branches, armed in every part with strong, crooked, black spines; the leaves are smaller than those of the two last sorts, and have a nearer resemblance to those of the first; the foot-stalks and midrib of the leaves are armed with the same sort of spines; the flowers are of a paler scarlet, and grow in looser spikes. The seeds are as large as those of the second sort, but are of a dark purple colour.

The seeds of the fifth sort were first sent me from *La Vera Cruz*, where the plants grow naturally; and since I have received seeds of the same sort from the *Cape of Good Hope*, so that it is a native of both countries. These are not half so large as those of the second or third sorts, and are of a bright scarlet colour; the leaves are also much smaller, and have long acute points; the branches are very closely armed with crooked greenish spines, as are also the ribs and foot-stalks of the leaves. The flowers grow in very long close spikes, and are of a beautiful scarlet colour.

The sixth sort grows in *Jamaica*, and some of the other islands in *America*. The pods of this sort are longer, and not more than half so thick as those of the second sort; the seeds are of a bright scarlet colour; the leaves are small and acute-pointed, the stalks are smooth and without spines; this doth not grow very large, but shoots out into branches at a little distance from the ground, which grow erect, so form a bushy shrub. The flowers come out at the end of the branches in short spikes; the standard of the flower is long, and the sides turn down over the wings, which are also longer than those of the other species, and the whole flower is more closed.

These plants when they produce their flowers, are some of the greatest ornaments to the stoves, for their flowers are produced in large spikes, and are of a beautiful scarlet, so they make a fine appearance, but they do not often flower in any of the northern parts of *Europe*; yet in the countries where they naturally grow, they produce flowers in great plenty every year, so that it is very common there to see most of their branches terminated by large spikes of flowers, when they have no leaves upon them.

These plants are best propagated by seeds, when they can be procured from the countries where they naturally grow. The seeds should be sown in small pots and plunged into a moderate hot-bed, where, if they are good, the plants will come up in a month or five weeks; when they are two inches high, they should be carefully shaken out of the pots, and each planted in a separate small pot, and plunged into a moderate hot-bed of tanners bark, where they must be shaded from the sun till they have taken new root; then they should have a large share of air admitted to them when the weather is warm: as the plants increase in strength, so they must have a larger share of air. In the autumn the plants should be removed into the stove, and for the two or three first winters while the plants are young, they will require more warmth than when they have acquired more strength. During the time the leaves continue in vigour, the plants will require to have water two or three times a week; but when they are destitute of leaves, it must be sparingly given, for moisture then is very hurtful to them. As the plants grow in strength, so they may be more hardily treated, and by managing them differently, there will be a greater chance of getting them to flower. The third sort is frequently planted in the gardens near *Lisbon*, where they annually flower and ripen their seeds.

These plants may also be propagated by cuttings, which, if planted in pots during the summer month, and plunged

into a hot-bed will take root, but the seedling plants are best.

ERYTHRONIUM. *Lin. Gen. Plant.* 375. Dog's Tooth or Dog's Tooth Violet.

The Characters are,

The flower is bell shaped, composed of six oblong petals, which spread open to their base. It hath six stamina joined to the style. In the center is situated an oblong three cornered germen, which afterward becomes an oblong obtuse capsule, with three cells filled with flat seeds.

The Species are,

1. ERYTHRONIUM *foliis ovatis*. Erythronium with oval leaves; or, Dog's Tooth Violet with a broader and rounder leaf, and a purple red flower.

2. ERYTHRONIUM *foliis lanceolatis*. Dog's Tooth Violet, with a longer and narrower leaf, and a purplish white flower.

The first sort sends out two oval leaves, which are joined at their base, three inches long, and one and an half broad in the middle; these at first embrace each other inclosing the flower, but afterward they spread flat upon the ground; they are spotted with purple and white spots all over their surface; between these rises a single naked stalk about four inches high, of a purple colour; this sustains one flower, composed of six spear-shaped petals, which in this are purple, but in some they are white; the flower hangs downward, and the petals reflex and spread open to their base. In the center is situated the oblong three-cornered germen supporting a single style which is longer than the stamina, and crowned by a triple stigma. The plant flowers early in *April*. The root of this plant is white, oblong, and fleshy, and shaped like a tooth, from whence it had the title of Dog's Tooth.

The second sort differs from the first in the shape of its leaves, which are longer and narrower, and the flowers are a little larger but not so well coloured. They grow naturally in *Hungary*, and in some parts of *Italy*.

They are propagated by offsets from their roots. They love a shady situation and a gentle loamy soil, but should not be too often removed. They may be transplanted any time after the beginning of *June*, when their leaves will be quite decayed, till the middle of *September*; but the roots should not be kept very long out of the ground, for if they shrink, it will often cause them to rot. The roots of these flowers should not be planted scattering in the borders of the flower-garden, but in patches near each other, where they will make a good appearance.

ESPALIERS, are either formed of rows of trees planted about a whole garden or plantation, or in hedges, so as to inclose quarters or separate parts of a garden, which are trained up flat like a hedge, for the defence of tender plants against the violence of wind and weather. See HERBES.

The most commonly received notion of Espaliers are hedges of fruit trees, which are trained up regularly to a lattice of wood work, formed either of Ash-poles, or square long timbers cut out of Fir, &c. and it is of this sort of Espalier that I shall treat in this place.

Espaliers of fruit trees are commonly planted to surround the quarters of a kitchen garden, for which purpose they are of admirable use and beauty; for by laying out the walks of this garden regularly, which are bounded on each side by these hedges, when they are handsomely managed, they have a wonderful effect in sheltering the kitchen plants in the quarters, and also screening them from the sight of persons in the walks; so that a kitchen-garden well laid out in this manner and properly managed, will be equal to the finest regular parterre for beauty.

The trees chiefly planted for Espaliers are Apples, Pears, and some Plumbs, but the two former are mostly used: some

plant Espaliers of Apples grafted upon Paràdise stocks, but these being of humble growth and short duration, are not so proper for this purpose, unless for very small gardens; therefore I should rather advise the having them upon Crab stocks, or (if in smaller gardens, where the trees cannot be allowed to grow so high) upon what the gardeners call the *Dutch stock*; which will cause them to bear sooner, and prevent their growing too luxuriant, and these will continue many years in vigour.

In choosing the trees for an Espalier, the several sorts which are nearly of the same growth should be planted in the same line, that the Espalier may be the more regular, and of an equal height, which greatly adds to their beauty; for if they are planted with trees which shoot unequally, it will be impossible to have the Espalier regular: besides, the distance of the trees must be in proportion to their growth; for some trees, *viz.* those of a larger growth, should be planted thirty or thirty-five feet asunder; whereas those of smaller growth, need not be above twenty-five feet distance.

The width of the walks and borders between these Espaliers should (in a large garden) be fourteen or sixteen feet at least; and if the trees are designed to be carried up pretty high, the distance should be greater, that each side may receive the advantage of the sun and air, which is absolutely necessary, if you would have the fruit well tasted. And if your ground is so situated, that you are at full liberty which way to make the Espaliers, I would advise the placing the lines from the east a little inclining to the south, and toward the west a little inclining to the north, that the sun may shine between the rows in the morning and evening when it is low; for in the middle of the day, when the sun is advanced far above the horizon, it will shine over the tops of the Espaliers, and reach the surface of the earth about the roots, which is a matter of more consequence than many people are aware of.

The sorts of Apples proper for Espaliers, are the Golden Pippin, Nonpareil, Rennette Grise, Aromatick Pippin, *Holland Pippin*, *French Pippin*, *Wheeler's Ruffet*, *Pile's Ruffet*, with some others. The season for planting, and the method of pruning and training these trees may be seen under the articles of APPLES and PRUNING.

The sorts of Pears proper for an Espalier, are chiefly the summer and autumn fruits, for some of the winter Pears seldom succeed in an Espalier. These trees, if designed for a strong moist soil, should be upon Quince stocks; but if for a dry soil, upon free stocks. Their distance of planting must also be regulated by the growth of the trees, which are more unequal in Pears than Apples, and should therefore be more carefully examined before they are planted. As for those Pears upon free stocks, the distance should never be less than thirty feet for moderate growing trees; but for vigorous shooters, forty feet is little enough, especially if the soil be strong, in which case they should be planted at a greater distance. The particular sorts of Pears I would recommend for an Espalier, are the Jargonelle, Blanquette, Summer Boncretien, *Hamden's Burgamot*, Autumn Burgamot, L'Ambrette, Gros Rousselet, Chaumontelle, Beurre du Roy, Cressane, *Holland Bergamot*, and La Chassery; always remembering, that those Pears which are of the melting kind, will do better in Espalier than the breaking Pears, which seldom ripen so well on an Espalier; as also that many sorts of Pears will ripen well on an Espalier in a warm soil and situation, which require a wall in other places. As to the method of planting, see the article PEAR; and for pruning and managing, see PRUNING.

I shall now give directions for making the Espalier, to which the trees are to be trained; but this should not be done until the third year after the trees are planted, for

while they are young, it will be sufficient to drive a few stakes into the ground on each side of the trees, to which the branches should be fastened in an horizontal position, in order to train them properly for the Espalier; which stakes may be placed nearer, or at a farther distance, according as the shoots produced may require, and these will be sufficient for the three first years; for should you frame the Espalier the first year the trees are planted, the Espalier would rot before the trees will cover it. The cheapest method to make these Espaliers is with Ash-poles, of two sorts; one of the largest size, which contains thirteen poles in a bundle, and the other size those of half an hundred. The first or largest size poles, should be cut about seven feet and an half long; these are intended for upright stakes, and must be sharpened at the largest end, that they may, with more ease, be driven into the ground; these should be placed at a foot distance from each other in a direct line, and of an equal height, about six feet above ground; then a row of strait slender poles should be nailed upon the top of the upright stakes, which will keep them exactly even, and continue to cross the stakes with the smaller poles, at about nine inches distance, row from row, from the top to within a foot of the bottom of the stakes. These rows of poles should be fastened with wire to the stakes, which, if painted or oiled will last a long time.

When the Espalier is thus framed, the branches of the trees should be fastened thereto, either with small Osier twigs, rope yarn, or some such binding, training them in a horizontal position, and at equal distances; being careful not to cross any of the branches, nor to lay them in too thick. The distance which should be allowed for the branches of Pears and Apples, must be proportioned to the size of their fruit; such of those whose fruit is large, as the Summer Boncretien, Monsieur John, and Beurre du Roy Pears, and the Rennet Grise, *Holland Pippin*, *French Pippin*, and other large Apples, should have their branches six or eight inches distance at least; and to those of lesser growth, four or five inches will be sufficient. But for farther directions, I shall refer to the articles of the several fruits; as also that of PRUNING, where these particulars will be sufficiently explained.

But besides this sort of Espalier made with Ash-poles, there is another sort that is by many people preferred, which is framed with square timbers cut to a proper size. These, though they appear more lightly, when well fixed and painted, are not of longer duration than one of the former, provided it is well made, and the poles are strong which are set upright; nor will they answer the purpose better, though they are vastly more expensive; for the great beauty of Espaliers consists in the regular training the branches of the trees, which, especially in summer, when the leaves are on, will entirely hide from the sight the frame of the Espalier; therefore all expence in erecting these is needless, farther than making provision to keep the branches of the trees in good order.

EVER-GREEN THORN. See Mespilus.

EVERLASTING PEA. See Lathyrus.

EUONYMUS. *Lin. Gen. Plant.* 240. The Spindle Tree, or Prickwood.

The Characters are,

The flower hath four or five oval petals, which spread open, and four or five short stamina joined at their base to the germen. In the center is situated a large oval germen, which afterward becomes a succulent four or five-cornered coloured capsule, having so many cells as angles, each containing one oval seed.

The Species are,

1. EUONYMUS *foliis lanceolatis, floribus tetandriis, fructu tetragono.* The common Spindle Tree.

2. *EUONYMUS foliis ovato-lanceolatis, floribus pentandriis, fructu pentagono, pedunculis longissimis.* Broad-leaved Spindle Tree.

3. *EUONYMUS floribus omnibus quinquesidis.* Lin. Sp. Pl. 197. Virginian Ever-green Spindle Tree, with rough warty seed vessels.

4. *EUONYMUS foliis pinnatis, fructu racemoso trigono.* Spindle Tree with an unbranching stalk, a winged leaf, and a round fruit, having three seeds.

The first sort grows naturally in *England*, and is very common in hedges. This, when growing in hedges, is seldom seen of any considerable size, but rather appears like a shrub; but if planted single, and trained up like other trees, will have a strong woody stem, and rise more than twenty feet high, dividing into many branches, garnished with spear-shaped leaves, three inches long, and one inch and a quarter broad; they are entire, of a deep green colour, and are placed opposite. The flowers come out in small bunches from the side of the branches, upon slender foot-stalks; they are composed of four whitish petals, which expand in form of a cross. The empalement is divided into four parts. The flowers have four stamina, and the fruit is four-cornered, and opens into four cells. The fruit ripens in *October*, at which time the seed vessels spread open and expose the seeds, which are of a beautiful red colour, so that when the branches are well stored with them, the trees make a good appearance at that season. The wood of this tree is used by the musical instrument makers for tooting of organs and virginal keys; the branches are cut into tooth-picks, for making of skewers, and spindles are made of this wood, from whence the tree was titled Spindle Tree; but in some counties it is called Dogwood.

The second sort grows naturally in *Austria* and *Hungary*; this rises with a stronger stem than the first, and grows to a larger size. The leaves are oval and spear-shaped, about four inches long, and two inches broad in the middle, of a light green colour; they are placed opposite on the branches, with short foot-stalks. The flowers come out from the side of the branches, upon very long slender foot-stalks; these branch out into a loose bunch, so that the flowers stand upon separate foot-stalks. The flowers have five petals, which at first are white, but afterward change to a purple colour; the empalement of the flower is divided into five parts. It hath five stamina, and the fruit is five-cornered; the fruit is also much larger than that of the common sort.

The third sort grows naturally in *Virginia*, *Carolina*, and other parts of *North America*; it rises with a shrubby stalk eight or ten feet high, dividing into many branches, which come out opposite at every joint, garnished with spear-shaped leaves, two inches long, and three quarters of an inch broad; they are placed opposite, and continue all the year. The flowers are produced at the end of the branches, and also from the sides, in small clusters, which are succeeded by round capsules, which are closely armed with rough protuberances.

As this is an ever-green shrub, so it merits a place in curious gardens, and particularly in all plantations of ever-green trees and shrubs; there is a variety of this with variegated leaves, which is preserved in the nursery-gardens.

The fourth sort grows naturally in *Jamaica*, and some of the other islands in the *West-Indies*; this rises with an upright woody stalk, ten or twelve feet high; it divides into two or three short branches, garnished by winged leaves, composed of six or seven pair of small leaves (or lobes); these leaves come out without order, standing upon long foot-stalks. The flowers come out in clusters from the side of the branches, toward their end, and are succeeded by roundish capsules, having a thick brown cover, which open in three cells, each containing a single hard seed.

The two first sorts may be propagated either by seeds, or layers; if by seeds, they should be sown in autumn, soon after they are ripe; then the plants will come up the spring following, but if the seeds are not sown till the spring, the plants will not appear till the year after, whereby a whole year is lost. If they are sown upon a shady border, they will succeed better than when they are more exposed to the sun. When the plants come up, they will require no other care but to keep them clean from weeds till the following autumn, when, as soon as their leaves decay, the plants should be taken up and transplanted into a nursery, in rows two feet distant, and the plants one foot asunder in the rows; in this place they may remain two years, and then they may be removed to the places where they are to remain.

They may also be propagated by laying down the young shoots in the autumn, which will take root in one year, and may then be planted in a nursery, to remain a year or two, then may be planted where they are to remain.

The last sort is too tender to live in this country without the assistance of an hot-house, therefore when any of the plants are brought over, they should be planted in pots, and plunged into the tan-bed, and afterward treated in the same way as other plants from hot countries.

EUPATORIOPHALACRON. See *Verbesina*.

EUPATORIUM. Lin. Gen. Plant. 842. Hemp Agrimony.

The Characters are,

It hath a compound flower, composed of hermaphrodite florets, included in one common scaly empalement, whose scales are narrow, erect, and unequal. The florets have each five short stamina. In the bottom is situated a small germer, which afterward becomes an oblong seed, crowned with down, sitting in the empalement.

The Species are,

1. *EUPATORIUM foliis digitatis.* Hort. Cliff. 396. Common Hemp Agrimony.

2. *EUPATORIUM foliis lanceolato-ovatis, serratis, petiolatis, caule erecto.* Hort. Cliff. 396. New England Hemp Agrimony, with Nettle leaves, purplish flowers, and spotted stalks.

3. *EUPATORIUM foliis subverticillatis, lanceolatis serratis, petiolatis rugosis.* Lin. Sp. Pl. 838. Canada Hemp Agrimony, with a long rough leaf and purplish stalk.

4. *EUPATORIUM caule volubili, foliis cordatis dentatis acutis.* Hort. Cliff. 396. Climbing American Hemp Agrimony, with a spear-like sharp-pointed leaf.

5. *EUPATORIUM foliis sessilibus distinctis subrotundo-cordatis.* Lin. Sp. Plant. 837. American Hemp Agrimony with round leaves, having no foot-stalk.

6. *EUPATORIUM foliis ovatis, obtusè serratis petiolatis trinerviis, calycibus simplicibus.* Lin. Sp. Plant. 839. American Hemp Agrimony, with a Tree Germander leaf and a white flower.

7. *EUPATORIUM foliis connatis tomentosis.* Hort. Cliff. 396. Virginian perfoliate Hemp Agrimony, with long Sage-like leaves, closely surrounding the stalks.

8. *EUPATORIUM foliis cordatis serratis caule erecto arboreo.* Eupatorium with heart-shaped sawed leaves, and an upright tree like stalk.

9. *EUPATORIUM foliis lanceolato-linearibus trinerviis integerrimis.* Lin. Sp. Pl. 836. Virginian Hemp Agrimony, with a narrow leaf and white flowers.

10. *EUPATORIUM foliis cordatis acuminatis, caule volubili, floribus spicatis racemosis.* Eupatorium with heart-shaped pointed leaves, a twining stalk, and branching spiked flowers.

11. *EUPATORIUM foliis cordato-ovatis, obtusè serratis petiolatis, calycibus multifloris.* Lin. Sp. Pl. 838. Hemp Agrimony, with a Wood Sage leaf and a blue flower.

This last sort grows naturally in *Carolina*, from whence the late Dr. Dale sent me the seeds; the plants flowered very finely the year after they were raised, but never have flowered since, for the roots creep greatly in the ground, but never send up any stalks.

The first sort grows naturally by the side of rivers and ditches in most parts of *England*, and is the only species of this genus, which is known to grow naturally in *Europe*; this is esteemed as a very good vulnerary herb, so stands in the list of medicinal plants. It is seldom admitted into gardens, because wherever it is suffered to seed, the ground will be well stored with the plants to a great distance.

The second sort grows naturally in several parts of *North America*; this hath a perennial root, but an annual stalk, which rises two feet and an half high; it is purple, and has many dark spots upon it. The leaves are rough, oval, and spear-shaped, having foot-stalks; they are placed by threes round the stalk toward the bottom, but upward by pairs opposite at each joint. The stalks are terminated by clusters of purple flowers, growing in a sort of corymbus.

The third sort grows naturally in *North America*; this rises with an upright stalk six or seven feet high, garnished with long, narrow, spear-shaped leaves at each joint; these are deeply sawed on their edges, and the midrib is oblique to the foot stalks; they are placed by fours round the stalk in whorls, and are of a dark green colour. The stalks are terminated by bunches of purple flowers like the last. This hath a perennial root and an annual stalk.

The fourth sort grows naturally in *Virginia* and *Carolina*; this hath a perennial root, which sends out many twining stalks in the spring, which twist about any neighbouring support, and rise to the height of five or six feet, garnished at each joint with two heart-shaped leaves, which are indented on their edges, and terminate in acute points; and at each joint there are two small side branches come out, which are terminated by clusters of white flowers, so that the stalks seem covered with them most part of their length; but as these come pretty late in the season, so unless the summers prove warm, the plants do not flower in *England*.

There is another of these plants with purple flowers, standing upon longer foot-stalks, which was sent me from *Camppeachy*, but the stalks and leaves are like those of this sort, so that I doubt whether it be a distinct species.

The fifth sort grows naturally in *New England* and *Virginia*, from both which countries I have received the seeds; it hath a perennial root and an annual stalk, which rises a foot high, with joints pretty near each other, garnished with roundish heart-shaped leaves, sitting close to the stalks; they are sawed on their edges, of a light green colour. The flowers are produced in small loose panicles at the top of the stalks, which are white, and have two small green leaves immediately under the flowers.

The sixth sort rises with upright stalks three feet high, garnished with oval sawed leaves at each joint, placed opposite, and have very short foot-stalks; from the sides of the stalks, at every joint, is produced two slender branches, which stand erect; these, and the principal stalks also, are terminated by clusters of white flowers, which appear in *August* and *September*, and the stalks decay in winter, but the root is perennial. This grows naturally in *Pensylvania*, and other parts of *America*.

The seventh sort grows naturally in *Virginia* and *Philadelphia*; this hath a perennial root and an annual stalk, which rises three feet high, hairy, and garnished with rough leaves at each joint, which are from three to four inches long, and about an inch broad at their base, gradually lessening to a very acute point; the two leaves are joined at their base, so the stalks seem to grow through them.

The upper part of the stalk divides into several slender foot-stalks, each sustaining a close cluster of white flowers. These come out in *July*, and in warm seasons the seeds will sometimes ripen in *England*.

The eighth sort was sent me by the late Dr. *Houfston* from *La Vera Cruz*, where he found it growing naturally; this hath a thick woody stalk, which rises twelve or fourteen feet high, sending out many channelled branches, covered with a brown bark, garnished with regular heart-shaped leaves, as large as those of the Mulberry tree; they are of a light green colour, and sawed on their edges, placed opposite upon foot stalks, near two inches long; the upper part of the branches are terminated by four or five pair of foot-stalks, which come out opposite from the joints, and the top is terminated by an odd one; these sustain branching panicles of white flowers, which together form a long, loose, pyramidal thyrse, and make a fine appearance, for there are no leaves intermixed with the flowers, but so far as the spike reaches the stalks are naked. This sort has flowered in the *Chelsea* garden, but did not produce seeds.

The ninth sort rises with an upright round stalk, to the height of three feet, sending out several branches toward the top, which come out regularly by pairs; they are garnished with leaves placed opposite, which are two inches and an half long, and about one third of an inch broad, having three longitudinal veins; they are of a light green colour, and entire. The flowers stand upon long foot stalks at the end of the branches, some sustaining one, some two, and others three or four flowers; they are white, and appear late in autumn. This grows naturally in *Carolina*.

The tenth sort was sent me from *Jamaica*, by the late Dr. *Houfston*; this hath slender twining stalks, which fasten themselves to any neighbouring support, and rise eight or ten feet high, sending out small branches by pairs, at most of the upper joints. The leaves on the lower part of the stalk are heart-shaped, ending in acute points; the upper leaves are almost triangular, they are smooth, and of a lucid green; the upper part of the stalks have long branching spikes of white flowers, which are small, and sit close to the foot-stalks.

The eleventh sort grows naturally in *Carolina*; this hath a creeping root, which spreads and multiplies very fast. The stalks rise about two feet high; they are garnished with oval, heart-shaped, sawed leaves. The flowers are produced at the top of the stalks in a sort of corymbus; they are of a fine blue colour, but the roots spread so much as to cause barrenness of flowers after the first year.

All these sorts may be propagated by seeds; several of them ripen their seeds in *England*: these should be sown in autumn, as soon as they are ripe, for then the plants will come up the following spring; but if they are kept out of the ground till spring, the plants will not come up till the year after; and those seeds which are procured from *America* should be sown as soon as they arrive, for though they may not grow the first year, yet there will be a greater certainty of their succeeding, than when they are kept longer out of the ground.

The second, third, fifth, sixth, seventh, and eleventh sorts, are hardy plants, so the seeds of these may be sown in the full ground, but there must be care taken in the sowing to keep the sorts separate; for as the seeds of these plants have a light down adhering to them, they are easily displaced by the least wind, so that the best way will be to sow them in drills; but these should be but shallow, for if the seeds are buried too deep, they will not grow. The bed in which these are sown, should not be too much exposed to the sun, but rather have an east aspect, where the morning sun only reaches it; the ground should be kept pretty moist, for as these plants generally grow in moist shady situations

in their native countries, they will succeed better when they have a soil and situation somewhat like that.

When the young plants come up, they must be kept clean from weeds, and where they are too close, some of them should be drawn out, to give room for the others to grow; and if these are wanted, they may be planted in another bed, where, if they are shaded and watered, they will soon take root; after which they will require no farther care but to keep them clean from weeds till the following autumn, when they may be transplanted to the places where they are to remain. As the roots of some of the sorts spread out to a considerable distance, they should not be allowed less than three feet from any other plants, and some of the largest growing should be allowed four feet. If the soil in which they are planted is a soft gentle loam, they will thrive much better, and flower stronger than in light dry ground, in which if they are not duly watered in dry summers, their leaves will shrink, and their stalks will not grow to half their usual height.

All these sorts have perennial roots, by which they may be propagated; for as some of them do not perfect their seeds in *England*, so the other is the only way of increasing the plants here; those which have creeping roots send out offsets in great plenty, so are easily propagated; and the others may be taken up, or the heads taken off from them every other year, in doing of which there should be care taken not to cut or injure the old plants too much. The best time to remove these plants is in autumn, as soon as they have done growing, that they may get fresh roots before the frost comes on; but if that should happen soon after their removal, if the surface of the ground is covered with tan, or dried leaves, to keep out the frost, it will effectually secure them; and if this is done to the old plants in very severe winters, it will always preserve them.

The fourth sort sends out many weak twining stalks which require support, so there should be some stakes fixed down by their roots in the spring when they begin to shoot, to which the young stalks should be led and fastened, and afterward they will naturally twine round them, and rise four or five feet high; if they are supplied with water, in warm seasons they will produce plenty of white flowers in *August*. This sort is sometimes killed in very severe winters, if they are not covered; but if when the stalks decay in the autumn, the ground about them be covered with some old tanners bark, it will effectually secure the roots.

EUPHORBIA. *Lin. Gen. Pl.* 536. Spurge.

The Characters are,

The flower hath four or five thick truncated petals, and twelve or more stamina which are inserted in the receptacle. In the center is situated a three-cornered germen, supporting three bifid styles, which afterward becomes a roundish capsule with three cells, each containing one roundish seed.

The Species are,

1. EUPHORBIA *aculeata triangularis subnuda articulata, ramis patentibus. Lin. Hort. Cliff.* 196. Prickly triangular-pointed Euphorbia, with spreading branches, commonly called the true Euphorbium of the ancients.

2. EUPHORBIA *aculeata nuda subquingularis, aculeis geminatis. Hort. Cliff.* 196. Canary Euphorbium, with four or five angles, which have twin spines.

3. EUPHORBIA *aculeata nuda triangularis articulata, ramis erectis.* Prickly Euphorbium, having three and four angles with compressed branches.

4. EUPHORBIA *aculeata nuda multangularis, aculeis geminatis. Lin. Hort. Cliff.* 196. Torch-shaped Euphorbium, with thick stalks armed with strong twin spines.

5. EUPHORBIA *aculeata seminuda, angulis oblique tuberculatis. Lin. Hort. Cliff.* 196. Angular Euphorbium, with broad Oleander leaves.

6. EUPHORBIA *aculeata nuda, septem angularis, spinis solitariis subulatis floriferis. Lin. Hort. Cliff.* 196. Euphorbium with seven angles, and very long single spines bearing fruit at their tops.

7. EUPHORBIA *inermis testa tuberculis imbricatis, foliolo lineari instructis. Lin. Hort. Cliff.* 197. African Euphorbium with a thick scaly stalk, and branches disposed like *Medusa's* head.

8. EUPHORBIA *aculeata nuda, angulis tuberosis spinis interstinctis. Lin. Sp. Pl.* 451. Euphorbium with many angles, and long spines growing out from between the knots.

9. EUPHORBIA *aculeata nuda, multangularis, spinis solitariis subulatis. Prod. Leyd.* 195. Euphorbium with the appearance of Torch Thistle, and a slender stalk.

10. EUPHORBIA *inermis imbricata tuberculis foliolo lineari instructis. Hort. Cliff.* 197. African Euphorbium with the appearance of Pine fruit, commonly called Little *Medusa's* Head.

11. EUPHORBIA *inermis, ramis patulis simplicibus teretibus, foliolis linearibus instructis.* Euphorbia without spines, and single spreading branches which are taper, terminated with very narrow leaves.

12. EUPHORBIA *inermis ramis teretibus procumbentibus tuberculis quadrangulis.* Euphorbia without spines, with trailing branches and quadrangular tubercles.

13. EUPHORBIA *inermis, ramis plurimis procumbentibus, squamosis, foliis deciduis.* Euphorbia without spines, having many trailing branches which are scaly, and deciduous leaves.

14. EUPHORBIA *inermis fruticosa subnuda filiformis erecta, ramis patulis determinate confertis. Lin. Hort. Cliff.* 197. Indian shrubby Spurge.

15. EUPHORBIA *inermis fruticosa nuda filiformis volubilis, cicatricibus oppositis. Hort. Cliff.* 197. Indian Spurge, with slender twining stalks entirely without leaves.

16. EUPHORBIA *inermis fruticosa seminuda filiformis flaccida, foliis alternis. Lin. Hort. Cliff.* 197. Mauritanian Spurge without leaves.

17. EUPHORBIA *foliis oppositis subcordatis petiolatis emarginatis integerrimis, caule fruticoso. Lin. Sp. Plant.* 453. Tree American Spurge with a *Venice* Sumach leaf.

18. EUPHORBIA *umbellâ quadrifidâ, dichotomâ, foliis oppositis integerrimis. Lin. Sp. Plant.* 457. Broad-leaved Spurge, called *Cataputia minor*.

19. EUPHORBIA *umbellâ subobtusidâ, bifidâ, involuclis subovatis, foliis spatulatis patentibus carnosis mucronatis margine scabris. Lin. Sp. Plant.* 461. Broad-leaved Myrtle Spurge.

20. EUPHORBIA *umbellâ multifidâ, dichotomâ, involuclis subcordatis, primariis triphyllis, caule arboreo. Lin. Sp. Plant.* 462. Myrtle-leaved Tree Spurge.

21. EUPHORBIA *umbellâ multifidâ, dichotomâ, involuclis perfoliatis orbiculatis, foliis obtusis. Lin. Sp. Plant.* 463. Common Wood Spurge.

22. EUPHORBIA *umbellâ multifidâ, subtrifidâ, bifidâ, involuclis ovatis, foliis lanceolatis, ramis sterilibus. Lin. Sp. Pl.* 462. Shrubby Marsh Spurge.

23. EUPHORBIA *umbellâ quinquesidâ, quadrifidâ, dichotomâ, involuclis subrotundis acutis, foliis lanceolatis. Lin. Sp. Plant.* 460. Eastern Spurge with a Willow leaf, a purple stalk, and large flower.

24. EUPHORBIA *umbellâ quinquesidâ, trifidâ, dichotomâ, involuclis ovatis, foliis lanceolatis, capsulis lanatis. Lin. Sp. Plant.* 460. Tree Spurge with a red stalk, a *St. John's* Wort leaf, and bearded capsule.

25. EUPHORBIA *umbellâ sextifidâ, dichotomâ, involuclis ovalibus, foliis integerrimis, ramis nullis capsulis verrucosis. Lin. Sp. Pl.* 462. Irish Spurge, called *Machingboy*.

26. *EUPHORBIA umbellâ quinquesidâ, bifidâ, involucellis obcordatis. Lin. Sp. Plant. 457.* Spurge with a tuberous Pear-shaped root.

27. *EUPHORBIA umbellâ quinquesidâ, dichotomâ, involucellis ovato-lanceolatis mucronatis, foliis inferioribus setaceis. Lin. Sp. Plant. 458.* Cypress Spurge.

28. *EUPHORBIA umbellâ multifidâ, bifidâ, involucellis orbiculatis, foliis lineari lanceolatis villosis. Cretan Wood Spurge,* with narrow, hairy, and hoary leaves.

29. *EUPHORBIA umbellâ multifidâ, dichotomâ, involucellis perfoliatis, subcordatis, foliis lanceolatis integerrimis. Lin. Sp. Pl. 463.* Wood Spurge with a moon-shaped flower.

30. *EUPHORBIA inermis foliis ferratis petiolatis difformibus ovatis lanceolatis panduriformibus. Lin. Sp. Plant. 453.* Spurge from *Curassao*, with variable leaves like Willow and Orach, and a green stalk.

31. *EUPHORBIA dichotomâ, foliis ferratis ovali-oblongis glabris, corymbis terminalibus, ramis divaricatis. Lin. Sp. Pl. 454.* Upright acrid Spurge, with smooth Pellitory leaves, and flowers growing in clusters from the joints of the stalk.

32. *EUPHORBIA inermis, herbacea, ramosa, foliis subcordatis integerrimis petiolatis floribus solitariis. Lin. Sp. Pl. 453.* Upright, annual, branching Spurge of *America*, with leaves like Small Basil.

The first sort has been generally taken for the true Euphorbium of the ancients, and as such hath been directed for medicinal use; but it is from the second sort, that the drug now imported under that title in *England* is taken. Dr. *Linnaeus* supposes the fourth to be the sort which should be used, though as they are all nearly of the same quality, so it may be indifferent which of them that drug is taken from, which is the inspissated juice of the plant.

The first sort hath a triangular, compressed, succulent stalk, which is jointed, and rises to the height of seven or eight feet, sending out many irregular twisting branches, for the most part three-cornered, but have sometimes only two, and at others four angles; they are compressed, succulent, and spread out on every side the stalk; at the extremity of the branches there are a few short roundish leaves, which soon fall off; and near these come out now and then a few flowers, which have five thick whitish petals, with a large three-cornered germen in the center, which soon drop off without having any seeds. It grows naturally in *India*.

The second sort grows naturally in the *Canary* islands, from whence I have been credibly informed, the Euphorbium which is imported in *England*, is now brought, and is the inspissated juice of this plant. In its native country, it grows to the height of twenty feet or more, but in *England* it is rarely seen more than six or eight; nor is it of any advantage to have them so tall here, because they send out many branches which are large and succulent, so render the plants too heavy to be easily removed. It hath a very thick succulent stalk, with four or five large angles or corners, closely armed with black crooked spines, which come out by pairs at every indenture: the stalks send out large succulent branches of the same form, which turn their ends upwards, so that when the plants are well grown, they have some resemblance to a branched chandelier; these are closely armed with black spines like the stalks; at the end of the branches come out the flowers, which are shaped like those of the first sort.

The third sort hath a naked, three-cornered, compressed stalk, sending out a great number of erect branches, which join up to the main stalk, and are generally three-cornered, but some vary to four; they are jointed and armed with short crooked spines, but have no leaves, nor do the plants produce flowers here. This grows naturally in *India*.

The fourth sort puts out many stalks just above the surface of the ground, which are thick, succulent, and taper, hav-

ing eight or ten angles while they are young, but as they grow old they loose their angles, and become round; the branches grow distorted and irregular, first horizontal, and afterward turn upward; they are armed with small crooked spines on their angles, and on the upper part of the branches come out the flowers, which are small, and of a greenish white, shaped like those of the second sort. This grows naturally in *India*.

The fifth sort rises with a strong upright stalk five or six feet high, which hath irregular angles, and protuberances which are oblique to the angles; the lower part of the stalk is naked, the upper part is branching, and the branches are armed with crooked spines; at every protuberance they are garnished with oblong leaves of a lucid green, which are very smooth, entire, and rounded at their ends; these fall off, and the plants remain naked for some months, and then the flowers come out, which sit close to the branches, of a greenish white colour; the leaves come out in the autumn, and fall off in the spring.

The sixth sort rises with a roundish, upright, succulent stalk about three feet high, putting out several branches on the side of the same form; which have seven angles or furrows, armed with long, single, black thorns; at the end of which come out small flowers, of the same form with those of the other sorts, and are sometimes succeeded by small fruit.

The seventh sort hath thick, roundish, succulent stalks, which are scaly, sending out many branches from their sides of the same form, which are twisted, and run one over another, so as to appear like a parcel of serpents coming out from the stalks, from whence it had the appellation of *Medusa's Head*. The ends of the branches are garnished with narrow, thick, succulent leaves, which soon drop off, and round the upper part of the branches the flowers come out, which are white, and of the same form with those of the other species, but larger, and are frequently succeeded by round smooth capsules with three cells, each including a single roundish seed.

The eighth sort hath roundish stalks, which swell out like a belly in the middle, and have knobbed angles, between which come out long spines which are strait; these stalks rise two feet high, and put out a few branches on their side of the same form; the flowers are produced at the end of the branches, sitting close upon the angles; they are small, of a yellowish green colour, and shaped like those of the other species.

The ninth sort hath stalks and branches very like those of the fourth, but much slenderer; the spines of this are single, and those of the other double, and the ends of the branches are closely garnished with flowers on every angle, in which it differs from the fourth sort.

The tenth sort hath a thick short stalk, which seldom rises more than eight or ten inches high, from which come out a great number of trailing branches which are slender, and grow about a foot in length: these intermix with each other like those of the seventh sort, but they are much smaller, and do not grow near so long, but has the same appearance, from whence it is called *Little Medusa's Head*; the ends of these branches are beset with narrow leaves, between which the flowers come out which are white, and shaped like those of the other species.

The eleventh sort rises with a taper stalk six or seven inches high, sending out from the top a few taper branches, which spread out on every side; these are not scaly, like those of the last sort, but taper, and garnished at their ends with several small narrow leaves which drop off.

The twelfth sort hath a short thick stalk, which never rises three inches high, so that the branches spread on the surface of the ground; these seldom grow more than six inches

inches long, and their scales swell into a sort of protuberances which are square; they have no leaves, and very rarely produce flowers in *England*.

The thirteenth sort is very like the seventh, but the stalks never rise more than a foot or fifteen inches high, so that the branches spread out near the ground; these are much shorter than those of the seventh, but have the same appearance, and are garnished with narrow leaves at their end, which fall off as the branches are extended in length: this produces a great number of small white flowers at the end of the branches, which are shaped like those of the other species, and are frequently succeeded by smooth round capsules with three cells, including one or two roundish seeds which ripen here.

These sorts have been by most of the modern botanists ranged under title of Euphorbium, and have been distinguished from the Tithymali, more from the structure and outward appearance of the plants, than any real difference in their characters; but as the number of species of those commonly called Spurge was very great, so many of the writers were willing to separate the Euphorbia from that genus, to lessen the number of species.

These plants are preserved in many curious gardens, more for the oddness of their structure, than any real beauty; but being so extremely different in their form, from almost any plants of *European* production, many curious persons have been induced to preserve the several sorts in their gardens.

They are all of them full of a milky acrid juice, which flows out on their being wounded in any part; this juice will blister the flesh, if it happens to lie upon any tender part for a short time, and will burn linen almost as bad as aqua fortis, therefore the plants should be handled with great caution: nor should the ends of their branches be ever bruised or injured, for if they are, it frequently occasions their rotting down to the next joint, and sometimes will destroy the whole plant, if those injured branches are not cut off in time; so that whenever the branches appear to have been injured, the sooner they are cut from the plants, the less danger there will be of their suffering from it; nor should any of the branches be cut between the joints, for the same reason.

The greatest part of these milky succulent plants grow naturally upon barren rocky places, or in dry sandy soils, where few other plants will thrive; therefore they should never be planted in rich earth here, nor suffered to receive much wet, which will cause them to rot. The best mixture of earth for these plants is, about a fourth part of screened lime rubbish, a fourth part of sea sand, and half of light fresh earth from a common; these should be mixed well together, and frequently turned over before it is used, that the parts may be incorporated, and the compost sweetened by being exposed to the air.

All the sorts are easily propagated by cuttings, which should be taken from the old plants in *June*; they must be cut at a joint, otherwise they will rot: when these cuttings are taken off, the milky juice of the old plants will flow out in plenty; therefore there should be some dry earth or sand applied upon the wounded part, which will harden and stop the sap from flowing out; and the wounded part of the cuttings should also be rubbed in sand, or dry earth, for the same purpose; then the cuttings should be laid in a dry part of the stove, for ten days or a fortnight; and some of those whose branches are large and very succulent, may lie a month or more before they are planted, that their wounds may be healed and hardened, otherwise they will rot. When the cuttings are planted, they should be each put into a small halfpenny pot, laying stones or rubbish in the bottom, and filling the pots with the mixture

before directed; then plunge the pots into a moderate hot-bed, and if the weather is very hot, the glasses of the hot-bed should be shaded in the middle of the day, and the cuttings should be gently watered once a week, according as the earth may dry: in about six weeks the cuttings will have put out roots, so if the bed is not very warm, the plants may continue there, provided they have free air admitted to them every day, otherwise it will be better to remove them into the stove, where they may be hardened before the winter; for if they are too much drawn in summer, they are very apt to decay in winter, unless they are very carefully managed. During the summer season, these plants should be gently watered once a week, according to the warmth of the season; but in winter they must not be watered oftener than once in a fortnight, or three weeks, which should be given more sparingly at that season, especially if the stove is not warm: the first sort will require more warmth in the winter than any of the other, as also less water. This, if well managed, will grow seven or eight feet high, but the plants must constantly remain in the stove, giving them a large share of air in warm weather, and in winter the stove should be kept in a temperate degree of warmth.

The sixth sort is at present the most rare in *England*, for most of the plants have been destroyed by placing them in stoves, where, by the heat, they have in one day turned black, and rotted immediately after. This sort may be placed in winter in a dry airy glass-case, with other succulent plants, where they may have free air in mild weather, and be protected from frost; in summer the plants may be exposed in the open air, in a warm situation, but should be screened from too much wet: with this treatment they will thrive much better than if they are more tenderly nursed.

The seventh, eighth, tenth, eleventh, twelfth, and thirteenth sorts, are also pretty hardy, so will live in a good glass-case in winter without fire, provided the frost is kept entirely out, and in summer they may be placed abroad in a warm situation: as these are very succulent plants, they should not have too much wet; therefore, if the summer should prove very moist, it will be very proper to place them under some shelter, where they may enjoy the free air, but may be screened from the rain.

The seventh sort will require to be supported, otherwise the weight of the branches will draw them upon the pots; and, by training of the stems up to stakes, they will grow four or five feet high, and a great number of side branches will be produced; these being very succulent and heavy, are very apt to draw down the stem, if it hath not support.

The following sorts have been, by all the writers on botany, placed under the title of Tithymalus; but the fourteenth and fifteenth sorts should, according to their own distinction, have been placed in the genus of Euphorbia, because they are as destitute of leaves as most of the species which they have there placed.

The fourteenth sort rises with a taper succulent stalk, to the height of eighteen or twenty feet, sending out many branches of the same form, which subdivide into many smaller, which are jointed; they are smooth, and of a deep green colour, with a few small leaves at their extremities, which soon fall off. As the plants grow older, so their stalks become stronger and less succulent, especially toward the bottom, when they turn to a brown colour, and become a little woody. The branches grow diffused and intermix with each other, so form a sort of bush toward the top.

The fifteenth sort sends out a great number of slender taper stalks, of a dark green colour, which are smooth, and

and twist about each other, or any neighbouring support, whereby they will rise to the height of ten or twelve feet, putting out smaller branches upward, which also twine and intermix with the other stalks; they are naked, having no leaves.

The sixteenth sort sends out many taper succulent stalks from the root, which rise about four feet high; they are slender and weak, so require support to prevent their falling to the ground; these have a light green bark, their lower parts are naked, but their upper parts are garnished with oblong leaves, which are smooth, entire, and placed alternate on every side the stalks: the flowers are produced in small clusters at the end of the branches, they are of a yellowish green colour, and are sometimes succeeded by smooth round fruit, but the seeds rarely ripen in *England*. This sort grows naturally on the *African* shore in the *Mediterranean*.

The seventeenth sort grows naturally in most of the islands in the *West-Indies*, and also upon the continent there. This hath an upright stalk, which rises to the height of six or seven feet, covered with a light brown bark; it divides upward into many branches, garnished with roundish leaves, indented at their ends: they are smooth and of a beautiful green, but fall away in winter; so that in the spring, they are almost naked; the flowers come out from the end of the branches, which are yellow and small, soon falling away without having any fruit succeed them here.

These sorts are propagated by cuttings, in the same manner as the *Euphorbia*, and the plants must be treated in the same way, as hath been directed for them.

The fourteenth, fifteenth, and seventeenth sorts are tender, so require a stove, and must have the same treatment as the tender kinds of *Euphorbiums*, but the sixteenth sort will live in a common green-house in winter, and may be exposed abroad in the summer.

The eighteenth sort stands in the list of medicinal plants, but is rarely used in *England* at present; this is a biennial plant, which perishes after the seeds are ripe. It grows naturally in *Italy* and the south of *France*, and where it is allowed to scatter its seeds in a garden, becomes a weed here. This rises with an upright succulent stalk, from three to four feet high, garnished with oblong smooth leaves placed opposite, sitting close to the stalks; the upper part of the stalk divides by pairs into smaller branches, and from the fork between these divisions come out the umbels of flowers, each fork having one; that which is situated in the first division being the largest, and those in the upper are the smallest. The flowers are of a greenish yellow colour, the fruit follows soon after, which is divided into three lobes, has three cells, each containing one roundish seed, which is cast out to a distance by the elasticity of the capsule. This sort will propagate itself fast enough when it is once introduced into gardens, so requires no care but to keep it clean from weeds.

The nineteenth sort grows naturally in the south of *France*, in *Spain*, and *Italy*. This sends out many trailing branches from the root, which grow about a foot long, lying upon the ground, closely garnished with thick, flat, succulent leaves placed alternate, sitting close to the stalks: the flowers are produced in large umbels at the end of the branches; the involucre of the principal umbel is composed of several oval-pointed leaves, but those of the small umbels have only two heart-shaped concave leaves, whose borders are rough; the flowers are yellow, and are succeeded by three seeds, inclosed in a roundish capsule with three cells. This plant will continue two or three years upon a dry warm soil, and will ripen seeds annually, which, if permitted to scatter, the plants will come up, and require no other care but to keep them clean from weeds.

The twentieth sort grows naturally in *Crete*, and in several islands of the *Archipelago*; this has a great resemblance to the common Wood Spurge, but the leaves are narrower, longer, and are hoary. It is easily propagated by cuttings during any of the summer months, and requires a little protection from the frost in hard winters.

The twenty-first sort grows naturally in the woods, in many parts of *England*; it rises with a shrubby stalk three feet high; the flowers are produced in umbels sitting close to the stalks, so form a long spike; the empalements are of a greenish yellow, and the petals black, so they make an odd appearance. It flowers in *May*, and the seeds ripen in *July*. If the seeds of this are sown under trees in the autumn, the plants will rise the following spring, and require no culture.

The twenty-second sort stands in the list of medicinal plants by the title of *Esula major*, but at present is seldom used: it grows naturally in *France* and *Germany* upon marshy places, where it rises three or four feet high. It hath a perennial root, by which it may be propagated better than by seeds, which seldom grow unless they are sown soon after they are ripe.

The twenty-third sort was discovered in the *Levant* by *Dr. Tournefort*. This hath a perennial root, from which arise succulent stalks three feet high, covered with a purple bark, garnished with oblong smooth leaves, shaped like those of Willow, of a dark green colour. The upper part of the stalks divide, and in the fork is situated an umbel of flowers, of a greenish yellow colour, which are succeeded by round capsules with three cells, each containing a single seed. It flowers in *June*, and the seeds are ripe in *August*; this may be propagated by parting of the roots, or by sowing of the seeds in autumn. The plant is hardy, so will endure the greatest cold of this country, if it is planted in a dry soil.

The twenty-fourth sort grows naturally in *Sicily*, and on the borders of the *Mediterranean* sea; this rises with several shrubby stalks to the height of five or six feet, garnished with oblong, smooth, blunt leaves, which are placed alternate. The flowers are yellow, and grow in small umbels from the division of their branches, and are succeeded by roundish capsules which are rough, having three cells like the other species. This is easily propagated by cuttings during any of the summer months, and requires protection from the frost in winter.

The twenty-fifth sort grows naturally in *Ireland*. This hath thick fibrous roots, which send up several erect stalks, about a foot long, garnished with oblong leaves, placed alternate. The flowers are yellow, and are produced in small umbels at the top of the stalks, and are succeeded by rough warted capsules with three cells. This may be propagated by the roots, which should be planted in a shady situation and a moist soil.

The twenty-sixth sort grows naturally in the *Levant*; this hath a knobbed Pear-shaped root, from which arise two or three stalks, about a foot high, garnished with oblong hairy leaves placed alternate. The flowers are produced in small umbels from the divisions of the stalk; they are small, of a greenish yellow colour, and are seldom succeeded by seeds here. It may be propagated by offsets, sent out from the main root; these may be taken off in autumn, and planted in a shady situation, where they will thrive better than in the full sun.

The twenty-seventh sort grows naturally at *Aleppo*, and in other parts of the *Levant*; this hath a perennial creeping root, by which it multiplies very fast where it is once established. The stalks of this rise a foot and an half high; the lower leaves are narrow, stiff, and bristly; but those on the upper part of the stalk are shaped like the narrow-leaved

leaved Myrtle. The flowers are yellow, and are produced in large umbels from the divisions of the stalk, but are rarely succeeded by seeds in this country. The roots of this should be confined in pots, for when they are planted in the full ground, they creep about to a great distance.

The twenty-eighth sort grows naturally in many parts of the *Levant*, and also in *Spain* and *Portugal*. The seeds of this were sent me from *Portugal*, by *Robert More*, Esq; who found the plants growing there naturally. It rises with a purple shrubby stalk, three feet high, garnished with narrow, spear-shaped, hairy leaves, set closely on the stalk alternately; the upper part of the stalk is terminated by umbels of flowers, which form a sort of spike. The greater umbels are multifid, but the small ones are bifid. The involucrum of the flowers are yellow, and the petals of the flowers black. The young plants which have been raised from seeds are generally fruitful, but the old ones, and those raised by cuttings are barren: this may be propagated by cuttings, and will live abroad if planted in a dry rubbishy soil and a warm situation, otherwise they are frequently killed by severe frost.

The twenty-ninth sort grows naturally in the south of *France*, in *Spain*, and *Italy*; it is a biennial plant, from whose root arise two or three stalks, which grow two or three feet high, garnished with spear-shaped leaves, which are entire. The umbels of flowers arise from the division of the branches; the involucrum are heart-shaped, and surround the pedicle at their base. The flowers are yellow, and appear in *June*. The seeds ripen in *August*, which, if permitted to scatter, the plants will come up, and require no care.

The thirtieth sort grows naturally at *La Vera Cruz*. This is an annual plant, which rises from two to three feet high. The leaves are sometimes narrow and entire, at other times oval, and divided in the middle almost to the midrib, in shape of a fiddle; they also vary in their colour, some being

inclined to purple, others of a light green, sawed on their edges, and stand upon short foot-stalks. The flowers are produced in small umbels at the end of the branches, of a greenish white, and are succeeded by small round capsules with three cells.

The thirty-first sort grows naturally in most of the islands in the *West-Indies*; it is an annual plant, which rises with a branching stalk about two feet high, garnished with oblong, oval, smooth leaves, sawed on their edges. The flowers grow in small umbels at the foot-stalks of the leaves, gathered into close bunches; they are white, and are succeeded by small round capsules, inclosing three seeds.

The seeds of the thirty-second sort were sent me from *La Vera Cruz*, by the late *Dr. Houstoun*; this is also an annual plant, which rises with an upright stalk about a foot high, dividing into a great number of branches, which spread very wide, garnished with roundish heart-shaped leaves, which are entire, standing upon pretty long foot-stalks. The flowers come out singly from the divisions of the stalk; they are small, and of an herbaceous colour, and are succeeded by small round capsules, containing three seeds.

The last three sorts are annual; the seeds of these must be sown upon a hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a small pot filled with light earth, and plunged into the hot-bed again, and must afterward be treated in the same manner as other tender annual plants from warm countries.

EUPHRASIA, Eyebright.

This is a medicinal plant, which grows naturally in sterile fields and commons in most parts of *England*, always among Grass, Heath, Furz, or some other cover, and will not grow when these are cleared from about it, nor will the seeds grow when they are sown in a garden; for which reason I shall not trouble the reader with a description, or any farther account of it, than that the herb-women supply the markets with it in plenty from the fields.

F.

F A B

FABA. *Tourn. Inst. R. H. 391. tab. 212.* The Bean.

The Characters are,

The flower is of the butterfly kind. The standard is large, oval, and indented at the end; it hath two oblong erect wings, which inclose the keel, being much longer. The keel is short, swelling, and closely covers the parts of generation; the nine stamina are in three parts, and one stands separate. At the bottom is situated an oblong compressed germen, which afterward becomes a long, compressed, leathery pod, having one cell, filled with compressed kidney shaped seeds.

There are several varieties of the Garden Bean, which are known and distinguished by the gardeners, but do not essentially differ from each other, so I shall not enumerate them as distinct species, but shall not join these to the Horse Bean, as some have done, who have supposed them to be but one species; for, from having cultivated them more than thirty years, without finding the Garden Bean degenerate to

F A B

the Horse Bean, or the latter improving to the former, I conclude they are distinct.

There are a great variety of the Garden Beans, now cultivated in the kitchen gardens in *England*, which differ in size and shape; some of them producing their pods much earlier in the year than others, for which they are greatly esteemed by the gardeners, whose profit arises from their early crops of most esculent plants.

I shall begin with the Garden Bean, called by the botanists *Faba major*, to distinguish it from the Horse Bean, which they have titled *Faba minor seu equina*, and shall only mention the names of each variety, by which they are known among the gardeners, placing them according to their time of ripening for the table.

The *Mazagan* Bean is the first and best sort of early Beans at present known; these are brought from a settlement of the *Portuguese* of the same name on the coast of *Africa*, just

without the freights of *Gibraltar*; the seeds of this sort are much smaller than those of the Horse Bean, and as the *Portuguese* are but slovenly gardeners, there is commonly a great number of bad seeds among them. If this sort is sown in *October*, under a warm hedge, pale, or wall, and carefully earthed up when the plants are advanced, they will be fit for the table by the beginning of *May*: the stems of this sort are very slender, therefore should be supported by strings close to the hedge, or pale, to preserve them from the morning frosts, which are sometimes severe in the spring, and retards their growth; these Beans bear plentifully, but they ripen nearly together, so that there are seldom more than two gatherings from the same plants; if the seeds of this sort are saved two years in *England*, the Beans will become much larger, and not ripen so soon, which is called a degeneracy.

The next sort is the early *Portugal* Bean, which appears to be the *Mazagan* sort saved in *Portugal*, for it is very like those which are the first year saved in *England*; this is the most common sort used by the gardeners for their first crop, but they are not near so well tasted as the *Mazagan*; therefore when the *Mazagan* Bean can be procured, no person of skill would plant the other.

The next is the small *Spanish* Bean; this will come in soon after the *Portugal* sort, and is a sweeter Bean, therefore should be preferred to it.

Then comes the broad *Spanish*, which is a little later than the other, but comes in before the common sorts, and is a good bearer, therefore is frequently planted.

The *Sandwich* Bean comes soon after the *Spanish*, and is almost as large as the *Windsor* Bean, but, being hardier, is commonly sown a month sooner; this is a plentiful bearer.

The *Toker* Bean, as it is generally called, comes about the same time with the *Sandwich*, and is a great bearer, therefore is now much planted.

The white and black Blossom Beans are also by some persons much esteemed; the Beans of the former are, when boiled, almost as green as Pease, and being a sweet Bean, renders it more valuable; these sorts are very apt to degenerate, if their seeds are not saved with great care.

The *Windsor* Bean is allowed to be the best of all the sorts for the table; when these are planted on a good soil, and are allowed sufficient room, their seeds will be very large, and in great plenty; and when they are gathered young, are the sweetest and best tasted of all the sorts; but these should be carefully saved, by pulling out such of the plants as are not perfectly right, and afterward by sorting out all the good from the bad Beans when they are out of the pods.

This sort of Bean is seldom planted before *Christmas*, because it will not bear the frost so well as many of the other sorts, so it is generally planted for the great crop, to come in *June* and *July*.
