THE SOCIETY FOR THE DIFFUSION OF
USEFUL KNOWLEDGE.

M U R

MURILLO, BARTOLOMEO ESTEBAN, the most eminent artist of the school of Seville, and the most distinguished colourist of the Spanish painters, was born at Seville in the year 1618. As he manifested at a very early age an inclination to painting, he was placed under his uncle, Juan del Castillo, an artist of merit, whose favourite subjects were fairs and markets, and whose pupils, Alonso Cano, Murillo, and Pedro Moya, rank as the best Andalusian artists. Under him Murillo made rapid progress, and painted several pictures while he remained with his uncle. After leaving him he continued to improve in drawing as well as in painting. For some time he painted in the Florentine style, which then prevailed in Spain, and several works of this his first period are still preserved at Seville. In order to improve himself in drawing, he was on the point of going to England to see Vandyck, when he heard of the death of that great master. He then applied with great diligence to the painting of small pictures of saints, for the trade with America, by which he obtained funds sufficient to undertake, in 1643, a journey to Madrid. Here he derived great advantage from the instruction of his countryman Velazquez, who likewise obtained for him permission to copy the master-pieces of Titian, Rubens, Vandyck, and Ribera, in the royal collection. Returning to Seville in 1645, he excited general admiration by his paintings in the convent of St. Francis. They were in the style of Spagnoletto (José Ribera) and Velazquez, then unknown at Seville, and procured him many commissions. He painted several historical pictures for the king of Spain, which gained him great reputation in his own country, and, being sent to Rome as a present to the pope, so highly pleased the Italians, that they called him a second Paul Veronese. He likewise painted many grand altar-pieces for the churches and convents in Madrid, Seville, Cordova, Cadiz, and Granada. Among these are eight large pictures representing the works of Mercy, for the church of St. George in the hospital 'De la Caridad' of Seville, which are distinguished for their admirable composition and force of colouring. Other equally excellent works adorned the church of Los Venerables and the Capucin convent, for which latter he painted twenty-eight pictures, which were afterwards sent to America. He was engaged on an altar-piece representing the marriage of St. Catherine, for the Capucin convent at Cadiz, when he met with an accident on the scaffolding, from which he never recovered, and he died at Seville, on the 3rd of April, 1685.

But though Murillo was thus eminent in the higher departments of the art, his favourite subjects were beggar boys as large as life engaged in various amusements, which he generally designed after nature. His pictures of such subjects are highly esteemed for their merit, and may be seen in the collections of the English nobility; but there are numberless copies. Murillo excelled likewise in portraits and landscapes. His works are distinguished by their striking character of truth, nature, and simplicity; by the entire absence of the servility of imitation; and by the delicacy of his touch, and the mellowness of his colouring, which in fact seem perfect in every particular. Among his finest pictures are 'Moses striking the Rock,' and 'Christ feeding the Five Thousand,' in the convent of St. Francis, at Seville; and 'St. Antony of Padua,' in the cathedral of that

P. C., No. 977.

M U R

city and in the National Museum at Madrid. Many of his works are in France, particularly in the collection of Marshal Soult,* and in the collections of the English nobility and gentry. The Dresden Gallery has a fine 'Virgin and Child' by his hand. Several of his pictures are at Munich, and others at Vienna, in the possession of Prince Esterhazy. By the collection of several Murillos from the convents of Seville, a museum has recently been formed in the cathedral of that city; and there are many more in the National Museum at Madrid. The picture which Murillo preferred to all his other works was that of 'St. Thomas de Villa Nueva distributing Alms to the Sick and the Poor.' This, we presume, is the picture in the possession of Mr. Wells, of which Dr. Waagen says, 'This fine picture was formerly in the church of the Franciscans at Genoa. The subject was a peculiarly happy one for Murillo. In the head of the saint, in which priestly dignity and gravity are admirably expressed, he proves his ability in treating such religious subjects from the legends of the monkish saints. The cripples and the sick afforded him, on the other hand, an ample field to show his skill in representations from common life, which we so highly admire in his beggar boys.' Dr. Waagen describes likewise another picture of the same subject, 10 feet high and 6 feet wide, now in Lord Ashburton's collection, purchased by his lordship of General Sebastiani, and which was formerly at Seville. We refer to Dr. Waagen's work on 'Arts and Artists in England' for descriptions of the numerous pictures by Murillo in our English collections. Murillo raised the art of painting in Spain not only by his own works, but by founding an academy at Seville, of which he was president from the year 1660 till his death. (Cean Bermudez, *Diccion. de Profes. Españo. de Bellas Artes*; Ponz, *Viage de España*; *El Artista*, 1835; *La Revista de Madrid*, Enero, 1839.)

MURPHY, ARTHUR, a dramatic and miscellaneous writer, was born near Elphin, in the county of Roscommon, Ireland, December 27, 1730. His father was a merchant in Dublin. In 1740, Arthur Murphy was entered at the college of St. Omor, where he remained nearly seven years, and, on his return to Ireland, passed two years in a merchant's counting-house at Cork. From thence he came to London, and obtained a situation as clerk in a banking-house, shortly after which he commenced his career as a public writer. On the 21st of October, 1752, he started 'The Gray's Inn Journal,' a periodical in the style of the 'Spectator,' which he carried on to October 12th, 1754. On the 18th of the same month he tried his fortune as an actor on the stage of Covent Garden, and in the character of Othello. His success was but moderate, and after a second season, during which he acted at Drury Lane, he quitted the boards for ever, and resumed his former occupation as a writer by commencing a periodical political journal called 'The Test.' He also began to study the law, but was refused admission to the societies of the Temple and of Gray's Inn on the ground of his having been an actor. He succeeded finally in obtaining admission to Lincoln's Inn, was called to the bar, appointed a commissioner of bankrupts, and died at Knightsbridge, June 18th, 1805, in the seventy-fifth year of his age. His principal works

* Two of these, the 'Prodigal Son' and 'Abraham and the three Angels' have been purchased by the Duke of Sutherland.

translation of Tacitus, which is in a diffuse style, and somewhat loose and inaccurate performance; the Fielding (whose works he edited), Johnson, and upwards of twenty dramatic pieces. The most esteemed of his dramatic pieces are the comedies of 'The Way to keep him,' 'All in the wrong,' 'Know your own Mind,' and 'Three Weeks after Marriage.' His plays, poems, and miscellanies, in 7 vols. 8vo., edited by himself, were published in 1786.

MURRAY RIVER. [AUSTRALIA.]

MURRAY, W. [MANSFIELD, LORD.]

MURRAY, JAMES STUART, EARL OF, known in Scottish history by the name of the 'Good Regent,' was the eldest of three illegitimate brothers, children of King James V. His mother was the Lady Margaret, daughter of John lord Erskine of Mar, a nobleman of rank and influence at court, and one of those to whom the custody of the king, when an infant, had been committed.

He is supposed to have been born about the year 1533, but the precise time of his birth is not known, nor any particulars of his early life, except only this, that when but a few years old, his father made him prior of St. Andrew's, with all the revenues of that rich benefice. He afterwards acquired also the priory of Pittenweem, and, after obtaining a dispensation from the holy see to hold three benefices together, that of Mascon in France in commendam; and in 1544 he took the oath of fealty to Pope Paul III. In 1548 however he gave proof of that intrepidity and military genius for which he was afterwards so distinguished. This was on occasion of the descent into Scotland by the lords Grey de Wilton and Clinton. When the fleet of the latter landed at St. Monan on the coast of Fife, the lord James (as he was then called) collected a little band as determined as himself, and, placing himself at their head, attacked the invaders and drove them back to their ships. Shortly before this he had been in France, having gone thither in the retinue of his youthful sister Queen Mary, when it was resolved she should be sent over to the Continent for her education; and at different times afterwards we find him again abroad. He was also present at Mary's marriage with the dauphin of France; and was soon afterwards deputed to carry to the latter the crown and other ensigns of royalty. Circumstances occurred however in Scotland which prevented the execution of this appointment: the Reformation was now rapidly diffusing itself among all classes of the community, and dissolving in its mighty progress the nearest and tenderest ties. In these struggles the prior of St. Andrew's joined the reformers, or, as they were called, the congregation, among whom, by his courage and military skill, the success of his undertakings, the sanctity or rather austerity of his character, and the bluntness of his manner, aided by the advantages of birth, countenance, and person which he possessed, he gradually acquired a very high degree of consideration. The queen regent (to whom he was opposed) of course endeavoured to destroy his influence, representing him in particular as an aspiring ambitious man who, under pretence of a reformation in religion, sought to overturn the existing government. That argument however had little weight, or rather it worked a contrary way: his influence continued to increase; and when, in the end of the year 1559, the congregation resolved on taking the government into their own hands, he was one of the council appointed for civil affairs. On the death of the queen regent he was made one of the lords of the articles; and on the dauphin's death he was directed by the convention of estates to proceed to France and invite Mary to return to her native country. Such an appointment suited the views of the prior well: for previous to the death of Francis the lord James had entered into a correspondence with the young queen, soliciting the renewal of his French pension, and in reply Mary had assured him not only of that, but of the highest favours, civil or ecclesiastical, which could be conferred upon him, provided he would return to his duty. He had also at the same moment applied through Throckmorton to Cecil, the English minister, requesting some pension or allowance in recompence for the losses he had sustained in the cause of the Reformation. He therefore willingly undertook the proposed mission, and setting out on the service accordingly, reached the palace and quickly gained admittance to the queen. He then found that an envoy from the Roman Catholic party in Scotland had preceded him; and in the interview which the prior had with his sister, he learnt that the disturbed state of the

country and his own ambitious views had been strongly insisted on. Mary however adopted her brother's suggestions, and agreed to return to Scotland without that armed force which the Roman Catholic envoy had represented as wholly indispensable. The lord James immediately communicated the result of the conference to Throckmorton, the English ambassador, but in a secret manner; and, contrary to Mary's express wishes, in returning home he waited on Elizabeth, to strengthen, no doubt, the friendship which subsisted between her and the reformers in Scotland, and no doubt also to acquaint her with the determination which Mary had been induced to form. It is observable that the letters from Throckmorton at this period strongly urge upon Elizabeth to secure the lord James's regard; and from one of them it may even be inferred that Elizabeth had done him some 'good turn,' as Throckmorton expresses it, for this very end.

The lord James returned to Edinburgh in the beginning of June, 1561, having been absent on his mission about two months. In ten weeks after, Mary embarked from Calais, and after a voyage of five days arrived in the port of Leith. On her arrival she found the prior among the first men in the kingdom; and he then naturally became her prime minister, confidant, and adviser. In this situation he acted with great tact and judgment, and at the same time with much tenderness to the queen. He protected her in the exercise of her own religion, and in return obtained from her a proclamation highly favourable to the reformers: he restrained the turbulence of the borders, moderated the zeal of the people against popery, and at once kept down the enemies of Mary's dynasty and strengthened the attachment of her friends. Mary rewarded his services by conferring on him the title of Earl of Mar, and honoured his marriage with the lady Agnes Keith, eldest daughter of the earl marischal, which took place about the same time, with a series of splendid entertainments. The greatness of the banqueting indeed, and the vanity thereof, offended the more strict of the reformers, and Knox took occasion to read the lord James a solemn admonition; 'for (said the preacher) unto this day the kirk of God hath received comfort by you and by your labours, in the which if hereafter ye be found fainter than before, it will be said your wife hath changed your nature.'

The earldom of Mar, which the prior had just obtained from Mary, having been claimed by Lord Erskine as his peculiar right, was soon after resigned with the property belonging to it; but in its place the prior received the earldom of Murray, which had been long the favourite object of his ambition. This grant was scarcely a less matter of jealousy to the prior's great rival, the Roman Catholic earl of Huntly, than the grant of Mar was to the lord Erskine. But all dispute on that head was soon ended; for Huntly was shortly after proclaimed a traitor for various overt acts of insubordination and rebellion, originating in disappointed ambition; and not long after that he suddenly expired. Murray was now left in undisputed possession of the chief authority in the kingdom next to the queen, who reposed in him almost unlimited confidence. An incident occurred about this period which showed the influence he possessed in the government, and at the same time how he was thought occasionally to use it. His services in the cause of the Reformation were manifest and important, yet the lord James was not all that the reformers wished; his religious zeal was not hot enough; and they lamented the protection he afforded to the queen in her use of the mass. But they were not prepared to find him now extending his protection to her and her ladies in what Knox calls 'the superfluities of their clothes,' which he said would bring down the vengeance of God 'not only on the foolish women but on the whole realm.' Knox imputed Murray's conduct on this occasion to a selfish fear of offending the queen, lest she should repent of her munificence and refuse to confirm her grant of the new earldom; and denouncing such motives in strong terms, accused him of sacrificing truth to convenience, and the service of God to the interests of his ambition. Murray was so incensed at this attack, that for a year and a half Knox and he scarcely exchanged words together. The queen's marriage with Darnley seems to have been among the first things to bring them together again; as it was also the first step in the subsequent estrangement between Murray and the queen. To this marriage Murray, Knox, and Elizabeth, and their respective followers, were all opposed. Knox and the reformers were opposed to it

on religious grounds, and it was opposed by Murray and Elizabeth partly on the same grounds, but partly also on personal or political considerations. Murray was not accessory however to Darnley's murder: he knew of it indeed; but, as he said, he did not wish to meddle with the business, and would neither aid nor hinder it. Accordingly he left Edinburgh abruptly on the morning of Sunday, the 9th of February, 1567, the last day of Darnley's life, alleging his wife's illness at St. Andrew's as the cause of his departure; and we do not hear of him in Edinburgh again till about a fortnight after all was over, when he had Bothwell (the perpetrator of the horrid deed) and Huntly, Argyle and Lothington, all parties to it, at dinner at his house. Nor did Murray remain in Edinburgh so as to be present at Bothwell's trial, for in the beginning of April he asked leave to go away to the Continent, but on what grounds is not known; and on the 9th, which was just two days before the trial, he set off, visiting London and the court of Elizabeth on his way. He remained abroad till the end of July, returning only a few days after the coronation of the young prince James. He was therefore absent from the parliament which was held immediately after Bothwell's acquittal, and from the famous supper at Ainslie's, when the principal nobility signed the bond acquitting Bothwell of all concern in Darnley's murder, and engaging to support him in obtaining Mary's hand in marriage. And he was thus also absent during the important occurrences attendant on the queen's marriage with Bothwell. He was not ignorant of all that was going on: Cecil too was in constant communication with him; and soon after the queen's surrender of herself to 'the prince's lords' at Carberry Hill, he sent an accredited agent into Scotland to attend to his interests.

He was at length proposed as regent of the kingdom. Before agreeing however, he resolved to visit Mary in person; and accordingly repaired to Lochleven Castle, where she was now a prisoner. When Mary saw her brother, she burst into tears, and they had afterwards a private conference together, the particulars of which are not fully known, but it is said that Mary was frequently bathed in tears with his upbraidings.

On the 22nd of August, 1567, he was proclaimed regent; and with his usual vigour he immediately proceeded to establish himself in the government. He now held the situation even against the queen herself; for when, having made her escape from Lochleven, she called on him to resign the regency, he at once refused, and took the field against her at Langside, where she sustained a complete defeat. Nor did his determination end here; for being summoned by Elizabeth to bear testimony in the trial which had been instituted by that queen against Mary, he immediately repaired to the appointed place, and did not hesitate in bearing witness against the unhappy prisoner. His own fate however was settled before that of his sister. For while passing through the streets of Linlithgow, on the 23rd of January, 1570, he was shot through the body by a bullet fired from a window by James Hamilton of Bothwellhaugh, nephew to the archbishop of St. Andrew's, in revenge for some personal injury committed by the regent years before. Murray survived till midnight, when he died, in the thirty-eighth year of his age.

MURRAY, SIR ROBERT, son of Sir Robert Murray of Craigie, entered in early life into the French service, where, by the favour of Cardinal Richelieu, he soon obtained the rank of colonel. He returned to Scotland when the difficulties of King Charles I. were beginning to assume their most alarming aspect; and at Newcastle he had a design for the king's escape, which seems to have been frustrated only by Charles's want of resolution. 'The design,' says Burnet, 'proceeded so far that the king put himself in disguise and went down the back stairs with Sir Robert Murray; but his majesty, apprehending it was scarce possible to pass through all the guards without being discovered, and judging it highly indecent to be caught in such a condition, changed his resolution and went back, as Sir Robert informed the writer.' (*Mem. of Duke of Hamilton*, 307.)

On the fall of the royal cause he appears to have gone again to France; and on the 22nd of May, 1650, two letters from that kingdom were read to the parliament of Scotland, one from the young king, the other from the queen-regent, in answer to a letter from the parliament in favour of Sir Robert Murray, in both which they promised, 'from

their respect and love to the Scots nation, that they would see their desire performed, so far as possibly the convenience of their affairs would permit, and that he should be paid off his arrears.' (4 *Balf. Ann.*, 17.)

He must have returned to Scotland soon after this; for on the 21st of May, 1651, while Charles was in command of the army there, Murray was appointed justice-clerk, an office which appears to have remained vacant since the deprivation of Sir John Hamilton, in the month of February, 1649. A few days after this appointment Sir Robert was sworn a privy-counsellor; and on the 6th of June, 1651, he was nominated a lord of session; but the court being suspended by Cromwell's proceedings, he never sat on the bench. At the Restoration his appointments as a lord of session and justice-clerk were renewed. He was then also made one of the lords-auditors of exchequer. In speaking of the second of these appointments, Mr. Laing falls into an error: he says, 'Sir Robert Murray, whom the Royal Society should revere as its father, was appointed justice-clerk, and the people were pleased and gratified when a *judicial office so important and dangerous* was conferred on the most upright and accomplished character which the nation produced.' (*Laing, Hist. of Scotland*, iv. 51.) At that time however the office of justice-clerk was not the important situation which it now is; nor was it for a dozen years after that the justice-clerk became vice-president of the judiciary court. He was however an assessor to the justiciar or justice-general; he was the first who had the style of lord-justice-clerk; and it is highly probable that his character and reputation paved the way for the advancement of his successors. It does not appear that Murray ever sat on the bench at all. He was made a judge of three courts at one time, not perhaps that he might be a judge in any, but that the emoluments might attach him as a partisan. He was not bred to the law, and does not appear ever to have been in circumstances to acquire a knowledge of it. In the above passage however Laing refers to an event in Sir Robert's life of great interest and importance: he was the father of the Royal Society. That body had existed as a debating club previous to the time of the Commonwealth, when its members were dispersed. At the Restoration the Society assembled again, and conducted their proceedings on a more extensive scale. On the 28th of November, 1660, we find Sir Robert present at what was probably the first meeting, when it was proposed 'that some course might be thought of to improve this meeting to a more regular way of debating things; and that, according to the manner in other countries, where there were voluntary associations of men into academies for the advancement of various parts of learning, they might do something answerable here for the promoting of experimental philosophy.' (1 *Kirch., Hist. Royal Soc.*, 3.)

It was Sir Robert Murray who undertook to communicate the views of the Society to the court, and at the next meeting he returned an answer indicative of encouragement from that quarter; and after rules for the government of the Society were established, Sir Robert was chosen first president. He was a member of almost all committees and councils, contributed several papers, and prepared and exhibited various experiments. The authors of the 'Historical Account of the Senators of the College of Justice' say he was re-appointed justice-clerk in 1667, and sent down to Scotland, which he continued to rule with a gentleness quite unknown to the counsels of his predecessors. But this is scarcely correct. Sir John Home of Renton, who was a great zealot in the cause of episcopacy, which Charles wished to introduce into Scotland, was appointed justice-clerk in 1663, in the room of Sir Robert Murray; and on his death, in 1671, he was succeeded by Sir James Lockhart of Lee.

Sir Robert Murray died suddenly, in the month of June, 1673. Burnet says, 'He was the most universally beloved and esteemed, by men of all sides and sorts, of any man I have ever known in my whole life. He was a pious man, and in the midst of armies and courts spent many hours a day in devotion, which was in a most elevating strain. He had gone through the easy part of mathematics, and knew the history of nature beyond any man I ever yet knew. He was the first former of the Royal Society, and its first president; and while he lived he was the life and soul of that body. He had an equality of temper in him which nothing could alter, and was in practice the only Stoic I ever knew. He had a most diffused love to all mankind, and delighted

in every occasion of doing good, which he managed with great discretion and zeal. He had a superiority of genius and comprehension to most men, and had the plainest but withal the softest way of reproving people for their faults that I ever know of.' (1 *Burnet's Own Times*, 59.)

MURRAY, PATRICK, fifth LORD ELIBANK, eldest son of Alexander, fourth lord, was born in February, 1703; and on the 22nd June, 1723, he passed advocate. (*Fac. Reg.*) He did not prosecute the legal profession however; perhaps he never meant to do so, but only, in accordance with a feeling in behalf of 'learning,' which prevailed and still prevails in Scotland, he acquired the name and status of a Scottish advocate. The same year he entered the army; and in 1740, which was about five years after he had succeeded by his father's death to the family honours, we find his lordship a lieutenant-colonel in the expedition to Carthage, of which expedition he wrote an account, which remains in manuscript, it seems, in the library of the Board of Trade. From that time he frequently committed his thoughts to paper, and was known among the literati of Edinburgh, his contemporaries, for the acuteness of his understanding and the varied nature of his information. In 1758 he published 'Thoughts on Money, Circulation, and Paper Currency;' and soon afterwards an 'Inquiry into the Origin and Consequence of the Public Debts.' In 1765 he published 'Queries relating to the proposed Plan for altering Entails in Scotland;' and in 1773, a 'Letter to Lord Hailes on his Remarks on the History of Scotland.' The same year, when Dr. Johnson visited Scotland, he addressed a letter to him, and had afterwards various interviews with him. In 1774 he published some 'Considerations on the present State of the Peerage of Scotland.' In political life he was an opposition lord; and is now known to have maintained a correspondence with the exiled house of Stuart. His younger brother Alexander Murray was likewise so enthusiastic a Jacobite as to propose leading an insurrection in favour of the Pretender. That brother, it may also be mentioned, was in 1750 confined, by order of the House of Commons, for violent interference with a Westminster election; and as he refused to express contrition on his knees according to the order of the house, he was detained in confinement upwards of a twelvemonth, and might have been confined longer had not a prorogation of parliament at that time occasioned his release. The fourth and youngest brother of Lord Elibank likewise attracted considerable notice, distinguishing himself greatly as an officer in high command during the Canadian war. Lord Elibank died without issue, 3rd August, 1778, in the seventy-sixth year of his age.

MURRAY, Dr. ALEXANDER, was born at Dunkitorick, in the stewartry of Kirkeudbright, on the 22nd October, 1775. He was the eldest child of his father's second marriage. His father Robert Murray had by his former marriage, which had subsisted full forty years, a numerous family; and in the course of about four years after his wife's death, himself now entering his 70th year, he married again, and had two children more. Robert was a healthy and vigorous shepherd or pastoral farm servant in one of the mountain districts of Galloway, and distinguished for his sagacity and habitual good conduct: his whole property consisted of four muirland-cows and some two or three scores of sheep, his reward for herding the farm of Kitterick for Mr. Laidlaw in Clatteringshaws. He had been a shepherd all his days, like his father before him, and both had constantly remained in the same neighbourhood. His wife was the daughter of a neighbouring shepherd: all the sons of his first marriage became shepherds; and to the same line of life he designed Alexander.

Alexander however was, in his father's opinion, a lazy useless boy, always committing some blunder or other when sent to herd or bring in the cattle. He was in fact a weakly child, not unhealthy, yet not stout; and he had neither the rapidity nor reach of vision which are indispensable to form a good *herd*: he was also of a sedentary and recluse turn; and thus quite unfitted for the vacant, indeed, but vigilant life of a shepherd. To the old man therefore, whose world was the dark and lonely glen where his cottage lay, and the adjoining hills which he sometimes ranged, young Murray must have been an object of no great concern. Accordingly it was not till he had reached his sixth year that he was taught the alphabet of his mother-tongue. The old man in that year laid out a halfpenny in the purchase of a catechism, and from the letters and syllables on the face of the book

he began to teach his son the elements of learning. It was however emphatically a *good book*, and only to be handled on Sundays or other suitable occasions; it was therefore commonly locked up, and, throughout the winter, the old man, who had been himself taught reading and writing in his youth, drew for his son the figures of the letters in his *written* hand on the board of an old *wool-card* with the black end of a burned heather-stem. In this way young Murray was initiated into literature; and working continually with his board and brand, he soon became both a reader and writer. The catechism was at length presented, and in a month or so he could read the easier parts of it. In the summer of 1782 he got a Psalm-book, then a New Testament, and at last a Bible, a book which he had heard read every night at family worship, which he often longed to get hold of, but which he was never allowed to open or even touch. He now read constantly, and having a good memory, he remembered well and would repeat numerous psalms and large portions of scripture. In 1783 his reading and memory were become the wonder of the rustic circle in which he lived; and a wish began to be generally entertained that he should be sent to school. The idea of school-wages however frightened his father; and in all likelihood nothing would have been done, had not William Cochran, a brother of his mother's, paid a visit to the place in the harvest of the above year. He had made a little money as a travelling merchant, and being informed of the *genius*, as it was called, of his young nephew, he generously undertook to place him next spring at the New Galloway school, which was about six miles off, and to lodge him in the house of the boy's grandfather by the mother's side, who lived about a mile from New Galloway. Accordingly at the Whit-Sunday term of 1784, young Murray, then in his ninth year, was brought to the New Galloway school; where, for a month at least, his pronunciation and awkward gait were a source of perpetual merriment to the scholars. They soon began however to regard him with other feelings. Being utterly neglected by his aged grandfather, he learned to curse and swear, to lie and do all sorts of bad tricks; but before the vacation in August he was also repeatedly *dux* of the Bible class. He continued at school for about a fortnight after the vacation had ended; but in the beginning of November he was seized with an illness which obliged him to be taken home. Here, so soon as his health got a little better, he was put to his old employment of a *herd*, with the rest of the family; and this course of life now continued for about three years. During all that time he spent every penny which he procured from friends or strangers in the purchase of books and ballads, carried bundles of these in his pockets, and read them in the glen or on the hills when tending the cattle, and was ever puzzling and surprising his illiterate neighbours with recitals of what he had learned. In 1787 he borrowed from a countryman Salmon's 'Geographical Grammar,' which delighted him beyond measure, particularly by the specimens it contained of the various languages of the world. In the winter of that year, being able to read and write, he was engaged by the heads of two families in a neighbouring parish to teach their children. He returned home in March, 1788, and with part of his fees, which were 15s. or 16s., he bought books of history and arithmetic. The following year his father and the family left Kitterick, and went by engagement to herd at a place four miles above Minnigaff, the school of which place Murray immediately resolved to attend. He entered himself accordingly, and during the summer months walked three days every week to Minnigaff school. Here he read incessantly, not only his own books, but, by coming an hour before the school met, the books of all the other scholars which were left in the school. At Martinmas, 1789, he was engaged by three families in the moors of Kells and Minnigaff to teach their children; and during that winter he migrated about, remaining six weeks in one family at a time, the families living at considerable distances from each other. He returned home a little before Whit-Sunday, 1790, and found that from that term his father was engaged as a shepherd on a farm within two miles of Minnigaff. To this farm the family accordingly removed, and Murray, having now easy access to the school, went thither regularly, and also determined on adding to his former acquisitions a little French, which he found was necessary for a clerk intending to go to America or the West Indies, a situation he had some thoughts of obtaining. He immediately borrowed a French grammar, and set to learning the language so hard

that in less than a fortnight, his indulgent master giving him whole pages of lessons at a time, he could read portions of the 'Diable Boiteux.' He then found one of the boys in possession of a Latin Rudiments: he borrowed it too, and by incessant reading and a little help from the master, before the vacation in August he beat a class of scholars who had been a considerable time at the study. At Martinmas, he went to teach in a family reading, writing, arithmetic, and Latin.

In this situation he applied to his books with his usual zeal; and having, among other works, bought an old and bulky edition of Ainsworth's 'Dictionary,' for eighteenpence, he literally read it through from A to Z, and again from Z to A. On Whit-Sunday, 1791, he returned to school, and finding a schoolfellow in possession of a Greek grammar, he commenced that language, after spending part of his winter's wages in the purchase of a grammar and lexicon. He had also by this time mastered the Hebrew alphabet, at first from an old Psalm-book, where the letters were marked in succession in the 119th psalm; and afterwards, together with some Hebrew vocables, from his Ainsworth. He now determined on learning that language also, and, accordingly, sent to Edinburgh for a grammar by the man who rode with the post: the man brought him the first edition of Robertson's 'Grammar,' which, over and above the Hebrew, contained on the last leaf the Arabic alphabet, to which, without delay, Murray next applied. At Martinmas of the above year he was again engaged to teach, but at the increased fee of 35s. or 40s., and in this situation he devoted every spare moment to French, Latin, Greek, and Hebrew. In summer he was again at school, and again, in the winter, teaching in a family; but on this occasion at a somewhat lower allowance than before, Murray having chosen the place from its convenience to a school which he wished to attend in the winter evenings. In this school he got hold of Bailey's 'English Dictionary,' which introduced him to the Anglo-Saxon language. He proceeded in this way, taking advantage of every circumstance to increase his knowledge of languages; and at length, in November, 1794, he came to Edinburgh, under the countenance and protection of the Rev. Dr. Baird of that city. Murray was at this time in the nineteenth year of his age. His subsequent progress was comparatively easy. In the course of two years he obtained a bursary or exhibition to the university of Edinburgh; and never relaxing in his pursuit of knowledge, he soon made himself acquainted with all the European languages, and began to form the design of tracing up all the languages of mankind to one source. His acquirements as a linguist naturally pointed him out to Constable, the well-known publisher, as a fit person to superintend a new edition of Bruce's 'Travels;' and in the preparation of that work he was employed for about three years, from September, 1802, Murray residing during that time chiefly at Kinnaird-house, where he had access to the papers left by the traveller. He was also at different times employed in contributing to the 'Edinburgh Review' and other periodicals. By the advice of his friends, he prosecuted the studies necessary for the Church, to which his attention was directed as a permanent source of employment; and at length, in Dec., 1806, he was appointed assistant and successor to Dr. Muirhead, minister of Urr, in the stewartry of Kirkeudbright, a charge to which he in 1808 succeeded as full stipendiary. Within six months after, he married the daughter of a farmer in the neighbourhood. He still continued his philological pursuits. In 1811 an incident occurred which brought him into prominent notice as a linguist: on the recommendation of Mr. Salt, envoy to Abyssinia, he was applied to by the Marquis Wellesley, as the only person in the British dominions qualified to translate a letter written in Geez, from the governor of Tigre to his Britannic Majesty; and he performed the task in the most satisfactory way. The following year a vacancy occurred in the chair of Oriental languages in the university of Edinburgh, of which the town-council of the city are the patrons. The income from this chair was small; the gross emoluments of the present professor, who was a competitor with Murray, and afterwards his successor, are considerably short of 300l. per annum. It was however perfectly suited to Murray's taste and habits: it brought him to Edinburgh, where his literary labours could be both assisted and valued; and there was a great probability that some other situation would soon, as at present, be con-

joined with it. Great exertions were accordingly made to secure his election; and notwithstanding some fears of his health giving way under it, his appointment took place. (*Scots Mag.*, July, 1812.) He was elected on the 8th July, 1812, and on the 15th the university conferred on him the degree of Doctor in Divinity. On the 26th of August he was formally inducted to the chair, and he began to lecture on the 31st October following. Soon after that he published, for the use of his students, a small work entitled 'Outlines of Oriental Philology,' which is known to have been both composed and prepared for publication after his arrival in Edinburgh; the subject indeed was perfectly familiar to him. He continued to teach his class with little interruption till the end of February or the beginning of March; and at such times as his health would not permit him to attend his public lecture, he taught a small Persian class in his own room. The pulmonary complaint however, with which he had been struggling through the winter, at length compelled him to suspend his prelections; yet, with its characteristic deceit, it always flattered him with hopes of resuming them; and, quite unconscious of his real situation, he continued engaged in his favourite studies till within a few days of his death, which took place on the 15th April, 1813, in the thirty-seventh year of his age. His body was interred in the Grey Friars' Church-yard, at the north-west corner of the church.

This great linguist was an eminent example of the pursuit of knowledge under difficulties. His life however may be described rather as the preparation for some result than as having accomplished much; and the performance by which he will be known in the literary world, though distinguished by profound and various learning, was both imperfect and posthumous. It appeared under the auspices of the Rev. Dr. Scot of Corstorphine, and is entitled a 'History of the European Languages, or Researches into the Affinities of the Teutonic, Greek, Celtic, Slavonic, and Indian Nations.' An extensive acquaintance with these languages convinced the author that all the European languages were closely connected; and in the work now named, it is his object to show that they all derive from, and may be traced to, nine euphonic primitives, which primitives he states to be *ag, bag, dwag, gwag, lag, mag, nag, rag,* and *swag*. 'By the help of these nine words and their compounds,' says he, 'all the European languages have been formed.'

MURRHINE (sometimes written *Myrrhine*) VASES, vessels used by the ancients, were made of the stone or hard substance, whatever it might be, termed *murrha* (μύρρα). They are frequently noticed by the classic writers, and usually described as transparent, though sometimes spotted or clouded, like our cups of agate. Pliny speaks of them as coming from the East, from Parthia and Carmania. He adds that they were first brought to Rome by Pompey after his victory over Mithridates. 'The same victory,' he observes, 'introduced Murrhine vessels into the city, and Pompey was the first who dedicated to Jupiter of the Capitol precious stones and cups, after his triumph on that occasion. They afterwards came into common use.' (Plin., *Hist. Nat.*, li. xxxvii., edit. Harduin, vol. ii., p. 767.) The abbé Le Blond, in the 43rd volume of the 'Mémoires de l'Acad. des Inscriptions,' supposes that these vessels were made of the oriental sardonix. Others have supposed the material to have been a kind of Chinese stone. The best alabaster in ancient times was furnished from the quarries of Carmania, which may possibly have supplied the materials for the murrhine vessels.

MURVIEDRO. [SAGUNTUM.]

MUS. [MURINE.]

MU'SA, IBN NOSSEYR, Governor of Mauritania. The origin and genealogy of this conqueror are differently stated by the Arabian writers. Some make him the son of Nosseyr, son of Abd-el-rahman, son of Zeyd, of the tribe of Bekr; others assert that he belonged to the illustrious tribe of Lakhm; while there are not wanting genealogists who deny his ever having had any connexion with either of the above-mentioned tribes, and suppose him to be the son of a liberated slave of Muawiyah Ibn Abi Sufyan, the first khalif of the race of Umeyyah in the East. All however agree that his father Nosseyr was a *mauli*, or adherent of Muawiyah, that he served under his banners against Ali, and, as a reward for his services, was raised to the post of commander of the khalif's body-guard.

According to all accounts, Músa's birth is placed in the

year 19 of the Flight (A.D. 640). He seems to have made his first campaigns under his father, and to have been present at almost all the battles then fought by the Moslems. His bravery and the military talents which he displayed on several occasions made him a favourite with 'Abd-el-'aziz Ibn Merwan, a prince of the royal family then governor of Egypt, who attached him to his person, raised him in command, and, having previously obtained leave from his brother the khalif, appointed him general of the armies destined to achieve the conquest of Africa, in the year 79 of the Flight (A.D. 698-9). What the first expeditions of Músa were, is not satisfactorily ascertained. The Arabian writers say, in vague terms, that he pushed his conquests far into the West, and penetrated into the interior of Africa, returning with a rich spoil and thousands of captives. But he seems to have achieved nothing brilliant until the year 88 (A.D. 707), when the khalif Al-walid named him governor of Mauritania, with instructions to complete the conquest of the country.

Músa took his departure from Egypt at the head of a numerous army, and, partly by persuasion, partly by force, succeeded in reducing to obedience the motley tribes that inhabited the northern shores of Africa. He seems to have experienced no difficulty in uniting under his standard men whose habits were not dissimilar from those of the Arabs, and who, relying on ancient traditions current among them, believed themselves to be sprung from the same stock as their invaders. [BERBERS.] Under such a belief, which Músa dexterously tried to strengthen, whole tribes flocked to his banners, embraced the religion of the Prophet, and, led by his lieutenants, marched to new conquests. Tangiers, Arsilla, and Ceuta, three insulated fortresses which still held out for the Goths, were speedily reduced; a fleet commanded by Abdullah, Músa's eldest son, scoured the Mediterranean, and ravaged the islands of Sicily, Sardinia, and Mallorca; and in the year 91 of the Flight (A.D. 709) the whole of northern Africa, from the Pillars of Hercules to the delta of Egypt, acknowledged the laws of the conqueror.

At this critical moment, when the restless ambition of the African governor had been stimulated by so much success, a favourable occasion presented itself to satisfy his appetite for conquest. Gothic Spain was a prey to the most horrible anarchy. After the death of King Wittiza, Roderic, the son of a provincial governor, had usurped the throne to the prejudice of Eba and Sisibuto, the two sons of that monarch, who had taken up arms in support of their rights. Unable however to keep the field against Roderic, the sons of Wittiza and the noblemen who followed their party (among whom was a certain Julian or Ilyán) despatched a messenger to Músa, inviting him to invade Spain, and promising to aid him in his enterprise.

No sooner was Músa made acquainted with the divisions among the Goths, than he eagerly seized on the opportunity of interfering in them. By his orders Tarif Ibn Malik, one of his servants, made a slight incursion in the month of Ramadhan, A.H. 91 (July, A.D. 710), and returned to Africa loaded with spoil. A second expedition, commanded by Tárik Ibn Zeyád, landed on the coast of Spain, in April, 711, and two months afterwards [Moors] Roderick was defeated and killed in the battle of Guadalete.

On the news of this signal victory reaching Africa, Músa, who was far from expecting so complete success, felt a desire to share in the laurels reaped by his lieutenant; and while he hastily made the necessary preparations to cross over into Spain, he sent orders to Tárik not to move from his position, and to wait for further instructions. But the Arabian general had gone too far to be stopped by a mere message from his master. Eager for plunder, and bent on the subjugation of the whole country, he penetrated into the heart of Spain, and, before his master Músa had set his foot on the peninsula, the opulent city of Toledo, the capital of the Gothic monarchy, together with an immense booty, had fallen into his hands.

At this period Músa arrived in Spain, breathing vengeance against the man who, by disobeying his commands, had deprived him of so rich a harvest of glory and wealth. He landed at Algesiras, in June, A.D. 712, at the head of 18,000 men. He took with him three of his sons, Abdulaziz, Merwán, and Abdulola, leaving his eldest son Abdullah to govern Africa in his stead. His first step was to subdue such provinces as, by Tárik's precipitate march upon Toledo, had

remained untouched. He laid siege to Seville, which he reduced in a month (July, 712). Carmona and other neighbouring cities shared the same fate. Thence he passed into Lusitania, and, almost without halting in his rapid march, seized on Niebla, Beja, and other considerable cities (August, 712). His victorious career was stopped for a time before the walls of Merida, which he reduced, after an obstinate defence on the part of the garrison, towards the end of November, 712. From Merida Músa marched to Toledo, where, having had an interview with Tárik, he publicly reproached him with his disobedience, caused him to be beaten with rods, confiscated his property, and had him cast into a dungeon, where he remained until orders came from the khalif to release him, and give him, as before, the command of one of the divisions of the army.

The remainder of Spain was speedily subdued. Tárik, at the head of his troops, marched eastwards, and, after reducing the intermediate provinces, laid siege to Saragossa. Músa took a northern direction, reduced Salamanca, advanced as far as Astorga, and thence, returning to the Douro, followed the course of that river to Seria, passed the mountains, and arrived in sight of Saragossa, which Tárik was then investing, and which surrendered in July, 713.

From thence Tárik proceeded to Valencia, which, together with Murviedro, Xativa, and other considerable cities of those districts, were reduced with amazing rapidity; while Músa himself, after detaching some forces under the command of his son Abdulaziz to subdue and plunder the plains of Murcia, marched towards the Pyrenees, reduced on his passage the cities of Calahorra, Lerida, Barcelona, and, crossing that mountain barrier, penetrated into France.

How far Músa advanced into that country is not satisfactorily ascertained. According to Al-makkari, an Arabian writer, who compiled a history of Spain from the best sources (*Arab. MSS.*, in the *Brit. Mus.*, 733-4), Músa subdued not only Narbonne, but the greatest part of the province known by the name of Gallia Gothica; but, as other Arabian historians are silent on the subject, and as the Christian chroniclers of France have not made the slightest mention of this invasion, we are authorised in thinking that, if Músa did really cross the Pyrenees, his invasion was unattended with any important results. On his return from this expedition to the Pyrenees, a messenger from the khalif Al-walid, who now became alarmed at Músa's increase of power, reached his camp, and summoned him, together with Tárik, to the royal presence.

Tárik hastened to obey the orders of the khalif, and departed immediately for the East (Sept., 713); but Músa, who, if any faith can be placed in the Arabian writers, had conceived the ambitious project of subduing Gaul, Italy, and Germany—and forcing his way from Spain to Constantinople, thus connecting the eastern and western possessions of the Arabs—refused to comply with the summons. Having prevailed upon the envoy Mugbeyth to accompany him in his conquests, by promising him a large share of the spoil, he directed his course towards Asturias and Galicia, which the Moslems had not yet visited. But his reluctance to obey the imperial mandate added to the suspicions already entertained about his views, which were represented as aiming at independence, and a more peremptory order was sent for his return. The khalif's second messenger, whose name was Abú Nasr, reached him at Lugo, in Galicia, caught the bridle of his horse, and, in presence of the army, commanded him to repair to Damascus. Músa did not venture to disobey the order of the khalif, and, entrusting the government of Spain to his son Abdulaziz, reluctantly commenced his journey, in March, 714.

On arriving in Africa, where he made some stay, he confirmed his son Abdullah in his government of Cairwán, gave to his son Abdulola the command of Tangier and other important fortresses on the coast, and taking the road to Egypt, proceeded to Syria with a numerous escort, and long trains of camels heavily laden with the spoil of the conquest, besides being followed by thousands of captives, among whom were 400 Gothic nobles, sumptuously arrayed.

Músa did not reach Syria until the end of 714 or the beginning of 715. Tárik had arrived many months before, and not only had justified himself against the charges brought against him, but had succeeded in throwing all the blame upon Músa. To this must be added that Al-walid was then suffering under an acute disease, which soon

after caused his death, so that Músa's reception was not so brilliant as he had anticipated. But if Al-walid's treatment of the man who had added so rich a jewel to his crown was tainted with deep ingratitude, that of his brother and successor Suleymán was not only unjust but cruel. It is generally asserted that while Músa and his escort were approaching the capital, he received from that prince an intimation not to enter Damascus in his brother's lifetime, but to delay his entrance until the commencement of the new reign, in order that the Spanish treasures and captives might grace his accession. This command, Músa, from motives of fidelity towards his sovereign, imprudently disregarded; and on the accession of Suleymán, remained exposed to all his vengeance. He was cast into prison, beaten with rods, exposed to the sun until he was nearly dead, and lastly, fined two hundred thousand pieces of gold, a sum which all his treasures amassed in Spain were insufficient to satisfy, and which was raised among his friends. Suleymán's vengeance did not stop there; the two sons whom Músa had left to govern Africa in his absence were deprived of their governments, and orders were despatched to Spain (Aug., 716) to put to death Abdulaziz, whose head was brought to Damascus and shown to his disconsolate father by Suleymán himself, who asked him, with a bitter smile, if he recognised it. The afflicted father turned away at the sight, exclaiming, 'Cursed be he who has slain a better man than himself.'

Músa died in the greatest poverty at Wádí-l-korá, in the Hejáz, in 717, at the age of seventy-nine lunar or Arabian years.

(Conde, *Hist. de la Dom.*, Mad., 1820-21; Cardonne, *Histoire de l'Afrique*, Paris, 1765; *The History of the Mohammedan Empire in Spain*, London, 1816; Casiri, *Bibl. Arab. Hisp. Esc.*, Madrid, 1760; Ibn Khallékán's *Wafiyatu-l-ayin* (or the Lives of Illustrious Moslems), MS.; Al-makkari, and other historians of Mohammedan Spain.)

MUSA, ABU ABDALLAH MOHAMMED BEN, of Khwarezm, the earliest Arabic writer on algebra, whose treatise on that science, 'Al-Jebra al Mokābala' (restoration and reduction), was composed for popular use at the command of the caliph Al Mamun. It contains rules and illustrations (rather than demonstrations) for the solution of simple and quadratic equations, with their application to various questions, mostly of a mercantile character. From internal evidence it appears to be drawn from Hindu writings, with which the author is known to have been acquainted; and the works of Diophantus were not translated into Arabic till after the time of Mohammed Ben Musa.

This work was (partially at least) translated into Latin at an early period; and M. Libri (*Hist. des Sci. Math. en Italie*, vol. 1., note 12) has printed all the part of Ben Musa's treatise which the Latin manuscripts in the Bibliothèque du Roi at Paris contain. The complete work, in Arabic, with an English translation and notes by the late Dr. Rosen, was published by the Oriental Translation Society, in 1831, from a manuscript in the Bodleian Library.

It is from this work that (so far as Europe is concerned) algebra derives both its name and introduction; and the writings of Leonard Bonacci, Lucas di Burgo, and the earlier Italians, bear strong marks not only of their Arabic masters, but even of the particular work before us. Accordingly Mohammed Ben Musa was frequently called the inventor of Algebra, a title to which he has no claim.

In our account of the VIGA GANITA a comparison is made of the Arabic algebra, as far as it goes, with that of the Hindus.

MUSA, ANTONIUS, was a physician of some celebrity at Rome. He was at one time the medical attendant of the emperor Augustus, whose slave he had formerly been; and he gained considerable reputation by the benefit which the emperor obtained, when, having been long under the care of Æmilius for arthritic pains, which had been unsuccessfully treated with warm applications, Musa ordered him cold affusions, and some other means equally contrary to his previous prescriptions. He prescribed a similar remedy also for Horace (*Æpist.*, i. 15).

MUSA, a name given to a genus of plants having oatable fruit in tropical countries. They consist of herbaceous plants, having a gigantic simple stem, thickly clothed with the sheathing petioles of long, broad, horizontal leaves, which form a tuft, like that of some palm, on the apex of

the stem." These leaves are of a firm but thin texture, and are undivided; but having simple veins running directly from the margin towards the midrib, and presenting a broad surface to the wind, they are always torn into broad strap-like divisions, which give them a compound appearance. From the midst of these leaves proceeds the inflorescence, consisting of a compound spike of great size, each of whose divisions is enclosed in a large bract or spathe, loaded with male flowers at its base, but bearing females or hermaphrodites at the upper end. The perianth consists of six superior divisions, five of which are grown together into a tube, slit at the back, while the sixth is small and concave. There are six stamens, one or more of which are imperfect. The ovary is inferior, 3-celled, with a double row of numerous ovules in each cell; the style is short; the stigma is funnel-shaped, and obscurely 6-lobed. The fruit is an oblong fleshy body, obscurely 3-5-cornered, containing numerous seeds buried in pulp. The latter are roundish, the size of a pea, flattened, with a hard brittle shell, which is indented at the hilum.

This genus is one of the most important of those found in tropical countries, to which the species are confined in a wild state. The *M. Sapientum*, or *Plantain*, of which the *Banana*, or *M. Paradisiaca*, is a slight variety, has a fruit used to a prodigious extent by the inhabitants of the torrid zone; and, from its nutritious qualities and general use, it

Musa Sapientum.

may, whether used in a raw or dressed form, be regarded rather as a necessary article of food than as an occasional luxury. In equinoctial Asia and America, in tropical Africa, in the islands of the Atlantic and Pacific oceans, wherever the mean heat of the year exceeds 24 centigrade degrees (75° Fahrenheit), the plantain is one of the most interesting objects of cultivation for the subsistence of man. Three dozen fruits will maintain a person, instead of bread, for a week, and appears better suited to him in warm countries than that kind of food. Indeed the plantain is often the whole support of an Indian family. The fruit is produced from among the immense leaves in bunches,

weighing 30, 60, and 80 lbs., of various colours, and of great diversity of form. It usually is long and narrow, of a pale-yellow or dark-red colour, with a yellow farinaceous flesh. But in form it varies to oblong and nearly spherical; and in colour it offers all the shades and variations of tints that the combination of yellow and red, in different proportions, can produce. Some sorts are said always to be of a bright green colour. In general, the character of the fruit to an European palate is that of mild insipidity; some sorts are even so coarse as not to be edible without preparation. The greater number however are used in their raw state, and some varieties acquire by cultivation a very exquisite flavour, even surpassing the finest pear. In the better sorts the flesh has the colour of the finest yellow butter, is of a delicate taste, and melts in the mouth like marmalade. To point out all the kinds that are cultivated in the East Indies alone would be as difficult as to describe the varieties of apples and pears in Europe, for the names vary according to the form, size, taste, and colour of the fruits: sixteen principal kinds are described at length by Rumphius from which all the others seem to have diverged. Of these the worst are, *Pisang Swangi*, *P. Tundo*, and *P. Gabba-Gabba*; and the best are the round, soft, yellowish sorts, called *P. Medji* and *P. Radja*. Some cultivators at Batavia boast of having eighty sorts. Rheede distinguishes fourteen varieties by name, as natives of Malabar. In Sumatra alone twenty varieties are cultivated, among which the *Pisang Amus*, or small yellow plantain, is esteemed the most delicate, and next to that the *P. Raja*, *P. Dingen*, and *P. Kallé*. In the West Indies, plantains appear to be even more extensively employed than in the Eastern world. The modes of eating them are various. The best sorts are served up raw at table, as in the East Indies, and have been compared for flavour to an excellent reinette apple after its sweetness has been condensed by keeping through the winter. Sometimes they are baked in their skins, and then they taste like the best stewed pears of Europe. They are also the principal ingredient in a variety of dishes, particularly in one called mantégue, which is made of slices of them fried in butter and powdered over with fine sugar. Of the many cultivated sorts, that called by the French *La Banane musquée* is considered the best; it is less than the others, but has a more delicate flavour. There are uncoloured figures of the plantain fruit in Rheede's 'Hortus Malabaricus,' vol. i., plates 12, 13, and 14; and coloured ones in Tussac's 'Flore des Antilles,' plates 1 and 2. All hot climates seem equally congenial to the growth of this plant: in Cuba it is even cultivated in situations where the thermometer descends to seven centesimal degrees (45° Fahrenheit), and sometimes nearly to the freezing point. There is a hardy variety called *Camburi*, which is grown with success at Malaga.

The plantain prefers a rich fat soil; for in sandy places, where it flowers abundantly, it produces no fruit.

In the climates that suit it, there is no plant more extensively useful, independently of its being an indispensable article of food. A tough fibre, capable of being made into thread of great fineness, is obtained from its stem; and the leaves, from their breadth and hardness, form an excellent material for the thatch of cottages. An intoxicating liquor is also made from the fruits when fermented, and the young shoots are eaten as a delicate vegetable.

The banana of hot countries is a mere variety of the plantain, distinguished by being dwarf, with a spotted stem and a more delicate fruit. Botanists call it *Musa paradisiaca*, in allusion to an old notion that it was the forbidden fruit of Scripture: it has also been supposed to be what was intended by the grapes, one bunch of which was borne upon a pole between two men, that the spies of Moses brought out of the Promised Land. The only argument of any importance in support of the latter opinion is, that there is no other fruit to which the weight of the fruit of Scripture will apply.

All the genus is Asiatic; the wild plantain is found in the forests of Chittagong, where it blossoms during the rains; *Musa coccinea*, a dwarf sort, with a stem not more than three or four feet high, is found in China; *M. ornata* and *superba* inhabit the forests of Bengal; *M. glauca* is from P'ogu; *M. textilis* is from the Philippines, where it furnishes the valuable thread called *Manilla hemp*. There is also in the gardens of England a plant called *M. Cavendishii*, not above three feet high, and fruiting abundantly at that size, the origin of which is said to be the Isle of France.

MUSA'CEÆ are a natural order of Endogens, of which the last genus is the representative. They are generally stately and always beautiful herbaceous plants with the aspect of a plantain, and with large bracts or spathes, which are usually coloured of some gay tint. The characteristic marks of the order are to have an inferior ovary, with very irregular and unsymmetrical flowers, whose sexual apparatus is not consolidated. It is chiefly by these distinctions that it is known from Amaryllidaceæ. In some the fruit is fleshy, as in the plantain; in others it is dry and capsular. Only four genera are known of this order; all consisting of species of striking beauty. The *Heliconias* are the principal American form, nearly all the others being found in the Old World; of these the species are conspicuous for their brilliantly coloured rigid boat-shaped bracts, sometimes yellow, sometimes scarlet, and even a mixture of both. The *Strelitzias* are Cape plants with rigid glaucous leaves, and singularly irregular flowers of considerable size, coloured yellow and blue, or pure white. Finally, the *Ravanula* of Madagascar, *Urania speciosa*, a noble palm-like plant, is remarkable for the brilliant blue colour of the lacerated pulpy aril which envelopes the seeds; the latter are used for dyeing in Madagascar, but none of the order are of any important use to man, with the exception of the Musas themselves.

1, a flower, with its inferior ovary; 2, the sexual apparatus of a male flower; 3, ditto of a female flower; 4, a section of an ovary; 5, a ripe fruit, 6, the same cut through transversely.

MUSÆUS. Two, if not more, Greek poets of this name are known. 1. The oldest of them lived in the mythic ages of Greece, and is said to have been by birth an Athenian, and the son, or at least the disciple, of Orpheus. Plato and Hermesionux, in a passage quoted by Athenæus (xiii. 597), state him to have been the son of Selene, or the moon: Diogenes Laërtius says that he was buried at Phalerum, and mentions his epitaph. His works, which are lost, have been quoted by Plato, Philostratus, Pausanias, Clemens Alexandrinus, and other ancient writers: they consisted of religious hymns, a poem on the war of the giants, a theogony, a work on mysteries, and moral precepts to his son. A few scattered lines, gathered from the quotations of the above writers, were inserted by Henri Etienne in his collection of philosophical poetry. 2. Musæus, styled the Grammarian in the MSS., is the author of the very interesting Greek poem entitled 'Hero and Leander.' The age in which the author lived has been a subject of much dispute. Scaliger, against all probability, ascribed the poem to the Musæus of the mythic ages. The most general opinion is, that he lived in the lower ages of the Roman empire. Schrader, Schoell, and other critics suppose him to have lived in the fifth century of our æra, and to have been a contemporary of Nonnus, the author of the 'Dionysiaca.' (Schrader's Preface to his edition of Musæus, Leeuwarden, 1742.) The poem of 'Hero and Leander' was first discovered about

the thirteenth century. It consists of 340 hexameter lines, which contain the whole account of the beginning of the loves of Leander and Hero, the daring of the former in swimming by night across the strait from Abydos to Sestos to visit his mistress, and the tragical end of both lovers. Ovid has treated the same subject in Latin verse in one of his *Heroides*, in which Hero writes to Leander to urge him to swim across the Hellespont, as formerly, although the winter had set in, and yet at the same time expresses her fears of his risking his life. The story appears to have been an old tradition of a real fact.

The poem of *Musæus* has been a favourite with scholars, and has been repeatedly published, commented on, and translated into various languages. Heinrich's edition, Hanover, 1793, and Schäfer's edition, Greek and Latin, Leipzig, 1825, which is an improved republication of Schrader's edition already mentioned, are among the best. The poem has been translated into Italian by Salvini, Pompei, and others; French by Marot, Gail, and Mollevant, Paris, 1805; English, with notes by Stapylton, in 1649, and again in 1797; and into German by Passow, Leipzig, 1810.

MUSÆUS, JOHANN KARL AUGUST, the admired author of the '*Volkmärchen der Deutschen*,' or '*Popular Legends of Germany*,' was born at Jena in 1735, in which university he studied theology with the intention of taking orders, but did not do so. His first literary production, which appeared in 1760, was his '*Grandison the Second*,' a parody on Richardson's celebrated novel, at that period extravagantly admired in Germany. This satirical performance was so well received as to pass through several editions; yet, notwithstanding its success, several years elapsed before the author resumed his pen as a candidate for literary fame; for, in order to eke out his small salary as a professor at the gymnasium of Weimar, he took pupils into his own house, and had consequently little leisure for studious occupation. At length, after an interval of eighteen years, he published his '*Physiognomical Travels*,' intended, if not as a satire upon Lavater's system, to correct by wholesome ridicule the extravagant abuse of it into which his countrymen had fallen. The success of this work induced him to throw off his incognito and avow himself the author; whereupon he became the literary idol of the day, and was for awhile an object of attraction to 'lion-hunting' visitors anxious to have a sight of the retired schoolmaster who had mystified them by his pleasantry. This sudden acquisition of celebrity and importance had no other effect upon *Musæus* than to encourage him to proceed. Accordingly, he forthwith set about his '*Volksmärchen*,' which were actually what they professed to be, for he is said, while composing them, to have collected all the stories of the kind he could, from old women at their spinning-wheels, and even from children in the street. But if this circumstance in some measure deprives him of the merit of invention, the fascinating charm of narrative with which he dressed up such homely materials, the humour and naïveté which he imparted to them, were all his own. The success of these popular tales was complete, for they have become a classical and standard work of their kind, while a legion of original novels and romances, all favourites with the public for awhile, have now sunk into utter oblivion. His next production was that entitled '*Freund Heins Erscheinungen, in Holbeins Manier*,' a kind of literary '*Dance of Death*' (*Freund Hein* being a jocose appellation for that grim personage), where, in a series of moral and satirical sketches, he shows how many human projects and follies are suddenly cut short by the unwelcome yet inevitable visitor. Excepting a collection of novellettes and tales, entitled '*Straussfedern*,' and another for the use of children, '*Freund Hein*' was his last work, for he himself had his summons from him about two years after, October 28, 1787.

In 1791 a collection of his posthumous pieces, to which was prefixed '*Some Traits of the Life of the Good Musæus*,' was published by his pupil Augustus von Kotzebue. To the epithet so markedly bestowed upon him few have had a better claim than *Musæus*: a mild philosophy, of which his own life furnished a practical example, together with shrewd good sense and quiet humour, pervades all his writings.

MUSCA (the Fly), a constellation so called by Lacaille, being the *Apis* of Bayer. It is situated immediately below *Crux*, and between the latter and the South Pole.

MUSCAT, or MUSKAT. [ARABIA.]

MUSCHELKALK, a calcareous rock interposed in the midst of the new red-sandstone system, receives this name in Germany, and though it is not more carboniferous than some other limestones, yet it is much richer in organic remains than the average of the strata with which it is associated. This rock occupies a considerable space in the vicinity of the Harz, Schwarzwald, and Vosges Mountains, but is unknown in the British Isles, though several small bands of calcareous rock interlamine the variegated clays of the red-sandstone system. Brown ('*Lithæa Geognostica*'), presents the following synopsis of the strata in this formation, as it appears on the flanks of the Black Forest:—

Keuper formation.

Muschelkalk.	{	Dolomite . . .	Dolomite (Nagelsfels, Malbstein)
		Limestone . . .	Pectinite limestone.
		of	Rogenstein (oolitic).
		Friedrichshall. . .	{ Encrinitic limestone.
			{ Palinurenkalk.
			{ Encrinitic limestone.
Anhydrite . . .	Dark clay and anhydrite, with dolomite, swinestone, and rock-salt.		
Wellenkalk . . .	Limestone and dolomitic marls with gypsum and rock-salt.		

Bunter Sandstein.

The fossil remains of the muschelkalk participate in the more common species of the Bunter sandstein below, and the Keuper above; but among the peculiar species may be reckoned *Encrinus moniliformis* and *Ammonites (ceratites) nodosus*. Saurian reptiles occur in this rock.

MUSCI, or MOSSES, constitute a group of cryptogamic or flowerless plants, of considerable extent and of great interest on account of their very singular structure. They are in all cases of small size, never exceeding a few inches in height, and though often of almost microscopical minuteness, are furnished with leaves arranged over a distinct axis of growth, and are propagated by means of reproductive apparatus of a peculiar nature. They have no trace of spiral or other vessels in their tissue, but are formed entirely of cellular tissue, in the stem lengthened into tubes. For long time they were thought to be destitute of a breathing apparatus, but the apertures through which this function is performed have at length been discovered by Treviranus and Unger, and especially by Mr. Valentine. (*Transactions of the Linnean Society*, vol. xviii., p. 239.) It is however remarkable that they should be confined to the organs of fructification, and not found on those of vegetation.

The organs of fructification are of two kinds; the most universal and most conspicuous is the urn (*sporangium*, or *theca*) in which the spores, or seed-like bodies, are generated. If the axils of the leaves of a moss are examined at the proper season of the year, there will be found in some of them clusters of articulated filaments swollen at the base, from among which some one will be larger than the remainder, and go on growing while they are arrested in their development. After awhile this body is found to have an exterior membranous coating, which separates from the base by a circular incision, but which otherwise adheres to the part beneath it. The latter, which is the young urn, gradually acquires a stalk, called the *seta*, upon which it is elevated above the leaves, carrying the outer membrane upwards on its point, so that when full grown it is covered by it as with a cap; then called a *calyptra*. The urn itself is closed by a lid, or *operculum*, and contains the spores arranged in a cavity surrounding a central column, or *columella*. Its rim is bordered by a double row of processes.

often resembling jointed teeth, and called the peristome; one set of which appears to belong to the outer shell of the urn, and the other to the inner. Usually the urn grows from a fleshy tubercle called the *apophysis*, the station of which is in most cases at the base of the seta, but in *Splanchnum* forms a curious process at the apex of the seta, immediately below the urn

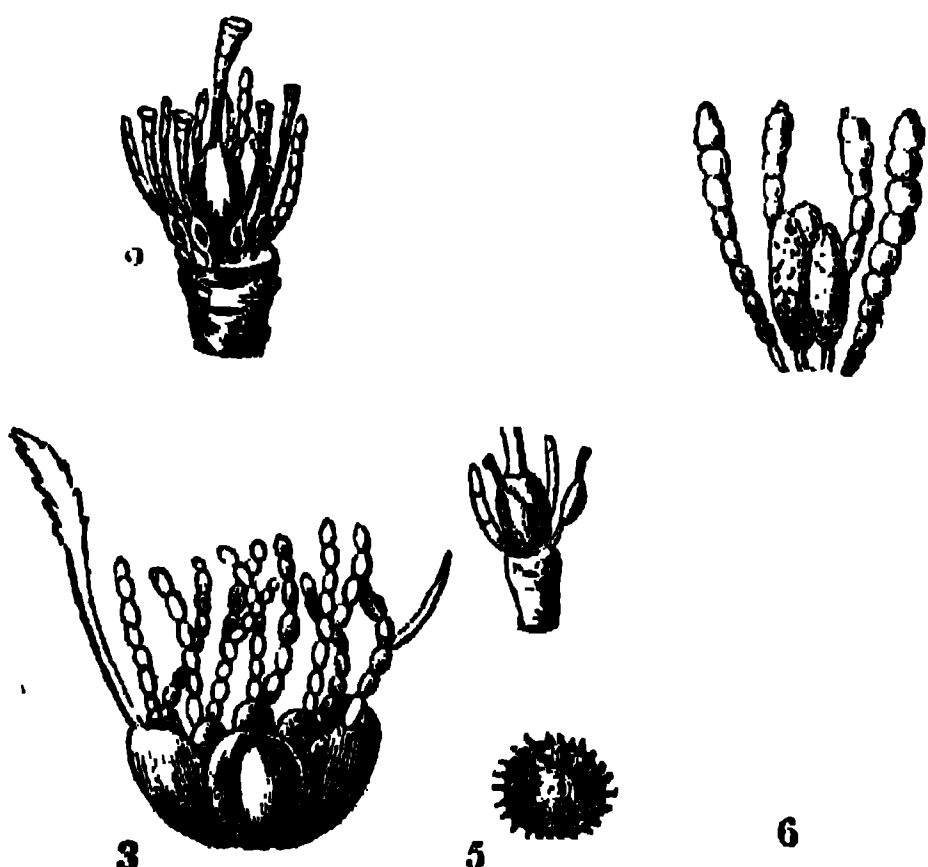

Fissidens Adiantoides.

1, an entire plant, much magnified; 2, a cluster of young urns; 3, an urn, full grown, with its calyptra, 4, removed; 5, the urn with the operculum fallen off, 6, a portion of the peristome.

In some mosses there occur organs of a second kind, by some supposed to be male, but whose use is really unknown, to which the name of *antheridia* or *stamidia* has been applied. These are also found clustered in the axils of leaves; they consist of membranous, cylindrical, jointed or jointless bodies, irregularly opening at the point, and discharging a mucous turbid fluid; they are surrounded by *paraphyses*, or jointed filaments, like the urns themselves.

When the spores of mosses germinate, they produce a jointed filament from any part of their surface, of which one part rises upwards, forming the beginning of a stem, while the other is directed downwards as a root; from the axils of the branches of the stem-filament the leaves are eventually developed.

Gymnostomum Ovatum.

1, a seta, bearing on the apex an urn, from which the operculum is rising, proceeding from an apophysis at the base, where it is surrounded by paraphyses; 2, a group of young urns, among which a few paraphyses are mixed; 3, a cluster of stamidia and paraphyses, surrounded by scale-like leaves; 4, three stamidia surrounded by four paraphyses; 5, a spore; 6, the same in the first stage of germination; 7, the same in a more advanced state.

The genera of mosses are principally characterised by peculiarities in the peristome, or by modifications of the calyptra, and of the position of the urn. Linnæus admitted very few genera, but modern muscologists have elevated the number to more than 120; concerning the goodness of

which there is however some difference of opinion. In the most recent enumeration of the genera the old order Musci is broken up into three: of which *ANDRÆACEÆ* have an urn splitting into four valves; *SPHAGNACKÆ*, a valveless urn, a calyptra separating in the middle, and a toothed ring surrounding the peristome; *BRYACEÆ*, a valveless urn, a calyptra separating at the base, and a ringless peristome.

Mosses are among the first plants that spring up on the surface of inorganic matter, at first appearing like a green stain, when they merely consist of germinating spores, but soon clothing themselves with leaves and then by their decay producing the earliest portion of decomposed vegetable matter with which the soil is fertilised. (Bridel, *Bryologia Universalis*; Hedwig, *Theoria Generationis, &c. Plantarum Cryptogamicarum*; Endlicher, *Genera Plantarum* Hooker and Taylor, *Muscologia Britannica*.)

MUSCICA'PIDÆ, *Flycatchers*; a family of insectivorous birds, so named from their mode of taking their prey. Thus, M. Temminck states, that the Flycatchers (*Gobemouches*) feed entirely on flies and other winged insects, which they catch as they fly (*Mmanuel d'Ornithologie*); and our countryman White says, 'There is one circumstance characteristic of this bird (the Spotted Flycatcher, *Muscicapa grisola*) which seems to have escaped observation; and that is, it takes its stand on the top of some stake or post, from whence it springs forth on its prey, catching a fly in the air, and hardly ever touching the ground, but returning still to the same stand for many times together.' (*Nat. Hist. of Selborne*.)

Linnæus, in his last edition of the *Systema Naturæ*, places the genus *Muscicapa*, containing the true flycatchers, the *Tyrants* (*Muscicapa Tyrannus*), and several other species, to the amount of twenty-one, between the genera *Fringilla* and *Molucilla*.

Cuvier places the *Gobe-mouches* (*Muscicapa*, Linn.) between the *Pies Grêches* (Butcher-birds, *Lanius*, Linn.) and the *Cotingas* (*Ampelis*, Linn.).

He describes the group as having the bill depressed horizontally, and furnished with hairs or *vibrissæ* at its base, and its point more or less hooked and notched; and he makes the Flycatchers consist of the *Tyrants* (*Tyrannus*, Linn.); the *Moucheroles* (*Muscipeta*, Cuv.); the *Platyrrhynques* or *Broad-bills*; certain species high on the legs and with a short tail (*Turdus auritus*, Gm.—*Conopophaga*, Vieillot); the *True Flycatchers* (*Muscicapa*, Cuv.); and other variations of form, principally in the bill, which becomes more slender in some, thus approximating to the *Figuers*, and, in others, has the *arête* a little more elevated, whilst it is curved towards the point, thus leading to *Saricola*. Cuvier finishes by observing that there are various genera or subgenera which come very near to certain links of the series of Flycatchers, though they much surpass those birds in size, such as the *Bald Tyrants* (*Gymnocephalus*, Geoff.), and *Cephalopterus* (Geoff.). [*CORACINA*, vol. VIII., pp. 4, 5.]

M. Temminck places his genus *Gobe-mouche* (*Muscicapa*, Linn.) between *Lanius* (Linn.) and *Turdus* (Linn.).

M. Vieillot places the *Myothères* or Flycatchers between the *Chélidons* (Swallows and Gootsuckers) and the *Collurions* (Butcher-birds).

Mr. Vigors, at the commencement of the section treating of the order *Dentirostres*, observes that the depressed bill and insect-food of the *Todidæ* introduce us at once to the *Muscicapidæ*, with which they are immediately connected by the genus *Platyrrhynchus*, Desm. The species that compose the latter group were, he remarks, originally included in the genus *Todus*, and were separated from it only on account of the comparative strength of their legs. 'The whole of the *Muscicapidæ*, indeed,' continues Mr. Vigors, 'with which family *Platyrrhynchus* is now united, have a decided affinity to the last tribe, or the birds which feed upon the wing, in their broad-based bills, the *vibrissæ* that surround them, and their similar habits of darting upon their prey while on the wing. Separated from them chiefly by the strength and more perfect structure of the leg and foot, they form the extreme of the succeeding tribe, in which they are numbered in consequence of these distinguishing characters. The line of affinity between the two tribes may thus be assumed as established.' Mr. Vigors then states that the families composing the order *Dentirostres* appear to succeed each other as follows:—*Muscicapidæ*; *Laniidæ*; *Merulidæ*; *Sylviadæ*; *Pipridæ*. These families are thus grouped by him in their typical disposition:—

Normal Group

Rostris fortioribus { *Laniadæ.*
Merulidæ.

Aberrant Group.

Rostris debilioribus { *Sylviadæ.*
Pipridæ.
Muscicapidæ.

He further remarks that the *Muscicapidæ* contain a multitude of species, diffused over every quarter of the globe, and differing in many points of generic distinction; but hitherto so ill-defined, and so unsatisfactorily grouped, that any attempt to trace them in detail through their affinities in their present confusion would be hopeless. They are all however, he adds, well united together by the essential characters which distinguish the type of the group—the notched, depressed, and angular bill, and the strong hairs or vibrissæ that surround its base. In these characters, as well as in their manners, they partially correspond with the *Laniadæ*, from the earlier families of which they chiefly differ in their inferior power and robustness. Mr. Vigors then enters among the *Laniadæ* by the genus *Tyrannus*, Cuv., which, in his opinion, unites them with the *Muscicapidæ*, in which family indeed that genus has generally been classed, and from which he would separate it, chiefly on account of the strength of the bill, wherein the character of a *Shrike* is more conspicuous than that of a *Flycatcher*.

M. Lesson makes the *Muscicapidæ* consist of the genera *Tyrannus*, *Monacha*, *Eurylaimus*, *Platyrhynchus*, *Todus*, *Myiagra*, *Muscicapa*, *Alectrurus*, *Drymophila*, *Formicivora*, *Rhipidura*, *Seisura*, *Psophodes*, and *Enicurus*.

Mr. Swainson (*Classification of Birds*) is of opinion that the Water-chats (*Fluvicolinæ*) seem to connect the Tyrant Shrikes with the Flycatching family, or *Muscicapidæ*, the most insectivorous of the *Dentirostres*; a group, he remarks, hardly less numerous than that of the Warblers, and composed, like them, almost entirely of small birds. Both families, he continues, are insectivorous, that is, habitual devourers of insects; but very many of the warblers (even in the more typical genera) feed also upon fruits, of which the robin, the blackcap, and the whitethroat are notable examples. 'The Flycatchers however,' adds Mr. Swainson, 'properly so called, seem to be strictly and exclusively insectivorous, or, at least, it has not yet been ascertained that any of the species composing the typical group *Muscicapinæ* ever partake of fruits. This peculiarity of diet, independent of many others, separates them from the warblers on one side, and from the *Ampelidæ*, or Chat-teters, on the other; while another is to be found in the mode or manner of their feeding. The warblers fly about, hunting down their prey, searching among trees, and roaming from place to place after their favourite food; hence they become ambulating flycatchers, and their feet are consequently large and strong in comparison to the size of their bodies. We need only look to the gold-crested and wood warblers as exemplifications of this remark, even among those species which frequent trees; but in such, as in the Stonechats, *Saxicolinæ*, and *Motacillinæ*, as habitually walk, the feet are much stronger and the shanks more lengthened. Now, the very reverse of this structure is the typical distinction of the Flycatchers; their legs are remarkably small and weak,—more so, perhaps, than those of any dentirostral birds,—showing at once that their feet are but little used; and such we find to be the case. The Flycatchers constitute the fissirostral type of form among the leading divisions of the *Dentirostres*, and they consequently exhibit all the chief indications of that primary type of nature, as it is exhibited in the feathered creation. These, as the intelligent ornithologist already knows, are manifested in a large and rather wide mouth and bill; short, feeble, and often imperfect feet; great powers of flight and often a considerable length of wing: the development of this latter structure is not always apparent, but it is the peculiar power of their flight upon which they chiefly depend for procuring subsistence. They are mostly sedentary, and only dart upon such insects as come within a sudden swoop, without attempting to pursue their game further, if unsuccessful in the first instance: they return, in fact, to the spot they left, or to another very near, and there await patiently until another insect passes within the proper distance. This habit of feeding at once explains the reason of the feet being so small and weak, by showing that they

are merely used to support the body; or, at least, that they are not employed in constant exercise or exertion, as in the generality of other birds. Other characters accompany these, no less indicative of birds which feed exclusively upon the wing: the bill is always considerably depressed or flattened, particularly at its base; and the sides of the mouth are defended with stiff bristles, to confine the struggles of their prey.'

Mr. Swainson thinks that the primary divisions appear to be represented by the genera *Eurylaimus*, *Muscicapa*, *Fluvicola*, *Psaris*, and *Querula*, and these, according to his views, constitute the types of so many subfamilies, very unequal indeed in their contents, yet blending sufficiently into each other to point out their circular succession. He considers the first two of these to be the typical and sub-typical groups; and the three next to be aberrant.

The Prince of Musignano (*Geographical and Comparative List*) places the *Muscicapidæ* between the *Turdidæ* and the *Laniadæ*; and he makes the *Muscicapidæ* consist of the following subfamilies and genera.

a.

Muscicapinæ.

Genera:—*Setophaga*, Sw. *Tyrannula*, Sw. *Tyrannus*, Vieill. *Milvulus*, Sw. *Butalis*, Boie. *Muscicapa*, Linn. *Erythrosterina*, Bonap.

b.

Vireoninæ.

Genera:—*Icteria*, Vieill. *Vireo*, Vieill. *Vireosylva*, Bonap.

In considering this arrangement, the student should remember that it only applies to the birds of Europe and North America.

Mr. Swainson thus defines the family:—

Stature small. Bill considerably depressed its entire length, broad: the edge of the upper mandible folding over that of the lower; the tip abruptly bent and notched. Rictus wide, defended with strong rigid bristles pointing forwards. Feet almost always short (except in the rasorial types, where of course they are longer), small, and weak. Feed solely upon insects captured during flight. Habits sedentary.

Subfamily *Querulinæ.*

Bill strong, broad, much depressed; gape wide. Rictus with strong bristles. Feet short, resembling those of the typical *Ampelidæ*. Lateral scales minute. (Sw.)

Mr. Swainson is of opinion that the genus *Querula* is the type of this family, and he observes that by some of the Linnæan writers this remarkable bird is classed as a *Muscicapinæ*; while by others, even among the moderns, it is considered an *Ampelis*; and he thinks that both of these opinions may be reconciled, by viewing it—as it stands in his arrangement—as the connecting link between these families. He remarks that all the other Flycatchers, according to his system, so far as we yet know, feed entirely upon insects; but there is unquestionable testimony that this species lives also upon fruits, thus uniting in itself the characteristic of the two families which it connects. 'In the bill, he adds, there is much of the form and strength of that of *Psaris*, but it is wide and more depressed; whilst the stiff bristles at the rictus betray its insectivorous habit: the feet are remarkably short for the size of the bird, and are calculated only, like those of the *Ampelidæ*, for perching. All these characters, in the opinion of Mr. Swainson, not only point out this genus as the fissirostral type, but perfect the union of the families of *Muscicapidæ* and *Ampelidæ*.

Genera.

Querula, Vieill. and *Lathria*, Sw. Of these we select the former as an example.

Generic Character.—Bill large, broad, and strong. Gonyx long and straight. Nostrils concealed by incumbent reflected feathers. Wings long and broad, fourth quill longest. Toes unequal; inner toe shortest, of equal length with the hind toe. Tail even.

Example, *Querula rubricollis*, The Common Piahau.

Description.—Black with a purple throat. It is the *Muscicapa rubricollis* of Gmelin.

Locality and Habits.—America, where they go in troops in the woods in pursuit of insects.

Querula Rubricollis.

Psariacæ.

Bill large, thick, subcylindrical. Culmen convex, and without any ridge; the tip abruptly bent and notched. Head large, depressed. Mouth very wide. Feet weak: lateral toes unequal; interior scales of the tarsi transverse; lateral scales small, numerous. Wings long.

Psaris Cayanensis.

Mr. Swainson (who gives the above as the characters of the subfamily to which, in his opinion, *Alectura* immediately leads) states that in the *Psariacæ* there are but three ascertained genera. 'These birds,' says Mr. Swainson, 'like their representatives, *Monacha* and *Psarisoma*, depart considerably from the types of this family: the bill is less depressed than in any other of the flycatchers, and its structure is altogether stronger and thicker; they are all natives of Tropical America, and are generally found only in thick forests. *Gubernetes* is the genus by which they appear to be connected with the waterchats, through the medium of *Alectura*. One species only is yet known, the *Gubernetes forficatus*, remarkable for its long forked tail:

to this succeeds *Psaris*, where we find nearly all the species coloured alike; that is, they are more or less of a grey or pearl white, with black head, wings, and tail: they remind us immediately of the gulls, and this analogy is one of the most beautiful, when worked out, in the whole family. The smaller birds of the genus *Pachyrynchus* immediately follow. Two or three already prepare us for the next* division (*Querulinæ*), by the great depression of their bills, and the singularly formed red feathers on the throat.' (*Classification of Birds*, part iii.) In the *Synopsis* (part iv.) only two genera are given, *Psaris*, Cuv., and *Pachyrynchus*, Spix. Of these we select *Psaris* as an example.

Generic Character.—Bill large. The rictus smooth, often naked round the eye. Wings lengthened; the first quill equal to or longer than the fourth. Tail short, even. Inner toe shorter than the outer. (Sw.)

Example, *Psaris Cayanensis*.

Description.—Ash-coloured head, wings, and tail black. This is the *Lanius Cayanensis cinereus* of Brisson; *Lanius Cayanus* of Linnæus and Gmelin; *Pie-grièche grise de Cayenne* of Buffon; *Cayenne Shrike* of Latham; and is the type of Cuvier's genus *Psaris*.

Locality and Habits.—South America. Cayenne particularly. Cuvier says that its manners are those of the *Shrikes*.

Fluvicolinæ.

Legs formed for walking. Tarsi lengthened, strong. Inhabit the sides of marshes and rivers in Tropical America. *Seisura* alone is Australian. (Sw.)

Mr. Swainson states that the *Fluvicolinæ*, or waterchats, with the exception of one genus, whose situation is still somewhat doubtful, are entirely restricted to the warm latitudes of America, where they seem to represent the stonechats and the wagtails of the Old World. 'They are,' continues this author, 'strictly ambulating Flycatchers, and constitute the rasorial division of this family. The legs are consequently very long, and formed especially for walking; the toes are also long, quite divided to their base, and furnished with long and slightly curved claws. This structure enables these birds to run with great celerity; and they are generally seen on the sides of streams and rivers, feeding upon flying insects which resort to such situations; for they never hunt among trees, and rarely perch; such at least are the manners of the typical species; but there are of course various modifications of habit, corresponding to those, which will now be glanced at, in their structure.' Mr. Swainson exhibits some variation in his views as to this group in the third and fourth parts of the *Classification of Birds*. In the third part the first genus, with which he begins the series, is that of *Seisura*, differing only from *Rhipidura* by its more lengthened bill and feet: indeed he by no means feels satisfied that *Seisura* is naturally separated from *Rhipidura*, although, for the present, he adopts the group as proposed by Mr. Vigors and Dr. Horsfield. He nevertheless expresses his suspicion that all the genera of the *Fluvicolinæ* may prove to be natives of Tropical America, and that *Seisura* is only composed of aberrant species of *Rhipidura* which pass into the *Fluvicolinæ*. Both these divisions (*Seisura* and *Rhipidura*), as well as that of *Seicircus*, have broad fan-shaped tails, which, he observes, plainly indicate the type to which they belong, although the rank they respectively hold cannot, in our present state of knowledge, be clearly ascertained. 'Leaving this group,' says Mr. Swainson in continuation, 'we reach that of *Fluvicola*, by means of certain black and glossy birds of Brazil, some of which have distinct crests: these latter conduct us to the typical *Fluvicolæ*, having the legs unusually long, the bill depressed, the tail lengthened, and the plumage differently varied with white and black. One of the most characteristic of these singular birds is the *Fluvicola cursoria*, of the size of a lark; but some are nearly equal to a small thrush. *Perspicilla*, so called from the naked fleshy lobe which surrounds the eyes like spectacles, is the next genus: this is succeeded by *Alectura*, one of the most distinct and well defined groups in the whole circle of ornithology: the remarkable development of the tail-feathers in this group only finds a parallel in the genus *Vidua* among the finches and that of *Gallus* on the rasorial circle. Besides these genera, there are several black and white coloured birds

* In the third part of Mr. Swainson's 'Classification of Birds,' the sub-families stand in the following order:—*Eurylaiminæ*, *Muscicapinæ*, *Fluvicolinæ*, *Psariacæ*, *Querulinæ*. In the fourth part ('Synopsis') they are thus arranged:—*Querulinæ*, *Psariacæ*, *Fluvicolinæ*, *Muscicapinæ*, *Eurylaiminæ*.

having a general resemblance to the foregoing, which would seem to enter among the waterchats; yet, as we have not sufficiently analyzed the group, we must leave this point undetermined: among these are the white-headed tody of the old writers, which is either a *Tyrannula* or an aberrant *Fluvicola*, as well as the *Muscicapa leucocilla* of Hahn, which, in outward appearance, so much resembles a manakin, that it may possibly prove a representative of that family in the present circle.* In the fourth part the subfamily is made to consist of the following genera, arranged in the order here given:—

Gubernetes, Vig. *Alectrurus*, Vieill. *Fluvicola*, Sw. (with its subgenus *Blechnopus*, Sw. *Pepoaza*, D'Azar.). *Seisura*, Horsf. and Vig. *Perspicilla*, Sw. Of these we select *Gubernetes*.

Generic Character.—Bill thick, subdepressed, raised at the base, culmen rounded; upper mandible slightly notched at the apex; nostrils rounded; the rictus furnished with close-set rigid vibrissæ. *Wings* moderate; quills, from the 1st to the 5th nearly equal, the first the shortest, the second the longest; the external boards (pogoniis), except the beards of the first feather, notched in the middle; internal beards entire. *Feet* with moderate tarsi; the acrotarsia and paratarsia scutellated; soles reticulated with oval scales. *Tail* very long and forked. (Vig.)

Example, *Gubernetes Cunninghamsi*.

Description.—Ash-coloured, longitudinally lined with brown, throat and rump white, lunulated pectoral band purplish-brown, wings and tail brownish-black; quills longitudinally banded with ferruginous.

Gubernetes Cunninghamsi. (Vig., *Zool. Journ.*)

Mr. Vigors, whose generic and specific descriptions we have given above, says that this bird, which he named after Colonel Cunningham of Rio Janeiro, appears to have a considerable affinity to the genus *Psaris* of Cuvier in the structure of its bill and wings, but that it differs from it by other such essential characters, as to have induced Mr. Vigors to place it in a separate genus. Besides the difference in the structure of the tail, an important character, he observes, in the group of the *Laniidae*, which still retain some of the powers of flight belonging to the *Fissirostres*, he notes the following differences between the two forms. The rictal bristles of his bird are strong and numerous,

while in *Psaris* they are scarcely perceptible. The *tarsi*, though somewhat weaker than those of *Psaris*, are in a slight degree weaker, while the toes are longer and stronger. The lateral scales of the tarsi are square and far asunder, while in *Psaris* they are rounded and numerous. The hinder scales also are less rounded, less close, and less conspicuous than in the latter genus. (*Zool. Journ.*, vol. ii.)

Muscicapinae.

Feet weak, formed only for perching, generally short (excepting in *Todus*), but always very slender, and often syndactyle. **Bill** more or less depressed. **Gape** with stiff bristles. **Claws** small, considerably curved. **Lateral toes** unequal. **Inhabits** warm and tropical latitudes, but excluded from North America. (Sw.)

This extensive subfamily contains the ordinary Flycatchers, the generality of which do not exceed the dimensions of *Muscicapa grisola*. Mr. Swainson remarks that the bill, although it is rarely so broad as in the *Eurylaiminae*, is much more flattened, and the bristles at the gape are more developed. 'Their whole structure also,' continues Mr. Swainson, 'is more slight and delicate; but their colouring, although sometimes elegant, is almost devoid of vivid tints. The different form and length of the bill and feet furnish the characters by which the genera and subgenera are distinguished; while the species, which are exceedingly numerous, with the exception of the genus *Todus*, are only found in the Old World. The typical genera are *Todus* and *Muscicapa*; the aberrant are *Megalophus*, *Monacha*, and *Rhipidura*: the two first are so numerous in species as to contain subgenera.' Mr. Swainson then enters into a lengthened notice of the different genera and subgenera; exhibits the circle of *Todus*, which he considers to be complete with that of *Muscicapa*; and gives the following as a table, showing the comparison of *Todus* with the orders of birds, and the tribes of the *Perchers*.

Subgenera of <i>Todus</i> .	Genus <i>Todus</i> . Analogies.	Tribe of <i>Perchers</i> .	Order of Birds.
<i>Todus</i> .	{ Bill lengthened, conic, slightly notched. }	COMIROSTRES.	INSESSORES.
<i>Platyrhynchus</i> .	{ Bill short; tip abruptly hooked; notch or tooth very distinct. }	DENTIROSTRES.	RAPTORES.
<i>Conopophaga</i> .	{ Feet syndactyle; head large. }	FISSIROSTRES.	NATATORES.
<i>Platystera</i> .	Bill slender.	TENIROSTRES.	GRALLATORES.
<i>Lepturus</i> .	{ Feet large; toes cleft; wings short; tail long. }	SCANSORES.	RASORES.

This illustration Mr. Swainson considers to be perfect. (*Classification of Birds*, part iii.)

The genera and subgenera of the *Muscicapinae* are, in the fourth part of the work last quoted, placed in the following order:—

Rhipidura, Horsf. and Vig.; *Monacha*, Horsf. and Vig.; *Megalophus*, Sw.; *Todus*, Auct. (with the following subgenera:—*Conopophaga*, Vieill.; *Platyrhynchus*, Desm.; *Todus*, Linn.; *Lepturus*, Sw.; *Platystera*, Jard. and Selby); *Muscicapa*, Linn. (with the following subgenera:—*Cryptolopha*,* Sw.; *Muscipeta*, Cuv.; *Myiagra*, Horsf. and Vig.; *Muscicapa*, Linn.; and *Hyliota*, Sw.).

Our limits will not permit more than a selection of some of these forms, and we must confine ourselves in this article to an attempt to illustrate those of *Rhipidura*, *Todus*, and *Muscicapa*.

Rhipidura.

Generic Character.—Bill short, depressed, broad at the base, compressed at the apex, the culmen arched; upper mandible notched at the apex; *nostrils* basal, oval, nearly covered with bristles and plumules; *rictus* furnished with close-set bristles, generally exceeding the mandibles in length. *Wings* moderate, subacuminate; the first quill shortest, the second longer by twice, the third and fourth (which last is the longest) gradually longer. *Tail* elongated, patulous, rounded at the tip. *Feet* moderate, slender; the *acrotarsia* and *paratarsia* entire. (Vig. and Horsf.)

Example, *Rhipidura flabellifera*.

Description.—Brown-black; superciliary and postocular spot, throat, points of the wing-coverts, and stems and tips of the tail-feathers white; abdomen inclining to ferruginous. (V. and H.) This is the *Muscicapa flabellifera* of Gmelin; the *Fan-tailed Flycatcher* of Latham.

Mr. Vigors and Dr. Horsfield remark that the figure of this species given by Dr. Latham has much more white on

* Substituted for *Seicircus*.

the lateral tail-feathers than the bird described by them, but they add that the Dr. affirms that the species is subject to much variation.

Habits.—Mr. Caley, speaking of this species under the name of *Fan-tail*, says, 'There is something singular in the habits of this bird. It frequents the small trees and bushes, from whence it suddenly darts at its prey, spreading out its tail like a fan, and, to appearance, turning over like a *tumbler Pigeon*, and then immediately returning to the same twig or bough from whence it sprung. These actions it continues constantly to repeat. The skin is very tender; and it is difficult, after having taken it off the body, to restore it again to its proper shape.'

Localities.—Australia. Mr. Caley says that the species is very common about Paramatta, and he does not recollect having missed it at any period of the year. Gmelin, quoting Forster, gives New Zealand as the habitat.

Rhipidura flabellifera.

Todus.

Generic Character.—Bill lengthened, broad throughout, contracting suddenly at the tip, very flat. Bristles short, weak, or none. Tail short, very slender, rounded. Legs long, weak. Toes short; the outer more or less united to the middle one. Tropical America only. (Sw.)

Example, *Todus viridis.*

Description.—Bright-green above, whitish beneath; throat scarlet; sides rosy; lower tail-coverts yellow. This species appears to be the *Rubecula viridis elegantissima*, *Green Sparrow*, or *Green Humming-bird* of Sloane (*Jam.*, vol. 2, p. 306; *Ray, Syn. Append.*, p. 187); *Todus viridis, pectore rubro, rostro recto* of Brown (*Jam.*, p. 476); *Todier de St. Domingue* of Buffon; the *Green Tody* of English authors.

Habits, Food, &c.—Sloane says of this specimen that the belly or stomach was pretty thick, and very well filled with *cimices* and small vermin of the like kind. It loves, he adds, melancholy places, and scarce will stir from any one till they take it. 'It is,' says Sloane in conclusion, 'one of the most beautiful small birds I ever saw.' Browne states that it is a very familiar and beautiful bird, and will often let a man come within a few feet, and look for minutes together at it, before it moves. 'It keeps,' he adds, 'much about houses in the country parts, flies very slow, and probably may be easily tamed.'

M. Lesson, who places the genus with doubt between *Platyrhynchus* and *Myiagra*, says that the birds composing the genus have the greatest approximations to the Kingfishers, near which, and in the syndactylous tribe, Cuvier has arranged them. M. Lesson is of opinion that they are united to the Kingfishers by his genus *Todiramphus*, though he at the same time observes that M. Temminck admits only one Tody, viz. *Todus viridis*, placing it near *Platyrhynchus* and before the *Moucherolles*, an opinion which appears to M. Lesson to be well founded. The

Todies, he adds, are very small birds of America, living upon insects which they catch in the mud or in the water. 'They are,' says he, 'in truth, water *Moucherolles*; their wide and flattened bill, furnished with asperities, or teeth, permits them to sift the mud and retain their prey: they also seek for small insects under the moss and on the banks of small streams.'

The bird is placed by Mr. Vigors among the *Fissirostres*.

Locality.—The Antilles.

*Todus viridis.**

Muscicapa. (Butalis, Boie.)

Generic Character.—Bill moderate, triangular, and not much dilated at the base, which is furnished with long and stiff hairs. Nostrils basal, lateral, ovoid, partially covered with hairs directed forwards. Wings rather pointed; first quill small and spurious, second rather shorter than the third and fourth, which are the longest. Tail rather short or moderate, even or slightly forked. Feet rather strong; tarsus and middle toe lengthened; inner toe almost as long as the outer toe.

Example, *Muscicapa grisola.*

Description.—All the upper parts ash-brown; forehead approaching to whitish; a longitudinal stripe of a deep brown on the head; throat and middle of the belly white, sides of the neck, breast and sides sprinkled with longitudinal stains of ash-brown.

This is the *Gobe-mouche proprement dit* of Buffon; *Gobe-mouche gris* of Temminck; *Fliegenfänger* and *Ge-fleckter Fliegenfänger* of the Germans; *Stoparola* of Aldrovandus and Ray; *y Gwybedog* of the ancient British; *Spotted Flycatcher* and (provincial) *Beam-bird, Raster, Post-bird, &c.*, of the modern British.

Geographical Distribution, Food, Habits, Reproduction.—The *Spotted Flycatcher*, one of the latest of our summer visitants, rarely arrives in these islands before the latter part of May, when its insect food, which consists principally of flies and other dipterous insects, abounds. Its mode of capturing them is well described by White in the passage quoted at the commencement of this article. Temminck says that it rarely eats caterpillars and ants. Pennant states that it is very fond of cherries; but Mr. Selby says that he has not been able to verify this, and that he is inclined to believe that the *Greater Pettychaps* (*Sylvia hortensis*), a

* The attitudes are taken from the figures in Mr. Swainson's second series of 'Zoological Illustrations,' as being the most characteristic known to us.

keen devourer of all the smaller fruits, has in most instances been mistaken for the present bird. The same author tells us that it is of rare occurrence in Scotland; Mr. Gould says that it is found throughout England and a portion of Scotland, wherever there exists a locality suitable to its economy. It quits us in September and October, having bred and brought up its young here. M. Temminck says that it is spread in Europe as far as Sweden, and that it is found in the temperate provinces of Russia; but that it is rare in Holland. Mr. Selby states that its summer or polar migration extends as far as Sweden and Norway. The Prince of Musignano (*Specchio Comparativo*) notes it as rare in the summer near Rome; and as found in Europe generally. (*Geographical and Comparative List.*) Mr. Gould says, 'The Spotted Flycatcher appears to enjoy a wide range over the continent of Europe, being generally dispersed from the border of the Arctic circle to its most southern boundary; and we have also frequently observed it among collections from India.' The nest, loosely constructed of moss, fibres, catkins of the hazel, or small twigs lined with straw and wool or hair and feathers, is often placed upon the jutting ends of beams and rafters in tool-houses, or other garden or farm buildings, whence its name of *Beam-bird*. The four or five eggs are greyish-white, with pale orange-brown spots. When the young are able to leave the nest, the parents lead them to some place where insects abound. There the young soon learn to capture their prey after the manner of the old birds.

The sexes are alike in plumage. The young, for a short time after they begin to fly, have the feathers tipped with yellowish-white, which gives them a mottled appearance. The chirp of this Flycatcher, its only note, is weak.

Muscivora Griseola (male).

Eurylaiminae.

Size large. Structure powerful. Bill short, excessively broad; the upper mandible convex above, dilated at its base, and the margins folding over those of the upper mandible; the tip abruptly hooked. Wings rather short. Feet strong, moderate. The outer toe connected for half its length to the middle toe; hinder toe long; inner toe shortest.

Mr. Swainson, who gives this as the character of the sub-family, observes that the *Eurylaiminae* are the most remarkable birds of the whole family; the species are very few, and their geographical limits seem to be restricted to the hottest parts of India, where they inhabit the forests. 'In size,' continues Mr. Swainson, 'they exceed all others, save the genus *Querula*, in this family, being about the size of starlings, while the enormous breadth of their bills and the peculiar brightness of their colouring render it impossible for the student to mistake them for any other genus. The bill is not only excessively broad, but the margins of the base are so dilated that they often project over those of the lower mandible, while its substance seems much more solid than in the ordinary Flycatchers. Although very few species have hitherto been discovered, it is quite clear that

the five leading types have come to light, although only one example of the genera *Serilophus*, *Pearisoma*, and *Platystoma*, are yet known. It may here be observed that notwithstanding the great width of the bill in all these birds, it is nevertheless much more convex above, and in some instances is even more raised on the culmen than any of the others; the feet also and the whole structure of the body are more robust. Hence, although the width of the mouth and the great size of the head would indicate this to be the pre-eminent typical group, yet all the other characters would place it as the typical. *Serilophus* is evidently the rasorial or crested type; and it departs considerably from the others by the only species yet known being very fond of fruits; this is in conformity with the strong and remarkable analogy it shows, even in its outward appearance, to the wax-winged chatteringers (*Bombycilla*).

The genera given by Mr. Swainson in the 'Synopsis' are—*Eurylaimus*, Horsf.; *Cymbirhynchus*, Vig.; *Platystomus*, Sw. (both of which are placed by M. Lesson in his genus *Erolla*); *Pearisoma*, Sw.; and *Serilophus*, Sw. Mr. Swainson considers *Eurylaimus* to be the pre-eminent type; *Cymbirhynchus* the subtypical type; *Platystomus* the fissirostral type; and *Serilophus* the rasorial type; by which last and *Megalophus regius* he considers that the *Eurylaiminae* and *Muscicapinae* are united. Of these genera we select

Eurylaimus.

Generic Character.—Bill broader than the head; under mandible very thin, particularly at the base. Nostrils basal, transverse, oval; the aperture naked. First quill slightly, second almost imperceptibly graduated. Tail short, rounded.

*a, bill of *Eurylaimus Javanicus* seen in profile; b, seen from above; c, anterior toes of the same, to show their relative connexion. (Horsfield.)

Example, *Eurylaimus Javanicus* (*Eurylaimus Horsfieldii*, Temm.)

Description.—Entire length eight inches. Head, sides of the neck, and the whole of the neck and body underneath violet, or rather vinous, varying in intensity. The part of the forehead around the bill nearly black. Upper part of the neck brown, darker towards the back, where the tint is sooty. Wings very deep blackish-brown above, more intense near the shoulder, and lighter towards the extremity. A yellow streak between the coverts and secondary quills. Wings beneath from the axillæ to the shoulder yellow, which borders the wing externally. Tail-coverts black at the base and yellow at the tips, so that the rump appears yellow, which is the colour at the vent. Two intermediate tail-feathers black, four next on each side black, with a white transverse band near the extremity. On the two external feathers the band is near the middle, and rather broader. Bill reddish-brown at the base, with both mandibles irregularly variegated, and striped towards the extremity; culmen yellowish; cutting-edges intensely black and shining. Tarsi and toes dusky yellowish; claws brown, inclining to black.

Geographical Distribution and Habits.—Dr. Horsfield

Raffles in the catalogue of a zoological collection made in the island of Sumatra under his direction, and communicated to the Linnean Society, we can also in some measure determine the range of this genus: 'It extends,' continues the Doctor, 'from Sumatra eastward to Singapura, and thence south to the eastern extremity of Java near the Straits of Baly, where I discovered it in the year 1806; since that period I have not met with it again. We are indebted to Sir Stamford Raffles for the following remarks on the first species:—'It frequents the banks of rivers and lakes, feeding on insects and worms. It builds its nest pendent from the branch of a tree or bush which overhangs the water.' I found it in Java, in one of the most distant and inaccessible parts covered with extensive forests and abounding with rivers and marshes.'

Eurylaimus Javanicus.

Dr. Horsfield placed the genus among the *Meropidae* or *Syndactylæ*.

MUSCIDÆ, a family of Dipterous insects of the subsection *Athericera*. The insects of this family were for the most part included in the genus *Musca* by the older authors, and *Muscidæ* may be regarded as the typical group of the second great division of two-winged flies (the *Brachocera*), in which the antennæ are short and composed of only three joints, and the joints of the palpi are reduced to one or two.

In the most recent work on Dipterous insects* the section *Brachocera* is divided into three groups:—first, the *Hexachætes*, in which the proboscis is composed of six setæ in the females; the palpi are ovate and elevated in the males, conical and decumbent in the females, and adhering to the base of the setæ; the third joint of the antennæ curved.

The second subdivision, *Tetrachætes*, is thus characterised:—proboscis composed of four setæ; palpi generally adhering to the base of the setæ; third joint of the antennæ either curved or simple, with the stylet usually terminal; wings generally with four or five posterior cells.

In the third subdivision, *Dichætes*, the proboscis has only two setæ, the palpi are generally placed on the base of the proboscis, and the stylet is situated on the upper surface of the third joint of the antennæ: the wings have usually but one submarginal cell; three posterior cells; the anal cell is usually short, and there are sometimes no transverse cells.

The subsection *Athericera*, which forms one of the subdivisions of the great group *Dichætes*, is distinguished by the sucker being enclosed in the proboscis; the antennæ having the last joint usually patelliform. In the *Muscidæ* the proboscis is always very distinct and susceptible of being entirely retracted within the oral cavity; the sucker is composed of two pieces; the stylet of the antennæ is usually plumose to the apex; the body is short and tolerably broad; the eyes, in the male sex, are usually contiguous.

The genus *Musca*, as now restricted, contains such species as have the third joint of the antennæ twice or three

times as large as the second; the first posterior cellule of the wings extends to the margin.

The common house-fly (*Musca domestica* of authors) affords a familiar example of this genus, and is too well known to require description. The larvæ, called maggots, live in putrid substances.

MUSCLE is an animal tissue composed of bundles of soft and usually reddish fibres, endowed with a peculiar power of contracting.

The muscles are divided into two classes; the voluntary and the involuntary. The former class, those over which the will exercises a direct control, are subservient to all the actions by which the animal is placed in active relation with the external world, as in all the motions of the limbs, of speech, of the eyes, ears, &c., and they are therefore often called the muscles of animal life; the latter class, comprehending those whose actions are connected with the internal and nutritive functions of the body, over which the will has no immediate or constant control, form the muscular system of organic life, as the heart, the muscular coat of the stomach, &c.

Each voluntary muscle is composed of a number of parallel or nearly parallel fleshy bundles, enclosed in coverings of cellular tissue, by which each is connected with and at the same time isolated from those adjacent to it. Each bundle is again divided into smaller fasciculi similarly ensheathed, and so on through an uncertain number of gradations till one arrives at the muscular fibre, the only definite and fixed form in the system, and the only part which possesses characters common to the muscles of all classes of animals. The muscles being thus divided, each fibre or each fasciculus may be regarded as a separate contractile organ, which though usually acting in concert with those adjacent to it, is capable of independent contraction; and the power of a whole muscle will thus be equal to the sum of the powers of its separate fibres, and will bear a direct proportion to their number.

The voluntary muscular fibre is of a cylindrical or prismatic form; its diameter (taking the average of the results of several observations) is $\frac{1}{700}$ of an inch, and it varies in length in different muscles. Each fibre is enclosed in a sheath of extremely delicate cellular tissue, and is marked externally by transverse striæ, by which it is at once distinguished from the fibre peculiar to any other tissue.

The muscular fibre is hollow, and contains a small quantity of glutinous fluid and numerous very minute filaments. These filaments are delicate cylindrical threads, about $\frac{1}{15000}$ of an inch in diameter, and about 100 of them are arranged parallel to each other within the fibre.

In the involuntary muscles the fibres and fasciculi are not arranged in parallel lines, but form varied interlacements, crossing and appearing to anastomose with each other, so as to present only a trace of the general direction in which they act. The fasciculi are connected by less cellular tissue than those of the voluntary muscles. They are generally of a paler colour, and the fibres are not marked by transverse striæ, except those of the heart, on which they are faintly visible.

All the muscles receive large arteries and veins from the trunks passing near to them, whose branches run in the cellular interspaces between the fasciculi, and form at last an irregular network among the fibres. They receive also a large supply of nerves, probably more than any other organs in the body. Nearly one-half of the brain and spinal chord is for the supply of nerves through which the will may act upon the voluntary muscles, or through which their motions may be excited by other stimuli. The involuntary muscles are chiefly supplied from the ganglionic or sympathetic system of nerves. [NERVES.]

Chemically, the muscles are composed chiefly of fibrine. Those of animals, which form a large portion of our food, have been carefully analyzed by Berzelius and many others, who have found that the muscular tissue generally contains about 77 per cent. of water, the rest being composed of fleshy fibre or fibrine, a small quantity of fat and gelatine, albumen, and colouring matter, and a number of peculiar extracts, of which the chief are osmazome, on which the odour of meats depends, and zomidine, from which they acquire their peculiar flavour. The nutritive qualities of meat are, *cæteris paribus*, in direct proportion to the quantity of fibrine which it contains; and this may generally be judged of by the strength and ruddiness of the fibres: hence the more nutritious quality of the muscles of adult than of young animals, and

* 'Histoire Naturelle des Insectes—Diptères,' par M. Macquart, in the 'Suites à Buffon.'

of those parts of animals which are most exercised; though for cooking it is necessary to avoid the toughness of fibre which usually coincides with great strength and a large quantity of fibrine.

The colour of the muscles is dependent partly on the blood which they contain, but chiefly on a peculiar colouring matter, very similar to that of the blood, which is fixed in their tissue. Their colour is distinctly though remotely connected with the quantity and condition of red blood in the system, and its depth is one of the best signs of robustness and full health. Thus in all quadrupeds and birds the muscles are more or less red, and the colour is deepest in the parts which are most actively employed, but pale and scarcely perceptible in those which have not been frequently exerted, and also in those animals which, by being closely stabled and stabled, are killed in a condition of great debility; hence the difference between red and white meats. In amphibia, which have less red blood than mammalia and birds, the muscles are usually pale: in fish, which have still less, they are, with the exception of the heart, and those which move the fins and are particularly exerted, quite white. There are however some exceptions, as the salmon and tunny. In animals of a still lower order, the muscles, though still preserving the same structure, are all quite white.

The peculiar vital power of the muscular tissue is its contractility; that is, the power which its fibres possess, when stimulated by the will or other means, of shortening themselves, and thus approximating the points to which their extremities are attached. When muscles contract, they become shorter, harder, and thicker, but their actual size remains the same, for what they lose in length they exactly gain in breadth and thickness. The fasciculi are also wrinkled or thrown into undulated lines, which are most visible when the contraction is least powerful and rather trembling, and the fibres vibrate so as to produce a distinct sound. The more powerful the contraction, the more rapid are the vibrations of the muscular fibres, the higher the note which they produce, and the greater the difficulty of perceiving them with the eye. The simplest method of observing the sound of muscular contraction is that which Dr. Wollaston pointed out ('Croonian Lecture,' 1809); when the tip of the thumb or of one of the fingers is put into the external ear, while some of the muscles of the former are in a state of contraction, a sound is heard like that of carriages running rapidly over a distant stone pavement. This sound is not heard when the same degree of pressure is applied to the same part by any other means than those in which muscular contraction is concerned. By rubbing a piece of stick over the notched edge of a board so as to produce a similar sound, and counting the number of notches whose edges were struck in a given time, Dr. Wollaston concluded that the number of vibrations of a contracted muscle is between twenty and thirty in a second. The sound thus produced has acquired great importance from its application in auscultation. It is the cause of the first sound of the heart [HEART], and as some modification in its tone and intensity must be produced by the morbid changes to which that organ is subject, it affords one of the indications for the diagnosis of its diseases.

The relaxation of a muscle presents phenomena exactly the converse of those of its contraction. The power by which the voluntary muscles are lengthened after having contracted is generally the extension to which, when they cease to act, they are subjected by some other muscles (their antagonists), whose action is the opposite of their own. The hollow involuntary muscles are usually extended after contraction by the accumulation of fluids or other substances forced into their cavities by some external power. It may be yet a question whether muscles have a vital and independent power of dilatation as well as of contraction, but on the whole the evidence is in favour of their possessing such a power, for the heart will contract and dilate when empty, if external stimuli are applied, and the hearts of reptiles when hung in the air will sometimes go on contracting and dilating till they are nearly dry and stiff. Were there no vital power of dilatation, it is difficult to conceive how the heart or any other muscle when separated from the body should, after having once contracted, be dilated so as to be able to contract again.

When muscles shorten however it is not always by an exercise of their peculiar vital contractility, but often by their elasticity, by which, like all the other tissues, they are always maintained in a certain degree of tension. Thus when a muscle is divided, its ends retract as well after

death, or when its nerves are cut, as during life and health. It is by this power that muscles, after having been much extended, generally return to their natural size; thus when a muscle on one side of the joint of any limb shortens, it is evident that its antagonist on the opposite side must be lengthened in the same proportion, and when the contracting muscle ceases to act, the elasticity of the extended one (increased by the tension to which it has been subjected) will be alone sufficient in most cases to restore the limb to its position of rest.

The actual power with which a muscle contracts is in direct proportion to the number of its fibres and inversely as their length. Hence in all the muscles in which great strength is required, as in the chief muscles of the shoulder and hip, the fibres do not run straight from the general point of origin to that of insertion, but the whole mass of the muscle is divided into a number of small portions, in which a multitude of short fibres are attached to separate points within the muscle, so that they may act separately, or, when great exertion is necessary, altogether, and with far greater power than a smaller number of long straight fibres could. The strength of a muscle is very commonly increased by its fibres not running parallel to the line in which the muscle has to draw the part to which it is attached, but with various degrees of obliquity to that line. Thus in many muscles the fibres and fasciculi are attached obliquely to one or both sides of a tendon, as the fibres of a feather are attached to its shaft; by which arrangement, though each muscular fibre contracts in its own direction, the general result of their contraction and the direction in which the resistance will act upon them forms an oblique angle with their direction and much of the danger of their being ruptured is removed. There are indeed but few instances of rectilinear muscles in the body; in nearly all, the fibres are placed more or less obliquely to the line in which they have to draw the part to which they are attached; a plan by which, though individually they lose in active power, they gain in resistance, and by which a far greater number may in the same space be brought to bear upon a given point.

An almost infinite variety of arrangement is found in the muscular fibres adapted to the especial purpose which each muscle has to fulfil, whether it be chiefly strength of action, or rapidity or extent of motion; and all are guided by the nicest mechanical rules. Wherever strength is more necessary than a wide extent of motion, the fibres are increased in number and placed obliquely to the direction of the resistance; wherever extent of motion is more needed than strength, the fibres are long and run almost straight from one point to the other, so as to give the full benefit of their contraction; where velocity is required, they are placed at a part of a lever close by the centre of motion, the resistance being placed on a part more distant from the centre. In general the absolute power exerted by a muscle in contracting is much less than its efficient power, a great part of its force being lost in its being inserted obliquely on the lever which it has to move, or in the distance of the resistance from the centre of motion, or in the resistance which other muscles and the adjacent tissues, which have to be extended, present, &c. But it is constantly found that where power is lost, a corresponding gain of velocity or extent of motion, or of convenience and compactness of form, and readiness of action, is obtained.

MUSCLE, or MUSSEL. [MYTILIDÆ.]

MUSES (*Musæ*, in Latin; *Μοῦσαι*, in Greek), the name of certain sister goddesses in the Greek mythology, who were supposed to preside over the arts of poetry and music, and the sciences of history and astronomy. The original conception of the Muses must be sought for in that disposition of the human mind which prompts us to embody abstract ideas in a sensuous form. Such seems likewise to have been the origin of the Graces, Fates, Furies, and other mythological personages of that class. [GRACES.] In the instance of the Muses, the powers of memory, music, and song were personified into individual goddesses, who were supposed to inspire men with these gifts. At first the Muses were said to be only three: Mneme, that is, 'memory'; Melete, or 'meditation'; and Aoide, or 'song'; and they resided of old on Mount Helicon in Bœotia. (Pausanias, ix. 29.) According to the poet Aloman, they were the daughters of Uranus and Gæa, or the earth. Cicero (*De Natura Deorum*, iii. 21) mentions four, namely, Thelxinoe, 'mind-soother'; Arche, or 'beginning'; Aoide; and Melete; and he says that they were the offspring of the second Jupiter. [JUP.]

TER.] He goes on to say that there were other Muses, nine in number, born of the third Jupiter (the son of Saturn) and of Mnemosyne; and also a third family of Muses, called Pierides by the poets, who were the daughters of the third Jupiter and Antiope, and were similar in their names and equal in number to the preceding. Hesiod, in his 'Theogony' (53), reckons nine Muses, daughters of Zeus and Mnemosyne, and gives their names as follows:—Calliope, Clio, Melpomene, Thalia, Euterpe, Terpsichore, Erato, Polyhymnia, and Urania, and he says that Pieria in Macedonia was their first dwelling-place. These are the Musos generally alluded to by the poets. It appears that the worship of the Muses was introduced from Macedonia into Bœotia, Phocis, and other parts of Hellas. The story of the contest of the Muses with the nine daughters of Pierus, a Macedonian, who pretended to rival the Muses in singing, but were vanquished and changed into magpies (Ovidius, *Metamorph.*, v.) may have been, as some critics have conjectured, an allegory originating in the national vanity of the Greeks, to show their superiority in the arts and sciences over their Macedonian neighbours. The Thracian bard Thamyras tried a like chance, with a like result: he had his eyes put out and was deprived of his lyre.

Homer mentions the Muses as the goddesses of song, who inhabited lofty Olympus, but he does not specify their number or names. In the second book of the Iliad he invokes them, 'to whom all things are known,' to assist his memory while he is enumerating the leaders of the Greek forces at Troy. The occupations of the Muses were singing, dancing, and attending the banquets of the Gods. They were the attendants of Apollo and also of Bacchus. The name *Musa* is supposed by some to be derived from a Greek verb which means 'to discover,' because the Muses were said to be acquainted with recondite mysteries and future events; but this etymology is mere trifling, and the origin of the name is unknown. They were represented as handsome and modest virgins, dressed in long tunics, with wreaths of laurel, ivy, or palm leaves on their heads. It was only in later ages that peculiar attributes were given to each of them by the artists, and a peculiar department of science was assigned to each by the poets. In several paintings of Herculaneum they are represented with their respective attributes, and with their respective names written under each. By comparing these with several reliefs, medals, and mosaics, their identity becomes confirmed. (Millin, *Galérie Mythologique*, plates 19 to 23, and explanation thereof.) The following is a list of them, with the allegorical meaning of their names:—

Clio, from *cleio*, 'to celebrate glorious deeds,' is represented with a scroll in her hand, and also sometimes with a 'scrinium' to keep MSS. in, by her side. She has been styled the Muse of History.

Calliope, 'fine voice,' is represented with tablets and a style; sometimes with a trumpet in her hand; in some instances, as at Herculaneum, with a scroll like Clio. She was the Epic Muse.

Melpomene, 'the singer,' wears a royal diadem round her head, and a wreath of vine leaves, with cothurni on her feet; a mask in one hand, and a club in the other. She was the Muse of Tragedy.

Thalia, 'the joyous,' the Muse of Comedy, is also crowned with vine leaves, has a crook in one hand and a grotesque mask in the other.

Euterpe, 'the pleasing,' carries a double flute. She presided over music.

Terpsichore, 'dance-loving,' carried a lyre, and presided over lyric poetry and dance.

Erato, 'the lovely,' carries also a lyre. She was the Muse of elegy and amatory song.

Polyhymnia, 'of many songs,' is represented wrapped up in her cloak, and buried in meditation, with the fore-finger of her right hand across her mouth, in token of reserve and caution. She was the Muse of religious song, allegories, and mythical strains.

Urania, 'the heavenly,' has the globe and compasses in her hands, which are the emblems of her calling, astronomy.

The corruption which, in the course of ages, pervaded mythological symbols, did not spare the Muses, and accordingly we find their chastity denied by several writers. According to Apollodorus, Ovid, and others, Clio had Orpheus by Apollo, Euterpe had Rhoesus by the Strymon, Calliope was the mother of the Sirens by Achelous, &c.

The favourite haunts of the Muses were, Mount Parnas-

sus in Phocis, Helicon in Bœotia, Pierius, Pindus, and Olympus, in Thessaly, &c. The swan, the nightingale, and the grasshopper were sacred to them. The Roman poets called the Muses *Camænas*, an Etruscan name—for it appears that the Etruscans had also their Muses (*Micali*)—and also *Pierides*.

(Creuzer, *Symbolik und Mythologie*; Petersen, *De Musarum Origine*, in Münter's *Miscellanea Hafniensia*; Hermannus, *De Musis fluvialibus*; Millin, *Galérie Mythologique*; Keightley's *Mythology of Ancient Greece and Italy*.)

MUSE'UM, a place dedicated to the Muses, from the Greek *Mouseion* (*Μουσείον*); hence any place where learning is pursued, or which is set apart as a repository for things that have some immediate relation to the arts, is so termed. The earliest institution we are acquainted with which received this appellation was the museum founded at Alexandria by Ptolemy Philadelphus. The buildings of this institution were afterwards enlarged by the emperor Claudius. (Suet., *Claud.*, 42.)

MUSGRAVE, WILLIAM, born in 1657, in the county of Somerset, studied at Oxford, where he took his degree of M.D. In 1684 he became secretary to the Royal Society of London. In 1691 he fixed his residence at Exeter, where he practised as a physician, and where he died in 1721. Dr. Musgrave was a good scholar, and well versed in antiquity. He published—1, 'Geta Britannicus,' being the life of Geta by Capitolinus, with notes, to which he added a dissertation by way of commentary. 2, 'Julii Vitalis Epitaphium, cum Notis Criticis H. Dodwelli, et Commentario Guil. Musgrave.' This is a commentary on a Roman epitaph found near Bath. 3, 'De Aquillis Romanis Epistola.' 4, 'De Legionibus Epistola.' 5, 'Belgium Britannicum, in quo illius Limites, Fluvii, Urbes, Viæ Militares, Populus, Lingua, Dei, Monumenta, aliaque permulta clarius et uberius exponuntur,' 8vo., 1719. He wrote also several medical works.

MUSGRAVE, SAMUEL, M.D., the grandson of the above, also practised as a physician in Exeter, and died there in 1782. Besides a few works on medical subjects, he was the author of 'Exercitationes in Euripidem,' 8vo., Leyden, 1762; 'Animadversiones in Sophoclem,' 3 vols. 8vo., Oxford, 1800; and 'Two Dissertations—1, On the Mythology of the Greeks; 2, An Examination of Sir Isaac Newton's Objections to the Chronology of the Olympiads.' He also assisted in the edition of Euripides, 4 vols. 8vo., Oxford, 1778. Schweighäuser, in his edition of Appian, has cited many of Musgrave's emendations and conjectures on that author from the marginal notes in Musgrave's copy of Appian. Schweighäuser justly calls him a good Greek scholar and an acute critic.

MUSHROOM. The species of mushroom usually cultivated is the *Agaricus campestris*. In the order of fungi, which includes that plant, most species are poisonous, and fatal consequences have resulted from ignorance of the characters by which the wholesome mushroom is distinguished from such allied species as are liable to be mistaken for it. These characters have been already pointed out. [AGARICUS.] What remains to be noticed relates to cultivation.

Mushrooms are indigenous; they spring up abundantly in fields where cattle have been pastured, if the soil and temperature prove favourable for the development of the *spawn*, a term which is applied to the substance in which the reproductive principle is embodied, which presents to the naked eye the appearance of whitish mouldiness, and which is in reality the flocculent subterranean stem, while the mushroom itself is the fruit. In this state spawn may be kept for years if moisture be withheld; but if the latter be supplied, in conjunction with a proper degree of temperature, it is further developed into white filaments and tubercles, which ultimately rise above the soil in the form of mushrooms. These spring up sometimes singly, but frequently in a gregarious manner.

Mushrooms appear in the fields chiefly after Midsummer, in the months of July, August, and most abundantly in September. On a ten years' average the temperature of these months respectively in the neighbourhood of London has been found to be 64°, 62°, and 57°; and in the same periods the temperature of the earth one foot below the surface is a few degrees higher; but at the depth of two or three inches, where the vegetating spawn is situated, the temperature in hot sunny weather is frequently as high as 80°. Whilst such hot weather continues, mushrooms are

rarely met with; but when the atmosphere changes to a humid state, and when the earth becomes sufficiently moistened and lowered in temperature, in consequence of rain and absence of sun-heat, to between 60° and 65°, mushrooms become plentiful. Hence it may be concluded that spawn will not be injured by a heat of 80° during what may be termed its underground state of progression. This is corroborated by the fact that spawn introduced into melon-frames when the beds are moulded, increases whilst the melons are grown in a heat of about 80°, and when the melon crop is over, the frame cleared, and the heat of the bed naturally abated, a gentle watering, with shade, is all that is necessary to bring up an excellent crop of mushrooms from the spawn so deposited. It is evident from what has been stated that the spawn requires a high temperature for its diffusion; but when this has taken place a declining temperature is requisite, till gradually the bottom heat is lowered to 60° or 65°, and the temperature of the air limited between 55° and 65°, when the production first appears above the soil.

With regard to moisture it may be observed that a dry atmosphere is injurious, not only to artificial crops, but also to those in the fields; for the latter warm foggy mornings are most favourable, and these should be imitated as closely in cultivation as circumstances will permit. A gentle steam is more easily maintained in mushroom-houses than in structures adapted for other subjects of cultivation where light is an object of importance; but mushrooms do not require its agency, and consequently a glass roof is unnecessary: on the contrary, the roof and walls where they are intended to be grown should be composed of such substances as will cause the least possible condensation of the internal vapour, and which are in other respects eligible for the purpose.

A thatched roof of a good thickness is very proper; a slated or tiled one is on the contrary objectionable unless a ceiling be formed under it. If the cavity between the ceiling and the external covering were filled with dry moss, a more complete protection would be formed against any sudden vicissitudes of cold and heat, an object of importance towards success either in the cold winter months or during the greatest heat of summer.

The materials of which beds for the growth of mushrooms are composed usually contain spawn; but as they may or may not happen to do so, it is necessary to be provided with some, in order that it may be introduced when the beds are in the best state for accelerating its development. Spawn may be purchased; or a small quantity having been procured about old melon-beds, horse-tracks under cover, dry places where cattle usually take shelter, or elsewhere, it may be propagated by incorporating to the consistency of mortar a quantity of horse-droppings, cow-dung, and loam; and if the last be taken from places where mushrooms have been grown, so much the better. This composition, or in fact any one of a similar kind that may be equally adapted for a matrix wherein the spawn may extend itself, should be spread to the depth of three inches, and afterwards cut into cakes, or formed into small flat bricks with one or two holes in each, into which portions of the previously collected spawn are inserted. The bricks should be in a firm state when the spawn is introduced, but not dry. The whole should then be formed into a pile, not too compact, some spawny soil being sprinkled as the strata are being deposited, if such can be readily obtained, and a covering of hot dung applied. In a short time the spawn becomes diffused throughout the mass; and whenever this is found to be the case, the bricks must be uncovered and allowed to dry, for the purpose of arresting the progress of vegetation in the spawn till it is required for use.

Various compositions have been successfully employed in the formation of mushroom-beds. Horse-dung, chiefly fresh droppings, or with only some of the shortest litter intermixed, is however principally esteemed; and such should be collected when the horses are not on green food, but are being fed on corn, or on corn and hay. If the beds are intended to be formed of considerable thickness, which some prefer because they continue longer in a bearing state, then it is proper that the fresh dung should be mixed with some old hot-bed materials, or with light loam, in such proportion as will prevent a too violent fermentation. In all cases the composition should only possess sufficient moisture to induce fermentation. It may then be compactly deposited in any dark situation where the temperature and moderate moisture of the atmosphere can be rendered

congenial, either in boxes that are moveable or in such as are fixed on purpose along the walls of a shed or mushroom-house, the construction of which may be that of any convenient form, provided its adaptation to the principles here mentioned be kept in view. The bed should not however be in immediate contact with the ground, unless under circumstances which may occasion the latter to possess a temperature of between 60° and 65°.

It is desirable that the materials should not ferment higher than 80°; when slowly on the decline from this temperature, the spawn should be introduced by inserting small pieces merely within the surface of the bed, through which it will soon become diffused; and whilst this is being effected, a covering of rich loam to the depth of two inches is spread over the bed, which, as well as the whole of the materials, should be rendered very compact.

Extremes of moisture and dryness are alike to be avoided. Waterings, when at all necessary, should be light; and it is particularly essential that the water should be of an equal temperature with the bed. A covering of hay and mats is very useful for preserving uniformity of temperature and moisture in the beds, especially in situations not adapted for having the regulation of these conditions fully at command.

As wooden shelves or boxes are soon rotted by the dung, brick arches have been in some cases substituted; but these occupy much space. Slate would be a better material, since it can be had of ample dimensions and of sufficient strength. The shelves may be of any convenient width; but in order to contain a sufficient depth of materials for producing the requisite degree of fermentation, the front ledge ought to be at least eight inches deep.

Objections have been made to the use of slate on account of its not absorbing moisture, whilst at the same time it occasions condensation. Moisture may indeed be observed to be very copiously deposited on slate, but this only takes place when the temperature of the slate is lower than that of the air in contact with it. Therefore in a mushroom-house properly regulated no condensation would take place, for as the materials of the beds are at least always as warm as the atmosphere of the house, and in generally more so, the slates in contact must be equally warm, and consequently not liable to the above objection.

MUSIC (*Musique*, Fr.; *Musica*, Lat.; *Μουσική*, Gr., from *μουσα*, a *muse* or *song*) is the artistic union of inarticulate sounds and rhythm, exciting agreeable sensations, and raising mental images and emotions directly or indirectly pleasing. Such is pure unmixed music. When conjoined to poetry, it is an art not of diminished importance, but of a dependent nature, its office then being to enforce the meaning of the words and add a colouring to them. As an adjunct it is a beautiful illustration of language; combined with the sister art, it becomes a highly ornamented kind of eloquence. Hence it will be seen that we widely differ from one who has been looked up to as an unquestionable authority, from the celebrated Rousseau, whose well-known definition of music—'l'art de combiner des sons d'une manière agréable à l'oreille' (*the art of combining sounds in a manner agreeable to the ear*)—has been so generally received, and even adopted by those whose capacities and knowledge might have enabled them to take a much more enlarged view of the subject. One very learned Frenchman however has repudiated the degrading description given by his distinguished countryman: M. Villoteau stamps it with the epithets insignificant and vulgar, considering it absurd and puerile; for with as much propriety might oratory be described as *the art of combining words in a manner agreeable to the ear*, or painting as *the art of combining colours in a manner agreeable to the eye*.

Music is a kind of language, and as such, says Metastasio, it possesses that advantage over poetry which a universal language has over a particular one; for this last speaks only to its own age and country; the other speaks to all ages and countries. James Harris, in his philosophical *Discourse on Music, Painting, and Poetry*, expresses the same opinion, even going to the length of asserting, that while a description in words has rarely any relation to the several ideas of which those words are the symbols, 'musical imitations are intelligible to all men.' Music is a language that speaks by imitating, and as such it is understood by those who have successfully studied the art, and likewise by mere amateurs, who, with little if any knowledge of its principles, have learnt the meaning of its expressions by long practice, by frequently hearing and enjoy-

ing its performance; but it can only express passion and sentiment very generally, and commonly fails when it attempts to particularise. This want of absolute decision in what is called musical language is by some writers reckoned among its advantages, because it gives the hearer great latitude in interpreting it, which he usually does in a manner as congenial as possible to his own feelings at the time. Madame de Staël goes so far as to prefer instrumental to vocal music, on account of the *vagueness* which she thinks one of the attributes of the former—that very same vagueness which Fontenelle meant to impute to it as an egregious fault, when, in a transport of impatience, he exclaimed, '*Sonate, que me vœux tu ?*' Burke's opinion however coincides with Madame de Staël's, if it did not actually prompt it. He says, 'the passions may be considerably operated upon, without presenting any image at all, by certain sounds adapted to that purpose, of which we have a sufficient proof in the acknowledged and powerful effects of instrumental music.' He however soon afterwards adds, that 'in reality a great clearness helps but little towards affecting the passions, as it is in some sort an enemy to all enthusiasm whatever.' This is rather startling as a general proposition: if we admit it as applied to vocal music, we must, *a fortiori*, allow that the finest compositions of that kind, which certainly leave nothing to the imagination of the hearer, exercise little if any influence over the passions. But being decidedly opposed to such an opinion, we must condemn it, though advanced by the eminent writer of the *Enquiry concerning the Sublime and Beautiful*, and supported by the distinguished author of *Allemagne*. No one has written in a more enthusiastic strain on the power of music in imitating than Rousseau. The reader of the article 'Imitation,' in his Dictionary, will find little difficulty in believing all that is said of Orpheus and Amphion, if he suffers himself to be convinced by the florid, declamatory, extravagant passage to which we allude. The writer of the first *Bridgewater Treatise*, Dr. Chalmers, has argued no less earnestly in favour of that musical language of which we are speaking. 'Music,' he says, 'apart from words, is powerfully fitted both to represent and awaken the mental processes, insomuch that, without the aid of spoken characters, many a story of deepest interest is most impressively told, many a noble or tender sentiment is most emphatically conveyed by it. . . . The power and expressiveness of music may well be regarded as a most beautiful adaptation of external nature to the moral constitution of man. . . . Its sweetest sounds are those of kind affection: its sublimest sounds are those most expressive of moral heroism, or most fitted to prompt the aspirations and resolves of exalted piety.' Fontenelle, on one side, and Rousseau, with Dr. Chalmers, on the other, are at the two extremes on this question: the one, from a deficiency of musical feeling, granting too little; the others, from an excess of it, admitting too much.

A musical sound,—which is a curious compound of other sounds, called harmonics, resulting from a number of vibrations in equal times,—when produced by a fine voice, a rich-toned violoncello, or a 'mellow horn,' excites in all who possess a moderate share of nervous sensibility, a pleasurable sensation; and this, Sir John Herschel observes, 'is perhaps the only instance of a sensation for whose pleasing impression a distinct and intelligible reason can be assigned.'

Dr. Beattie does not think it absurd to suppose that the body may be mechanically affected by sound. 'If,' he says, 'in a church one feels the floor and the pew tremble to certain tones of the organ; if one string vibrates of its own accord when another is sounded near it, of equal length, tension, and thickness; if a person speaks loud in the neighbourhood of a harpsichord, and often hears the strings of the instrument murmur in the same tone, we need not wonder that some of the finer fibres of the human frame should be put in a tremulous motion when they happen to be in unison with any notes proceeding from external objects.' Most persons must have witnessed the effect of a street-organ on some of the canine species, apparently willing auditors, who, if not driven away, continue to howl all the while the instrument is playing. Whether they are painfully affected, and their tones those of distress, or agreeably, and they become responsive, does not appear; though if distressed, the probability is that they would fly from the cause. But Dr. Mead tells us that a celebrated violinist of his acquaintance, perceiving that his dog betrayed symptoms of great

suffering on hearing a certain passage performed, repeated it for some time, in order to try the result, and the experiment proved fatal to the poor animal, who 'dropped down at the feet of his master, where in a few seconds he died in the most horrid convulsions.' The surprising and hitherto unexplained connection between form and vibrations producing musical sounds, so beautifully shown in Chladni's experiments on plates of glass strewed with sand, and put into sonorous vibration, thereby throwing the sand into various symmetrical figures, may be here incidentally mentioned, though it does not now seem to shed any new light on the subject before us; nevertheless by proving something like sympathy, and of a much more extraordinary kind than that between two strings, in mere matter, it may at a future period lead to interesting discoveries.

The effect of Rhythm, or measure, is universally felt and admitted: the most polished inhabitants of Europe, and the most barbarous natives of the arctic regions, are alive to its influence; it is that which reduces unmeaning sounds to order, converts them into melody, and bestows on them proportion and a power to charm. The chirping, or whistling, or singing as it is called, of most birds, being devoid of rhythm, affords no pleasure but what is derived from association; while the single note of a drum beaten in time, combining sound and measure, is gratifying in a certain degree to every hearer. Indeed, with the ancients rhythm was of paramount importance, if not almost everything, in what they denominated music, a term under which was included much that it does not imply in modern language. Aristides Quintilianus, the best of the seven Greek writers on music collected by Meibomius, remarks that rhythm is the object of three senses, namely, the sight, as in dancing; the hearing, as in music; and the touch, as in the pulsations of the arteries.

Much of the effect of music on the mind is ascribed to Imitation, which is either direct or indirect. And it must be understood that we are still speaking of music strictly instrumental, not vocal. The power of direct imitation is confined within very narrow limits indeed, though composers have often attempted to enlarge the boundaries, exposing their own weakness and that of their art. The song of some birds, the whistling of winds, the rearing of the tempest, the sound of cannon, the ringing and tolling of bells, and perhaps the tones of the human voice expressive of certain emotions, are legitimate objects of direct imitation; but the rattling of hail, the fall of snow, the motions of animals, actions at sea, battles on land, &c., are not only unrepresentable by any kind of musical instrument at present known, but unfit for imitation if instruments could be constructed for the express purpose. Greatly we admire the introduction to the oratorio of *The Creation*, considered as a most original and ingenious composition, but cannot bring ourselves to believe that any idea of *chaos* is to be excited by exquisite harmony. Still less can we be convinced that *silence* can be imitated by sound, though the author of this musical solecism (which appears in a symphony intended to be descriptive) is a man of rare talent, whose works are highly esteemed in England, and still more so where better known, in Germany, his native country. Music can imitate in a direct manner only by its actual resemblance to the sound of the thing imitated. Of all the powers of music, in the opinion of an admirable critic, the Rev. Thos. Twining, that of raising ideas by direct resemblance is the weakest and least important. 'It is indeed so far from being essential to the pleasure of the art, that unless used with great caution, judgment, and delicacy, it will destroy the pleasure by becoming offensive or ridiculous. The highest power of music, and that from which it derives its greatest efficacy, is undoubtedly its power of raising emotions.'

Professor Hutcheson, in the early part of the last century, expressed nearly the same opinion. What he adds concerning the imitation of the human voice and accents is entitled to particular attention. He says, 'There is a charm in music to various persons which is distinct from the harmony occasioned by its raising agreeable passions. The human voice is obviously varied by all the stronger passions: now, when our ear discerns any resemblance between the air of a tune, whether sung or played on an instrument, either in its time or modulation, or any other circumstance, and the sound of the human voice in any passion, we shall be touched by it in a very sensible manner, and have melancholy, joy, gravity, thoughtfulness, excited in us by a sort

of sympathy or contagion.' (*Enquiry into our Ideas of Beauty, &c.*)

Plato, in the third book of his 'Republic,' speaks of a warlike air inspiring courage, because imitating the sounds and accents of the courageous man; and of a calm and sedate air producing tranquillity and gravity, on the same principle. This leads us to the consideration of indirect imitation, to which part of our subject it perhaps more properly belongs.

Indirect Imitation is that by which some quality common to music and the thing imitated is indicated by sounds, strong or weak, quick or slow. Rage is loud, anger is harsh, love and pity are gentle; therefore loud and harsh sounds raise ideas of the former passions and others of the same class; soft and tranquil sounds raise ideas of the latter and others of a similar character. Hence it will be seen, as before observed, that the hearer may interpret music in a manner corresponding in some degree to the state of mind in which it shall find him, but under certain restrictions from which he cannot be released. If agitated by any turbulent passion, he will find it impossible to convert smooth and delicate music into a language in unison with his irritated feelings; and if under the softening influence of some tender attachment, or of sorrow for the loss of one beloved or valued, he will be unable to construe bold and brilliant sounds as expressions of sympathy. But music that is not of a decided character will prove more or less convertible. And it is to this latter kind probably that Mr. Twining alludes, when, speaking of good instrumental music 'expressively' performed, he says, 'the very indecision of the expression, leaving the hearer to the free operation of his emotion upon his fancy, and, as it were, to the free choice of such ideas as are to him most adapted to react upon and heighten the emotion which occasioned them, produces a pleasure which nobody, I believe, who is able to feel it will deny to be one of the most delicious that music is capable of affording.' (*Dissertation on the word Imitative, &c.*)

It is proper to add that this very learned and able commentator on Aristotle considers the word *imitative* inapplicable to music, and proposes instead of it the term *suggestive*. This is perhaps an amendment in the case of what we have called 'indirect imitation;' but *direct imitation* does more than *suggest* the idea; it may be said, without any violent distortion of language, to represent it.

Association, which has so large a share in the operations of the human mind, often contributes much to the effect of music. Indeed some airs possessing no intrinsic merit owe their influence solely to this principle, and among these the famous *Rans des Vaches*, which, in times happily gone by, acted with such irresistible force on the expatriated Swiss soldier. It was many years after the battle of Culloden, and not till all fears of the Pretender had subsided, that the Scotch bagpipers ventured to play any of the Jacobite tunes, which, when revived, were heard with delight, though hardly one of them would have continued to be listened to but as connected with the history of the country. When Sir Joshua Reynolds was at Venice—we are told by Mr. Malone—'in compliment to the English gentlemen then residing there, the manager of the opera one night ordered the band to play an English ballad-tune. Happening to be the popular air which was played or sung in almost every street, just at the time of their leaving London, by suggesting to them that metropolis with all its connections and endearing circumstances, it immediately brought tears into the artist's eyes, as well as into those of his countrymen who were present.' To compositions of a very ordinary kind, association, Dr. Beattie remarks, gives a significance. 'We have heard them,' he says, 'performed, some time or other, in an agreeable place perhaps, or by an agreeable person; or have heard them in our early years, a period of life which we seldom look back upon without pleasure. Nor is it necessary that such melodies or harmonies should have much intrinsic merit. . . . If a song, or piece of music, should call up only a faint remembrance that we were happy the last time we heard it, nothing more would be needful to make us listen to it again with peculiar satisfaction.' To this latter part, however, we can only give our assent generally: painful experience has taught many that there is an exception to the rule. A composition which had been listened to with unalloyed pleasure when executed by one possessing all our tenderest and warmest affection, only excites the idea of lost, of irrecoverable happiness, if heard when death has deprived us

of the performer who had imparted to the music its greatest charm. Except in this particular instance, we fully agree with the elegant author of *Essays on Poetry and Music*, in the preceding observations; though Boethius, in his treatise 'De Consolatione Philosophiæ,' and after him Dante, in his *Inferno*—both high authorities—express the opposite opinion, namely, that in distress and adversity the greatest misery is the recollection of former happiness. But the poetical notion of the Hindus regarding musical effect, which they strictly connect with past events, seems to us the finest that ever was conceived;—they say that it arises from our recalling to memory the airs of Paradise, heard in a state of pre-existence.

After all, however, that has been written and said, from the days of Aristotle down to the present period, of music as an imitative art, it must be conceded that modulated sounds please, by some mysterious means, many to whom they present no imitation of anything material or immaterial, and who associate with them no other idea than that of melody or of harmony. These are, probably, the persons whom Rousseau had in view when, mistaking the exception for the rule, it seems to have been his design, in one of his wayward moments, to reduce that which is at once an art and a science, to the low rank of a sensual gratification. But in justice to that eloquent writer, it should be added, that, in his *Essai sur l'Origine des Langues*, he at once demolishes his own definition—which, unfortunately, has been so widely circulated—by the interposition of a simple negative: e.g.—'La musique n'est pas l'art de combiner des sons d'une manière agréable à l'oreille.'

Thus far our attention has been directed to instrumental music, or that which is dependent on no auxiliary for effect, on no words to explain its meaning, on no gesticulation or scenery to illustrate it. We have now to consider music as produced by the human voice in alliance with language, whether poetical or prose, and with or without instrumental accompaniment.

Vocal music is entirely devoid of that ambiguity which some think a merit in instrumental music, and some consider a defect. Words fix the intention of musical sounds, leaving nothing for the bearer to conjecture; for though the more or less of truth in the expression will depend on the skill of the composer, yet he must be utterly destitute of reason to give to revenge the tones of love, or to joy those of despair. It is true that he does not always read with discriminating judgment the words selected by him, or committed to his charge—that in emphasis he is sometimes erroneous, and in accentuation frequently faulty; and for these failings in the artist, the art itself has been unjustly condemned by writers whose repute gives weight to their censure. But the heaviest charge brought against composers of vocal music, and that which has exposed them to the keenest ridicule, is their eagerness to express the literal meaning of a particular word rather than the sentiment, the sense of the entire passage. This exceedingly vulgar kind of imitation, which has not unaptly been called *musical punning*, may be traced to a gross misapprehension of the rule, that 'the sound should seem an echo to the sense,' and is the vice not only of composers of an inferior order, but, occasionally, of some of the highest class. The great Handel himself is not wholly exempt from its influence. In the fine chorus, 'Wretched lovers, quit your dream' (in *Acis and Galatea*), when the line 'Hark! how the thundering giant roars' occurs, he makes the bases roar in a long division, till they nearly gasp for breath. But this is a verb that proves very seductive to composers; in two of our best glees it sets the voice a-roaring through several bars:—in the one, because the poet (Ossian) asks, 'Who comes so dark from ocean's roar?' In the other, because the poet (Gray) says, 'The rocks and nodding groves rebel to the roar!' Handel's favorite air, 'What passion cannot music raise and quell?' from Dryden's *Ode to St. Cecilia's Day*, sends the voice tumbling down a full octave at the words 'faces fell.' In the same work the singer is condemned to ascend to a note which few can reach, and none can sustain without lungs of very unusual capacity, merely because the author says, 'The trumpet shall be raised on high.' Our greatest English composer, Purcell, could not resist the temptation offered by the words 'They that go down to the sea in ships,' from the 107th Psalm, in setting which he commits the base voice to so very low a deep, that there was only one man in his day who could

sing the anthem. 'Some eminent musicians,' Sir William Jones observes, 'have been absurd enough to think of imitating laughter and other noises; but if they had succeeded, they would not have made amends for their want of taste in attempting it; for such ridiculous imitations must necessarily destroy the spirit and dignity of the finest poems.' This discerning and elegant writer most likely points at the song and chorus, 'Haste thee, nymph,' in Handel's setting of Milton's *L'Allegro*, in which is the line, 'And Laughter holding both his sides.' The singers in this, it must be allowed, never baulk the intention of the composer, but affect to laugh almost convulsively. To carry out the design to its utmost extent, they should cast away their books, press their ribs firmly with both hands, and, by adding action to sound, complete the living picture. In another song by Handel, which was once very popular, in the oratorio of *Semele*, is a remarkable instance of a mistaken attempt at imitation. The words are—

'The morning lark to mine accords his note,
And tunes to my distress his warbling throat.'

These lines (foisted into Congreve's poem) are silly enough; but the composer has rendered them perfectly ludicrous, by one of those long-winded *divisions* which were the besetting sin of the age, on the word 'warbling.' In the midst of her distress, Semele and two fiddles—the latter representing the bird—strive who shall best mimic the soaring songster, till the lady is obliged to yield, from pure exhaustion. The mention of the lark has entrapped many a composer; the musical follies committed in his name are innumerable. Handel's song, 'Sweet Bird,' from *Il Penseroso*, always has been, and most likely always will be, admired as music, and it affords an opportunity for the display of talent in the singer and the flute-player, but it cannot stand the test of criticism. The same objection exists to this as to the air just noticed; the divisions are in themselves absurd, but as imitations are still more so. Surely the composer must have been aware that the note of the nightingale is the simplest that is practised by the feathered race, yet he has here given the melancholy bird sounds which, as regards variety, rapidity, and compass, only able performers can produce from a fine voice and a perfect instrument. Handel's supremacy in the art renders him especially liable to animadversion when misled by an erroneous conception of the words; but he has been charged with many supposed imitations which he never contemplated, such as the *whipping-chorus*, the *rocking-chorus*, &c. We have however said as much as is necessary on this part of our subject.

In the accompaniment to vocal music, much greater freedom of imitation is allowable than in the voice part: kept within those bounds which good sense and cultivated taste prescribe, it affords very efficient aid, by giving greater force to the poetry, and contributing to the completion of the general design. It also adds harmony to song, a most important, if not an indispensable support. Nearly all that imitation can do, should—as the elder Dr. Gregory, of Edinburgh, in some admirable remarks on music has observed—be assigned to the accompaniments, as these, on account of the greater compass and variety of instruments, are better adapted to such a purpose than the voice, which ought to be left at liberty to express the sentiments. If Handel has sometimes failed in imitations by the voice, he has often succeeded in those by the accompanying instruments. We need but refer in proof to his beautiful song in *Il Penseroso*—

'Oft on a plat of rising ground
I hear the far-off curfew sound,'—

where he has imitated the bell by the deep-toned strings of the bases, confining the voice to those notes of pleasing, contemplative melancholy, the idea of which the words so completely excite. The same skill and discrimination are shown in the song of Galatea, 'Hush! ye pretty warbling quire,' in which the flute imitates the birds, leaving the singer to express in simple sounds that languishing tenderness indicated by the poetry. Handel was the first who endeavoured to excite the idea of light through the agency of musical sounds: his chorus in the oratorio of *Samson*, 'O first created beam!' was written with this design; and moreover suggested to Haydn that grand composition on the same subject which is admitted to be one of his noblest triumphs. But the still bolder attempt of the former great master was to convey to the mind, through the same medium, a notion of darkness. With this view he composed

the sublime chorus in *Israel in Egypt*, beginning, 'He sent a thick darkness over all the land,' the accompaniments to which, assisted by the words, produce on persons susceptible of musical impressions, all that solemnity of effect, not unmixed with awe, intended by the author.

Haydn, though sometimes ambitious of achieving by musical means more than the art can accomplish, was often most happy in indirect imitation by instrumental accompaniments; witness the magnificent burst of sound in the first chorus—to which we have just alluded—in *The Creation*, at the words, 'and there was light.' Witness also his musical picture, in the same oratorio, of the rising sun, the slow swell of the instruments in ascending notes describing the gradual progress of the luminary towards the horizon, and the full power of the band depicting its refulgent splendour. And how beautifully the composer contrasts with the solar blaze, the soft, serene beams of the comparatively small orb which reflects its borrowed light! Madame de Staël heard the first of these most masterly compositions performed at Vienna, 'in a manner,' she tells us, 'worthy of the great work,' and describes the sound of the combined voices and instruments as a *terrible noise!* She adds, that *at the appearance of light it was necessary to stop one's ears.* We forgive the bad taste for the sake of the wit. This generally sagacious and acute, and always brilliant, writer, is quite an Italian in her musical criticism: she says that the Germans 'put too much mind in their works; they reflect too much on what they are doing.' Of Mozart, whose illustrations of the poet are enumerated among his excellencies by most critics, Madame de Staël speaks in what we consider highly laudatory terms, but by which she means to express some degree of disapprobation. She thinks that 'of all musicians he has shown most skill in "marrying" the music to the words:' that in his operas, particularly *Don Giovanni*, he makes us sensible of all the effect of dramatic representation: that 'this ingenious alliance of the musician and poet gives us a sort of pleasure, but it is a pleasure which springs from *reflection*, and that does not belong to the wonderful sphere of the arts.' (*De l'Allemagne*.) The 'alliance' here complained of could not have been alleged as a fault in Rossini's earlier works, beautiful as some of them are in other respects; though the air 'La Calunnia,' the first finale in *Otello*, and two or three other things, offer as fine examples of what is meant by musical imitation as can be found. But in his 'second style'—the manner in which his later operas are written—he seems to have been *infected*, as Madame de Staël would have said, by German intellectuality. We know not if the highly-talented lady whose judgment in music we have ventured to impugn was acquainted with the compositions of Weber; if she ever heard his *Freischütz* or *Obéron*, he must have been placed by her very high on the list of those who damage and degrade music by rendering it expressive,—who, as Pope ironically says, in some lines complimentary to Handel,

'—meanly borrow aid from sense.'

Music, which is both a science and an art, is divided into *Speculative* or theoretical, and *Practical*. Speculative Music explains the nature of musical sounds; shows, by demonstrating their ratios, how they are related to each other; and investigates their physical and moral effects when in a simple or in a combined state: it is, in few words, the philosophy of the art. Practical Music is the application of theoretical principles,—the proper conduct of sounds as to their progression, duration, union, and adaptation to words, voices, and instruments, and is the art of composition. The performer, who merely executes, stands in the same relation to music as the actor does to the drama, or the reciter to the poem: though he requires, in order to excel, considerable knowledge of the subject and superior taste, yet he is but an operator—a singer or a player, and not, strictly speaking, a musician.

Speculative Music is subdivided into Acoustical, Mathematical and Metaphysical. [ACOUSTICS; HARMONICS; SOUND; TEMPERAMENT.] Practical Music, into Vocal and Instrumental, the several kinds of which are noticed under their respective heads. The chief component parts of practical music are, MELODY, HARMONY, and RHYTHM, to which we refer. See likewise ACCENT, AIR, CHORD, COMPOSITION, COUNTERPOINT, MODULATION, THOROUGH-BASE, TIME, &c.

MUSIC, HISTORY OF. The origin of music is involved in an obscurity which no ingenuity, no labour, has hitherto

been able to dispel; analogy and conjecture therefore have supplied the want of facts, in the absence of any assistance except what doubtful histories and the fables of mythologists have afforded, which at best have held out but a dim light, and more often misled than aided the inquirer in his researches.

It has been supposed by some writers whose names stamp a value on all that has proceeded from them, that song and speech are coeval, an opinion which will hardly be disputed, if by song are meant sounds which, though vocal and sustained, are devoid of rhythm, governed by no scale, and consequently productive of no melody, in the modern acceptation of the word: but if the term is intended to signify a regular system of tunable, measured notes, then we shall not hesitate to say, that such advance towards art could only have been made by people proceeding fast in civilization, and communing through the medium of a language adequate to all the ordinary purposes of man in a social state.

We are told by Lucretius, in a passage often quoted from the fifth book of his poem *De Rerum Natura* (*Of the Nature of Things*), that the birds taught man to sing, and that the invention of musical instruments of the inflated kind was suggested to him by the sounds produced from reeds when the western wind blew over them.

— the birds instructed man,
And taught him songs before his art began.
And while soft evening gales flew o'er the plains,
And shook the sounding reeds, they taught the swains;
And thus the pipe was fram'd, and tuneful reed.

This has certainly the merit of being very poetical, whatever reliance the historian may place on it. The same notion concerning wind instruments is found in Ovid's beautiful account of the transformation of the nymph Syrinx into reeds. But Thomas Aquinas, the 'Angelic doctor,' cited by the good Padre Giambattista Martini, in his *Storia della Musica*, disdains to follow the example of the heathen author of the 'Metamorphoses,' or the disciple of Epicurus, and leaves the origin of music to chance; on the contrary, the noble Italian saint informs us that the first man was endowed by the Creator with every kind of knowledge, and that he excelled in music, as well as in all other arts and sciences.

But quitting the ingenious guesses and fictions of poets and the reveries of enthusiasts, we find Jubal, the seventh in descent from Adam, mentioned in Scripture as 'the father of such as handle the harp and organ.' These terms however must not be understood quite literally; they are generic, and signify all instruments of the stringed and tube kind. The different versions vary in the translation of the original: the French render the word *harp* by *violon*. Though the earliest authentic record of music extant is that in *Genesis*, yet it is nearly certain that the Jews acquired their knowledge of it from the Egyptians. That Moses himself was educated by Pharaoh's daughter as her own son, and was 'learned in all the wisdom of the Egyptians,' is stated in the *Acts of the Apostles*; and Clemens Alexandrinus adds, that 'he was instructed by them, in his maturer age, in arithmetic, geometry, rhythm, harmony, but, above all, in medicine and music.' The whole generation of the Israelites led forth by the lawgiver from their captivity were born in Egypt, in which it seems to be agreed music as an art originated; though Diodorus Siculus even denies that it was ever practised there: but his assertion is not only in opposition to Herodotus, and at utter variance with what Plato says, who travelled into that country to become acquainted with the arts and sciences, but is proved by modern discoveries to be the very reverse of truth. The fresco painting of a harp, found by Bruce in an ancient tomb near the ruins of Thebes, which is undoubtedly of very high antiquity, is an indisputable proof of the progress made by the early Egyptians in music. In form, dimensions, and ornament, this instrument might be mistaken for one of modern date, inasmuch that when a drawing of it was first shown in London, considerable doubts were entertained of its fidelity. Forty years after, however, M. Denon bore testimony to the truth of Bruce's description and the accuracy of his sketch; since which Rosellini's *Monumenti dell' Egitto*, a splendid work published in 1832, has confirmed all that the two former had said on the subject. Another instrument, which is found sculptured on an Egyptian obelisk brought to Rome by Augustus, furnishes additional evidence of the state of music in Egypt in the remotest times. It is fully described

by Dr. Burney, who gives a wood-cut of it, by which it appears that it was nearly the same as the Neapolitan *Calascione* of the present day. It had only two strings, but, being provided with a long neck, was capable of producing that series of sounds which the ancients called a heptachord; and if the strings were tuned fifths, like those on the *calascione*, they would give a complete octave, an advantage which none of the Grecian instruments possessed till many ages later. Montfaucon says that 'in examining the representations of near five hundred ancient lyres, &c., he never met with one in which there was any contrivance for shortening strings, during the time of performance, by a neck and finger-board.' These two instruments then are sufficient proofs of early Egyptian knowledge in the musical art.* That it continued to be cultivated in Egypt under the Macedonian dynasty there can be no doubt. Athenæus, in his account of a Bacchic festival given by Ptolemy Philadelphus—the munificent patron of all the liberal and useful arts, who made Egypt the mart of the world—tells us that more than six hundred musicians were employed in the chorus, and that among these were three hundred performers on the cithara, or lyre.

Of the music of the Hebrews, nearly all that is known is to be collected from the Scriptures, and the Bible is in the possession of every one. There we meet with the first recorded song, which Moses sang at the head of the tribes, after the miraculous passage of the Red Sea. To this responded Miriam the prophetess, having a timbrel or tambourine in her hand, and being attended by all the women, carrying the same instruments, and dancing. Music formed an essential part of every Jewish ceremony. The priesthood were musicians by office, which was hereditary: they were four thousand in number, divided into bodies, each of which had its chief or leader. At the dedication of Solomon's temple, a prodigious band of priests, blowing trumpets, attended. Josephus tells us that 200,000 musicians were engaged; but as his statement is unsupported by scriptural history, we may venture to consider it as a mistake arising from some misapprehension, or else as a manuscript error. A Hebrew writer enumerates thirty-six musical instruments that were kept in the sanctuary, on all of which, he says, the prophet-king David could play. These are reduced to thirty-three by another account. It is worthy of remark that many of them, under other names, are still met with in the East and in Egypt, and, as far as can be ascertained, very little changed from their original form. Martini has given, from a manuscript of 1599, what he believes to be specimens of the melodies sung by the Jews to certain Psalms; but they are printed in the obsolete notation, without bars, and having no words added to them by which the measure might perhaps have been made out, it is impossible to enter thoroughly into their meaning.

The Music of the Greeks has engaged the notice of so many searching antiquaries and patient mathematicians—such profound learning and unwearied labour have been bestowed on it—it has provoked so much controversy, and the dispute has proved so barren, that we enter on the subject reluctantly, if not fearfully; and though bound to give it as much attention as a matter of some importance is entitled to, yet we do not deem it expedient or feel inclined to afford it more than is rigorously its due. Dr. Burney, who had devoted months, if not years, to the inquiry, declared to a friend, a few months before his decease, that 'he never understood the Greek music, or found any one that did understand it.'

But before proceeding further, we think it right to say, with all possible respect for those who have toiled in this unproductive field, that, after a diligent investigation of the subject, on which we entered with an unprejudiced mind, it is our decided opinion that what is now called Greek music has hitherto proved perplexing chiefly, if not solely, on account of the term having been misunderstood. We believe that by *mousike* (*μουσική*) the Greeks meant *poetry sung*, with some sort of accompaniment, and that the moderns have fallen into error by overrating the importance of the melodic part, treating this as the principal, and poetry only as an ally.

Music was a comprehensive term with the Greeks, embracing among other things which we shall have occasion

* There are some Egyptian paintings in the British Museum, which were brought from the grottoes in the western hills of Thebes. In one of them (No. 179) a female figure is represented blowing the double pipe, and another appears to be playing on a musical instrument. (*Lib. of Entertaining Knowledge: British Museum, vol. II, p. 76.*)

to mention, melody (*Melopœia*—literally the *making*, or composition, of the song) and poetry. There is no one, M. Villoteau remarks, who, after an attentive perusal of the antient writers, is not convinced that eloquence, poetry, and melody were, in early times, governed by musical principles; that they were taught by the same master, and that the three arts were but one science. 'The goddess Persuasion,' says Lord Shaftesbury, 'must have been in a manner the mother of poetry, rhetoric, music, and the other kindred arts;' and tradition, he adds, 'could not better represent the first founders of large societies than as real songsters. . . . Nor can it be doubted that the same artists who so industriously applied themselves to study the numbers of speech, must have made proportionable improvements in the study of mere sounds and natural harmony.' The Greeks never separated poetry from melody; the poet himself set the notes to his own verses, and in the early times sang them at the public games and festivals. The Greek tragedies were *operas*, observes Payne Knight, meaning, we presume, that they were in a kind of recitative; and he is borne out in his assertion by the best authorities. Aristotle, in his treatise on poetry, considers the *music* of tragedy as one of its most essential parts. The nature of this *music* is indicated by several writers, but is more clearly pointed out by Philodemus than by any other, in his work in abuse of music (one of the *papyri* found in Herculaneum, unrolled and published at Naples in 1793), wherein it is described as a melody nearly approaching ordinary speech; that is to say, recitative. Horace calls Apollo *the singer*. The antient poets give us to understand that their verses were *sung*, and this is to be construed literally in the case of the Greek poets. Homer, according to tradition, sang his own epics. But it is needless to multiply proofs of a fact so generally received.

Admitting, then, that Greek poetry of all kinds, religious, epic, dramatic, &c., was really sung, and perhaps granting, what many believe, that oratory partook much of the nature of song, let us inquire what was meant by the word *singing*. It is not to be imagined that Homer, Tyrtæus, Pindar, &c. were singers, in our acceptation of the word; the supposition is too absurd to be entertained for a moment. But even allowing them to have been as perfect in the vocal art as the moderns are, would they have condescended to deliver their poetry in long flights of notes, in divisions, in trills, and in passages that render it difficult, and sometimes impossible, to get at the sense? If, however, they had attempted to make their 'heaven-bred poesy' subservient to song, would they have found a patient audience?—Assuredly not; for the animating appeal, the interesting narrative clothed in poetical language, the pathetic description, were what the Greeks delighted in, and certainly would not have surrendered for the sake of a tune. Moreover, it must be recollected, and is a very important consideration, that when the art of printing was unknown, and manuscript copies of poems, &c. were unattainable by the people at large, on account of the expense, the multitude had no means of becoming acquainted with the productions of their poets but by hearing them recited; and as crowds assembled for this purpose, the best mode of rendering the voice of the reciter audible to many, and these congregated in open places, was, to pitch it rather high, and confine it to a small number of fixed musical notes. Such is still the practice, and with the same intent, in all cathedrals, and is called chanting, a usage which has doubtless been transmitted from the remotest ages. Such too is the method adopted by the *improvisatori*, whose art, we are persuaded, is of the highest antiquity, and whose singing, it is our belief, much resembles that of the ancient Greeks in delivering their verses. Those extemporaneous poets always require an instrumental accompaniment of a simple kind, to keep the voice in tune, and, as they confess, to animate them. The Greek reciters also were accompanied, either by the lyre or the flute, and probably for the same purposes. The flute was the companion of elegiac poetry; the lyre of the epic and the ode.

By what is called Greek music, therefore, we understand the union of poetry and music, the former of the two exercising the greatest sway over the mind, because expressing noble sentiments—gracefully inculcating religion and morality—teaching obedience to the laws—exciting generous feelings—and inspiring patriotism and courage by the praise of those who had distinguished themselves by their public services and their valour. It is thus we account for the

effects said to have been wrought by antient music; for it is impossible that Plato should have been thinking of more vocal melody and the sounds of mean and imperfect instruments, when he said that no change can be made in music without affecting the constitution of the state, an opinion in which Aristotle acquiesced, and Cicero afterwards adopted:—it is not to be credited that the laws of Lycurgus, set to measured sounds by Terpander, were turned into a song, or that this Lesbian musician quelled a sedition in Sparta by singing some pretty air to the mob:—it is absurd to suppose that when Polybius tells us of a savage nation civilised by music, he means to say, by coarse pipes and guitars;—and not less ridiculous is it to imagine that men were raised to the rank of chiefs and the dignity of legislators, solely on account of their taste in singing, or their skill on the lyre and the flute.

We cannot quit the subject of the vocal music of Greece, without adding a few words concerning the Greek *Nomes* and *Scolia*. The former (from νόμος, *nomos*, a law) were so called, says Plutarch, because they were not allowed to transgress certain melodic rules by which they were characterised, and were at first hymns to the Gods. The latter were songs of a less restrained kind, sung at banquets and entertainments, by great proficient; hence Hesychius derives the term from σκολιός (*skolios*, *difficult to sing*). But others think that the word should be rendered literally,—*crooked, following a tortuous course*—because, at table, it did not pass regularly, but only to those who were skilful singers. Plutarch, on the authority of Pindar, tells us that the *scolia* were invented by Terpander. Dr. Burney has an entertaining chapter on the subject, vol. i., 464; but the reader will find it more learnedly discussed in Potter's 'Antiquities,' ii. 403.

As to the instrumental music of the Greeks, we confess our inability to treat the subject in a satisfactory manner. The accounts given of it by the ancient writers are either so suspicious or so indefinite, that nearly all our labour in endeavouring to gain some knowledge of its nature has been expended in vain. Having Bianchini's learned work on ancient instruments before us, we are enabled to form some opinion of their capabilities, and our opinion is not in their favour. They appear to have been rude, and suited only to music of the simplest description.

The Musical scale, or disdiapason, of the Greeks comprised two octaves, the lowest note of which was A, the first space in the base of the moderns. This was divided into five Tetrachords, or subdivisions of four sounds in each, the extremes being at the distance of a fourth. [TETRACHORD.] And it must here be observed, that the antient lyre had but four strings; the first and fourth fixed, the middle ones admitting of being tightened or relaxed according to the genus of the melody. Two conjoint tetrachords, with one additional note, formed the Octachord, or octave, to which the improved lyre extended. The three different divisions of the tetrachord produced as many Genera [GENERA], the Diatonic, the Chromatic, and the Enharmonic; which see. The first was composed of the sounds which the moderns name E, F, G, A; the second of E, F, F#, A; the third of E, E#, F, A. The notes, or sounds, were represented by the letters of the alphabet, great and small, which, in order to extend their application and distinguish the various modes, were placed in different positions—the direct, the averted, the inverted, and the horizontal; and these were, as occasion required, altered in form. The time, or duration, of the notes was known by the long and short syllables to which they were set; the long syllable was in duration as two; the short as one. But we know only the comparative times of these; of the positive lengths of notes we remain in ignorance. The movement however of Greek music is supposed to have been slow. The Modes were, according to Alypius, fifteen in number: Aristoxenus makes them thirteen, each a semitone distant from the next in order. Under the word *Μοδαί* we have given the table of Alypius; we here insert that of Aristoxenus, the oldest of the Greek writers on music, which commences with the Hypodorian, the lowest.

Hypodorian	B
Hypophrygian	Grave	C
Ditto	Acute	C#
Hypolydian	Grave	D
Ditto	Acute	D#

Dorian	E
Ionian	F
Phrygian	F
Æolian, or grave Lydian	G
Lydian Acute	G#
Mixolydian Grave	A
Ditto Acute	A#
Hypermixolydian	B

It will be here observed, that what may be called the key-note of the various modes does not agree with that in the table before given. In the above we have followed the Abbé Barthélemy, after having in vain resorted to numerous authorities for some means of reconciling the discrepancy. No two writers on this obscure subject are thoroughly agreed, and it is probable that none in future will attempt to explain that which holds out so little hope to labour and patience, and offers so small a reward for success. The three principal and most antient modes had different characters: the Dorian was grave and majestic; the Lydian, soft and complaining; the Phrygian, bold, enthusiastic, and used in religious ceremonies. Plato banished the Lydian and Ionian modes from his Republic, because exciting the enervating passions; but the Dorian and Phrygian he allowed, as manly and decent. Pindar set his fourteenth Olympic ode to the Lydian, as being addressed to the Graces. According to Lucretius, the Phrygian was employed in the horrid solemnities of Cybele; and Statius introduces it in the funeral rites of Archemorus.

By the word *μῆλος* (*melos*) the Greeks generally signified what we call air, or something like it; but sometimes, Twining remarks, 'they used it in the sense of *ἀρμονία*, i.e. *melody* abstracted from rhythm, or time: sometimes for *measured melody*; and sometimes as equivalent to *song*, including melody, rhythm, and words.' By *ἀρμονία* (*harmonia*) they intended simply to express, as we have in a former article observed, the proper relationship of one sound to another—the pleasing agreement of intervals; that is to say, melody. Metastasio believes that by this term the Greeks signified what we mean by melody, founding his opinion on the following passage from Plato (*De Legib.*, lib. ii.):—'The regulation of the movement is called rhythm; but the regulation of the voice is called harmony. Rousseau says—'The sense given by the Greeks to this word, in their music, is the more difficult to ascertain because, having originally been a proper name, it has no roots by which it can be decomposed in order to arrive at its etymology. In the antient treatises which remain, *harmony* seems to be that which had for its object an agreeable succession of sounds as regards high or low, in opposition to the other parts called *rhythmica* and *metrica*, which relate to time and measure.' But though very difficult to determine with exactness the meaning of the word harmony as applicable to Greek music, yet this difficulty does not arise from the cause assigned by the French writer.

The long-contested question, whether the Greeks understood counterpoint, or music in parts, seems now to be set at rest, and determined in the negative by a preponderating weight of authority and a large majority of voices. To what we have before remarked on this subject [HARMONY], we now add, that further inquiry and reflection have only confirmed the opinion we have long entertained, namely, that though the antients, by mere accident, if not from experiment, must have been acquainted with the effect of simultaneous sounds, nevertheless that which we call harmony formed no part of their musical art, either theoretically or practically. And we repeat our belief, that in the union of poetry and song, which undeniably operated with such amazing force on all classes of the people,—which inflamed them with ardour, softened them into obedience, and melted them into pity,—music was but the ally of verse.

Of their instrumental music, or music without the voice, we are told that the flute-players by profession—who certainly were exceedingly encouraged and most extravagantly paid for their services in the later times of Greece—piqued themselves chiefly on the strength of the sounds they could produce from the instrument; and that the trumpeters thought themselves fortunate if, in their contests at the public games, they escaped without the rupture of a blood-vessel by the violence of their exertions. It is to such performances Aristotle must allude in saying, 'I disapprove all kinds of difficulties in the use of instruments, and, indeed, in music generally; I mean such tricks as are prac-

tised at the public games, where the musician, instead of recollecting what is the true object of his art, endeavours only to flatter the corrupt taste of the multitude.' Facts and remarks like these do not lead to any favourable opinion of Grecian performers. It is likely however that they pleased most when they played the airs set to the favourite poems and popular verses. And there seems some reason to believe that they extended these by additions, sometimes studied, but often extemporaneous, resembling what are in modern language called variations, or an amplification of the theme.

It was a tradition that Cadmus, with his Phœnicians, introduced music into Greece. But Plutarch, in his 'Dialogue on Music,' first makes Lycias, a professor of the art, repeat the statement of Heraclides, that Amphion, the son of Jupiter and Antiope, taught the Greeks to compose and sing lyric poetry: then, by a second interlocutor, Soterichus, contradicts the first, assigning to Apollo the merit of having converted Greece into a musical nation. The invention of the lyre of three strings is given to the Egyptian Mercury, or Thoth; that of seven strings, to the second or Grecian Mercury. Chiron, the centaur, taught Achilles music. Orpheus was the musical pupil of Linus, and master of Hercules. Then came Olympos, Terpander, and others. Terpander is said to have appeased an insurrection in Lacedæmon by his songs. He rendered a most important service to the art by inventing a method of representing musical sounds. Till his time music was quite traditional, and depended on the memory, and sometimes the caprice, of the performer. Plutarch says of him, on the authority of Alexander, an historian, that he took Homer for his model in versification, and Orpheus for the style of his melodies. The musical compositions of Orpheus, the same writer adds, were wholly original.

Many very celebrated players on the flute are mentioned in musical history. Damon taught Pericles and Socrates the use of this instrument. Antigenides and Dorion were also renowned for their talents. But the performer who excited most admiration was of the gentler sex. Lamia was no less distinguished by wit and ability than by personal charms. After captivating many by her skill as a flute-player, and by her beauty, Demetrius Poliorcetes became violently enamoured of her, and, through her influence, conferred such extraordinary benefits on the Athenians, that they dedicated a temple to her. Whatever may have been the style of flute-playing, or of the music, it is certain that in Greece the performers were in great favour. Xenophon says, that if an indifferent player wished to pass for one of superior talent, he must furnish his house richly, and appear abroad with a large retinue of servants, as the great performers do. It is said that a flute used by a celebrated Theban musician, Ismenias, cost nearly six hundred pounds sterling.

Pythagoras, of whom an idle story was long current, about a blacksmith's shop, hammers, and anvils, contributed much to the improvement of music by his calculations and philosophical experiments. To him also is attributed the addition of an eighth string to the lyre. His notion concerning *the music of the spheres*—music produced by the motions of the heavenly bodies—was one of those whims in which great geniuses are apt, now and then, to indulge. He was of the sect of severe musicians, of those who reduced music to mathematical precision, and regulated all sounds by calculations, allowing no licence to the ear. Of an opposing school was Aristoxenus, born at Tarentum in Italy, about 350 years B.C., who thought the ear entitled to share with mathematical principles in determining the effect of modulated sounds. He was a most voluminous writer on many learned subjects. Of these his *Elements of Harmonics* are all that have reached us, and stand first in the collection published by Meibomius. Next in that excellent work is an *Introduction to Harmonics*, by Euclid, the geometrician; and this is followed by his *Section of the Canon*, containing short and clear explanations of the constituent parts of Greek music. Ptolemy, an Egyptian, and not the astronomer, wrote a treatise in three books on *Harmonics*, which Dr. Wallis printed, with a Latin version, a preface, and appendix, in 1682. He enters at large and deeply into the subject, and his principles have a tendency to reconcile the hostile sects of Pythagoreans and Aristoxenians. This object was pursued with success, by Sir F. H. Styles, in his paper published in the 51st volume of the *Philosophical Transactions*. In Plutarch's 'Dia-

logue on Music' much information concerning antient Greek music is to be found, but not of the most valuable kind. Aristides Quintilianus wrote a treatise on music, printed in the collection of Meibomius, which has proved a useful work to all subsequent writers on the subject. He was enthusiastic and fanciful, but in matters of fact and calculation is worthy of confidence.

The Romans acquired all their knowledge of the arts and sciences from the Greeks; their music therefore in no way differs from that of the latter; though they must have had some kind of song before any direct intercourse had taken place between them and the polished nations of Greece. It is certain that the art was never advanced by that warlike people, notwithstanding the share it had in all their religious ceremonies and public games, and the use made of it to animate their troops and add effect to their triumphs, and though it formed an essential part of their theatrical exhibitions of every kind, and was even adopted, or affected to be adopted, as a profession by one of their emperors.

The importance of music in the estimation of the early Romans is shown by a regulation attributed to Servius Tullius, who, in dividing the people into classes, directed that two whole centuries should consist of *trumpeters, blowers of the horn, &c.*, and of such as, *without any other instrument, sounded the charge.* It is further proved by a law of the Twelve Tables, which limited the number of *players on the flute* at funerals to ten. And another of those laws enacted, that at the praises of honoured men in the assemblies of the people, there should be mournful songs accompanied by a flute. But a passage in Livy leaves no doubt on this subject, and being as curious as it is illustrative, we shall give it entire, availing ourselves of Dr. Burney's translation. 'I should omit a circumstance,' he says, 'hardly worth mentioning, if it did not seem connected with religion. The *Tibicines* (or flute-players), taking offence at the preceding censors for having refused them the privilege of eating in the temple of Jupiter, according to custom, withdrew in a body to Tibur (Tivoli), so that there were no performers left to play before the sacrifices. This created religious scruples in the minds of the senators, and ambassadors were sent to Tibur to persuade the fugitives to return to Rome. The Tiburtines promised to use their utmost endeavours to this end, and first summoning the discontented band before their senate, exhorted them to return to Rome: but finding them deaf to reason or entreaty, they had recourse to an artifice well suited to the dispositions of these men; for, on a certain festival, they were all invited, under pretence of assisting in the celebration of a feast. As men of this profession are generally much addicted to wine, they were supplied with it, till, being quite intoxicated, they fell fast asleep, and in this condition were flung into carts, and carried to Rome, where they passed the remaining part of the night in the Forum, without perceiving what had happened. The next day, while full of the fumes of their debauch, upon opening their eyes they were accosted by the Roman people, who flocked about them, and having been prevailed upon to stay in their native city, they were allowed the privilege of strolling through all the streets in their robes, three days in every year, playing on their instruments, and indulging in those licentious excesses which are practised on the same occasion to this day' (that is, to the time of Augustus). 'The privilege of eating in the temple was also restored to such as should be employed in playing before the sacrifices.' This happened 309 B.C. 'The Roman flute-players,' Burney adds, 'were incorporated, and formed into a *college* or company.' Ovid, in his 'Fasti,' (lib. vi.), acknowledges the importance of the *Tibicines*, and repeats in verse the above story of Livy, but drops the scruples of the *Patres Conscripti*.

That the Roman drama was in some way musical, is proved by the title, or *didascalia*, prefixed to each of Terence's plays. A further proof of this is found in the Institutes of Quintilian, where, after showing the necessity of instructing children in music, he adds, 'that he does not desire that they should learn such music as prevails on the stage, the modulations of which are so intermixed with impudence and wantonness, that they may justly be charged with having extinguished the poor remains of manly courage which had been left.' That the theatrical music of the Romans was similar to that of the Greeks there seems to be little doubt; that it was distorted by the performers in Quintilian's time is very likely.

It is remarked by Dr. Burney, that even during the Augustan age the Romans had no sculptor, painter, or musician, and but one architect, Vitruvius; those, he says, 'who have been celebrated in the arts at Rome having been Asiatics or European Greeks, who came to exercise such arts among the Latins as the Latins had not among themselves. This custom was continued under the successors of Augustus; and those Romans who were prevented from going into Greece contrived in a manner to bring Greece to Rome, by receiving into their service the most able professors of Greece and Asia in all the arts.'

The Roman writers on music are few, and almost worthless. Vitruvius, in his work on architecture, treats of the sound of the voice, of reverberating vases, and of a *water-organ*; but no one has yet been able to discover what he means by this instrument. He also endeavours to make plain the harmonical system of Aristoxenus, though he acknowledges the difficulty of the task. St. Augustin wrote on rhythm and metre; Boethius devoted five books to music, merely to explain the principles of harmonics; and Aurelius Cassiodorus treats of music, among other things, but his work, or sketch, is said to consist of little more than some general definitions and divisions.

There is every reason to conclude that music remained stationary till the tenth or eleventh century. The Romans, having borrowed the art from Greece, seem to have been convinced of its perfection in the state in which they received it, for there is no evidence of their having attempted to enlarge its narrow boundaries, or in any way to improve it; though a people of more ingenuity and taste would have advanced it at least a few steps towards that point which it slowly has attained.

In the primitive Christian church the service consisted partly of music, which is supposed to have been chiefly that of the Greeks, with an admixture of Hebrew melody. Mestrier conjectures that the early ecclesiastical manner of singing was like that of the ancient theatre, and Dr. Burney concurs in this opinion; though we cannot but think it more likely that the 'songs of Zion,' as performed in the Jewish temple, and the chanting of the hymns at the Pagan altars, were chosen as vocal models for devotional purposes, rather than the airs, or recitatives, in which the comedies of Plautus and Terence were delivered. Towards the end of the fourth century, St. Ambrose digested a musical service for the church of Milan, which is called the Ambrosian chant, and was founded on four of the Greek modes. About the year 600 Gregory the Great enlarged and much improved the chant of the church, by the admission of four other modes, and gave it that form which it still retains in the Catholic service, and in which it is known by his name. According to Bishop Stillingfleet, music was introduced into the English church by St. Augustin, in the latter part of the sixth century, and was subsequently much improved by St. Dunstan, an excellent musician, who, it is said, furnished some few churches with an organ.

The organ—the most majestic and comprehensive of all musical instruments in its present almost perfect state—is supposed to have been an improvement of the hydraulic, or water-organ, of the Greeks. The first mentioned in musical history was sent, in 757, as a present to King Pepin, from the Byzantine emperor Constantine Copronymus. In the tenth century the organ was in use in several parts of Europe; but it is reasonable to conclude that it was then exceedingly simple, possessing little power, and rude in mechanism: nevertheless, it may fairly be assumed that the invention of the organ hastened the discovery or practice of harmony. [ORGAN.]

To Guido, of Arezzo, we are indebted for many of those improvements in music which led to our present system; though the origin of counterpoint has been erroneously ascribed to that active and ingenious ecclesiastic. [GUIDO.] *Magister Franco*, a member of the cathedral of Cologne in the eleventh century, is considered as the inventor of what in the middle ages was called *Cantus Mensurabilis*, which meant, notes showing, by their forms, their time or duration. Most of those, however, have fallen into disuse, for the shortest in his table is the semibreve. Nevertheless his system, carried out further by De Muris, and by degrees extended, till it has proceeded to an extravagant length—is that of the present day, and is so sound in principle that it probably will never be abandoned.

From the eleventh to the fifteenth century, scarcely anything is known of the progress of music. For its history

from the latter period, we refer to the biographical sketches of its most eminent professors which appear in our work;—to the articles *ACADEMY, CONCERT, OPERA, ORATORIO, &c.*;—to the names of musical instruments;—and to all the terms under which musical compositions of every kind are described. From these sources may be gathered much of the information, if not all, that will be required by the general reader.

MUSK. (Zoology.) [MOSCHIDÆ.]

MUSK. This substance is an extremely odorous secretion, lodged in a bag which is attached and peculiar to the abdomen of the male musk-animal. The elevated regions frequented by the creature, its timidity and speed in flight, render it very difficult to obtain the substance, while the high price borne by it offers great inducements to substitute other articles for that which is genuine. The musk-bag varies much in form, colour, size, and quality, circumstances which suggest the belief that it is procured either from two or more species of musk-animals, or that it has been obtained at different periods of the year, or from very differently-aged animals. In the very young animal the bag is quite empty, while in the old and feeble the musk is in small quantity and of inferior strength. It is said to be secreted in greatest abundance during the rutting season, and to have then its sensible qualities most developed. The secretion has a much stronger odour in the animal which inhabits Tibet and China than in that which frequents the more northern districts of Siberia. In the fresh state the musk has an extract-like consistence, and a reddish-brown colour, with an odour so powerful that the huntsmen can scarcely endure it. By drying this odour diminishes, and the musk acquires a friable granular state, and a dark-brownish colour. In Siberia the chase occurs in spring and summer. In Tibet the pursuit is restricted by the government to certain periods, and the bags which are obtained are stamped with the royal signet. In commerce two and occasionally three varieties of musk are met with.

1. The Tonquin or Tibet musk, received through the East India Company, occurs in small oblong-rectangular boxes, lined with lead, and covered with paper or silk. Each bag, or pod, as it is termed, is wrapped in thin blue or red paper, on which are marked some Chinese characters. Sometimes the bags are enveloped in a deep yellow-brownish nearly transparent paper, which becomes brittle by time. The most distinctive mark of this sort of musk is, that it is slightly flattened, nearly round, and very rarely pear-shaped. The yellow or yellowish-brown hairs, chiefly at the sides, are often cut, while those which remain in the centre are darker coloured, finer, and less bristly. Generally the hairs converge or point towards a small natural opening. The pods are mostly about two and a half inches long, and one and three-quarters broad. The weight of different specimens varies considerably, some being merely three drachms thirty grains, others nine drachms forty-seven and a half grains; the average is six drachms twelve grains. The average quantity of musk contained in the sacks is about two and a half drachms.

By careful removal of the bag, there remains the musk, which is solid, in grains of different sizes, adhering to each other, soft, and unctuous to the feel, of a reddish-brown colour, like a clot of blood dried, having frequently a number of hairs intermixed, derived from the inner side of the orifice already described. The taste is bitterish, acrid, disagreeable, and somewhat astringent. The odour is strong, peculiar (musky), penetrating, very lasting, and extraordinarily diffusible. It is stated that a single grain can constantly fill the air of a large apartment with a sensible impregnation for many years, without its weight being perceptibly diminished; and one part can communicate its odour to 3000 parts of an inodorous powder.

It should be kept in glass-bottles, very closely stopped, and preserved in a place neither very dry nor too damp.

By the analysis of Geizar and Reiman it appears to consist of: 1, a peculiar volatile principle (which can exist in a free state); 2, ammonia; 3, a peculiar, fixed, uncrystallizable acid (these three are in undeterminable quantity); 4, stearine and oleine; 5, cholesterine; 6, a peculiar bitter resin; 7, osmazome, with several salts; 8, a mouldy-like substance, in part combined with ammonia, and numerous salts; 9, sand; 10, water, acid, &c., with some volatile odorous matter.

It has not been ascertained upon what musk depends for

its peculiar properties. It has been conjectured that a kind of putrefaction goes on which evolves the peculiar odour. Moisture seems to favour this, and musk which, when dry, yields little scent, becomes powerful when moistened. The odour is augmented by adding a few drops of the solution of subcarbonate of potass.

2. Kabardin, Russian, or Siberian musk, is either received through St. Petersburg, or, it is said, sent to China, and laid for some time among the bags of genuine Tonquin musk, to acquire the odour of the latter, and then shipped to Europe. The pods of this sort are in general larger, more oval, more compressed, and the margins often have large portions of the skin of the abdomen attached to them. The colour of the hairs is a dirty milk-white. The musk exhibits a more homogeneous and less granular appearance, having a much fainter odour and taste than the preceding kind. The odour is augmented by moisture, but is somewhat nauseous and disagreeable. The wood-cuts show the difference of aspect of the two kinds.

1, Tonquin Musk. 2, Kabardin Musk.

Musk is more soluble in water than in alcohol. Of 100 parts of genuine Tonquin musk, boiling-water dissolves 90 parts, alcohol only 50. Of Kabardin musk, water dissolves only 50 per cent. It is likewise soluble in æther, acetic acid, and yolk of egg.

3. A very small kind of pod is sometimes met with, which is not flattened, but perfectly round: the hairs of a yellowish-brown colour. This is probably the musk-bag of the *Moschus Altaicus*.

It is safest to purchase the musk out of the pod, as there is then less opportunity of adulteration. Infusion of genuine musk is not precipitated by a solution of bichloride of mercury (corrosive sublimate); but genuine musk is precipitated by nitric and other strong acids, by acetate of lead (sugar of lead), and infusion of galls. The musk-bags are used by perfumers to prepare 'essence of musk.' An artificial musk is sometimes made with nitric acid and oil of amber. This should never be used for medical purposes.

Taken in the dose of a few grains, musk rouses the energy of the digestive organs; and it soon afterwards produces sympathetic phenomena, the powers of the whole animal system appearing suddenly increased. By repeating the dose till half a drachm or a drachm is consumed, the active prin-

oiples penetrate the whole frame, influencing all the tissues, and exciting effects demonstrative of its stimulating property; the blood circulates with more force, accompanied sometimes with bleeding from the nose: the perspiration and other secretions are perceptibly increased. Other effects prove that it also acts on the brain, spinal chord, and ganglionic nerves, such as tendency to sleep, convulsive movements, and particularly spasms of the chest and abdomen. Owing to idiosyncrasies, musk produces in some persons very extraordinary effects, at times so violent that they cannot bear the faintest odour of it.

Musk has been recommended in typhus and other fevers, when there exist low delirium, hiccup, twitching of the tendons, &c. But its beneficial action is not so constant as to justify much reliance upon it. It is much more useful in diseases purely nervous and spasmodic, where no inflammatory action has preceded or is present. Hence even in epilepsy, as well as hysteria, it is serviceable. In combination with ammonia it is useful in arresting a tendency to gangrene. Likewise in retrocedent gout it has proved successful. It was found of little avail in severe cases of Asiatic cholera, though useful in the milder forms of it.

MUSK-RAT. [MUSQUASH]

MUSKERRY MOUNTAINS. [CORK.]

MUSKET. [ARMS, p. 373.]

MUSKINGUM. [MISSISSIPPI, River.]

MUSLIN, a thin cloth made of cotton. The name is supposed to be derived from Masalia, since called Masulipatam, from which place such fabrics were first imported into Europe. Until the early part of the present century all the muslin used in Europe was of the manufacture of India. These fabrics are still superior to any that are made in Europe, both as regards their fineness and their durability, which latter quality is not, as some people have supposed, the consequence of any superiority in the quality of the material of which they are made, for the raw cotton of India is far inferior to that which is used for these fine fabrics in Europe, and which is brought from America and from Egypt. The excellence of India muslins is owing to the skilfulness and patience of the spinners and weavers in that country. Some of the muslins of India, and especially those of Dacca, are of the most astonishing degree of fineness, so as to justify their poetical description as 'webs of woven wind.' Such however has been the result of the mechanical inventions of England in this branch of industry, that not only are muslins of British manufacture now used at home, to the exclusion of those woven in India, but large quantities are exported to all parts of the world, and find their way even far into the interior of India.

The great seat of the muslin manufacture in this country is Paisley near Glasgow. The greater part of the yarn used for these fine fabrics is spun in the cotton-mills of Manchester. Muslin cloths are both plain and figured. By a late invention they are sometimes embroidered by means of machinery.

MUSONIUS RUFUS, CAIUS, a Stoic philosopher of the first century of our æra, is mentioned with praise by Tacitus (*Ann.*, xiv. 59), and also by Pliny the younger, Philostratus, Themistius, and others. He was a native of Vulturnum in Etruria, and belonged to the Equestrian order. He was a friend of Thrasea Paetus, Barea Soranus, Rubellius Plautus, and other stoics, who were the victims of Nero's suspicion and cruelty. Musonius was banished to Gyarus, where he is said to have been visited by many Greeks for the purpose of listening to his lessons. Being recalled after Nero's death, he lived at Rome under Vespasian, who excepted him from the sentence of exile pronounced by that prince against the Stoic philosophers. This scanty information is all that we have concerning the biography of Musonius Rufus. (*Nieuwland, Dissertatio de Musonio Rufo, Philosopho Stoico.*) Fragments of his works are found in Stobæus, and have been collected and published, with the above dissertation and copious notes, under the title of 'C. Musonii Rufi, Philosophi Stoici, Reliquiæ, et Apophthegmata, cum Annotatione, edidit T. Venhuizen Peerlkamp, Corrector Gymnasii Harlemensis,' 8vo., Haarlem, 1822. These fragments of Musonius are full of the purest morality and wisdom.

MUSOPHAGIDÆ (*Plantain-eaters*). Mr. Vigors* notices the genera *Musophaga* and *Corythæix* as nearly and evidently allied to the Gallinaceous families, and as

in 'Link.' Natural Affinities that connect the Orders and Families of Birds,' vol. xiv., pp. 476-481.

being found among the Scansorial birds; and speaks of the genus *Vinago* [COLUMBIDÆ, vol. vii.] as united by their comparatively stronger and more solid bills to *Penelope* and *Cyrax*, which in his arrangement form the opposite extreme of the order *Rasores*, as well as to *Musophaga* and *Corythæix*, which approach the whole of the Rasorial groups and connect them with the *Perchers*. [INSESSORÆ, vol. xii.]

Mr. Swainson raises the group of *Plantain-eaters* to the rank of a family under the title which heads this article; and they constitute, according to his arrangement, the fifth great division of the conirostral tribe of perchers. Not that he considers it as by any means clear that *Musophaga* is the real type of the whole family, though he designates that genus as the most conspicuous of the group.

He thus characterises the family:—

Bill short, upper mandible high, the culmen arched, the margins either serrated or entire, the under mandible very thin. Feet short, formed for clinging. The toes various.

The place which this family occupies in Mr. Swainson's arrangement is next to the *Fringillidæ*, at the end of the *Perching Birds*, and immediately before the *Scansores*, intermediate between the *Finches* and the *Hornbills*. He observes that those which betray their affinity to the bullfinches are small, whilst others, whose size and peculiar structure assimilate them more to the hornbills, are of a size proportionate to those birds, remarking that, with the exception of one genus, they all possess a short but very strong and thick bill, more or less curved on the top, the cutting margins being minutely serrated, like the teeth of a saw. The food, it is stated, seems to be entirely vegetable, and of the most tender and delicate description: and Mr. Swainson remarks that it is singular to observe that the bill in this family (in outward appearance much stronger than that of the finches) should yet be employed in procuring the softest vegetable food; while the short bill, posterior nostrils, hopping gait, and purely vegetable food, are all exemplified in such birds as *Buceros galeatus*, and proclaim the affinity of the *Plantain-eaters* to the *Hornbills*.

Mr. Swainson further remarks that the economy of these birds, so far as they have been observed by travellers, is directly against the theory of their being likened to the gallinaceous order; and he quotes some of the statements of Cuvier and those of Yarrell in support of his opinion. The former, in the *Règne Animal*, states that *Corythæix* and *Musophaga* appear to him to have some analogy with the gallinaceous birds, and particularly with the Hobbies. They have the wings and the tail of those birds, and, like them, keep on trees; their bill, he continues, is short, and the upper mandible convex; their feet have a short membrane between the anterior toes; but it is true that the external toe is often directed backwards like that of the owls. Their nostrils also are simply placed in the horn of the bill, the edges of the mandibles are dentilated, and the sternum (at least that of the *Touraco*) has not the great notches which are ordinary in the Gallinaceous birds. Mr. Swainson observes that this admission of Cuvier, that *Corythæix* and *Musophaga* only present 'quelque analogie avec les gallinacés,' and that they have not the notched sternum of the latter, is directly opposed to the theory of these birds leading to the *Gallinacea*, a view of the subject which is confirmed by Mr. Yarrell's observations. The latter zoologist dissected a *Touraco* (*Corythæix Persa*) which had died in the menagerie of the Zoological Society of London, and he found the general appearance of the inside of the body of the bird inclining rather to that of the *Perchers* than of the *Gallinæ*. (*Zool. Journ.*, vol. iv., p. 319.) Mr. Swainson separates the family into the following subfamilies and genera:—

Phytotomidæ, Plant-cutters.

Bill serrated, but not swollen. Feet with two or three toes forward and one backward. (Sw.)

Genera.

Phytotoma, Molina. *Hyreus*, Stevens. Of these we select *Phytotoma*.

Generic Character.—Bill short, compressed, the base widened; high at the base, and gradually curved; the lower mandible much weaker, straight; the commissure slightly arched, with the margins crested. Tongue short, pointed. Nostrils basal, small, rounded. Wings moderate; the two first quills graduated; tail moderate, even. Feet strong. Lateral toes unequal, the inner shortest. Claws slender, slightly curved. (Sw.)

Example, *Phytotoma rara*.

Description, Habits, &c.—Molina describes the *Rara* or *Chilian Plant-cutter* as nearly of the size of a quail, with the bill rather large, conical, straight, a little pointed, serrated, and half an inch in length; the tongue very short and obtuse, the pupil of the eye brown. Three well proportioned anterior toes, the fourth posterior and a little shorter. The tail moderate, but rounded. The colour is an obscure grey upon the back, rather brighter on the belly; the points of the quills and of the tail are black. The sound of its voice is hoarse and interrupted, and seems to express its name. It feeds on plants, but previously has the destructive habit of cutting them off close to the root, and often capriciously cuts off a quantity of them without touching them further. For this reason the peasants persecute this species, and carry on a continual war against these birds; moreover children who destroy their eggs are rewarded. The nest is built in obscure and but little frequented places on the most lofty trees, and thus these *Plant-cutters* escape the persecutions of their enemies. Notwithstanding such precautions however, their numbers are considerably diminished. 'I do not know,' says Molina in conclusion, 'whether this is because a price is set on its head, or on account of its naturally small degree of fecundity.'

Chilian Plant-cutter.

Mr. Swainson observes that in *Phytotoma* the four toes appear to be arranged as in the *Finches*, but in *Hyreus* the toes are only three. He compares the size and entire aspect of *Phytotoma* to that of a *Bullfinch*.

Colinæ. Colies.

The only definition of this subfamily given by Mr. Swainson is, 'all the four toes placed forward,'* and the only genus contained in it is

Colius. (Brisson and Gmelin.)

Generic Character.—Bill short, strong, conical, slightly compressed, entire, with the mandibles equal and the edges arched; nostrils rounded; nails arched and long, that of the hind-toe shortest; wings short; third quill longest; tail graduated and very long.

Habits, Geographical Distribution, &c. of the Genus.—The plumage of the species is soft and silky, and the colours generally sombre, whence they are called at the Cape, according to Le Vaillant, *Oiseaux Souris* (Mouse-birds). Africa and the East Indies are the localities where they have been found, the *Colius viridis* of Latham, said to be from New Holland, belonging probably to another genus. The *Colies* are gregarious, live upon fruits, and are the scourges of gardens. They walk badly, but they climb almost continually on the branches of trees, where they hold on, assisting themselves with their bills like the

* Other authorities state that the hind-toe is versatile; and this would more accord with their climbing habits.

Parakeets. They build their nests, which are spacious and round, in little groups; and Le Vaillant affirms that they sleep suspended with their heads downwards, and that, when it is cold, they are found so benumbed in the morning, that they may be taken one after the other. The number of eggs is generally five or six, and the flesh of the birds is said to be delicate. (Lesson.)

Example, *Colius Senegalensis*. (Latham.)

Description.—Round the eye a naked, reddish skin; forehead yellow; colour pearl-grey, with greenish reflections; abdomen ruddy.

This appears to be the *Colius Quirica*—the trivial name is taken probably from its note—of Le Vaillant; and the *Coliou huppé du Sénégal* of Buffon.

Colius Senegalensis.

Musophaginæ. Plantain-eaters.

Three toes forward and one backward; the outer toe placed obliquely. (Sw.)

Genera. *Corythaix*. (Ill.)

Generic Character.—Bill short, rather small, high, and greatly compressed. The frontal feathers reposing over and concealing the nostrils. Culmen high, curved to the tip. Lower mandible narrow; both mandibles distinctly notched at the tip and finely serrated. Wings short, rounded; the three first quills graduated. Tail long, broad, rounded. Feet short, strong. Middle toe longer than the tarsus; lateral toes equal, hind-toe shortest; external toe capable of being turned a quarter of the way backward. Claws short, thick, and much compressed.

The *Touracos* are most elegant birds, and feed principally on soft fruits. The prevailing colour of these birds is green, varied in some species with purple on the wings and tail. They are natives of Africa, where they perch on the highest branches of the forest trees, and thus keep out of gun-shot, as Le Vaillant found to his cost. Having at last succeeded in bringing one to the ground, he could not find it, and, stamping in his rage at the loss, he broke through into one of the covered pits which the *Hot-tentots* employed to catch ferocious animals, particularly elephants. This accident might have been fatal. 'When I recovered my first surprise,' says he, 'I began to consider how I should extricate myself from this embarrassment, ex-

tremely happy that I had not been impaled on the sharp-pointed stake placed in the bottom of the pit; and still happier that I found in it no company. I was however apprehensive that some might arrive every moment, especially if I should be obliged to remain there during the night. In this dilemma Le Vaillant fired his fusce at intervals; the shots at last were answered, and he was delivered by his Hottentots. But he did not forget his Touraco, and now, by the aid of his dogs, which had followed the Hottentots, found it squatted under a tufted bush. He afterwards laid snares for them on the fruit-trees, to which they resorted to feed, and took them alive.

The following cuts will give but an imperfect idea of these elegant birds.

Head of *Corythæx erythrolophus*.

This beautiful species is the *Opæthus erythrolophus* of Vieillot; the *Musophaga Paulina* of Temminck; and *Corythæx igniceps* of Lesson.

Our figure was taken from a specimen that lived for some time in the gardens of the Zoological Society in the Regent's Park.

Locality, Africa.

Head of *Corythæx Senegalensis*.*

Corythæx Senegalensis.

Corythæx erythrolophus.

Several specimens of Touracos are to be found in our museums, and there are at present (September, 1839) two (*Corythæx Buffoni*) living at the gardens of the Zoological Society, Regent's Park.

Chizærhis. (Wagler.)

Generic Character.—Bill large, high and thick at the base, compressed beyond. Culmen thick, convex, considerably arched. Lower mandible not half so high as the upper; the tips of both deeply notched, with their margins finely crenated. Nostrils basal, placed close to the top of the bill, naked, lunular, and pierced in the substance of the bill. Wings lengthened; the four first quills graduated. Tail lengthened, slightly rounded; the tips very obtuse. Feet as in *Corythæx*. (Sw.)

Example, *Chizærhis variegata*.

Perhaps the most delicate species is *Corythæx erythrolophus*, Sw.

Description.—Crest, which is red, erect and compressed; sides of the head, ears and throat, and patch round the eye (which is large, red, and brilliant), white; general plumage green, inclining to bluish on the body and belly; quills rich purple violet; tail rounded; bill yellow; feet greyish-black.

* N.B. The crest, when the bird is excited or in action, is elevated into a compressed subconical shape; and, when thus erected, it gives the head a helmeted air.

Description.—Light grey above; a blackish stripe down each feather; front, top of the head, chin, and throat as far as the breast, chestnut-brown; under plumage beyond the breast white, but each feather with a dark middle stripe; primary and secondary quills blackish, with a spot of pure white varying in size in the middle of their inner webs; tertiaries and middle tail-feathers grey, tipped with black; lateral tail-feathers black; bill yellow; feet grey. Crest placed very far back on the nape. Total length about 20 inches.

This appears to be the *Touraco huppé-col* of Le Vaillant; *Phasianus Africanus* of Latham, and *Musophaga variegata* of Vieillot.

Locality, Africa.

Chizærhis variegata.

Musophaga. (Lært.)

Generic Character.—Bill resembling that of *Chizærhis*;

Musophaga violacea.

but the base enormously dilated, so as to spread like a casque or helmet over the fore part of the head as far as the crown, where its thickened sides form a semicircle. Nostrils naked, oval, open, placed nearer to the tip than to the eyes, and pierced in the substance of the bill. Wings, feet, and tail as in the *Corythaix*. (Sw.)

Example, *Musophaga violacea*.

Description.—Bill rich yellow, passing into crimson; orbits naked, and, like the compact velvety feathers of the crown, glossy crimson; a white stripe beginning below the eye and extending above the ear; secondary and part of the primary quills carmine, with lilac reflections, margined and tipped with blackish violet, which is the general colour of the plumage, only that it changes into a very deep green on the under parts, and is very rich on the tail; legs strong and black; gape wide, opening beneath the eyes.

This magnificent bird appears to be the *Cuculus regius* of Shaw.

Locality, Africa: Gold Coast and Senegal.

MUSQUASH, the Cree name for the *Fiber Zibethicus* of Cuvier (*Ondatra* of Lacépède), a genus belonging to the family *Castoridae*.

Dr. Richardson (*Fauna Boreali-Americana*) gives the following synonyms of this rodent:—

Rat-Musqué of Sagard Theodat; *Castor Zibethicus* of Linnæus; *L'Ondatra* of Buffon; *Musk-Rat* of Lawson; *Musk-Beaver* of Pennant; *Musquash* of Josselyn; *Mus Zibethicus* of Lin., Gmelin; *Fiber Zibethicus* of Sahine and Harlan; *Musk-Rat* of Godman; *Ondathra* of the Hurons; *Musquash*, *Watsuss*, or *Wachush*, also *Peesquaw-Tupeyew* (the animal that sits on the ice in a round form), of the Cree Indians.

In a tract which has for its title 'A Perfect Description of Virginia,' 1649, we find among the 'Beasts great and small,' 'A Muske Rat, so called for his great sweetness and shape.'

Dental Formula.—Incisors, $\frac{2}{2}$; Molars, $\frac{3-3}{3-3} = 16$.

'Teeth of Musquash. (F. Cuv.)

Description.—Head short. Body thick and rather flat; legs very short; hind-feet large, not webbed.* Dark amber brown above; sides, anterior part of belly, middle of breast, lateral part of neck and cheeks, shining yellowish-brown; chin, throat, sides of the chest, and posterior part of the abdomen, ash-grey; tail compressed, convex on the sides, with its acute edges in a vertical plane, covered with a thin sleek coat of short hairs, which allow a number of small roundish scales, well separated from each other, and which, as well as the hair, are dusky-brown, to appear through them; acute margins of the tail (which is rather thicker in the middle than at the root, and tapers gradually from its middle to its extremity, which is not acute) covered with a close line of longer hairs dark brown on the upper edge and soiled white on the under one. Length of head and body 14 inches; of the tail 8 inches 6 lines.

The fur, which much resembles that of the *Beaver*, but is shorter, resists the water during the life of the animal, but is easily wetted immediately after death.

Habits; Utility to Man, Geographical Distribution, &c.—Charlevoix states that the Musk-Rat takes the field in

* Hearne erroneously says that the hind-feet are webbed.

Marsh, at which time its food consists of bits of wood, which it peels before it eats them. After the dissolving of the snows, he says that it lives upon the roots of nettles, and afterwards on the stalks and leaves of that plant. In summer it feeds on strawberries, &c., to which succeed the autumnal fruits. During this time, he states that the male and female are rarely seen asunder. According to the same author, they separate in winter, when each takes up its lodgings apart, in some hole or in the hollow of a tree, without any provision; and the Indians declared that not the least morsel of anything is eaten by them whilst the cold continues. 'They likewise,' adds Charlevoix, 'build cabins nearly in the form of those of the beavers, but far from being so well executed. As to their place of abode, it is always by the water-side, so that they have no need to build causeways. . . . The flesh is tolerably good eating, except in the time of rut, at which season it is impossible to cure it of a relish of musk, which is far from being as agreeable to the taste as it is to the scent.'

Dr. Richardson (*Fauna Boreali-Americana*), from whom the abridged description is taken, and to whose details we refer the reader, states that the Musquashes vary considerably in size, and that though they have a strong musky smell, particularly the males, in spring, their flesh, which somewhat resembles flabby pork, is eaten by the Indians, who prize it for a time when it is fat, but soon tire of it. They have, according to this author, three litters in the course of the summer, producing from three to seven at a litter, in 55° N. lat., and begin to breed before they attain their full growth. Great numbers are destroyed by the inundations which cover the low grounds where they haunt, and in severe winters they are almost extirpated from some localities by the freezing of the swamps inhabited by them. Famine in such cases drives them to destroy each other. A great mortality, the cause of which is unknown, also sweeps them away, and the deaths at such periods (which are uncertain) are so numerous, that a fur-post, where the *Musquash* is the principal return, is not unfrequently abandoned till the fecundity of the animal has repaired, which it does in a very few years, the ravages of disease.

Dr. Richardson places the southern limit of the *Musquash* about 30° N. lat. According to Bartram, they are found in the north of Georgia and Florida, and Dr. Richardson ascertained that they extended northwards to the mouth of the Mackenzie, 60° N. lat. Small grassy lakes or swamps, or the grassy borders of sluggish streams with muddy bottoms, are favourite haunts, and there they feed chiefly on vegetables. In the northern districts the roots and shoots of the bulrush and reed-mace, and the leaves of various carices and aquatic grasses, form their staple. Pennant states that they are very fond of the Sweet-flag (*Acorus Calamus*), which, according to Dr. Richardson, does not grow to the northward of Lake Winnipeg. The last-named author often saw small collections of fresh-water mussel-shells (*Unio*), on the animals of which they are said to feed, and which, he was informed, had been left by them.

The habitations of the Musquashes and the mode of hunting them are thus described by the Doctor:—'In the autumn, before the shallow lakes and swamps freeze over, the Musquash builds its house of mud, giving it a conical form, and a sufficient base to raise the chamber above the water. The chosen spot is generally amongst long grass, which is incorporated with the walls of the house, from the mud being deposited amongst it, but the animal does not appear to make any kind of composition or mortar by tempering the mud and grass together. There is however a dry bed of grass deposited in the chamber. The entrance is under water. When ice forms over the surface of the swamp, the Musquash makes breathing-holes through it, and protects them from the frost by a covering of mud. In severe winters however these holes freeze up in spite of their coverings, and many of the animals die. It is to be remarked that the small grassy lakes selected by the Musquash for its residence are never so firmly frozen nor covered with such thick ice as deeper and clearer water. The Indians kill these animals by spearing them through the walls of their houses, making their approach with great caution, for the Musquashes take to the water when alarmed by a sound on the ice. An experienced hunter is so well acquainted with the direction of the chamber and the position in which its inmates lie, that he can transfix four or five at a time. As soon as, from the motion of the spear, it is evident that the animal is struck, the house is broken

down and it is taken out. The principal seasons for taking the Musquash are, the autumn before the snow falls, and the spring, after it has disappeared, but while the ice is still entire. In the winter time the depth of snow prevents the houses and breathing-holes from being seen. One of the first operations of the hunter is to stop all the holes with the exception of one, at which he stations himself to spear the animals that have escaped being struck in their houses and come hither to breathe. In the summer the Musquash burrows in the banks of the lakes, making branched canals many yards in extent, and forming its nest in a chamber at the extremity, in which the young are brought forth. When its house is attacked in the autumn, it retreats to these passages, but in the spring they are frozen up. The Musquash is a watchful but not a very shy animal. It will come very near to a boat or canoe, but dives instantly on perceiving the flash of a gun. It may be frequently seen sitting on the shores of small muddy islands in a rounded form, and not easily to be distinguished from a piece of earth, until, on the approach of danger, it suddenly plunges into the water. In the act of diving, when surprised, it gives a smart blow to the water with its tail.'

Varieties.—Dr. Richardson records three varieties besides that above described.

1. The *Black Musquash*, rare.
2. The *Pied Musquash*, with dark, blackish-brown patches on a white ground.
3. The *White Musquash* (*Fiber Zibethicus-albus*, Sabine). This Albino is not unfrequent. Dr. Richardson saw several.

According to Hearne, the Musquash is easily tamed, soon becomes attached, and is cleanly and playful.

The fur is used in hat-making, and there is, according to Dr. Richardson, an annual importation of between four and five hundred thousand into Great Britain from North America for that manufacture. Charlevoix also notices the employment of the fur in the hat trade.

The Musquash.

MUSSCHENBROEK, PETER VAN, was born at Leyden, March 14th, 1692. He received a good classical education in the university of his native city, being a pupil of Perizonius and Gronovius, and afterwards applied himself to the study of medicine, which science, as well as those of chemistry and natural philosophy, he studied under Senguerd, Bidloo, Le Clerc, Burnard, Albinus, Boerhaave, and Rau. He was excessively fond of the mathematical sciences. In 1717 he formed an intimacy with the celebrated s'Gravesande, and their tastes being similar, they pursued their studies together. The introduction into Holland of the Newtonian system of philosophy, and the science of experimental physics, was principally owing to the labours of these two men. They worked together with equal zeal and success, but in different paths; s'Gravesande took the mathematical or theoretical part of physics, while Muschenbroek applied himself more particularly to experimental physics, in which he excelled, and in which he made a great many discoveries.

On the occasion of taking his degree of doctor of medicine, in 1718, Muschenbroek wrote an inaugural dissertation, 'De aëris præsentia in humoribus animalium,' a very

clever production, which contains a description of many careful experiments, from which accurate conclusions were drawn, and, though published more than a century ago, it may still be read with interest. The author showed in this dissertation both a fondness and talent for experimental philosophy, and he was luckily placed under favourable circumstances for the development of this talent. At the commencement of his career the speculations of Descartes were rapidly dissipating before the lights of the Newtonian philosophy, but they still retained some supporters; Musschenbroek therefore determined to visit England, for the purpose of seeing Newton and making himself fully acquainted with his system. While in London, he was introduced to Dr. Desaguliers, and other scientific men besides Newton; and on his return to Holland, he soon came into public notice. In 1719 he was appointed professor of philosophy and mathematics, and professor extraordinary of medicine in the university of Doosburg on the Rhine, where he gained great reputation by his lectures. In 1723 he was invited to fill the chair of philosophy and mathematics in the university of Utrecht, which had been long distinguished as a school for legal studies, and which Musschenbroek soon rendered equally well known in the department of natural philosophy. He remained at Utrecht many years, and this city was the seat of his principal labours. The curators of the university were so fully impressed with the importance of keeping his services, that they conferred on him, in 1732, the professorship of astronomy. In 1737 George II. of England, elector of Hanover, offered to Musschenbroek a professorship in the newly established university of Göttingen. The offer was refused, but two years afterwards he accepted the professorship of mathematics in his native city, Leyden, which had become vacant by the death of Wittichius. Musschenbroek remained attached to the university of Leyden for the remainder of his life, though he was successively invited to fill other appointments by the kings of Prussia and Spain, and by the emperor of Russia. He died on the 19th of September, 1761, in the seventieth year of his age.

The following are Musschenbroek's principal works:—

1. 'Epitome elementorum physico-mathematicorum,' 12mo., Leyden, 1726. This work went through several editions, each succeeding edition being considerably altered and improved. It was reprinted in 1734, under the altered title of 'Elementa Physicæ,' 8vo., Leyden. An English translation is mentioned as having been made of this work by Colson, in 1741, 2 vols. 8vo., but we have not been able to meet with it. The last edition of this work appeared after the death of the author in 1762, and was named 'Introductio ad Philosophiam Naturalem.' This edition is much more complete than either of the former, and contains a very good summary of all that was then known on natural philosophy. These three editions are often spoken of as distinct works, though it is only the titles that are different.

This introduction to natural philosophy (the last edition is here referred to, which is the most complete) contains many original researches, on the cohesion of bodies, on the phosphorescent properties which many substances acquire from exposure to light, and on various points in experimental physics. It also includes a much more complete table of specific gravities than had before been published, entirely formed from the author's own investigations. Rigaud de Lafond translated the 'Introductio ad Philosophiam' into French (1769, 3 vols.). This translation must not be confounded with another which appeared at an earlier date (1739) with the title of 'Essai de Physique,' which was translated by Dr. Massuet from a Dutch edition of the same work, published by Musschenbroek, which Dutch edition (containing many researches which were not included in the later Latin ones) was written in a popular style for the purpose, which it fully answered, of diffusing a taste for natural philosophy in Holland among those who were not acquainted with the learned languages.

2. The work which has gained the author most celebrity is his 'Physicæ Experimentales, et Geometricæ Dissertationes,' Leyden, 1729, 4to. This work consists of four treatises: one on the magnet, one on capillary attraction, one on the size of the earth, and one on the cohesion of bodies. All these dissertations contain many interesting researches and new experiments, which were conducted with great care. The labours of Musschenbroek on the power of cohesion between different bodies were very great; and he afterwards

P. C., No. 981.

rendered his observations on this subject more complete in the introduction to natural philosophy mentioned above. He greatly extended the science of magnetism by his memoir in the present work, though he improved his knowledge at a later period respecting the laws of magnetic attraction, and in 1754 published,

3. 'Dissertatio Physica Experimentalis de Magneto,' 4to., Vienna.

4. In 1731 Musschenbroek published, at Leyden, in 4to., a Latin translation of the 'Saggi di Naturali Esperienze fatte nell' Accademia del Cimento,' which appeared at Florence in 1667. This work, valuable in itself, was rendered much more so in the translation by the numerous notes and additions of Musschenbroek, which contain an account of some new experiments on the dilatation of different bodies by heat, and also a description of a pyrometer which he had invented, and which was the first instrument of the kind which had been made.

Besides the above works Musschenbroek delivered several public orations, which have been published. He also wrote many papers on meteorology (a subject to which he paid considerable attention), some of which appeared in the 'Memoirs of the French Academy of Sciences,' and some in the 'Transactions of the Royal Society of London.' He published some observations on the Leyden phial, in the 'Memoirs of the French Academy of Sciences' for 1746; and a 'Dissertation on Barometers,' which was printed in the 'Memoirs of the Academy of St. Petersburg.'

MUSSELBURGH, an antient burgh of royalty in the parish of Inveresk and shire of Edinburgh. It is seated on the right bank of the Esk, near the confluence of that river with the Frith of Forth, and is about five miles east from the city of Edinburgh, with which communication is kept up by stage-coaches. The name is supposed to refer to a mussel-bank near the mouth of the Esk.

The monks of Dunfermline were the sole proprietors of all the territory comprised within the limits of the burgh, down to the time of the Reformation. After that event the property came into the possession of the king, James VI., by whom the lordship and royalty, together with the patronage of the church of Inveresk, were conferred upon his chancellor, Lord Thirlstane, from whom they have descended, by inheritance and purchase, to the family of Buccleuch, the present proprietors.

The high street is spacious, and contains many good houses, and the town is surrounded by gardens and villas. To the south is the suburb of Newbigging, which branches off to the church of Inveresk. On the opposite bank of the Esk is the suburb of Fisher-row, inhabited chiefly by fishermen, who supply the markets of Edinburgh during the greater part of the year. There is a stone pier, and the harbour, though small, is convenient. The management of the affairs of the town and suburbs is vested in a council of 18 members, of whom 10 are chosen from among the inhabitants of Musselburgh, and the rest from those of Fisher-row. The tanning of leather, making of sailcloth, hats, bricks, earthenware, &c., and the manufacture of fishing-nets by looms, constitute the principal business of the place. The salmon-fishery is carried on by 'stake-nets,' but is not very productive. A branch of the Commercial Bank of Edinburgh has been established, and elegant gas-works for the supply of the town have recently been erected.

Four bridges cross the Esk, two of which are of stone; the uppermost is of considerable antiquity; the new bridge is a handsome structure erected from a design by Rennie. In 1831 the population of the burgh and the rest of the parish of Inveresk was 8961. By the Reform Act, Musselburgh, Leith, and Portobello were erected into a parliamentary district which now returns one member.

For a description of Pinkie House, formerly the residence of the abbot of Dunfermline, and now the abode of Sir John Hope, bart., the reader is referred to Chambers's *Gazetteer of Scotland*, 8vo., 1832; from which, and the *Parliamentary Report on Scotch Burghs*, this notice is chiefly drawn. In the former work will be found many interesting particulars relative to the antiquities of the place and the historical events with which it is connected.

MUSSULMAN. [MOHAMMED.]

MUSTAPHA I., sultan of the Turks, succeeded, in 1617, his brother Ahmed I., but, a few months after, was deposed by the janizaries, who placed on the throne his nephew Othman. A few years later the janizaries revolted again, deposed Othman, put him to death, and recalled

VOL. XVI.—F

Mustapha to the throne in 1622. Soon after a fresh revolt deposed him again, and he was taken to the castle of the Seven Towers, in 1623, where he was strangled some years afterwards. (Knolles; Rycout.)

MUSTAPHA II., son of Mahomet IV., succeeded his uncle Ahmed II. in 1695. In the following year he defeated the Austrians at the battle of Temeswar, but was defeated in September, 1697, by Prince Eugene, near Zenta in Hungary. The seraskier in the mean time had reconquered Chios from the Venetians. By the peace of Carlowitz, in 1699, the sultan acknowledged the dominion of Venice over the Morea and several districts in Dalmatia, and gave up Azof to Russia, and Kaminiak to Poland.

Mustapha then withdrew to Adrianople, where he gave himself up to sensuality. His neglect of the public affairs caused a formidable revolt to break out in the capital, and the insurgents marched upon Adrianople, and at the same time offered the throne to Ahmed, Mustapha's brother, who took the title of Ahmed III. Mustapha died in confinement, it was reported by a natural death, six months after his deposition, in 1703.

MUSTAPHA III., son of Ahmed III., succeeded his cousin, Othman III., in 1757. He had been strictly confined in the seraglio ever since the deposition of his father in 1730, but after ascending the throne he showed considerable firmness of character, and effected several reforms in the administration. He engaged, in 1769, in an unlucky war against Russia, in which he lost the Crimea and Bessarabia, but did not live to see its termination. He died in 1774, and was succeeded by his brother, Abdul Hamid. His son Selim afterwards succeeded Abdul Hamid, in 1789. [SELIM III.]

MUSTAPHA IV., son of Abdul Hamid, was placed on the throne by the janizaries, who had deposed sultan Selim III., in May, 1807. Mustapha was ignorant, weak, and cruel, and a tool in the hands of the janizaries. Mustapha Bairactar, pasha of Rudshuk, and a friend of Selim, collected an army and marched to the rescue of his master. He entered Constantinople and attacked the seraglio, demanding that Selim should be restored to him. Mustapha gave him up, but it was only the dead body of Selim, for he had been strangled by order of Mustapha at the approach of his deliverers. Bairactar deposed Mustapha, and placed his brother Mahmood on the throne, in July, 1808. In the following November a revolt of the janizaries broke out, which lasted three days, and a great part of Constantinople was burnt down. Bairactar, Mahmood's grand-vizier, perished in the flames; and the janizaries, being triumphant, were shouting for the deposed Mustapha when Mahmood gave orders to put his brother to death. Mahmood was now the sole remaining prince of the Ottoman dynasty, and the janizaries submitted to him, after making their own conditions. A vivid account of these fearful transactions is given by Macfarlane in his 'Constantinople in 1828.'

MUSTARD. [SINAPI.]

MUSTE'LA. [WEASELS.]

MUSTE'LIDÆ. [WEASELS.]

MUSU'RUS, MARCUS. a native of the island of Candia, emigrated to Venice about the end of the fifteenth century, and taught Greek in that city with great success. He edited several Greek works, which were printed by Aldus Manutius. Afterwards he proceeded to Rome, where Leo X. showed him great favour, and nominated him bishop of Epidaurus in the Morea. He died at Rome in 1517. He published the first edition of *Athenæus*, printed by Aldus, Venice, 1514. Musurus published also the '*Etymologicum Magnum Græcum*,' folio, Venice, 1499, reprinted in 1549, in 1594, and 1710; and some Greek epigrams and other poetry, among others a poem in praise of Plato, which he prefixed to his edition of that philosopher's works, and which was translated into Latin verse by Zenobio Acciajoli, 'Carmen in Platonem,' Cambridge, 1797.

MUTE. [DEAF AND DUMB.]

MUTINA. [MODENA.]

MUTINY ACT is a series of regulations which, from year to year, are enacted by the British legislature for the government of the military force of the country.

Laws have, at various times, been made by the authority of the crown for the maintenance of discipline in the army when in garrison, on a march, and in the presence of an enemy; these have been briefly hinted at in the article on Military Law, and may be seen at length in Grose's

'History of the English Army' (vol. ii.); but the code which is now in use is one of the first-fruits of the Revolution in 1688. Previously to that event the crown, except during the civil wars and the subsequent protectorate, had, at least practically, the supreme power over the militia (that is, over the whole military force), which, with or without the consent of the nation, might be called out and employed as long as pay and quarters could be obtained for the troops. But the efforts then recently made to carry on a series of measures tending to the maintenance and extension of arbitrary power in the crown, joined to the increasing jealousy of the people for their civil and religious liberties, led the two houses of parliament to take the earliest opportunity, after the new king had been called to the throne, of expressing in some public act of legislation their authority over the regular troops of the nation; and an opportunity almost immediately presented itself, on a serious act of mutiny taking place in the army. The Royal Scotch and Dumbarton's regiments, under Marshal Schomberg, in their progress to the coast for the purpose of being embarked for Holland, being quartered at Ipswich, a large body of men, refusing to proceed to their destination, disarmed their officers, seized the military chest, and, with four pieces of cannon, began their march for Scotland. Being pursued by General Ginckel, with three regiments of Dutch dragoons, they surrendered at discretion; but, in consequence of this event, and on the spur of the moment, a bill was passed (April 12th, 1689) by which the army was put at once under the control of the law with respect to discipline, and under its protection with respect to pay and quarters.

The enactments of this bill were particularly directed against the crimes of mutiny and desertion, for which the bill was immediately required; but the Act itself begins by laying down as maxims that the raising or keeping a standing army in the country in time of peace, unless it be with the consent of parliament, is against law; and that no man can be forejudged of life or limb, or subject to any kind of punishment in any other manner than according to the established laws of the realm. It then states that it is judged necessary, by their majesties and the parliament, during the present time of danger and for the defence of the Protestant religion, to continue and augment the forces which are now on foot. Avoiding the acknowledgment that any power exists in the crown for the appointment of courts-martial, it authorises their majesties to grant commissions to general officers to assemble such courts for the purpose of trying and punishing such offences as mutiny and desertion. Provisions are also made that nothing in the Act shall exempt an officer or soldier from the ordinary processes of law; that it shall not concern the militia troops, and that it shall only continue in force till the 10th of November in the same year. The Act has ever since, with one exception, been annually renewed: after the bill which passed in April, 1697, for one year as usual, had expired, no other was passed till March, 1702; and, on a few occasions, the bill has been suffered to expire for several days before the following one received the royal assent.

The Mutiny Act has, with time, varied in many particulars from that which was first passed, but it has been uniform in all its principal points; such as the dependence of a standing army on the consent of parliament, and the subjection of military men to all the processes of ordinary law. Instead however of the original formula above-mentioned, by which the reason of keeping up a military force was expressed, the Act now asserts that it is judged necessary by the crown and parliament to continue a body of forces (the number being exactly specified) for the safety of the United Kingdom and the preservation of the balance of power in Europe. In all the Acts which passed down to the commencement of Queen Anne's reign the articles were few in number, and some of them were very ill defined; but, from that time, parliament seems to have intended to exercise a general legislative jurisdiction over the army. Many new articles were then inserted; others have since been added, as the want became apparent; and the Mutiny Act may now be considered as a good general code of law, in which are defined strictly but briefly all military offences of the higher class, and, as precisely as possible, nearly all those of minor importance. The military offences of the higher class, thirteen in number, consist in a commissioned or non-commissioned officer, or a soldier, exciting mutiny, or not using his best endeavours to suppress it; in misbehaving before an enemy; abandoning or deliver-

ing to the enemy any garrison, fortress, or post; compelling or using means to induce the governor of such garrison to do so; quitting his post without leave, or sleeping at his post; holding correspondence with the enemy, or entering into terms with the enemy without licence; striking a superior officer, or disobeying his lawful commands; and, finally, in deserting the service. For all these offences the Act prescribes 'death, or such other punishment as a general court-martial shall award.' A clause of the Act enumerates the military offences of minor importance which may be tried before a district or garrison court-martial: these consist in a non-commissioned officer or soldier wilfully maiming himself, or tampering with his eyes; malingering, or feigning disease; stealing government stores; stealing from an officer or a comrade; procuring false accounts; embezzling public money; and, lastly, in any fraudulent or disgraceful conduct. For these offences may be awarded corporeal punishment, imprisonment, forfeiture of the additional pay to which, for length of service, the individual might be entitled, and forfeiture of pension on being discharged. And in another clause it is stated that imprisonment, with or without hard labour, or solitary confinement, may be awarded by regimental courts-martial for drunkenness, or insubordination on parade or on the line of march.

Besides the above laws, which relate particularly to the discipline of the army, the Act defines the constitution and powers of courts-martial; it contains clauses relating to the enlistment of recruits, the issue of pay and marching money, the quartering of soldiers, and the supplying of carriages for the conveyance of troops and baggage. The Act moreover contains a repetition of the original clause in which it is declared that the ordinary course of law is not to be interfered with when a soldier is accused of a capital crime; and it states that a man cannot be taken from the service for a debt under 30*l*.

The Mutiny Act is declared to be applicable to all persons employed in the recruiting-service; to the forces of the East India Company while in any part of the United Kingdom, and till their arrival in the territories of the Company; to the officers and men employed in the service of the artillery and engineers; to the corps of sappers and miners; to the military surveyors and draughtsmen in the ordnance department; and to foreign troops serving in any part of the British dominions abroad. Its provisions are also stated to extend to the islands of Guernsey, Jersey, Alderney, Sark, and Man. In one of the clauses it is expressly mentioned that nothing in the act extends to any of the militia forces, or yeomanry, or volunteer corps in Great Britain or Ireland; it is understood however that its provisions are applicable to the corps of marines when on shore, and also to officers holding rank by brevet, though not to such as are on half-pay. An effort was made in 1749, when the bill was introduced as usual into parliament, to subject officers of this class to martial law, but the clause was abandoned by the minister. Before the union of Ireland with Great Britain there was a separate Mutiny Act for the former country, but now the same act applies to both. The officers and troops of the East India Company are subject to their own Mutiny Act, which however agrees exactly with that of the government forces.

Previously to the year 1750 the members of courts-martial were bound by an oath not to disclose the ground on which they gave their votes; but in that year the act was so far mitigated as to release them from such oath when required to give evidence in any court of justice or court-martial. The power of disclosing, in that case only, the votes or opinions given is implied in the forms of the oaths which are now taken by the judge-advocate and members of the court-martial, and which are printed among the schedules to which the act refers. The act of the same year also contains a clause, in which it is stated that no sentence pronounced by a court-martial, and signed by the president, shall be more than once revised; previously to that time a general-officer had power to order the revival of any sentence as often as he pleased, and thus he might retain in confinement a man who had been acquitted on a fair trial.

The gradual extension of the provisions of the Mutiny Act to those military offences which may be considered as secondary in the scale does not seem to have been noticed on behalf of the crown further than by the occasional reservation of its right to make Articles of War for the better

government of the forces, which is expressed in the acts passed during the reign of Queen Anne. In the first year of George I. this right of the crown was formally allowed; and the clause containing it has been repeated in all subsequent mutiny acts, with the provision that no person within the United Kingdom and British Isles shall be subject to transportation, or to any punishment affecting life or limb, for crimes specified in the Articles of War, except such as by the Mutiny Act itself are liable to the same punishments.

The Articles of War which are at present in force, and which have from time to time been promulgated, are divided into twenty-four sections. Many of these correspond exactly to clauses in the Mutiny Act; others, though relating to subjects in the latter, define the particulars of the crime and the punishment applicable to it with more precision; and there are articles which have no counterparts in the act. The first section of the Articles of War relates to divine worship, frequent attendance on which is prescribed, and punishments are awarded for profaning the places in which it is celebrated, as also for scandalous or vicious behaviour in a chaplain. The seventh section contains fifteen articles relating to quarrels and the sending of challenges; and the fourteenth contains twenty-one articles concerning the duties of troops in quarters or in the field. Many of these articles prescribe for the offence 'death, or such other punishment as a court-martial may award;' and two of them prescribe death, without leaving any discretion to the court. The first of the crimes here mentioned is that of doing violence to persons bringing provisions to the camp, and the other is that of ill-treating a person to whom a *safe conduct* has been granted; the army in both cases being on service in foreign parts. The fifteenth section settles the relative rank of officers in the regular army; and the twenty-second the rank of officers in the royal army and in that of the East India Company, when serving together. The twenty-third section appoints that officers and soldiers while employed on board any ships having a royal commission shall conform to the laws and regulations established for the government and discipline of the navy.

The above articles, being made by the crown as head of the army, or by the commander-in-chief, are to be obeyed as being the commands of a superior officer; but the writers on military law observe that the legality of the articles may itself become the subject of examination in a court-martial, whereas the Mutiny Act must be obeyed without inquiry. In this particular therefore the Articles of War are to be distinguished from the Act; and whatever case may occur the letter only of the law, as contained in the Act, must be followed in awarding the punishment due to a crime affecting life.

The bill on which are founded the Articles of War for the Navy was passed in the 22nd Geo. II., and thus consolidated all the laws previously made for the government of the ships and vessels bearing royal commissions, as also of the forces at sea. Among the offences which in the Act constitute the crime of mutiny, are the running away with the ship, or with any ordnance, ammunition, or stores belonging to the same; neglect of duty, joining in or using means to produce any mutinous assemblage of persons, uttering mutinous or seditious words, or concealing any mutinous intention, and striking an officer or disobeying his lawful commands. Of the thirty-six articles, nine relate to crimes for which the punishment of death, without discretion in the court-martial, is awarded; and there are twelve to which are assigned 'death, or such other punishment as the nature and degree of the crime shall be found to deserve.' Two of these were originally in the former class, and the qualifying clause was added in the 19th Geo. III. Except this alteration, none has been made in the navy act since it was passed.

MUTTRA. [HINDUSTAN, vol. xii., p. 219.]

MUZARAB, *i.e.* a Christian living under the sway of the Arabs. Various etymologies have been assigned to this word. Some pretend that it comes from the two words *Musa* and *Arab*, and that it meant in the first instance those Christians who capitulated to Musa at the time of the Conquest, and was an epithet by which the Mohammedans of Spain designated the Christian population of their cities; others derive it from *Mixti-Arabs*, *i.e.* Christians mixed with the Arabs. The absurdity of these etymologies need not be dwelt upon. Musa granted no capitulation to the Christians of Spain in general; and if the

Arabs had wished to give a distinctive name to the Christians subject to their rule, it is not likely that they would have employed two Latin words to designate a people living under their sway and in the midst of them. The real derivation of the word *Muzarab* is the Arabic *Mustarab*, afterwards corrupted into *Muzarab*, which means a man who tries to imitate the Arabs, or to become one in his manners, language, and habits; and who, although knowing Arabic, speaks it like a foreigner. This name was given by the Moors of Spain to all Christians living under Moslem jurisdiction in Cordova, Seville, Granada, Toledo, and other large cities.

But the word *Muzarab* is better known to us as connected with the ancient liturgy of the Goths, which governed the Spanish church down to the twelfth century, and was called 'Muzarabic office' (*Missal Muzarabe*), owing to its being preserved by the Muzarab Christians of Toledo during the time of their subjection to the Arabs. The fate of the Muzarabic liturgy is singular enough. Though involving the same doctrines, it differed widely from the other offices of the church; it also contained many hymns composed by St. Eugenius, St. Ildefonso, St. Julian, St. Leander, and other great luminaries of the Visigoths. To produce uniformity in this respect, and substitute the Roman for the Spanish missal, became the principal aim of the holy see. Early in the tenth century a legate arrived in the Peninsula from Rome, sent by John X.; but the report which he made on his return proved to be a favourable one, and by the decision of a council, held at Rome, in 924, the Muzarabic office was not only sanctioned, but even praised. Another attempt, made in 1064, under Alexander II., had a similar result. Again, in 1067, new legates were sent, with a positive injunction to insist on the abolition of the ancient service; but the Spanish prelates resisting the innovation, the subject was laid before a council assembled at Mantua, and the Spanish missal was once more declared Catholic and orthodox. Still the holy see persisted in its object. No artifice or intrigue was spared; and the court of Castile was divided into two hostile factions, one in favour of and the other against the introduction of the Roman ritual. In the perplexity occasioned by this dispute the two parties resolved to leave the decision to the judgment of God, and the expedient adopted to discover the divine will was this: two wild bulls were procured, the one to represent the Roman, the other the Muzarabic ritual, and, in the presence of the king and the court, were matched against each other. After a bloody conflict, the *Muzarabic* remained victor. But this result did not deter Gregory VII. In 1087 the trial was repeated: a champion was chosen on each side, and the decision left to the fate of arms; but again victory was in favour of the ancient liturgy. Fire was then tried, and both missals were cast into the flames; but, if we believe the archbishop Don Rodrigo, who was present at the ceremony, the success was still more signal; for no sooner did the Roman volume touch the fire, than it jumped out of the flames half burnt, while the Spanish remained for a considerable time in the midst of them without receiving the least injury. The object was at last gained by other means. Alfonso, the renowned conqueror of Toledo, was won over to the interests of Rome, and, after much trouble and difficulty, he prevailed on the prelates of the kingdom to receive the universal office; and from that moment the Muzarabic, although not publicly condemned, fell into disuse. There is however still a chapel in the cathedral of Toledo where mass is performed every day agreeably to the Muzarabic ritual. It was founded by Cardinal Ximenes de Cisneros.

(Aguirre and Catalani, *Collectio Magna Conciliorum*, tom. iv., p. 193, &c.; Masden, *Historia Critica*, lib. ii.; Mariana, *Historia General de España*, lib. ix., chap. xviii.; Flores, *España Sagrada*, tom. iii. p. 187; *Missale Gothicum secundum Regulam Beati Isidori Hispalensis*, Romæ, 1804.)

MYA. [PYLORIDEA.]

MYA'RIA, Lamarck's name for a family of Dimyarian conchifers, consisting of the genera *Mya* and *Anatina*. [PYLORIDEA.]

MYCALE. [IONIA.]

MYCENÆ, an ancient town and state in Northern Peloponnesus, founded, it was said, by Perseus, and which in the time of its king Agamemnon was the most powerful state of Greece, ruling over the greater part of the Peloponnesus, besides many islands. [AGAMEMNON.] The small kingdom of Argos was then subject to Mycenæ. But after the

death of Agamemnon and the extinction of the dynasty of Atreus, Argos gained the ascendancy over Mycenæ, which however appears to have maintained a sort of independence, being protected by Sparta, with which Argos was often at variance. During the Persian war, Argos did not send any assistance to the Northern Greeks, but the contingent from Mycenæ was present at Thermopylæ. This added to the grudge which Argos bore against Mycenæ for its pride of antiquity and independence, and after the end of the Persian campaign, while Sparta was distracted by intestine commotion and afflicted by the consequences of an earthquake, the Argeii, being joined by the people of Tegea and Cleonæ, attacked Mycenæ, which they took after a stout resistance, and razed to the ground, B.C. 468. Part of the inhabitants were made slaves; the rest emigrated to Ceryneia, Cleonæ, and some even to Macedonia. (Diodorus, xi.; Herodotus; Pausanias.) Mycenæ never rose from its ruins, but these ruins, contrary to the assertion of Strabo (*Cas.*, 372-377), who evidently had not visited the spot, were, and still are, of considerable magnitude, and very remarkable. In the time of Pausanias (ii., ch. 15, 16) they consisted of a great part of the walls, with the gate called that of the Lions, from lions being sculptured above it, said to be the work of the Cyclopes; the fountain called Perseia; and the subterraneous buildings of Atreus and his sons, in which their treasures were deposited. There were likewise to be seen the tombs of Atreus, Agamemnon, of his charioteer Eurymedon, of Electra, and others. 'But Clytemnestra and Ægisthus,' adds Pausanias, 'were interred at a little distance from the walls, being thought unworthy of burial where Agamemnon lay and those who were slain together with him.'

The ruins of Mycenæ have been visited in recent times, among others, by Lord Elgin, by Cockerell, Dodwell, and Leake. We extract from the latter an account of their present appearance. Mycenæ was built upon a rugged height in a recess between two commanding summits of the range of mountains which border the eastern side of the Argolic plain, about seven miles north by east of Argos. The Acropolis, the entire circuit of which is still seen, the ruined walls being in some places from 15 to 20 feet high, resembled many other fortresses in Greece, being built on the summit of a steep hill between two torrents. Its length is about 400 yards and its breadth about 200. The ground rises considerably within the enclosure; on the summit are the openings of subterraneous cisterns or granaries built of large irregular stones lined with plaster. It has a great gate at the north-west angle and a postern towards the north-east. The door-case is formed of two massive upright blocks of stone, covered with another which is 15 feet long, 4 feet wide, and 6 feet 7 inches high. Upon this stands a triangular stone of green basalt 12 feet long, 10 feet high, and 2 feet thick, upon the face of which are represented in bas-relief two lions standing on their hind legs, one on each side of a round pillar or altar upon which they rest their fore-paws. The pillar becomes broader towards the top and is surmounted with a capital formed of a row of four circles enclosed between two parallel fillets. Below the Acropolis, in the direction of the modern village of Kharvati, are the Spiliâ, or subterraneous chambers, known in the time of Pausanias by the name of the treasury of Atreus. The largest of these chambers, which is of a conical form, is about 50 feet in diameter at the base. The door-ways are ornamented with half-columns of a style resembling the Tuscan, and have some other peculiar ornaments, minutely described by Leake, who gives sections of the chambers, as well as a plan of the ruins of Mycenæ. (*Travels in the Morea*, vol. ii.) 'Nothing,' observes Leake, 'can more strongly show the extreme antiquity of the remains at Mycenæ than the singularity of some parts of them and their general dissimilarity to other Hellenic remains. We find nothing in Greece resembling the lions or the column before the gate of the great Thesaurus, or the treasuries themselves. In the military part of the architecture there is not so remarkable a difference between the Cyclopean ruins and the other most ancient ruins remaining in Greece. In the walls are found specimens of construction of various ages, but the later reparations are easily recognised from the oldest part, which is of the kind called Cyclopean; and with this exception, everything left at Mycenæ dates of the heroic æge. Notwithstanding this remote antiquity, the description of Pausanias shows that Mycenæ has undergone less change since he travelled than any place in Greece.'

MYCETES, Illiger's name for a genus of *Quadrupana*, consisting of the largest monkeys of America, remarkable for the powerful development of the organ of the voice. The species are, as the name implies, *Howlers*, and the horrible yells sent forth by these animals from the depths of the forests are described by those who have heard the mournful sounds as surpassingly distressing and unearthly. Humboldt and Bonpland heard the *Araguato*, one of the species, at the distance of half a league.

The genus is distinguished by a pyramidal head with the upper jaw descending much lower than the *cranium*, while the lower has its ascending *rami* very high, to afford room for the bony drum formed by a convexity of the *os hyoides*, which communicates with the larynx, and gives to the voice the enormous volume above alluded to. Humboldt gives the following as the external form of the drum in this genus.

Drum of Howling Monkey

The tail in this genus is prehensile, and the part applied by the animal when laying hold of a branch or other body is naked below; so that such portion must have a higher sensibility of touch. M. F. Cuvier gives the following as the dentition of the Howling Monkeys, from the *Alouate sauve*.

Teeth of Howling Monkey. (F. Cuvier.)

Mr. Swainson (*Classification of Quadrupeds*) observes that it is rather singular that M. F. Cuvier should not have

specially noticed the remarkable size of the canine teeth in the Howlers, which he says are uncommonly large; and adds that in a specimen before him when he wrote, they are nearly six times bigger than the cutting-teeth, a structure which at once separates this group from the genus *Cebus*. Facial angle about 30°.

Cuvier, in common with most other zoologists, places the genus at the head of the monkeys of the New Continent.

Mr. Gray (*Annals of Phil.*, 1825) places the form among the Anthropomorphous *Primates* in the second family (*Sariguidæ*), and as the sole genus of its first subfamily *Mycetina*.

M. Lesson arranges it between *Lagothrix* and *Cebus*.

Mr. Swainson makes *Mycetes* the first genus of the *Cebidæ*, the second family of his first order *Quadrupana*.

Mr. Ogilby observed in the summer of 1829 that two living individuals of *Mycetes seniculus* did not use the extremities of their anterior limbs for the purpose of holding objects between the finger and thumb, as is common among the *Quadrupana*; and he ascertained also on closer examination that the thumb, as it has generally been considered, was not in these animals opposable to the other fingers, but originated in the same line with them. Struck with the apparent singularity of the fact, he was induced to pay particular attention to all the other animals referred by zoologists to the *Quadrumanous* family to which he had access; and the continued observation of more than six years assured him that the non-opposable character of the inner finger of the anterior extremities, which he first observed in the specimens referred to, is not confined to the genus *Mycetes*, but extends throughout the whole of the genera of the South American monkeys, individuals of all of which had been seen by him in a living state. He remarked that a true thumb existed on the anterior limbs of none of them, and that consequently they have been incorrectly referred to the *Quadrupana* by zoologists generally. [CHEIROPODA; QUADRUMANA; SIMIADÆ.]

The habits of these animals are social, and most of them have thick beards. Their deep and sonorous yells are supposed to be a call to their mates; in short, to be a hideous love-song. In their gregarious habits and howlings they may be considered as bearing some analogy to the Gibbons of the Old World [APE, vol. ii., pp. 149, 150; HYLوباتES]; whilst their low facial angle has induced some to look upon them as representing the baboons of the antient continent.

Geographical Distribution of the Genus.—South America.

Example, *Mycetes Ursinus* (*Stentor Ursinus* of Geoffroy). The *Araguato*.

Mycetes Ursinus. Araguato.

Description, Habits, &c.—Length nearly three feet, without including the tail. Hair, which is longer than that of

Mycetes seniculus (*Mono colorado* of Humboldt), of a golden red, but the beard, which is of a deeper colour than the rest, is less bushy than it is in *M. seniculus*; and the circumference of the face where the hair is red is also paler. Humboldt states that the eye, voice, and gait denote melancholy. He saw young ones brought up in the Indian huts, which never played like the *Sagoins*. [JACCHUS.] Lopez de Gomara speaks of the *Araguato de los Cumanenses* as having the face of a man, the beard of a goat, and a grave demeanor. Fruit and the leaves of plants form their food. The females carry the young upon the shoulder. Humboldt counted above forty upon one tree, and he does not doubt that upon a square league of the wild countries frequented by them above two thousand may be found. They were in great abundance near pools of stagnant water shaded by the *Mauritia flexuosa*.

Localities, Brazil, Venezuela, &c.

MYCETO'PODA, or MYCE'TOPUS, a genus of conchifers with elongated valves, established by M. d'Orbigny, and referrible to the family NAIADÆ of Lamarck. M. d'Orbigny states that this genus perforates like the *Pholadæ*.

MY'CONOS, MICONI, one of the Cyclades, is situated east of Delos, from which it is separated by a narrow channel. It is about 10 miles in length and 6 in its greatest breadth. The island is mountainous and not very fertile: it produces some corn, wine, and cotton, but is deficient in wood. The population is about 4000, according to Thiersch. The men are good sailors, and the women are handsome. (Dapper, *Description des Isles de l'Archipel*; Spon; Porcacchi; Baudrand.) According to the antient fable, the Centaurs killed by Hercules were buried in this island, from whence came the proverb, 'to put all things under one Myconus,' applied to those who were apt to range under one class things naturally disparate. (Strabo, Casaub. 487.) The inhabitants, being poor in their own country, had the reputation of being parasites at other people's tables, and hence the proverb 'Myconian guests' for people who invited themselves. Miconi belongs now to the new kingdom of Greece.

MYCTE'RIA. [JABIRU.]

MYDA'US. [WEASELS.]

MY'GALE (Mammalogy). [SORICIDÆ.]

MYGDO'NIA. [MACEDONIA; MESOPOTAMIA.]

MYIAGRA. [MUSCICAPIDÆ.]

MY'LODON. [MEGATHERIIDÆ, vol. xv., p. 70.]

MYOCINCLA. [MERULIDÆ.]

MYO'PHONUS. [MERULIDÆ.]

MYOPORA'CEÆ are a natural order of plants, distinguished from Verbenacæ by little except the ovules being pendulous and the albumen more abundant. The plants referred to Myoporacæ are chiefly shrubs of little interest, inhabiting the Australian regions and other parts of the southern hemisphere. The most remarkable thing connected with them is the presence of cysts of oil in their leaves, which thence have a dotted structure. The White Mangrove, a shore plant rooting in mud, is a curious species. Brown describes its roots as creeping to a considerable distance, often curved above the ground as much as six feet before they fix themselves, and throwing up naked suckers out of the mud in great abundance, which look like shoots of asparagus.

MYOPO'TAMUS. [COYPOU.]

N.B. It is now ascertained that the Coy pou has a *ligamentum teres*. In October, 1838, Mr. Owen exhibited to the Zoological Society of London a preparation of that ligament in the animal, which he had received from Mr. Otley of Exeter, and read the following extract in a letter from that gentleman:—

'I have enclosed with this the thigh-bone, and the *scapula*, *clavicle*, and *humerus* of a Coy pou, which came into my hands after having been mauled by a stuffer of animals, and which had been preserved alive for some weeks by a gentleman of this place. I believe that not many opportunities have occurred of dissecting this animal in England; and as I found a difference between the specimen in question and that described by Mr. Martin, I thought the portions I have forwarded might be interesting to you, had it not fallen to you to dissect one of these animals. Mr. Martin states that the thigh-bone had no round ligament: you will see that there exists a well-developed one in this, as there also was on the other thigh-bone.'

Mr. Martin observed, that, on referring to his account of

the dissection of this animal, it will be found that he is so far from asserting it as a fact positively determined, that the *ligamentum teres* is wanting; that, after giving an account of the state of the *acetabulum* and head of thigh-bones as he found them, he adds, 'It would be desirable that another specimen should be examined before this peculiarity (namely, the absence of a *ligamentum teres*) is insisted on as an ascertained fact.' (Zool. Proc., 1838.)

Mr. Darwin (*Journal and Remarks*) notices this rodent as common among the broken islets of the Cynos Archipelago, where it exclusively frequents salt-water. The same author remarks that the *Capybara* or *Carpincho* [*Hydrochoerus*] occasionally frequents the islands in the mouth of the Plata, where the water is quite salt, though it is far more abundant on the borders of fresh-water lakes and rivers.

MYOSO'REX. [SORICIDÆ.]

MYOTHE'RA. [MERULIDÆ.] Cuvier remarks that M. Vieillot has changed this name into *Myrmothera*.

MYOXUS. [MURIDÆ.]

MYRA'FRA, Dr. Horsfield's name for a genus of birds arranged by Mr. Swainson as a subgenus of *Calendula*, in the subfamily of *Alaudinæ* of the family FRINGILLIDÆ.

MYRIAD (*μυριάς*), the Greek term for ten thousand, usually employed in our idiom for an indefinite but very large number.

MYRICA'CEÆ are plants constituting a very small natural order of apetalous Exogens, with separate sexes. The most essential part of their character is expressed by Endlicher in the following terms: 'Flowers unisexual. *Males*: Bractlets, 2; calyx, 0. *Females*: Hypogynous scales from 2 to 6; ovary one-celled, with 2 styles; ovule 1, erect, orthotropous; drupe one-seeded; seed erect; embryo without albumen; radicle superior.' In general their flowers are arranged in a manner similar to those of Betulacæ and Salicacæ, with which latter however they seem to have no real affinity. From Casuaracæ, curious New Holland trees, with jointed leafless stems, like those of Equisetum, they are only distinguished by their erect ovule and orthotropous seeds. They are common in the temperate parts of the world, especially in North America and the Cape of Good Hope. With us the only species is the *Sweet Gale*, a common fragrant bush inhabiting wet commons. They are all more or less fragrant and aromatic; and one of them is called *Myrica cerifera*, or the wax-bearing, from the drupes being covered with a waxy secretion, which may be readily separated and manufactured into candles; whence has arisen its popular name of *Candleberry Myrtle*.

Myrica arguta.

1, a male flower; 2, an ovary; 3, a drupe cut open vertically to show the erect position of the seed within it.

MYRISTICA MOSCHA'TA, Thunberg (the *M. officinalis* of Linn., but not of Martius), a tree native of the Mo-

ness Islands, especially of Banda, but cultivated in Java, Sumatra, and elsewhere in the East, and lately in Cayenne and several of the West India Islands. It yields nutmegs and mace, the best of which are produced in the first-mentioned islands. The fruit is of the size and form of a peach, and, when ripe, the fleshy part separates into two nearly equal halves, exposing the kernel surrounded by an arillus, the former being the nutmeg, the latter the mace. The arillus is red when gathered, but being sprinkled with sea-water and dried, it assumes an orange-yellow colour. It has a fatty, shining appearance, yet is horny and brittle. The odour is strongly aromatic; the taste aromatic, but sharp and acrid. It contains both a fixed oil (in small quantity) and a volatile oil. One pound of mace yields by distillation one ounce of the latter. The former is not an article of European commerce, and what is termed the *expressed oil of mace* is obtained from the nutmeg, and should bear its name. An inferior mace is obtained from various species of *Myristica*, especially the *M. tomentosa* and *M. officinalis* (Martius), which is a Brazilian tree. The properties of mace are similar to those of the nutmeg.

On the removal of the mace is seen the shell, of an oval or ovate shape, and of a dark brown colour, in which is contained the seed or nut. This is closely invested by an inner shell or coat, which dips down into the substance of the albumen of the seed, and gives it the character which is termed *ruminated*. Two or three gatherings of the nutmegs are made in the year, generally in July and August, in December, and in April. The third period yields the best nutmegs. The collected nuts are dried in the sun or by the heat of a moderate fire, till the shells split: they are then sorted and dipped in lime-water, to preserve them from the attack of insects. The nuts are about an inch long, of the size of a hazel nut, but with a furrowed or sculptured surface. Those of good quality should be heavy, each weighing on an average 90 grains. The internal aspect is marbled and of a fatty appearance. The substance is grey, but the veins, which are of a reddish-brown, consist of cellular tissue abounding in oil, and are the processes of the internal coat already mentioned. Odour agreeable, strongly aromatic. Taste warm, aromatic, oily.

Besides the fixed oil, it contains a volatile oil, lighter than water, being of the specific gravity of 0.831-47, while a spurious oil of nutmeg is only 0.871. By keeping it deposits a stearopten, or Muscat-camphor, called *Myristicine*. The solid or fixed oil consists of stearine and elaine, with a slight portion of volatile oil intermixed. Both the fixed and volatile are used for medical purposes. Of the fixed there are two varieties, the English and Dutch, of which the former is the better. It occurs in pieces, wrapped in leaves of the banana, weighing about three-quarters of a pound. When cut into, it has a uniformly reddish-yellow colour. The Dutch sort is in larger pieces, wrapped sometimes in leaves, sometimes in paper, and of a lighter yellow colour. Both are frequently adulterated. The volatile oil is also mixed with purified oil of turpentine. Nutmegs are frequently either digested in alcohol or distilled to abstract the volatile oil, and then passed off as fresh. Such nutmegs are lighter, and, when a hot needle is inserted, do not give an oily coating to it. Old, worm-eaten, or wild nutmegs should be rejected. Genuine or cultivated nutmegs are called female, to distinguish them from the male or wild nutmegs, which are the produce either of the *M. moschata*, Var. *sphenocarpa*, or of *M. tomentosa*, Thunb. These are longer, heavier, weighing generally 110 grains, and of inferior quality. They are more apt to cause narcotic symptoms, giddiness, &c., than the true sort.

Nutmegs and mace, from the large quantity of volatile oil, are decidedly stimulant, and when used in abundance, produce, by exciting the circulation, narcotic effects. In moderation they promote the appetite and assist digestion. Either when grated, or when a few drops of the volatile oil are put on sugar, they relieve flatulency and colicky pains. They are chiefly used as additions to other medicines, to quicken their action or cover their taste. They should be entirely abstained from by persons having a tendency to apoplexy. [AROMATICS.] The fixed oil is employed externally as a rubefacient in rheumatism and other diseases.

MYRISTICA'CEÆ are tropical, fragrant, aromatic trees, with an astringent juice, alternate, coriaceous, simple leaves, without stipules, and dioecious flowers. Of the flowers the males have monadelphous stamens, the females a single one-celled ovary, containing an erect seed, and both have

for calyx a tubular, coriaceous envelope, with from 2 to 4, usually 3, valvate teeth. Their fruit is a two-valved succulent capsule, containing a single seed enveloped in an aril, and consisting of ruminated albumen, abounding in a powerful and agreeable aromatic secretion; the embryo is very small, and placed in a cavity at the base of the albumen.

The order is nearly allied to *Anonaceæ*, from which however it differs very remarkably in the total want of a corolla, and in the reduction of the number of carpels to one. To station it in the artificial division of apetalous Exogens, as is usually done, is to violate every principle of natural classification.

The *Nutmeg* of the shops, which is the seed of *Myristica Moschata*, is the only product of the order employed officinally. [MYRISTICA MOSCHATA.] Other species bear fruit that may be employed as a substitute, but they are all inferior to the real oriental *Myristica*. Three genera of the order have been distinguished, namely, *Myristica*, inhabiting the tropical woods of Asia and America, with *Knema* and *Pyrrhosa*, both confined to the tropics of India.

Myristica Aromaticum.

1, a calyx; 2, the monadelphous stamens of a male flower; 3, the pistil of a female flower; 4, the seed of the nutmeg, enveloped in the mace or aril; 5, a vertical section of the seed, showing the ruminated albumen and the small embryo at its base.

MYRMECOBIUS. [MARSUPIALIA, vol. xiv., p. 456.]

MYRMECOPHAGA. [ANT-EATER.]

N.B. In November, 1831, a letter from Sir R. Ker Porter was read to the Zoological Society of London, giving a detailed description of the *Myrmecophaga jubata*, Lam., under the name of *Orso Hormeguero*, or *Ant-Bear*, accompanied by a drawing of the full-grown individual from which the description was taken. The writer was particularly struck with the difference in structure which exists between the fore and hinder feet, and with the curious disposition of the parts of the former in the act of progression, which has been slightly referred to by D'Azara. In the figure (in which the animal is represented in a standing position) the claws of the fore-feet do not project in front, but are doubled backwards under the wrist, evincing a mode of progression in the *Myrmecophaga* similar to that described by Colonel Sykes as existing in the species of *Manis*. [PANGOLIN.] To receive the additional length and point of the middle toe, according to Sir R. Ker Porter, a protruding mass of hard flesh stood out from the wrist, wherein was a cavity destined for the reception of the unguled elongation when the animal was in a standing position, and as, from the awkward formation of the fore-feet, quickness of motion becomes impossible, these animals may be caught in the smallest open space (when seen) with little difficulty.

FOSSIL MYRMECOPHAGE.

See the article MEGATHERIIDE, vol. xv., pp. 69, 72, and 73.

MYRMOTHE'RA. [MYOTHE'RA.]

MYROSPERMUM, or *Myroxylon Peruiferum*, yields the balsam of Peru, and probably also the balsam of Tolu, though this is generally referred to *M. Toluiferum*. It is doubtful whether these are distinct species, or the same tree slightly differing, from circumstances connected with the place of growth. The two kinds of balsam are so similar that there is no difficulty in believing the differences between them to be owing to a difference of age in the individual trunk from which each was obtained, or to differences in the mode of extraction or of preparation.

Balsam of Peru occurs in two states; one called the white, the other the black. The former results either from spontaneous exudation from the bark, or from incisions made in it; it is also found in the inside of the seed-vessel wrapping the seed. At first it is liquid, of the consistence of recent honey, of a light-yellow colour, of an agreeable odour, resembling vanilla, and a somewhat acrid, bitterish, but aromatic taste. Its specific gravity is less than that of water. Heated in a platinum spoon it burns with a white smoke (which reddens litmus paper), and leaves no residual ash. It is completely soluble in alcohol, and also in æther, except some white material which separates from it. It contains much benzoic acid. By distillation with water it yields a volatile oil. By exposure to the air it hardens, and is then termed *Opobalsanum siccum*, which must not be confounded with the true *Opobalsanum*. [BALSAMODENDRON.] Balsam of Tolu is also sometimes called *Opobalsanum*.

Black balsam of Peru is stated to be procured by boiling the resinous bark of the trunk and branches of the tree. Th. Martius conjectures that it is procured by subjecting these parts and the pods to a kind of dry distillation, or *distillatio per descensum*, similar to that by which tar is obtained from pine-trees. This balsam has the consistence of syrup, but does not solidify with age, is scarcely tenacious, of a blackish-brown colour, and not transparent, somewhat oily to the touch, odour agreeable, balsamic, resembling vanilla, taste acrid, balsamic, bitterish, and enduring. Scarcely igniting when in contact with flame; not yielding by distillation with water any volatile oil, and not perfectly soluble even in absolute alcohol. Its chief constituents are the oil, which cannot be termed volatile, two kinds of resin, and benzoic acid.

Both sorts are extensively adulterated, chiefly with turpentine, copaiva, or volatile oils. One test of genuine black balsam is, when 1000 parts of balsam saturate 75 parts of pure crystallized carbonate of potass.

Balsam of Tolu flows from incisions in the tree, and is of the consistence of a strong turpentine. It is sent to Europe in earthenware jars or tin cases. It becomes tenacious with age, and in cold weather may be fractured, but melts again in summer, or with the warmth of the hand. It is of a yellow or brownish colour, transparent, with the taste and odour of the white balsam of Peru. This balsam likewise is much adulterated. All the three forms possess the ordinary qualities of balsamic substances, and, either in the state of syrup or tincture, are employed where such medicines are indicated. These have been already detailed [BALSAMS], and it is only necessary to state here, that their fragrance renders them pleasant adjuncts to cough mixtures, when the acute or active stage is passed, while the difference of price is the only reason for preferring one kind to another.

MYRRH. [BALSAMODENDRON.]

MYRSINACEÆ are chiefly subtropical plants of the Exogenous class, so nearly the same in their fructification as the Primulaceous species of northern climates, that scarcely any valid mark of distinction can be found between them. The indehiscent fruit in *Myrsinaceæ* is chiefly relied upon for the means of separating them. The general appearance of the two orders is however widely different; *Primulaceæ* consisting of herbs with no development of woody matter, while *Myrsinaceæ*, in all cases yet observed, are shrubs or trees. Many of the species have handsome foliage and gaily-coloured flowers, on which account they are frequently met with in gardens, but they are of no importance for useful purposes. *Ardisia* and *Jacquinia* are the two commonest genera.

MYRTACEÆ are polypetalous Exogens, forming a very extensive and important natural order of plants, exclusively inhabiting warm countries, and in all cases either shrubs or trees; an herbaceous form of the order is unknown. The

most northern station of the species is the south of Europe, where the common Myrtle grows apparently wild. If this plant is taken as the type of the order, it might be said to consist of aromatic plants with opposite leaves, dotted with transparent oil-cysts, bearing icosandrous monogynous polypetalous flowers, succeeded by an inferior succulent fruit; but this is the character rather of a section of the order, than of *Myrtaceæ* considered as a whole. In this division are however included nearly all the species employed for the use of man. Among the table-fruits of the tropics are the *Guava*, yielded by different species of *Psidium*; the *Rose Apple* and *Jamrosade*, produced by *Eugenia Malaccensis* and *Jambos*; of spices, *Cloves* are the flower-buds of *Caryophyllus Aromaticus*; and *Allspice* is the dried berries of *Eugenia Pimenta*: all which are obtained from plants belonging to the same section as the common Myrtle; the aromatic fruits of that plant were indeed used as a spice before cloves and allspice became common.

The deviations that take place from the typical structure of the order consist partly in the fruit being dry and capsular, instead of fleshy and indehiscent, and partly in the organization of the interior of the fruit being reduced to a state of great simplicity; besides which the leaves are often alternate instead of opposite. Some of the species have no corolla, and there is in many cases a very singular tendency to consolidate the floral organs of all kinds.

The species with capsular fruit are principally found in New Holland, where, in the form of *Eucalyptus* and *Leptospermum*, they constitute one of the most striking features of the vegetation. [EUCALYPTUS.] These plants abound in a powerful astringent secretion, chiefly found in their bark, on which account they are found valuable for the tanner's purposes; while the aromatic principle is also abundantly secreted in other cases, as, for example, in *Melaleuca Cajeputi*, from which the green stimulating oil *Cajepul* is procured.

It is more particularly among these species that anomalous conditions of the floral organs occur. In *Eucalyptus* there is no corolla, and the segments of the calyx are so completely united to each other as to form a fleshy cap, thrown off by the flowers when the time arrives for extricating the stamens. In *Melaleuca*, *Calothamnus*, and several others, the stamens are united to each other by their filaments, so as to form showy, petal-like, fringed expansions; and in *Eudesmia* the petals themselves are united into a cap, thrown off upon the expansion of the flower.

Psidium pomiferum,

1, a flower; 2, a stamen; 3, a transverse section of the ovary.

The most singular form of *Myrtaceæ* is that which derives its name from a New Holland plant, called *Chamaelaucium*, in which the interior of the ovary contains but one cell, with from two to five ovules rising up obliquely from its

base. These plants are all small heath-like shrubs, having in the majority of cases the edge of the petals prolonged into long and delicate fringes. Such plants are extremely abundant on the west coast of New Holland, where they form one of the most striking characters of the Flora.

The *Pomegranate*-tree is a most anomalous form of *Myrtaceæ*, remarkable for an almost total absence of transparent dotting, and consequently of aromatic qualities, and having a fruit consisting of two whorls of carpels, compacted together into an inferior ovary, the interior of which becomes altered and distended so much after the flower has fallen off, that the fruit is nothing but a collection of cavities filled with seeds, and having no apparent relation to each other.

MYRTEA, Dr. Turton's name for a genus of conchifers founded on the *Venus spinifera* of authors.

MYRTLE, the *Myrtus communis* of botanists, is a bush with evergreen opposite leaves, which, when seen by transmitted light, appear as if pierced with small holes, in consequence of their containing a great number of little reservoirs of a transparent aromatic oil; the flowers are white, and produced in axillary clusters; they have an inferior ovary, numerous stamens growing from an epigynous disk, a single style, five petals, and are followed by a small oblong succulent fleshy purple fruit.

The Myrtle is apparently wild along the south coast of France, and in Sicily it occupies large tracts of country; but it does not appear to be really a European plant, but a native of Persia. In this country the Myrtle is seldom able to bear the winter, except when planted in front of a south wall, and protected from severe weather. In the Isle of Wight, some stations along the south coast of England, and in many of the mild parts of Ireland, it however becomes an ornamental bush, without requiring any protection whatever.

For a detailed account of the Myrtle, see Loudon's 'Arboretum Britannicum,' vol. ii., p. 962.

MYRTUS PIMENTO. [PIMENTO.]

MYSICA, Dr. Turton's name for a genus consisting of certain species of the genus *Unio*. Type *Unio Pictorum*.

MY'SIA, the name of an ancient division of Asia Minor, forming the north-west extremity of that peninsula, and bounded on the north by the Propontis, on the west by the Hellespont and the Ægean Sea, on the south by Lydia, from which it was divided by the mountains which separate the valley of the Caicus from that of the Hermus, and on the east by the river Rhyndacus, which divided it from Bithynia. On the south-east the high land forming the interior of Mysia joins the central table-land of Phrygia towards the town of Azani. But the respective boundaries of Mysia, Bithynia, and Phrygia appear not to have been very clearly defined. (Strabo, b. xii.) Herodotus (vii. 74, 75) says that the Mysians were a Lydian colony; yet he adds, that the Bithynians affirmed that their ancestors had been driven from their former seat on the banks of the Strymon by the Teucrians and the Mysians. Strabo (vii., p. 295, Casaub.) says that the Mysi (Mœsians) and Getæ, who lived on the banks of the Ister, were considered by the old Greek writers to be Thracians, and that 'the Mysians of Asia, who dwelt between Phrygia, Lydia, and Troas, were a colony of the Mysians of Thrace.' [MÆSIA.] And in b. xii. he says that 'the Mysians of Asia were considered to be Lydians by some, and Thracians by others.' This may mean that Thracian immigrations became mixed with the previous inhabitants of Lydian race. Repeated Thracian immigrations are mentioned as having taken place before and after the Trojan war. Then came the Æoliâns, who occupied the maritime coast from the Hermus to the Æsepus, and built their cities there. [ÆOLIANS.] Geographers distinguished Æolia and Troas from Mysia. [TROAS.]

Mysia became subject to the Lydian monarchy, after the fall of which it formed part of one of the satrapies of the Persian empire which included also Lydia. It was afterwards in succession under the Macedonians, the kings of Pergamus, and the Romans. Under the Romans it formed part of the province called 'Asia.' Its principal towns were PERGAMUS, CYZICUS, ABYDOS, LAMPSACUS, ADRAMYTTIUM, and MILETROPOLIS, near the lake of the same name. The principal rivers of Mysia were the Caicus in the south and the Æsepus in the north; the smaller ones were the Evenus and the Granicus. The country now forms part of the Turkish province of Anadolî.

(Leake's *Asia Minor*; Charles Fellows, *Journal written during an Excursion in Asia Minor in 1838*, with an account of the remains of Assos and other towns of Mysia and Troas.)

P. C., No. 962.

MYSIS, the generic name for the *Opossum Shrimpe*. [STOMAPODES.]

MYSORE, a large province in the southern part of the peninsula of India, lying between 11° 40' and 15° N. lat., and between 75° and 78° 30' E. long. Its greatest length from south-east to north-west is 210 miles, and its average breadth about 140 miles. The province is bounded on the east by the Eastern Ghauts, on the south by Coimbatore and Salem, on the west by the Western Ghauts, and on the north by the southern Maharatta country and districts formerly ceded to the English by the rajah of Mysore. The province consists of elevated table-land, with many lofty hills, among which rise several of the rivers that traverse the low countries; the chief of these rivers are the Caveri, the Vadavati, the Bhadri, the Arkanati, the Pennar, and the Palar or Palaur. The level of the province varies from 1830 to 2800 feet above the sea. Sevagunga, the highest mountain in Mysore, in 13° 10' N. lat., 77° 20' E. long., is 4600 feet high. Owing to the general elevation of the country, the climate is temperate and healthy. The clouds are much broken by the Ghauts which bound this territory to the east and west, and although there are frequent heavy showers in the table-land of Mysore, they are seldom of long continuance.

Mysore is governed by a native prince or rajah, with whom the English have a subsidiary treaty, concluded in 1799, after the defeat and death of Tippoo. On this occasion Coimbatore, Canara, and Soonda were transferred to the English government. The territory which remains to the Mysore rajah is divided into three districts or subayenas, viz. Patana or Seringapatam, Nagara or Bednore, and Chatraçul. The first-named of these districts is by far the largest, and comprehends ninety one subdivisions; Nagara has nineteen, and Chatraçul has thirteen subdivisions: each of these subdivisions is superintended by a soubahdar. The situation of the natives who are of the superior class is upon the whole much better in Mysore than it is in the British presidencies, because the whole administration, civil and military, rests with them, instead of being vested in Europeans. In the Company's territories the natives, whatever be their station, with only few exceptions, have a master in every European, while in Mysore the governing class owns only one master, the rajah. But the lower orders of the people are, on the contrary, by no means so well off as in the British territory, the Mysore government being most oppressive to them. The province is, upon the whole, thinly inhabited. In 1804, the latest time as to which we have any statement upon that subject, the number of families was 482,612, and of individuals 2,171,754. Several times during the latter half of the eighteenth century the country was overrun by hostile armies, and ravaged to such a degree that many districts, which had previously been well peopled, were wholly deserted. During the present century the inhabitants have enjoyed a greater degree of security, and several good roads have been opened. The dwellings of the peasants, although built of mud, are more neat and commodious than in most parts of India. The population is supposed to have increased since 1804 under the improved state of things.

The rajahs of Mysore were for many years actively opposed to the extension of the British power in India. Hyder Ali Khan, who began his military career in 1749, and who assumed the sovereign power in 1760, invaded the lower Carnatic in 1780, and desolated the country to the very gates of Madras. His further progress was arrested by Sir Eyre Coote, but, being assisted by the French, he was able to continue the war until December, 1782, when he died, and was succeeded by his son Tippoo, who continued the war until the beginning of 1784. Peace being then concluded between France and England, he lost the assistance of his European allies, and concluded a treaty with the English. In 1790 Tippoo attacked the rajah of Travancore, whom the English were by treaty bound to assist, and a war ensued, which lasted until March, 1792, when a peace was concluded by Lord Cornwallis under the walls of Seringapatam, by the terms of which Tippoo was deprived of nearly one-half of his dominions. With the hope of recovering this territory, he endeavoured in 1798 to excite disaffection among the native subjects of the British, and sought the alliance of the French republic and of the sovereign of Caubul. In February of the following year the British army entered Mysore, and in April laid siege to Seringapatam, which fortress was taken by storm on the 4th of May

when Tippoo was killed. Upon this event the English government placed on the throne the Maha Rajah Krishna Udiaver, then a child only six years old, a lineal descendant of the antient rajahs of Mysore, whose dynasty had been displaced by Hyder Ali. Purneah, who had been one of Tippoo's ministers, was at the same time entrusted with the government, and a treaty was concluded whereby the English undertook to maintain a military force for the defence of Mysore against all invaders, for which service an annual payment was to be made to the Company's government of seven lacs of pagodas (280,000*l.*). This treaty has continued in operation to the present time. The Rajah Krishna Udiaver, having been brought up under European guardianship, usually dispenses with much of the ceremony that is commonly observed at the courts of the native princes of India, but on state occasions he goes abroad with much pomp in a carriage capable of holding thirty persons, and drawn by elephants.

The town of Mysore, the antient capital of the province, was about 1770 superseded in this respect by Seringapatam, but it again became the seat of government on the fall of that fortress in 1799. It is situated in 12° 19' N. lat. and 76° 42' E. long. It occupies a considerable space of ground, and is enclosed by a wall. The streets are laid out with some regard to regularity, and the houses, which are for the most part whitened, are intermingled with temples and trees. The fort is separated from the pettah, or town, by an esplanade, and, besides the rajah's palace, contains the dwellings of the principal merchants and bankers.

MYSTERY (*μυστήριον*). In the religion of the Greeks there were rites and doctrines which were kept secret from the mass of the people and only communicated to a chosen few. These things were called *mysteria*. This word has been adopted by the writers of the New Testament, who apply it to things which are kept secret for a time and afterwards revealed, or to things which are kept secret from some persons though they may be revealed to others, or lastly, to things which, though not kept perfectly secret, are only made known by symbols. Thus the term answers pretty well to the English word *secret*. It is frequently opposed to words which imply *discovery*. Thus the New Testament writers speak of a *mystery revealed* (*μυστήριον ἀποκαλυφθῆναι*) or *brought to light* (*φωτῶθῆναι*) or *made known* (*γνωρισθῆναι*). They call the gospel a mystery, as being a system which had formerly been kept secret, but was now revealed to them, and through them to the world (*Rom.* xvi. 25, 26; *1 Cor.* ii. 7-10; *Ephes.* iii. 9; vi. 19; *Coloss.* i. 26, 27; ii. 2; iv. 3). So Christ said to his disciples, 'To you it is given to know the mysteries of the kingdom of heaven, but to them it is not given' (*Matt.* xiii. 11; *Mark.* iv. 11; *Luke.* viii. 10), that is, you are permitted to understand those doctrines which are at present kept secret from others. But afterwards they were commanded to proclaim these secrets to the world (*Matt.* x. 26, 27; xxviii. 19, 20; *Mark.* iv. 22; xvi. 15; *1 Cor.* iv. 1). It is also applied to individual facts or doctrines. Thus the admission of the Gentiles to the privileges of the Christian religion is called a mystery, because it had never before been understood by the Jews (*Rom.* xi. 25; *Ephes.* iii. 3-5). The fact that the living will undergo a change at the resurrection is also called a mystery (*1 Cor.* xv. 51). To the same class belongs the only passage in which the word might perhaps be understood to imply something not merely *unknown* but actually *incomprehensible*, namely, *1 Tim.* iii. 16, 'Great is the mystery of godliness (or religion, *εὐσεβείας*); God was manifest in the flesh,' &c., which means, 'Great is the secret which our religion discloses—God was manifest in the flesh,' &c. In *2 Thess.* ii. 7, 'the mystery of wickedness' is 'wickedness which is already *secretly* at work in the church,' and of which the *revelation* is predicted in ver. 8 (*τὸ γὰρ μυστήριον ἤδη ἐνεργεῖται τῆς ἀνομίας, . . . καὶ τότε ἀποκαλυφθήσεται ὁ ἀνομος*). The word is used in rather a singular way, but still with the same meaning, in *1 Cor.* xiv. 2, where it is said of a person who speaks in an unknown tongue, 'in the spirit he speaketh mysteries,' that is, he communes with God in language unintelligible to those around. We have examples of the use of the word to denote the secret meaning of a figure or symbol in *Ephes.* v. 2; *Rev.* i. 20; xvii. 5, 7. This general signification of a *secret* is the only one in which the word *mystery* is used in the New Testament. In the Septuagint its meaning is the same (*Daniel.* ii. 18, 19, 27, 28, 29, 30, 47; iv. 9). The early ecclesiastical writers applied the word to solemn religious rites, and this is prob-

ably the reason why *μυστήριον* is translated in the Vulgate by *sacramentum*. In modern usage a *mystery* is a doctrine which is incomprehensible by the human understanding, or which appears to involve facts irreconcilable with each other. Thus the doctrine of the Trinity, the union of the divine and human nature in the person of Christ, the consistency of God's perfect foreknowledge and fixed plan of providence with the free-will of man, are spoken of as mysteries. Not that these doctrines are considered as self-contradictory; for if such contradiction be proved, the doctrine is no longer mysterious but impossible. We believe that they can be explained, though our mental powers are not strong enough to explain them. It is worthy of remark that mysteries (in the modern sense) are found in philosophy and natural religion as well as in revealed religion.

(Campbell *On the Gospels*,—*Dissertation on the word μυστήριον*.)

MYSTERIES, or MIRACLE-PLAYS. [ENGLISH DRAMA, p. 426.]

MYSTICS, a Christian sect which arose in the second century, and whose principles are probably to be traced to the philosophy of the Christian Platonists of Alexandria, Ammonius Saccas and his followers. They first appear as a distinct sect in the fourth century, under the teaching of a Grecian fanatic, who gave himself out to be Dionysius the Areopagite, one of St. Paul's converts (*Acts.* xvii. 34), and who is generally regarded as the founder of the sect of the Mystics.

Adopting the Platonic doctrine, that the human soul is a portion of the divine nature, they held that every man has a divine light within him which is sufficient for his guidance to present and future happiness, but that this light is obscured by the grossness of our material bodies and by the influence of external objects. To shake off these evil influences, and thus to keep the soul in as close connection as possible with its divine original, they considered to be the essence of religion; and this they endeavoured to accomplish by constant meditation on spiritual objects, secret communion with God, and an austere discipline of the body. As they considered everything external to the soul as only calculated to obscure the divine light within, they set no value upon accurate systems of doctrine nor upon religious observances as contributing to the advancement of religion. One of their leading doctrines was that real love to God must necessarily be disinterested, that is, uninfluenced by the expectation of reward or punishment.

The austere lives and apparent devotion of the Mystics caused their principles to spread extensively in the Eastern church. In the ninth century they were introduced into the West by a present which the Grecian emperor Michael Balbus made to Louis le Debonnaire, of the works of Dionysius the Areopagite, which however are undoubtedly spurious. The book was translated into Latin by the order of Louis, and the principles contained in it soon found many followers. In the thirteenth century the Mystics were the most formidable opponents of the schoolmen, and gradually many eminent men who were disgusted with the puerile conceits and lifeless religion of the latter, attached themselves to the Mystics (among these may be mentioned Thomas-à-Kempis); and just before the Reformation, nearly all the friends of spiritual religion were included in this sect. In the seventeenth century the doctrines of Mysticism were advocated by a Spanish priest, Michael de Molinos, from whose representations of religion, as consisting in the perfect tranquillity of a mind always engaged in communion with God, the sect obtained the new name of *Quietists*. At the end of the same century attention was called to Mysticism in France by the writings of Madame Guyon, whose sentiments were opposed by Bossuet and defended by Fénelon.

(Mosheim's *Ecclesiastical History*, and the works quoted by him.)

MYTHOLOGY (*μυθολογία*). The mythology of a people may be said to consist of those legends and traditions which have been, at some period or other, usually believed by the majority of the nation, but which cannot be regarded as historical truths on principles of sound criticism. The term therefore is not confined to the religious systems of the Pagan nations; it includes everything that has been an object of popular belief, not merely respecting the origin, attributes, and adventures of the gods, but also concerning the early heroes, migrations, and exploits of a people. The historical inquirer has frequently great difficulty in deter-

mining at what time the mythology of a nation may be said to cease, and its history to begin; and in fact it is impossible to determine the exact time, since the transition from mythology to history must be necessarily gradual; and many traditions, which appear at first sight entirely mythological, may, upon further examination, be proved to contain some great historical truths. The scepticism which calls upon us to reject as mythological everything in the early history of a people which appears to us extraordinary and unaccountable, is as little worthy of respect as the credulity which requires us to believe everything that has been recorded respecting the exploits and adventures of the early heroes of antiquity.

Though a mythological event may be fictitious, it appears that mythology differs from fiction or fable, in having been once generally believed by a people as an account of events which actually took place. That which is regarded by us as mythological, may therefore be considered by another people as an historical or religious truth; and in the same manner as the exploits and adventures of the gods and heroes in the Mahābhārata and Rāmāyana are viewed by us as mythological, so the exploits and adventures of the Israelites in the conquest of Canaan, in many respects as extraordinary and wonderful as those of the gods and heroes in the great Hindu poems, may be looked upon by the Brahmans as the mythology of the Christian religion.

On few subjects perhaps has more learning been thrown away, than in investigating the history and origin of the mythology of the principal nations of antiquity. Among the various theories that have been proposed on this subject, the four following appear to have met with the greatest number of supporters:—

1. *The Scriptural theory*, according to which all mythological legends are derived from the facts contained in the narratives of Scripture, though the real facts have been disguised and somewhat altered. The supporters of this theory maintain that all mythic personages may be found in the Scripture; that Deucalion is only another name for Noah, Hercules for Samson, Arion for Jonah, &c. This hypothesis has been supported with a profusion of learned ingenuity and absurdity by Jacob Bryant, in his 'Analysis of Antient Mythology,' who saw the patriarchs in every minute event of heathen mythology. Sir William Jones, in his dissertations, in the 'Asiatic Researches,' on the Hindu gods, applied Bryant's arguments to the Hindu mythology, though his good sense preserved him to a great extent from the follies which distinguish Bryant's work. Most of the Christian Fathers maintained that the principal deities in the antient mythology were in reality devils, and that their worship and history had been taught to mankind by the devils themselves. This theory has been adopted by Milton, in the first book of his 'Paradise Lost,' in those lines beginning with—

* First Moloch, horrid king, besmeared with blood
Of human sacrifice, and parents' tears; &c.

2. *The Historical theory*, according to which all the personages mentioned in mythology were once real human beings, and the legends and fabulous traditions relating to them are merely the additions and embellishments of later times. This mode of accounting for the origin of mythology appears to have been in some measure adopted by the Egyptian priests, and was maintained by many of the Greek writers. The Egyptian priests told Herodotus (ii. 144) that their deities originally reigned upon the earth, and that the last who reigned was Orus, the son of Osiris, whom the Greeks called Apollo. An instance of this mode of accounting for the origin of mythology may be seen in the explanation which the Egyptian priests gave to Herodotus of the myth respecting the foundation of the oracles of Dodona and Ammon, according to which the two black pigeons which came from Thebes, in Egypt, and commanded that the oracles should be established, were in reality two Egyptian priestesses, who had been carried away from Egypt by the Phœnicians, and brought respectively to Dodona and the Libyan desert. Livy also attempts, in a somewhat similar manner, to give an historical explanation of the myth respecting the suckling of Romulus and Remus by a she-wolf (i. 4).

The author of the 'Book of Wisdom' imagines that the heathen deities were originally human beings, and accounts for their becoming objects of religious adoration in the following manner: 'For a father afflicted with untimely mourning, when he hath made an image of his child soon

taken away, now knoweth him as a god, which was then a dead man, and delivered to those that were under him ceremonies and sacrifices.—Whom man could not know in presence, because they dwelt far off, they took the counterfeit of his visage from far, and made an express image of a king, whom they honoured, to the end that by this their forwardness they might flatter him that was absent, as if he were present' (xiv. 15, 17).

Among the Greeks this theory was adopted by Ephorus, and was carried to a great length by Euhemerus, in his 'Sacred History' (ἱερὰ Ἀναγραφὴ), fragments of which have been preserved by Diodorus Siculus and Eusebius. Some of the Christian fathers also adopted this view of mythology, and employed it with considerable success in their controversies with the supporters of the Pagan religion. Among the moderns this theory has been maintained by Banier, in his 'Mythology and Fables explained by History.'

3. *The Allegorical theory*, according to which all the myths of the antients were allegorical and symbolical, and contained some moral, religious, or philosophical truth, which was originally represented under the form of an allegory, but became, in process of time, to be understood literally. This view of mythology was first introduced into Greece by the Sophists, and an example of it is given by Protagoras in his explanation of the myth of Prometheus. (Plato, *Protagoras*.) In later times this view of mythology was adopted by the New Platonists in their controversies with the Christians; and their object was to show that the antient mythology, under the garb of allegory, taught all the important duties and doctrines of morality and religion. Thus the view of mythology given by Homer and Hesiod, which was considered by Plato, in his dialogues on the Republic, as mischievous and dangerous, because it attributed human passions and feelings to the gods, occasioned no difficulty with the later Platonists. There is a work of Proclus, of which the curious in such matters may find a translation in the first volume of Taylor's translation of Plato, written for the express purpose of proving, in opposition to Plato, that the mythology of Homer and Hesiod contained nothing contrary to sound principles of morality and religion, since the myths of these poets ought to be understood allegorically.

This method of interpreting the antient mythology has found much favour among modern writers. It has been adopted by Bacon, in his 'Wisdom of the Antients,' in which he observes, 'I freely and willingly confess that I am inclined to the opinion, that not a few of the fables of the antient poets contained from their very origin a hidden mystery and allegory. For who can be so obstinately blind to evidence, that, when he hears that after the extermination of the giants, Fame was brought forth as a posthumous sister to them, he does not immediately apply the story to those party murmurs and seditious rumours which are wont to spread themselves among a people for awhile after the suppression of rebellions. Or when he hears that the giant Typhon cut away and carried off the sinews of Jupiter, and that they were stolen from him, and restored to Jupiter by Mercury; how can he but perceive immediately that this is to be referred to powerful rebellions, by which the sinews of kings, their revenue and authority, are cut out; yet not so but that by mildness of address and wisdom of edicts, as it were by stolen means, the minds of subjects within a short time are reconciled and the power of kings restored to them. Or when he hears that in that memorable expedition of the gods against the giants, the ass of Silenus became by his braying an instrument of great value in dispersing these giants; must he not clearly see that this was imagined of those vast projects of rebels, which are mostly dissipated by light rumours and vain consternation? There is also another not unimportant indication of the existence of a hidden and involved sense; namely, that some of the fables are so absurd and senseless in their outward narration, that they seem to show their nature at first sight, and cry for exposition by means of a parable. Above all, one consideration has been of great weight and importance with me— that most of the fables of mythology appear by no means to have been invented by those who relate them, such as Homer, Hesiod, and the rest; for were it clearly made manifest to us that they proceeded from that age, and those authors by whom they are celebrated, and thence transmitted to us, we should surely, I conjecture, not have been induced to expect anything great or lofty from such an origin as this. But he who considers the subject more at-

tentively will discover that they are related to posterity as things already received and believed, not then for the first time imagined and offered to mankind. And this it is which has increased their estimation in my eyes, as being neither discovered by the poets themselves, nor belonging to their age, but a kind of sacred relics, the light airs of better ages, which, passing through the traditions of earlier nations, have been breathed into the trumpets and pipes of these Grecians.'

This view of mythology has been adopted and carried out to a great extent by Creuzer, in his 'Symbolik und Mythologie der alten Völker, besonders der Griechen.'

4. *The Physical theory*; according to which the elements air, fire, water, &c. were originally the objects of religious adoration, and the principal deities were personifications of the powers of nature. Thus the antient mythology of the Hindus, as developed in the Vedas, personifies the elements and the planets, and differs essentially from the hero worship of later times. The transition from a personification of the elements to the notion of a supernatural being presiding over and governing the different objects of nature was easy and natural; and thus we find in the Greek and Italian mythology that the deities presiding over the sun, the moon, the sea, &c., and not the objects themselves, are the subjects of religious adoration. The Greeks, whose imagination was lively, peopled all nature with invisible beings, and supposed that every object in nature, from the sun and sea to the smallest fountain and rivulet, was under the care of some particular divinity. Wordsworth, in his 'Excursion,' has beautifully developed this view of Grecian mythology.

* In that fair clime, the lonely Herdsman, stretched
On the soft grass through half a summer's day,
With music lulled his indolent repose;
And, in some fit of weariness, if he,
When his own breath was silent, chanced to hear
A distant strain, far sweeter than the sounds
Which his poor skill could make, his fancy fetched
Even from the blazing chariot of the Sun
A beardless youth, who touched a golden lute,
And filled the illumined groves with ravishment.
The mighty Hunter, lifting up his eyes
Towards the crescent Moon, with grateful heart
Called on the lovely Wanderer who bestowed
That timely light to share his joyous sport:
And hence a beaming Goddess with her nymphs
Across the lawn and through the darksome grove
(Not unaccompanied with tuneful notes
By echo multiplied from rock or cave)
Swept in the storm of chase, as moon and stars
Glance rapidly along the clouded heaven
When winds are blowing strong. The Traveller slaked
His thirst from rill or gushing fount, and thanked
The Naiad. Sunbeams upon distant hills
Gliding apace, with shadows in their train,
Might, with small help from fancy, be transformed
Into fleet Oreads sporting visibly.
The Zephyrs, fanning, as they passed, their wings,
Lacked not for love fair objects whom they wooed
With gentle whisper. Withered boughs grotesque,
Stripped of their leaves and twigs by hoary age,
From depth of shaggy covert peeping forth
In the low vale, or on steep mountain-side;
And sometimes intermixed with stirring horns
Of the live deer, or goat's depending beard;
These were the lurking Satyrs, a wild brood
Of gamesome deities; or Pan himself,
The simple shepherd's awe-inspiring God.'

Almost all the theories that have been brought forward, either in antient or modern times, to account for the origin of mythology, may be classed under one of these four divisions; but not one of them taken by itself is sufficient to account for all the mythological traditions of a nation. The error of most writers on mythology consists in referring the origin of all myths to one common source; whereas the mythology of almost all nations has arisen from various and distinct sources. All the theories which have been mentioned above are true to a certain extent. Even that mode of interpretation which we have ventured to call the Scriptural theory, perhaps the most unsound and unsatisfactory of all, will serve to throw light upon some myths which would otherwise be unaccountable. For instance, the legends which we find in the mythology of almost every people, respecting a period in which the world was covered with water, can hardly be explained upon any other hypothesis than that such an event actually took place as is recorded in the Mosiac books. It would therefore be more correct to say that the mythology of a nation has arisen from all the causes which have been mentioned, rather than from any one in particular; but it must also be recollected that there are many myths the origin of which cannot be accounted for on any of the hypotheses that have been proposed. A great number of legends in all countries have arisen from the desire of man to account for those natural phenomena which he cannot

understand; and not a few have had their rise from a similar desire of giving a reason for the names of places and persons. The 'Metamorphoses' of Ovid will supply numerous examples of such myths.

The preceding observations are only intended to give a general view of mythology, and of the principal systems which have been proposed in antient and modern times to account for its origin. The particular mythology of any nation must be acquired by aid of the articles in other parts of this work, such as BRAHMA, VISHNU, FAIRIES, HERO, GENII, JUPITER, JUNO, APOLLO, ARES, MARS, BELLONA, &c., and more particularly by the help of such works of reference as are enumerated below.

MYTILA'CEA. [MYTILIDÆ]

MYTI'LIDÆ, a family of marine conchifers.

The Linnean genus *Mytilus*, as it was left by the author in his last edition of the 'Systema Naturæ,' was divided into three sections. The first, 'Parasitici, unguibus affixi,' consisted of those species which are affixed by unguicular appendages to Gorgoniæ and other submarine bodies, both organic and inorganic, such as *Mytili Crista Galli*, *Hyotis*, and *Prons*, which have been since restored to the genus *Ostrea*. The second, 'Plani s. compressi, ut plani apparent et subauriti,' consisted of the *Pearl-bearing Muscle*, 'Matrix perlarum,' under the name of *Mytilus margariferus*, now separated generically under the names of *Meleagrina* and *Margarita* [AVICULA; MALLEACEA; MARGARITACEA], and *Mytilus unguis*, a species, if it be one, not larger than the human nail. The third, 'Ventricosiusculi,' comprised not only the true *Mytili*, of which *Mytilus edulis*, the *Common Muscle*, may be considered as the type, but also the *Mytilus Lithophagus*, the *Modiola*, the true *Avicula* (*Mytilus Hirundo*), and the fresh-water muscles (*Anodon*). The generic definition of this heterogeneous assemblage was, 'Mytilus. The animal an ascidia? The shell bivalve, rough (rudis), most frequently affixed by a byssus. The hinge toothless, marked (distinctus) by an excavated, longitudinal, subulate line.' Linnæus placed this genus between *Anomia* and *Pinna*.

Authors soon perceived the necessity of a reform in this arrangement, and the position which the genus occupied in the systems of the leading malacologists of more modern date will be found in the article MALACOLOGY, vol. xiv., pp. 318, 319, 324.

The genus *Pinna* of Linnæus ends the '*Bivalvia, conchæ*' of that author.

Cuvier makes the *Mytilacæ* the second family of his Testaceous Acephalous Mollusks. He characterises the family as having the mantle open in front, but with a separate aperture for the excrements, adding that all these bivalves have a foot serving the purpose of creeping, or at least to draw out, direct, and fix the byssus. They are, he states, in conclusion, known under the generic name of *Moules* (Muscles).

This family Cuvier subdivides into

I. The True or Marine Muscles (*Moules propres ou Moules de mer*. *Mytilus*, Linn.).

In this subdivision are placed *Mytilus* (*Mytilus edulis* and its congeners); *Modiola* (Lam.); and *Lithodomus* (Cuv.).

II. The Anodonts (*Anodontes*, Brug.), vulgarly Pond Muscles (*Moules d'Étang*).

III. Les Mulètes (Univ., Brug.), commonly called the Painters' Muscles, including *Hyria* and *Castalia*, Lamarek.

IV. Cardita. (Brug.)

V. Cypricardia. (Lam.)

VI. Les Coralliophages. (De Blainv.)

Vmericardia he considers as differing but little from *Cardita*, and he observes that both the one and the other approach *Cardium* in general form and the direction of the ribs (côtes). He states his suspicions that this is the place for *Crassatella*.

This family is placed by Cuvier between the *Ostracæ* and the *Camacæes*.

The genus *Pinna* is placed by this zoologist between *Avicula* and *Arca*.

Lamarck characterised his *Mytilacæes* as having the hinge with a sub-internal, marginal, linear, very entire ligament, occupying a great part of the anterior border, and the shell rarely foliated. In this family he places the genera *Modiola*, *Mytilus*, and *Pinna*.

M. Deshayes, in the last edition of Lamarck's work, allows that nearly all conchologists have admitted the family of *Mytilaceans* or *Mytilidæ*, either as it was constituted by Lamarck, or after having made it undergo some modifications of little importance. M. Deshayes remarks that he himself adopted it in the 'Encyclopédie,' having suppressed the genus *Modiola*, which, in his opinion, has not sufficient characters, and supplied its place by *Avicula*. But, setting aside all former opinion, M. Deshayes, in the last edition of Lamarck, enters into an examination whether the family ought to be preserved. The genus *Mytilus*, he observes, has always two adductor muscles, the anterior one very small, and the posterior much larger; the lobes of the mantle are united posteriorly at a single point, so that there exists but a solitary siphon for the anus. The aperture of the mouth is not papillose within. The *Modiolæ*, he continues, differ in nothing from the *Mytili*; their anterior muscle is indeed in some species rather larger, and the anterior extremity of the animal is a little prolonged beyond the *umbones*. These differences are, in his opinion, without importance, for we pass from one genus to the other by insensible gradations. In the genus *Pinna* we no longer find the mantle with a posterior commissure; consequently there is no anal siphon; there are two unequal muscles, and the mouth as well as the lips are covered internally with membranous papillæ. The ligament of the *Mytili* is external and convex, like that of the *Uniones* (Mulettes), &c.; that of the *Pinnae* is very narrow, elongated over nearly the whole of the posterior border, and often covered with a delicate testaceous lamina, losing nearly all the characters of external ligaments. The *Aviculæ* have no anterior adductor muscles, but, like the *Pinnae*, their mantle has no posterior commissure; the mouth is furnished with papillæ; the ligament has none of the characters of external ligaments, but is sunk in a superficial gutter, and takes all the characters of the ligaments of the *Ostraceans* and other *Monomyaria*. If, says M. Deshayes, in conclusion, a great value is attached to the existence of the siphons and their number, it is evident that, in following the rules laid down for classification, the *Mytili* should be separated from the *Pinnae*, and that we ought to constitute from them two very approximating families. Between the *Pinnae* and the *Aviculæ* there would seem to be more analogy than between the *Mytili* and *Pinnae*. Nevertheless, in this last genus there are two adductor muscles, whilst in the *Aviculæ* there is but one. Then we ought to remember that the character resting upon the number of the muscles is very important, and if we here apply that character, we shall be led to make the *Aviculæ* a small family separate from the *Pinnae*.

M. de Blainville thus characterises the *Mytilacea*, which he places between the *Margaritacea* and the *Arcucea* or *Polyodonta*. The genus *Avicula* among the *Margaritacea* thus immediately precedes the *Mytilacea*.

Character.—Mantle adhering towards the borders, slit throughout its inferior borders, with a distinct orifice for the anus, and an indication of the branchial orifice by the more considerable thickening of its posterior borders; a canaliculated, linguiform foot, with a byssus backwards at its base; two adductor muscles, the anterior of which is very small, besides the two pair of retractor muscles of the foot.

Shell regular, equivalve, often furnished with an epidermis, or corneous, with a toothless hinge, and a linear, dorsal ligament.

The genera placed in this family by M. de Blainville are *Mytilus*, with its subdivisions, and *Pinna*.

M. Rang gives the following as the characters of the family *Mytilacæes*:—

Animal having the mantle open throughout its inferior part, and adhering towards the borders; a separate aperture

behind for the excrements, forming very rarely a tube; the foot linguiform, canaliculated, and furnished with a byssus behind.

Shell rather delicate, generally with an epidermis, or corneous, equivalve, but very inequilateral; the hinge toothless; the ligament linear; anterior muscular impression very small; the posterior one rather large.

Marine (the genus *Mytilus* alone presents a species which is said to live in fresh water). (*Manuel, &c.*)

The genera arranged by M. Rang under this family are, *Mytilus*, with its subdivisions, including *Modiola*, *Lithodomus* (Cuv.), and *Pinna*.

Mr. G. B. Sowerby (*Genera*), after remarking that the Linnean genus *Mytilus*, on account of its principal character being its want of hinge teeth, consists of several forms that are widely distinct from each other, and which have well served as the types of several Lamarckian genera, such as *Avicula*, *Modiola*, *Anodon*, and others, in connection with the present genus, which deservedly retains the name of *Mytilus*, both on account of its form* and the priority of its claim, proceeds to observe that the other genera which have been united with it, but from which it appears necessary to distinguish it, because of a certain degree of general resemblance, are *Modiola* and *Lithodomus*: from *Anodon* and *Avicula*, together with Lamarck's *Meleagrina*, it is, he adds, obviously distinct; whilst one character, namely, the pointed terminal umbones, serves to distinguish it from *Modiola* and *Lithodomus*.

Mr. Garner, in his paper 'On the Anatomy of the Lamellibranchiate Conchifera' (*Zool. Trans.*, vol. ii), is disposed to regard the disposition and form of the *branchiæ* and *siphons* as being of great use in the classification of those animals; and he instances *Anomia*, *Pecten*, *Arca*, *Modiola*, *Unio*, &c., &c., as each having a particular disposition of the *branchiæ*, sac of the mantle, valves, *siphons*, &c., giving rise to particular modifications of the course of the aerating currents of water to the *branchiæ*. He observes that in the genera, some of which are above mentioned, no complete division of the sac of the mantle exists, while in *Solen Hiatella*, *Pholas*, &c., a different disposition takes place. With regard to the *Excretory system*, he found the oviduct distinct from the sac in *Modiola*, *Mytilus*, *Lithodomus*, &c., whilst in *Tellina*, *Cardium*, *Mactra*, *Pholas*, *Mya*, and most others, the *ova* are discharged into the excretory organs. With reference to the *Reproductive system*, Mr. Garner remarks that the ovaries of the *Lamellibranchiate Conchifera* differ much in their situation: sometimes they form distinct parts, sometimes they are found in the foot, sometimes they are ramified in the mantle, which last disposition is present in *Modiola*, *Anomia*, *Lithodomus*, *Hiatella*, and the like.

The same author in his 'Anatomical Classification of the Lamellibranchiata' (*loc. cit.*), thus arranges the genera *Mytilus*, *Modiola*, *Pinna*, *Lithodomus*, and *Unio*.

Mantle with a distinct anal orifice.	Foot small, byssiferous . . .	{ Anterior muscle small; retractile muscles of the foot numerous; byssus large . . .	{ Byssus divided to its base Byssus with a common cornuous centre . . . Anus furnished with a long linguulate valve.	MYTILUS.
				MODIOLA.
				PINNA.
			Muscles equal, two pairs of retractile muscles only; byssus rudimentary . . .	
	Foot large, not byssiferous			UNIO — <i>Cardita</i> , <i>Hyrida</i> , &c.

Genera. *Mytilus*.

This genus is abundant on most rocky coasts, where the species are to be found inoored by their coarse filamentous byssus, generally to such rocks or other submarine bodies as are exposed at some periods of the tide, where tides exist, and covered by the sea at high water. Mr. G. B. Sowerby does not think that, after being once attached, they habitually disengage themselves, though it appears to him probable that, when disengaged by the force of the sea, they may live for some time without being in any manner affixed.

M. Deshayes, in the last edition of Lamarck, thus describes the

Animal.—Oval, elongated; the lobes of the mantle simple or fringed, united posteriorly in a single point so as to

* The name is supposed to refer to the fancied resemblance between the shell of this Acepbalan and a Mouse. The Greek word Μύς is used to signify both a Mouse and a Muscle (*Mytilus*).

form an anal siphon; mouth rather large, furnished with two pairs of soft palps, which are pointed and fixed by their summit only. Foot slender, cylindraceous, carrying at its base, and posteriorly to it, a silky byssus; abdominal mass moderate, and on each side a pair of branchiæ nearly equal; two adductor muscles, the one anterior and very small, the other posterior, large, and rounded.

Gland of the byssus, mantle, oviduct, &c. of *Mytilus edulis*. (Garner.)

A, right lobe of the mantle; D, rectum; G, branchiæ; H, foot; J, posterior muscle; L, superior tube; O, heart; P, ventricle; Q, auricle; X, pericardium; a, tentacles; d, byssus; e, gland of the byssus; g, retractile muscle of the foot; h, valves of the mantle; i, oviduct; j, orifice of the excretory organ; k, internal ditto.

The species are numerous, and most of them are used as food; but they should be eaten with caution, for serious illness and even death have ensued from a meal made on some of them. The byssus or beard, as it is popularly called, should be carefully cleared away, and they should be particularly avoided when cholera is about, or even when diarrhœa is prevalent.

Captain P. P. King, R. N. (*Voyages of the Adventure and Beagle*, vol. i.), mentions the Choro (*Mytilus Choros* of Molina) as among those shell-fish of the island of Chilœ which are more particularly deserving of notice. Speaking of this large muscle, Captain King says, 'Molina has described the choro of Concepcion, which is not at all different from that of Chilœ. It is often found seven or eight inches long. The fish is as large as a goose's egg, and of a very rich flavour; there are two kinds, one of a dark brown, and the other of a yellow colour; but the last is most esteemed. There is also another sort, much larger than the choro, yet equally delicate and good, the fish of which is as large as a swan's egg: it is called cholgua; but as the shells seem to be of the same species, I think the distinction can only be owing to size. In Febres's "Dictionary of the Chileno language," the word cholchua is rendered into Spanish by "cascara de choros blancos," or shell of the white muscle. Cholhua, or Cholgua (the letters g and h are indiscriminately used), must be a corruption; for it is now used in Chilœ to distinguish the large from the small choros. The manner in which the natives of these islands, both Indians and descendants of foreigners, cook shell-fish is very similar to that used for baking in the South Sea Islands and on some parts of the coast of New Holland. A hole is dug in the ground, in which large smooth stones are laid, and upon them a fire is kindled. When they are sufficiently heated, the ashes are cleared away, and shell-fish are heaped upon the stones, and covered first with leaves or straw, and then with earth. The fish thus baked are exceedingly tender and good; and this mode of cooking them is very superior to any other, as they retain, within the shell, all their own juiciness.'

Geographical Distribution.—Very wide. Few rocky coasts are without some of the species, which are all littoral. They are sometimes found affixed to crustaceans, shells, and corals.

Mytili with a smooth shell.

Example, *Mytilus edulis*—Common Salt-water Muscle.

This species is too well known to require description: the figures will show the shape of the shell, which is strong when freed from the epidermis and polished, the under surface of the external part of the shell is exposed, and is of a deep blue. In this state it is often offered for sale at watering places. The inside of the valves is white with a dark rim.

The common edible muscle is found in extensive beds below low-water mark, and also at a greater depth. Rocks and stones between high-water and low-water marks are also covered with them. We once saw a lobster, which is now, we believe, in one of our museums, with its shell coated with them. The species is used largely as an article of food, and is considered rich and sapid by many; but it entirely disagrees with some constitutions, and, besides other derangements, has been known to cause blotches, swellings, &c. Some cases are recorded where these and other affections have been produced by eating these muscles, whilst some who have partaken from the same dish have escaped all evil consequences. These derangements have been attributed by some to the byssus, by others to the Pea-crab [PINNOTHERIANS], a little crustacean which shelters itself, especially at particular seasons, in the shell of the Muscle, and by others again to the muscle itself being in an unwholesome state or out of season. There can be little doubt that the muscle, like the oyster, and indeed like most other edible animals, is comparatively unfit for the food of man at certain periods; but that the Pea-crab has anything to do *per se* with the poisonous qualities of these esculents is denied by all who have written on the subject. When any symptoms of derangement occur after eating muscles, an emetic should be taken and afterwards a dose of castor-oil. Cases of this kind are however rare. Pennant remarks, that for one who is affected by eating muscles, a hundred remain uninjured. [See further, MYTILUS EDULIS.]

Particular localities are celebrated as producing this muscle in perfection. 'Ne fraudulentur gloriâ sua littora,' exclaims the author last quoted. 'I must, in justice to Lancashire, add, that the finest muscles are those called *Hambleton Hookers*, from a village in that county. They are taken out of the sea and placed in the river Weir, within reach of the tide, where they grow very fat and delicious.' In 'The Forme of Cury' (1390) is a receipt for dressing 'Muskeles in brewet,' and also one for making 'Cawdel of Muskeles.'

Small or seed pearls frequently occur in this species, and some years ago these were employed for medical purposes.

Ova of *Mytilus edulis*. ($\frac{1}{4}$ inch focus.)

Mytilus edulis.

a, detached valve;—the animal in situ with byssus;—the mantle slightly contracted; b, valves conjoined;—animal as seen when the shell is partly forced open, with byssus.

Shell of *Mytilus edulis*.

a, valves closed, with byssus; *b*, external view of one of the valves; *c*, internal view, showing the muscular impressions.

In the Museum of the Royal College of Surgeons (*Physiological Series*, No. 94) is one of the valves of this species, which has been steeped in an acid to dissolve and separate the earthy part (carbonate of lime) and show the animal part retaining the membranaceous form.

* *

Mytili with the shell striated longitudinally.

Example, *Mytilus Magellanicus*.

Description.—Shell oblong; whitish below, purple violet above, with long thick undulated furrows; the umbones acute, and not much curved. Length varying, generally from four to five inches.

Localities.—Straits of Magalhaens, Chiloe, &c.

The flesh is well-flavoured and nutritious. The shells of old individuals, when polished, are brilliant, with a nacreous deep purple tinged with violet.

It is not improbable that this species ministered in a degree to the wretched wants of Byron and his wretched companions after the wreck of the *Wager*. Having thus established, says that officer, some sort of settlement, we had the more leisure to look about us, and to make our researches with greater accuracy than we had before, after such supplies as the most desolate coasts are seldom unfurnished with. Accordingly we soon provided ourselves with some sea-fowl, and found limpets, mussels, and other shell-fish in tolerable abundance; but this rummaging of the shore was now become extremely irksome to those who had any feeling, by the bodies of our drowned people thrown among the rocks, some of which were hideous spectacles, from the mangled condition they were in by the violent surf

that drove in upon the coast. These horrors were overcome by the distresses of our people, who were even glad of the occasion of killing the gallinazo (the carrion crow of that country) while proying on these carcasses, in order to make a meal of them.

Mytilus Magellanicus—attached to a rock by its byssus.

Here may be introduced the *Mytilus polymorphus* of Pallas, Gmelin, and others, thus characterised as a genus by Dr. Vanbeneden, under the name of

Dreissina.*

Animal.—Mantle entirely shut, presenting three apertures, one of which is furnished with a siphon. Anterior extremity of the body bifurcated and lodging in the middle of the division the transverse anterior muscle. Abdomen depressed; extremities of the branchiæ floating in their posterior half.

Shell.—Regular, equivalve, inequilateral, umbo with a septum in its interior. Three muscular impressions, the middle one unique and linear.

Nervous System.—This consists of two pairs of ganglions and a great single ganglion; they are all united together, and represent a true chaplet (chapelet). The first pair of nerves, that which represents the brain, is situated on the lateral parts of the buccal opening between the two labial tentacles, but more approximated to the anterior tentacle. It cannot be said that it is placed above the œsophagus, for it is, if anything, below it. The skin, which forms the upper wall of the œsophagus, covers it, and it is placed between this skin and the anterior retractor muscle. The second or mesial pair is situated at the anterior part of the base of the retractor muscle, between it and the liver. The third pair is represented by a single ganglion, which occupies the mesial line, and of which the volume is considerable. It is situated in the middle of the posterior transverse muscle.

The muscular system is much the same as in *Mytilus*.

Dr. Vanbeneden thinks that the organ of the byssus, which he designates, after Poli, by the name of 'languette,' has been erroneously taken for the foot. The true foot, he observes, consists of a muscular tunic more or less thick, which covers the abdomen of the animal, and serves it as an organ of progression; whilst the organ, which always accompanies the byssus, possesses no character in common with the foot except its mobility. Instead of covering the abdomen as a muscular tunic, it forms a part of the retractor muscle, from which it cannot be separated. At the base of this organ, with which, when the byssus is torn away, the animal seems to explore the bodies in its neighbourhood, is the sheath in which the byssus is lodged.

The mantle entirely envelops the animal, and forms three apertures, one of which serves for the passage of the byssus and the 'languette'; the second terminates the animal in the siphon; the third is placed on the back, and gives passage to the excrements. The aperture of the siphon is elongated many lines in respiration, and can be bent in different directions.

Place in the Animal Series.—Dr. Vanbeneden comes to the conclusion, from the anatomical and physiological

* Named from M. Dreissens of Maseyk (province of Limburg).

structure of the animal, that its place is between *Mytilus* and *Anodon*.

Geographical Distribution.—The author above quoted states that this form is found throughout Europe, and that America possesses individuals which approach it. (*Mytilus recurvus*, Rafinesque, &c.)

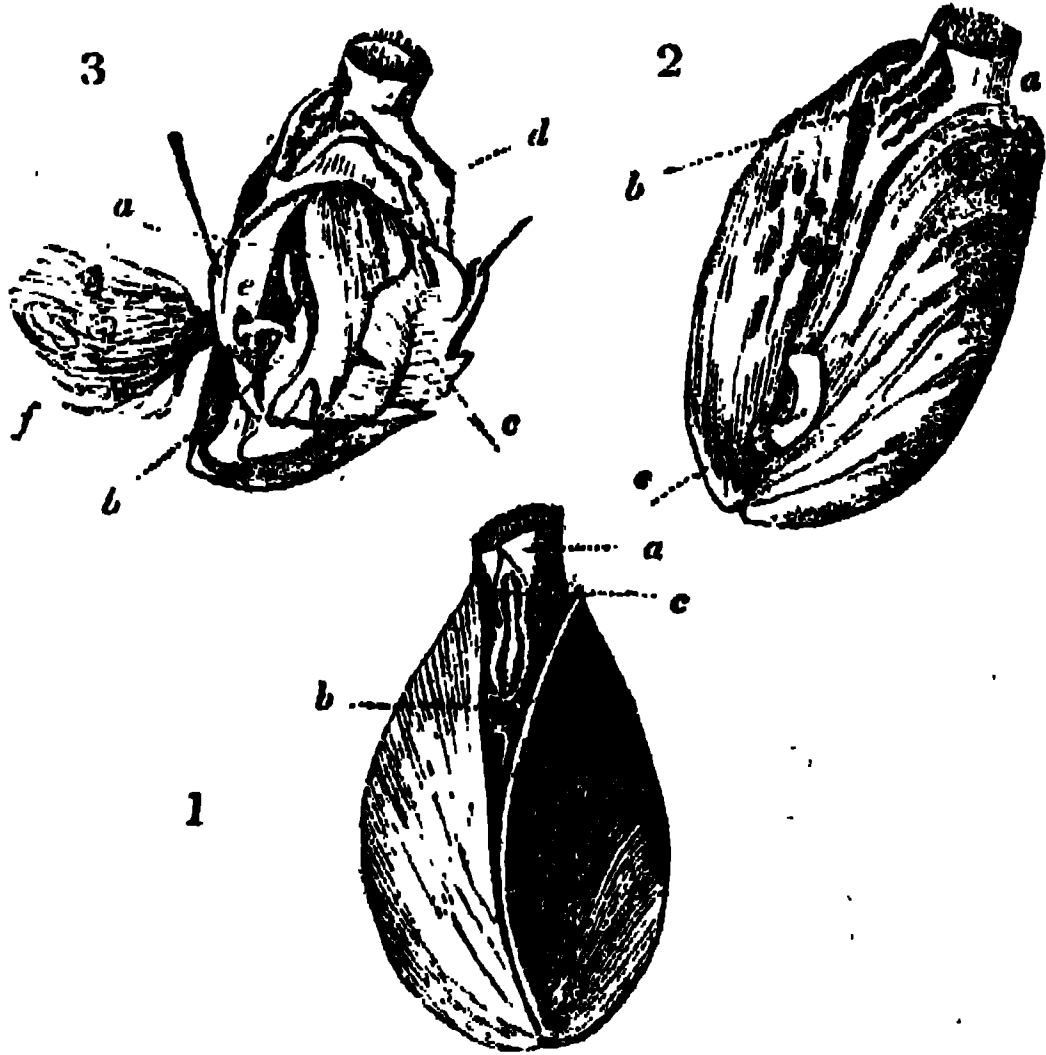

Dr. Vanbeneden records two recent species, *Dreissena polymorpha* and *Dreissena Africana*.

Example, *Dreissena polymorpha*. This appears to be the *Mytilus Wolgæ*, Chemn.; *M. Chemnitzii*, Fér.; *M. Hagenii*, De Baer; *M. lineatus*, Waardenburg, and *M. Arca*, Kickx.

Localities.—Inhabiting seas, lakes, rivers, and marshes; all these conditions seem favourable to it. Dr. Vanbeneden gives the following localities:—the Caspian Sea, the Black Sea, and the Baltic, the Danube, the Wolga, and the Rhine, where they are found in considerable quantities; the marshes of Syria (the Palatinate), the *Canal Guillaume* (Belgium), the lakes of Harlem (Holland), the *Lea* (our river Lea, we suppose, is meant), the *Docks* (the Commercial Docks, London, probably), and the neighbourhood of Edinburgh (Union Canal); so that this form extends nearly over the whole surface of Europe from lat. 43° N. to 56°; Turkey, Austria, Russia, Germany, Belgium, Holland, and England. (Vanbeneden.)

Mr. J. D. C. Sowerby appears to have been the first who noticed their introduction into the Commercial Docks, in the Thames, to which place he is of opinion that they had been probably brought in timber.

Habits, &c.—The species are found at the bottom of the water in beds, like the marine mytili, agglomerated in bunches by means of their byssus. They attach themselves to stones, to piles, to other shells (*Unio* and *Anodon*), and all the bodies which are in their neighbourhood. Dr. Vanbeneden remarks, in continuation, that they probably often adhere to the keels of boats, and that it is perhaps by such means that they are dispersed over such a considerable extent.

Dreissena polymorpha.

1. Animal of 'nat. size,' showing the siphon exerted, and the aperture which corresponds with the anus open; view of the back. *a*, The siphon; *b*, the posterior row of papillae; *c*, anal aperture.

2. View of the ventral side. *a*, The siphon; *b*, the anterior row of papillae; *c*, the languette.

3. Animal in the left valve. *a*, The abdomen; *b*, the languette in situ; *c*, the branchiae; *d*, the aperture which gives issue to the excrements; *e*, aperture of the byssus; *f*, the byssus. (Vanbeneden.)

Shell of *Dreissena polymorpha*.

a, View of inside of valve, showing the septum at the umbone; *b*, the outside of valve.

M. Deshayes (last edition of Lamarck), after alluding to the memoir of Dr. Vanbeneden, which the reader will find in the second series of the *Annales des Sciences Naturelles*,

vol. iii. (1835), allows that the animal does not entirely resemble the marine mytili, which have the mantle open nearly throughout its circumference, and only have the lobes united posteriorly in a single point, so as to form over against the anus a small canal for the issue of the excrements. The principal difference, he remarks, consists in the *Mytilus polymorphus* having two posterior apertures instead of one; the second aperture, larger than the other, prolonging itself into a short siphon destined to conduct the water over the branchiae. With regard to the other parts, he observes that they do not differ from the other mytili except by gradations similar to those which are found in the marine species. Thus the retractor of the foot is here less divided, and leaves only a single narrow and isolated impression on the valves. M. Deshayes states that he knows an analogous disposition in the marine species. The form of the foot, the position of the byssus, the form of the mouth and of the labial palps, and the interior disposition of those organs, resemble the same parts in the mytili. Some slight differences may perhaps be found in the distribution of the nerves; but M. Deshayes inquires whether it is clearly made out that this distribution does not vary as much in the marine muscles. He then adverts to the small transverse septum in each valve, the external surface of which gives attachment to the anterior adductor muscle of the valves, and he allows that if this character was only to be found in this species, coexisting with two posterior apertures in the mantle, a small generic group might be founded on this type; but he proceeds to state that many marine species, *Mytilus bilocularis*, for example, offer the same character, which loses its importance when we find it established by degrees, commencing in some species so as to be scarcely perceptible, increasing in others, and showing itself in its greatest development in the species last quoted. Unfortunately, he adds, the animal of *Mytilus bilocularis* is not known; so that we are unable to appreciate the value of the character which it offers in common with the genus *Dreissena* of Dr. Vanbeneden.

Modiola. (Lamarck.)

M. Rang makes *Modiola* the third group of the genus *Mytilus*. M. Deshayes, in his inquiry whether this genus ought to be preserved, observes that the *Mytili* and *Modiola* much resemble each other, as all admit, but they offer some difference, the importance of which he proceeds to test. Of the animals he says nothing, their analogy being so perfect, and all their characters, internal as well as external, being so similar that it is impossible to distinguish them. The habit which certain species have of living in the stones which they pierce has not changed their organization; and of the justice of this remark those interested in the subject may, he states, assure themselves by a comparison of the animals themselves, which are abundantly spread abroad in all seas. It is a received principle among all zoologists, he continues, that animals having the same organization ought to make a part of the same genus; but as there are persons who attach considerable importance to certain characters in the shells, it is right to reduce it to its just value. The *Modiola* differ from the *Mytili* in not having pointed and terminal umbones. On assembling a great number of living and fossil species of both genera, some will be observed whose umbones, nearly terminal, are overpassed by a small very short border; others in which this border is a little more extended; and so one passes by insensible degrees from the *Mytili* to the *Modiola* without the possibility of determining the point where one genus ends and the other begins. If the same comparison is continued between the *Modiola* and the *Lithodoni* the same passage may be observed, and then, concludes M. Deshayes, the observer will be convinced, as we are, of the inutility of these genera.

Mr. G. B. Sowerby, in whose *Genera*, No. xxvi., will be found very instructive figures showing the variety of form to which the *Modiola*, treated by him as a distinct genus, are subject, admits that the most important character which serves to distinguish *Modiola* from *Mytilus* consists in the smaller side of the former advancing before the umbones, and giving the shell a rounded termination anteriorly. In every other respect he admits that it resembles *Mytilus*, to which it was united in most of the older books, in connection with other genera that are exceedingly distinct. 'The *Modiola*, like the *Mytili*,' says Mr. Sowerby, in continuation, 'and many other genera, affix themselves to submarine productions by means of a bundle of rather coarse fibres, commonly called a byssus, each fibre of which

is fastened to the rock by its expanded external termination, and applied by the foot of the animal. The recent species of *Modiola* are not very numerous; we have however several species on the coasts of Britain, of which the most remarkable are the *M. discrepans* and *discors*. These two, together with some others that resemble them in form, differ much from the common *Modiola*, and might perhaps with propriety be considered as a distinct genus. The same author states his belief that *Modiola discrepans* and *discors* are, on our coasts, always found embedded in the common *Ascidia*, and appear to be destitute of a byssus; while the much larger specimens that are brought from the West Indies are found completely enveloped in a fine silky byssus closely matted together, and forming large bundles. Some cognate species however, that have been brought from the Northern Ocean, appear, he adds, to have been affixed by a few filaments only.

Mr. Garner remarks (*loc. cit.*) that when a foot is present there are three *ganglia*, or pairs of *ganglia*; when absent, but two. Two are situated at the mouth, more or less removed from each other, but always connected by a supra-oesophageal nerve; they are sometimes on a level with or before the mouth, sometimes behind it. They give off on each side filaments to the anterior muscle, tentacles, lips, and anterior part of the mantle. Each *ganglion* likewise gives off a twig going to the posterior *ganglia*, which are situated between the *branchiæ* on the posterior muscle. These are united into one, when the *branchiæ* are themselves united medianly, as in *Mastra*, *Mya*, *Solen*, &c., but are at a distance from each other when the *branchiæ* are remote: in this last case they are always connected by a transverse nerve, as in *Modiola*, *Avicula*, *Lithodomus*, *Arca*, &c.

M. Rang separates the group of *Mytili*, consisting of Lamarck's genus *Modiola*, into two subdivisions.

Shell sulcated long

Example, *Modiola sulcata*. Shell bluish white; epidermis yellowish; hinge-margin denticulated.
Locality.—Indian Seas. Lamarck.

Modiola sulcata.
a, Shell closed, with byssus; b, outside view of valve; c, inside view of valve.

Shell not sulcated longitudinally.

Example, *Modiola Silicula* (including, according to M. Deshayes, *Modiola cinnamomea*). Shell marone brown or whitish; epidermis deep marone brown.

Localities.—Lamarck gives the seas of the Isle of Franco as the habitat of *Modiola cinnamomea*, and the seas of New Holland as that of *Modiola Silicula*.

Modiola Silicula.

Lithodomus. (Cuv.)

Animal oblong, very much elongated, thick, having the mantle prolonged and fringed posteriorly; anal aperture mesial; mouth furnished with very small triangular appendages; foot linguiform, canaliculated, but little developed, and carrying a byssus at its base in the early stages of the animal's life.

Shell delicate, covered with an epidermis, oblong, very P. C., No. 993.

much elongated, subcylindrical, rounded anteriorly, not gaping; umbo subanterior, very distinct; hinge toothless; ligament linear, for the most part internal, inserted in a narrow and elongated furrow; anterior muscular impression of considerable size.

Example, *Lithodomus Dactylus* (*Modiola lithophaga*, Lam.; *Mytilus lithophagus*, Linn.).

We have seen the opinion of M. Deshayes, as to the separation of this genus. M. Rang, on the other hand, thinks that this form has been separated from the *Mytili*, by M. Cuvier, with more reason than Lamarck had for the separation of the *Modiola* from that genus. The singular habits of the *Lithodomi* and the form of their shell justify perhaps, he thinks, this generic distinction, which moreover has generally been adopted since. In the early stages of life the *Lithodomi* suspend themselves to rocks and madrepores, by means of their byssus; but they soon pierce those bodies, in order to introduce themselves, and thus form cavities which they can never leave, in consequence of their increasing volume as they advance in age. The byssus then becomes useless, and is no longer manifested. These shells, says M. Rang, in continuation, are very common in the Mediterranean and at the Antilles, where they are found in stones and masses of madrepora, and sometimes, but much more rarely, in some thick shells.

This species is highly nutritious and well-flavoured. Imprisoned as the animal is in the stone or madrepora, frequently with a very small opening communicating with the sea, it must obtain a plentiful supply of food, probably by means of the currents produced by the animal; for the shells are always full and the animal plump. A stew of these *Lithodomi* is described by those who have partaken of it as excellent.

With regard to the power of piercing rocks, stones, wood, &c., possessed by Lamellibranchiate animals, Mr. Garner, in the paper above quoted, observes that such piercing cannot in every case take place by the mechanical action of the valves, and he instances those of *Lithodomus* as not at all adapted for such an action. He also denies the possibility of the perforation being caused by a solvent fluid secreted by the animal. 'The fact appears to be,' says Mr. Garner, 'that the phenomenon is caused by the vibratile action of the parts exciting constant currents of water against the substances, aided by its impetus when drawn in down the

Lithodomus Dactylus.

a, Young, with byssus; b, full grown, inside of valve; c, ditto, outside of valve; d, three specimens in a mass of madrepora.

elongated body of the animal, and in some cases perhaps by the rasping of the valves.'

Pinna. (Linnæus.)

Animal elongated, rather thick, subtriangular; lobes of the mantle united on the dorsal border, separated throughout the rest of their extent, ordinarily ciliated on the edges; foot slender, conic, vermiform, carrying at its base a silky byssus; mouth between two lips foliaceous within, very much elongated, and terminated by two pairs of short palps; the two palps of one side soldered nearly throughout their length; two adductor muscles; the anus terminating behind the posterior one. (Deshayes.)

Shell fibrous, horny, rather delicate, fragile, compressed, regular, equivalve, longitudinal, triangular, pointed anteriorly, rounded or truncated posteriorly; anterior umbo but little distinct; hinge linear, striate, toothless; ligament marginal, a great portion of it internal, very narrow and compact, occupying more than the anterior half of the dorsal border of the shell, in a narrow and elongated gutter; anterior muscular impression very small and entirely in the angle, posterior muscular impression very large. (Rang.)

Poli has given beautiful figures of the animal, which he calls *Chimæra*, and most elaborate details of its anatomy; and to his great work we refer the reader. There are no projecting siphons, and the conic tongue-like foot is employed by the animal to fix itself by the byssus, which is not scanty and coarse, like that of the *Mytili*, but long, fine, lustrous, and abundant; so that, though it takes no dye, it is employed in manufacture in Italy. [Byssus; CONCHIFERA, vol. vii., p. 432.] The *Pinna* approximate more especially to the *Mytili*, but the shell of the former, with its straight umbones and its gaping opposite extremity, strongly distinguishes them. There is a tendency in their shell to divide itself into laminæ, and thus it approaches that of the *Malleacea*.

Example, *Pinna Flabellum*.

Pinna Flabellum.

a, Young, with siphons, and the byssus, nat. size; b, full-grown, inside view of valve, one-fifth nat. size.

Habits, Geographical Distribution, &c.—The species are

generally found in deep water, but they have been taken at depths ranging from the surface to 17 fathoms; most frequently on sandy bottoms, where they were moored by their byssus, and at no great distance from the shore. It is said that the animal sometimes fixes itself by the aid of its byssus, and sometimes removes itself by the aid of its foot. Small crustaceans, both brachyurous and macrurous, are sometimes found in their shells. Species occur nearly in all seas. Most of them are muricated when young with vaulted or subtubular spines; but as they increase in age, these are worn down, and at last almost entirely disappear. We have had individuals of the great Mediterranean *Pinna* before us, gradually increasing from a very small size to nearly two feet in length. When specimens taken at wide intervals were compared, the difference was so great that they might easily have passed as distinct species, as indeed they have been described by some authors. We have seen many pearls from this *Pinna* not ill formed and of an amber colour, but none of any considerable size.

Pinna Flabellum, full-grown, valves closed, outside view, with byssus, one-fifth nat. size.

FOSSIL MYTILIDÆ.

Mytilus.

Mr. G. B. Sowerby (*Genera*) states that the fossil species with which he is acquainted are not numerous; they occur however, he observes, in some of the beds below the chalk, as well as in most of those above it, but particularly in the cret

Deshayes, in his *Tables* (1833), makes the number of fossil species (tertiary) fifteen. *M. Chemnitzii* and *M. edulis* he states to be both living and fossil (tertiary). In the last edition of Lamarck (1836), he remarks that Brocchi mentions a fossil shell to which the latter gives the name of *Mytilus edulis*; but M. Deshayes does not believe that this fossil is the analogue of *Mytilus edulis*, Linn., but of an

other edible species very common in the Mediterranean. Of fossil species he admits nine only in that work. Dr. Mantell notices a species in the cliff between Brighton and Rottingdean (diluvium); and another, *M. lanceolatus*, in the Shanklin sand. Professor Phillips notes a *Mytilus cuneatus* from the inferior oolite, in his list of organic remains of the Yorkshire coast. Dr. Fitton, in his 'Systematic and Stratigraphical List of Fossils' (Strata below the chalk), enumerates the following species: *M. edentulus*, *inæquivalvis*, *lanceolatus*, *Lyellii*, *prælongus*, *tridens*, and an undetermined species.

Dreissina.

Fossil in the modern calcaire of Aratapak and Transylvania, in Moravia, and the environs of Vienna. (Van-beneden.)

Here we may perhaps place *Mytilus Brardi*. The septum comes very near to that of *Dreissina*.

Mytilus Brardi.

a, Hinge and septum enlarged; b, outside of valve; c, inside.

Modiola.

Mr. G. B. Sowerby states that the fossil species are not many. He observes that such as he knows seem to belong principally to some beds of the oolite series, and that there are others in the principal formations both above and below the chalk. M. Deshayes, in his Tables, makes the number of fossil species (tertiary) twenty-one; and *Mod. barbata discrepans* and *lithophaga* (Lithodomus), both living and fossil (tertiary). In the last edition of Lamarck the number given is twenty. The shell from Plaisance, considered by Lamarck to be a variety of *Modiola subcarinata*, is not, in the opinion of M. Deshayes, a variety of that species, but very probably the analogue of *Modiola barbata*; and he says that another (*Mod. lithophagites*) is not a *Modiola*, but a *Gervillia*. Dr. Mantell notes *Mod. elegans* in the arenaceous limestone or sandstone of Bognor, and *Modiolæ æqualis* and *bipartita* in the Shanklin sand. Professor Phillips enumerates the following species among the organic remains of the Yorkshire coast:—*Modiolæ scalprum* (marlstone), *plicata* (inferior oolite), *bipartita* (calc. grit), *cuneata*? (Oxford clay, Kelloways rock and cornbrash), *imbricata* (Bath oolite), *Hillana* (lias), *ungulata* (coralline, Bath and inferior oolite), *pulchra* (Kelloways rock), *aspera*? (inferior oolite), *inclusa* (coralline oolite). Mr. Lonsdale (*Oolitic District of Bath*) records *Modiolæ Hillana* (lias), *gibbosa* (inferior oolite), *Hillana*? and *plicata* (fullers' earth), *imbricata* (cornbrash), *bipartita* (Kelloways rock). Dr. Fitton (*loc. cit.*) gives the following list: *Modiolæ æqualis*, *alæformis*, *aspera*, *bella*, *bipartita*, *depressa*, *imbricata*, *lineata*, *parallela*, *reversa*, two now unnamed species, one (casts), and a doubtful species. These are principally from the lower green-sand. One (*bella*) occurs in the gault as well as in the green-sand, and *bipartita* also in the Oxford oolite. The new and doubtful species appear to have been found in the Purbeck and Portland stone, lower green-sand, and Oxford oolite. Mr. Murchison (*Silurian System*) notes *Mod. semisulcata* (lower Ludlow rock) and *M. antiqua* (Wenlock shale).

Lithodomus.

M. Deshayes (*Tables*) does not mention this genus in his Tables, and appears to place it under *Modiola*, a position which it occupies in Lamarck's work. M. Deshayes records *Modiola lithophaga* (var.)—*Lithodomus lithophagus*—as fossil at Paris. Mr. Lonsdale (*loc. cit.*) notices a *Lithodomus* in the inferior oolite, and another in the coral rag. Dr. Fitton (*loc. cit.*) records a new species and another species, both nameless, in the Portland stone.

Pinna.

Mr. G. B. Sowerby (*Genera*) states that he is acquainted with several fossil species, which occur in the secondary and tertiary beds of marine origin; one, in particular, he observes, is beautifully preserved in the indurated sandy bed of London clay at Bognor; and another, he adds, is not unfrequently met with in the calcaire grossier at Grignon. M. Deshayes gives the three as the number of fossil species

(tertiary), and records *P. nobilis* as both living and fossil (tertiary). In the last edition of Lamarck, he notices the fibrous structure of the shell in this genus [SHELL], and says that in the tertiary beds the fibrous part decomposes into calcareous filaments, which detach themselves from the nacreous part, the preservation of which is more perfect. When this last part is a little gone (degradé), the point or junction of the two parts of which the valves are formed is perceptible; and it is, he adds, to a similar disposition observed in an individual of the *Pinna nobilis*, or *squamosa* of Italy, that the creation of Lamarck's species, *Pinna quadrivalvis*, is due. *Pinna margaritacea* (Paris, Grignon, &c.), *P. ampla* (oolite in England, France, and Germany), and *P. Saussurei* (coral rag of St. Mihiel, Mont Salève, Normandy), are the other fossil species enumerated. Dr. Mantell notices *Pinna affinis* from the arenaceous limestone or sandstone of Bognor, and another nameless species, for which he cites Martin (*Geol. Mem. West Suss.*), from the Shanklin sand. Professor Phillips (*loc. cit.*) gives us *P. gracilis* (Speeton clay), *P. mitis* (Oxford clay and Kelloways rock), *P. lanceolata* (coralline oolite and calc. grit.), *P. cuneata* (cornbrash and Bath oolite), and *P. Folium* (lias). Mr. Lonsdale (*loc. cit.*) gives a species, nameless, from the inferior oolite, and another nameless, with a note of interrogation, from the Kelloways rock. Dr. Fitton (*loc. cit.*) enumerates *Pinna? crassa*, n. s., from the lower green-sand; *P. tetragona*, from the lower green-sand, Kent, Sussex, and Isle of Wight, and at Blackdown; and a cast and a species, new? from the lower green-sand (Sussex and Isle of Wight).

MYTILUS EDU'LIS, the edible muscle, a molluscous animal or shell-fish, common along the coast of Britain, is generally considered a safe and wholesome article of food, but it occasionally gives rise to troublesome and even fatal affections in those who partake of it. No anatomical investigation into the condition of such specimens as prove injurious, nor chemical analysis of their composition, has revealed the cause of the disorder; but as such casualties result mostly in summer, it is probable that some natural change is taking place in the animal, which renders it at that season unfit for food. It would therefore be prudent to use it only in the winter months. The idea that it is owing to the fish having absorbed copper is quite unfounded. The application of heat in cooking does not destroy the noxious property, as it does that of many vegetable poisons, for those which are dressed are as hurtful as those eaten raw. Neither does decay seem to be the source of the deleterious principle, since bad effects follow the use of those which are quite fresh; nor does decay decompose the poison, though most animal poisons are destroyed by putrefaction, for two fatal cases have ensued from the eating of decaying muscles. (See cases by Dr. Burrows, in *London Medical Repository*, iii., p. 445.) The consequences have been imputed to idiosyncrasy in those who eat the muscles; but this is obviously inadequate to explain the circumstances, since in most of the instances every person (amounting in one case to thirty individuals) who tasted them suffered; and even cats and dogs, as well as human beings, died from eating them. The morbid symptoms vary, and in some of the cases are connected with inflammation of the stomach and intestines, and require venesection for their relief; but more commonly 'the local effects have been trifling, and the prominent symptoms have been almost entirely indirect, and chiefly nervous. Two affections of this kind have been noticed: one is an eruptive disease, resembling nettle-rash, and accompanied with violent asthma; the other a comatose or paralytic disorder, of a very peculiar description. The symptoms have usually commenced between one and two hours after eating, and rapidly attained their greatest intensity. The first symptoms were like those of violent catarrh, swelling and itching of the eyelids, and generally nettle-rash followed; and the eruption afterwards gave place to symptoms of the most urgent asthma. The swelling is not always confined to the eyelids, but has usually extended over the whole face. In several cases the eruption was preceded by asthma, lividity of the face, insensibility, and convulsive movements of the extremities; in others, nausea and vomiting, followed by heat and constriction of the mouth and throat; difficulty of swallowing and speaking freely; numbness about the mouth, gradually extending to the arms, with great debility of the limbs. The abdomen is often affected with pain, increased on pressure; the functions of the kidneys disturbed, but generally

increased; the bowels sometimes obstinately constipated. Epileptic symptoms, or delirium, convulsions, and coma have appeared in the greater number of fatal cases, rather than inflammatory action.

Emetics, such as sulphate of zinc, which acts quickly, have been of service; but ether seems the most effectual means of relieving the difficulty of breathing and the other nervous symptoms. Purgatives were found of no avail in some of the fatal cases accompanied by constipation; yet in general sulphate of magnesia (Epsom salts) in a large quantity of fluid, acidulated with dilute sulphuric acid, taken in small and frequent doses, is very efficacious in removing the eruption of nettle-rash. (Combe, in *Edin. Med. and Surg. Journal*, vol. xxix., and Christison *On Poisons*.) [MYTILIDÆ, p. 46.]

MYXINE, a remarkable fish belonging to the order *Cyclostomi*, family *Petromyzidæ*, and genus *Gastrobranchus* according to Bloch. It is the *Mixine glutinosa* of Linnæus, who, from its worm-like form, placed it in the class Vermes.

The Myxine is usually about a foot in length, of a slender and nearly cylindrical form, compressed towards the tail; the

dorsal fin is very narrow and continued round the end of the tail to the vent; on the head is a single spiracle which communicates with the interior; the head is rounded and destitute of eyes; eight cirri, or feelers, have their origin on the lips; the mouth is large; on each side of the tongue there are two rows of strong pectinated teeth; the palate is furnished with a single hooked tooth: the branchial openings are two in number, and situated on the abdomen a little beyond one-fourth of the entire length.

This remarkable fish frequents the northern seas, and occurs also on our own coast. It is found in the bodies of other fishes, especially the cod and haddock, and sometimes five or six specimens are found in one fish. Pennant says 'it enters the mouths of other fish when on the hooks attached to the lines which remain a tide under water, and totally devours the whole except the skin and bones.' It is sometimes called the Hag, and also Borer, because it is said by some that the myxine pierces a small aperture in the skin, and thus makes its way into the body of the cod or other fishes which it attacks.

N.

N is one of the liquid or trembling series of letters. It is formed with the tongue at the point where the teeth and palate meet, and the sound passes chiefly through the nasal passage. For the characters by which this letter is represented, see ALPHABET.

The letter *n* is subject to the following changes:—

1. It is interchangeable with *nd*. Thus the Latin roots *men*, *fini*, *gen* (genus), appear in Saxon English as *mind*, *bind* or *bound*, *kind* or *kin*. The converse change is common in the provincial dialect of Somersetshire, where the English words *wind*, *hind* (behind), *find*, *round*, *and*, are pronounced *wins*, *hins*, *vins*, *rnon*, *an*; while on the contrary, *manner* is changed to *mander*. [D.]

2. Before *f*, *n* was silent in Latin. Hence the town *Confluentes*, at the junction of the Moselle and Rhine, is now called *Coblentz*. So the German *fünf* is in English *five*.

3. N final often becomes a more complete nasal, and is equivalent to *ng*. Thus the German infinitive in *en* appears to be the parent not only of the participle in *end*, but of the substantive in *ung*, with which are connected the English participle and substantive of the same form in *ing*. The Somersetshire dialect prefers the *n* without *g*, as *stanin*, *sparklin*, *starvin*, for *standing*, *sparkling*, *starving*. The Sanscrit alphabet has a particular character for this sound.

4. *Ni* or *ne* before a vowel often forms but one syllable with that vowel, the *i* or *e* being pronounced like the initial *y*. This sound is represented in Italian and French by *gn*, as *Signor*, *Seigneur*; in Spanish by *ñ*, as *Señor*; and in Portuguese by *nh*, as *Senhor*—all derived from the Latin *senior*, elder.

5. *N* is interchangeable with *l*. Hence the double form of *luncheon* and *nunchion*; but see *L*.

6. *N* with *m*, particularly at the end of words. [M.]

7. *On* and *o* are frequently interchanged. Hence the disappearance of the final *n* in the Latin nominatives *ratio*, *ordo*, *Laco*. The Portuguese also often discard an *n* so placed. On the other hand the Greek neuter nominative takes an *n* to which it is not entitled, as *αγαθον*. It is probably from a confusion between the two sounds that the question has arisen, whether the letter *ain* of the Hebrew alphabet is an *o* or an *n*.

8. *R* final with *rn*. Hence the double forms of the Latin verbs *cer* and *cern*, separate; *ster* and *stern*, strew; *sper* and *spern*, kick, despise. Again *star* (and the Latin must once have had *stera* in order to form from it the diminutive *stella*, as from *puera* comes *puella*) is in German *stern*. *Spur* in English is *sporn* in German, and of the same origin perhaps is the name of the *Spurn Head*, at the mouth of the Humber, as well as the Latin *spurn-ere*. The Latin *bur* (seen in *com-bur-o*) is the same word as the English *burn*; and even the Latin *curr-ere*, to run, has in Gothic the form *urn-an*, just as the south-western dialect of England has *hirn*, and the ordinary English, by a slipping of the *r* [R], *run*. In the same south-western dialect *before*, *avaurn*, *orn*, *norn*, *ourn*, are the forms employed for *before*, *afore*, or or either (Germ. *oder*)—*nor* or neither, *our*.

9. *N* with *s*. This change will not be readily admitted without consideration, as the sounds appear so different. The change however is very parallel to the admitted change of *l* and *d*; and indeed as the two letter letters are formed at the same part of the mouth, so are *n* and *s*. The close connection of the two letters will be most forcibly demonstrated by examples of suffixes in which the change occurs. Thus the English language has a double form of the plural suffix in *en* and *es*, as in *oxen* and *oxes*. The Greek verb has the same variety; first, in *ρωρηναι* and *ρωρηναι*; secondly, in *ρωρηναι*, which must have been the older form of *ρωρηναι*, and the so-called dual *ρωρηναι*. The Latin again has the *s* suffix in *scribitis* *scribitis*, but the *n* in *scribunt*. Again the Latin comparative has for its oldest suffix *ius*, as in *melior*, whence both *melior* and *melius*; or a better example occurs in *plac-* and *plac-*, whence the latter forms *plac-* and *plac-*. On the other hand the Greek suffix is *ος*, as *πλεος* and *πλεος*, from the same root as the Latin *plac-*, and with the same meaning. The old genitive plural suffix in Latin appears to

have been *um*, as *servosum*, whence *servorum*. The suffix for a female in Greek is either *na* or *sa*, with perhaps an *i* prefixed, as *βασιλιννα*, *μυλαινα*, *λαϊνα*, or *βασιλισσα*, *τυκτουσα* and in English we have *ess*, while the Germans have *inr*. Lastly, such verbs as *σβεν-νυμι* have *σβεν* for the radical part, which often takes the form *σβεν*, as *α-σβεν-τος*; and the same change appears in *σφρον*, Nom. *σφρων* and *σφροσωνη*. If the change be admitted, we see the cause of the anomaly in the Latin *pon-o*, *posu-i*, *pos-illum*.

10. *N* before *s* silent, but lengthening the preceding vowel. This fact is well exemplified throughout the grammar of the Greek language. The Latin had the same peculiarity. Hence *consul* was sometimes written *cosol*, and when abbreviated was always represented by the three first of the sounded letters, viz. *cos*. So *ensor*, *insans*, *viciens*, *vicensimus*, are often found in the form *cesor*, *insas*, *vicies*, *vicesimus*. We see too why the Greeks wrote the Latin words *κησωρ*, *Κησταντινος*, with a long vowel in the first syllable. Lastly, while the Germans write *gans*, *wünschen*, the English have *goose*, *wish*.

11. *N* silent at times before *t* and *th*. The English word *mutton* is derived from the French *mouton* and the Italian *montone*; and our word *tooth* in the older Gothic dialects was *teonth*, thus corresponding as nearly as it ought to do with the Greek *οδοντ*, and Latin *dent*.

12. *N* before *v* silent. Thus the Latin *convention*, assembly became *covention* (as it occurs in one of the oldest inscriptions), before it was reduced to *contion*, the assembly of the people, a word which modern editors, in spite of all the best MSS. and of etymology, persist in writing with a *c* for the fourth letter. Similarly from *conventu* came the French *couvent*; and though the English generally say *convent*, yet the name *Covent Garden* is a proof that the *n* was not always pronounced even here.

An initial *n* is sometimes prefixed to, and sometimes taken from words by error. Thus *nadder*, a snake, has now lost its *n* through a confusion of the phrase *a nadder* with *an adder*. On the other hand, the phrase *for then once*, i.e. *for this once*, in which the article has its old accusative form *then*, is now written *for the nonce*. Is it in this way that we should account for the prefixed *n* in the diminutives *Ned*, *Nol*, *Nan*, *Nelly*, for *Edmund* or *Edward*, *Oliver*, *Anne*, *Ellen*, as if the original phrases *mine Ed*, *mine Anne*, had been confounded with *my Ned*, *my Nan*? At any rate, *mine*, *thine*, *an*, were severally the original forms of *my*, *thy*, *a*, and used even before consonants; nay, in Somersetshire they have changed *aint* to *nānt*, *uncle* to *nuncle*, *awl* to *nawl*. Very similar is the prevailing error of calling the Greek negative particle *alpha privative* instead of *an privative*; the latter of which corresponds so accurately with the Latin *in* and the English *un*, to say nothing of the Greek *αυω*, and the German *ohne*. In fact, *n* at the end of words is often pronounced very faintly.

The Somersetshire dialect has been referred to because its peculiarities have been recorded with great care in Mr. Jennings's 'Observations.'

NABATHÆI. [ARABIA, p. 215.]

NABIS, tyrant of Sparta, attained the supreme power after the death of the tyrant Machanidas, who was killed about 206 B.C. He proved a cruel despot, and put to death a number of citizens. He had an ingenious engine of torture, described by Polybius (xiii.), which was called Nabis's wife, and which he applied to those who would not deliver up their money to him. He allied himself with Philip II. of Macedon, and took possession of Argos and other parts of the Peloponnese. After the defeat of Philip, and the peace which followed between him and Rome, the consul Flaminius marched against Nabis, defeated him, but afterwards granted him peace, taking his son as hostage to Rome. After the departure of the Romans, Nabis having begun to annoy his neighbours afresh, the Achæans sent against him their general Philopomenus, who defeated him and drove him back into Sparta, where Nabis was soon after treacherously killed by his own Ætolian auxiliaries, B.C. 192. (Livy, xxv. 36.) He appears to have been a very able commander in war.

NABLOUS. [SYRIA.]

NABOB, or NABAB, a corruption of the Hindustani Nuwwab, which was the title of the governor of a province under the Mogul empire, such as the Nuwwab of Arcot, of Oude, &c. (Gilchrist, *Vocabulary*.) Several of these became gradually independent during the decline of the empire, and are now either allies or dependents of the Anglo-Indian government. The word Nabob is sometimes used in Europe to mean a wealthy man who has made his fortune in India.

NABONASSAR, ERA OF. [PERIODS OF REVOLUTION.]

NABOPOLASSAR. [BABYLON.]

NACHITOCHEs. [LOUISIANA.]

NACRE. [SHELL.]

NACRITE, a mineral usually occurring in mica slate, taking the place of the mica; so that the rock becomes a mixture of quartz and nacrite. It is also found crystallized in granite. It occurs in four-sided prisms. Hardness 2.75. Colour silvery, or light greenish white. Lustre pearly, silky, splendid. Translucent. Specific gravity from 2.788 to 2.793. It occurs in Wicklow, Ireland, and in North America.

A specimen from Brunswick, Maine, analyzed by Dr. Thomson, gave—

Silica	64.440
Alumina	28.844
Protoxide of Iron	4.428
Water	1.

98.712

The crystals from Wicklow contained less oxide of iron, but a considerable portion of lime and of protoxide of manganese.

NADIR. [ZENITH.]

NĀDIR SHAH was born on the 11th of November, 1688, at the small village of Abuver, near Killaat, about 30 miles north-east of Mushed in the province of Khorassan. He was originally called *Nādir Kouli*, that is, 'a slave of the Wonderful,' or 'of God.' When he entered the service of Tāmāsp, king of Persia, he assumed the name of *Tāmāsp Kouli Khān*, that is, 'Khan, slave of Tāmāsp;' but on his accession to the throne he resumed his original name of *Nādir*.

The father of Nādir belonged to the tribe of Afshār, which was one of the seven Turkish tribes which had attached themselves to the kings of Persia. He was a person of no note or rank, and earned his livelihood by means of making coats and caps of sheep-skins. Nādir, after his elevation to the throne, used frequently to allude to his low birth. When the royal house of Delhi required that his son, who was about to marry a princess of that family, should give an account of his male ancestors for seven generations, Nādir exclaimed, 'Tell them that he is the son of Nādir Shah, the son of the sword, the grandson of the sword, and so on till they have a descent of seventy instead of seven generations.'

Nādir was distinguished in early years by his boldness and intrepidity. At the age of seventeen he was taken prisoner by the Usbega, who made annual incursions into Khorassan; but he effected his escape after a captivity of four years. On his return to Khorassan, he entered the service of a petty chief of his native country; but he became soon afterwards the leader of a formidable band of robbers. From this employment he rose, by a transition by no means uncommon in the East, to a high rank in the service of the governor of Khorassan; but having displeased his master, he was degraded and severely punished. After this he resumed his occupation as a robber; and in consequence of the unsettled state of the country, he acquired in a short time no small degree of power. In order to understand clearly the circumstances which facilitated the rise of Nādir, it is necessary to make a few remarks on the internal state of Persia at that time.

In the early part of the eighteenth century, Persia was attacked and eventually conquered by the Affghans. In 1722 Shah Hussein, the Saffavean monarch of Persia, abdicated the crown to Mahmud, the Affghan conqueror. Mahmud was succeeded in 1726 by Ashrāff; who reigned at Ispahan and had the supreme power, though Tāmāsp, the son of Hussein, maintained a precarious independence in a distant part of the empire. Though the power of the Saffavean monarchs had been entirely overthrown by the

Affghans, yet the latter had not been able to establish their own authority in the distant provinces of the kingdom; and the consequence was, that Khorassan and other remote provinces were left without any regular government. Nādir was thus enabled to prosecute his schemes without interruption; and having at length raised a body of 5000 men, he joined Tāmāsp in 1727, and declared his intention of expelling the Affghans from his native country. The oppressive rule of the Affghans and the renewal of Nādir quickly brought great numbers to his standard; and having been invested with the supreme command by Tāmāsp, which he acquired by putting to death Futtah Ali, who had previously commanded the forces of the king, he marched against the Affghans and took Mushed in the same year. He followed up his first success with several brilliant victories; Ispahan fell into his power; Ashrāff was taken and put to death; and by the close of the year 1729 few if any Affghans were left in Persia.

Such sudden and unexpected success rendered Nādir exceedingly popular; and he appears from this time to have resolved upon seizing the royal power as soon as circumstances would allow him to do so. In 1730 he received from Tāmāsp a grant of the four finest provinces of the kingdom, Khorassan, Mazanderan, Seistan, and Kerman; and was requested at the same time to assume the title of sultan. This honour however he declined; but at the same time he ordered money to be struck in his own name, which in the East is regarded as a virtual assumption of the sovereignty of the country.

In 1731 Nādir was engaged in a war with the Turks, whom he defeated on the plains of Hamadan; but having been obliged to march to Khorassan to quell a rebellion, Tāmāsp seized the opportunity of assuming the command of the army, and marched himself against the Turks. Being defeated in battle, he concluded a treaty with the Turks, by which he ceded to them several provinces of the Persian empire. As soon as Nādir heard of this treaty, he took advantage of the discontents which it excited, to carry into execution the plans he had long meditated for seizing the royal power. He published a proclamation, in which he bitterly inveighed against the peace, and announced his intention of prosecuting the war. Having thus secured the good will of the people, he invited Tāmāsp to his camp; and on his arrival, he caused him to be seized and carried away to Khorassan. Instead however of proclaiming himself king, he considered it more prudent for the present to place on the throne the son of Tāmāsp, who was an infant eight months old.

Having completed these arrangements, Nādir continued the war against the Turks, and after experiencing some reverses, he obliged them to sue for peace, which was granted in 1735. The infant sovereign of Persia having died about the same time, Nādir summoned a grand council, consisting of almost every person of rank and consideration in the kingdom, to meet in the plains of Chowal Moyām, which extend from the neighbourhood of Ardebil to the mouth of the Cyrus, in order to take into consideration the state of the kingdom. Upwards of 100,000 persons are said to have attended this assembly, in which the sovereignty was offered to Nādir, who accepted it with apparent reluctance, on the 26th of February, 1736, on condition that the Sheah sect, which had hitherto been supported by the great majority of the Persians, should be entirely abolished, and the sect of the Sunnes established in its place. He also stipulated that the Imam Jaaffer should be placed at the head of the national religion; and that as there were four orthodox sects among the Sunnes, the Persians should be considered as a fifth, under the name of the sect of Jaaffer. It is difficult to determine the reasons which induced Nādir to make this violent change in the religion of the country; but it appears most probable that he wished to destroy the Sheah sect, since it had always warmly supported the dynasty of the Saffavean princes. All the religious property of this sect, which was very considerable, was confiscated by Nādir, and this impolitic attack upon the established religion tended to produce discontents at the very commencement of his reign. Nādir himself appears to have possessed little or no religion; and the Korān as well as the Gospels, which were translated into Persian by his order, were frequently the subjects of his merriment and sarcasm.

Soon after his accession to the throne, Nādir made vigorous preparations for the extinction of the Affghans as a separate power; and as this object could not be accom-

plished without the reduction of the city and province of Candahar, which were then in the possession of the brothers of Mohammed, the late Afghan monarch of Persia, he commenced the war by an invasion of this province. The city of Candahar fell into his power in 1738, and many of the Afghans fled into the northern provinces of Hindustan, where they were hospitably received. Nâdir required of the emperor of Delhi that none of the Afghan fugitives should find shelter in his dominions, but as no attention was paid to his demands, he marched into Hindustan in the following year, and after defeating the Mogul troops, entered Delhi on the 8th of March, where he seized the immense treasures which had been amassed in the course of nearly two centuries by the Mogul monarchs. Soon after his arrival, a report having been spread through the city that Nâdir was dead, the inhabitants made a general attack upon his soldiers. Nâdir in vain endeavoured to undeceive the populace; his moderation only inflamed the fury of those whom, according to Hindu historians, it was his desire to save; and at length, unable to restrain the people, he gave orders for a general massacre. These commands were too well obeyed; and from sunrise till noon the inhabitants were butchered by his soldiery without any distinction of sex and age. At the intercession of Mohammed, the emperor of Delhi, Nâdir at length commanded the massacre to be stopped; and it is recorded as a proof of the high state of discipline of his troops, that his commands were immediately obeyed. The number of those who perished in this massacre is variously stated by different writers. Fraser says that 120,000 persons were killed; but a Hindu historian reduces the number to only 8000. (*Scott's Translation of the History of the Dekhan*, vol. ii., p. 207.)

Nâdir did not attempt to make any permanent conquests in Hindustan. He returned to Persia in the following year, and directed his attention towards the reduction of the nations on the north of Persia. He crossed the Oxus in order to punish the sovereign of Bokharah, who had, during his absence in Hindustan, made incursions into Khorassan. This monarch having submitted to his power, Nâdir next marched against the king of Khaurizm, whose dominions extended westward of Bokharah along both banks of the Oxus as far as the Caspian. The king of Khaurizm, refusing to submit to Nâdir, was defeated in battle, taken prisoner, and put to death, 1740.

By these conquests Nâdir had completely secured the peace of Persia. He had delivered his native country from the tyranny of the Afghans, and had extended its dominions to the Indus on the east, the Oxus on the north, and almost to the plains of Bagdad on the west. The Turks, who frequently endeavoured during his reign to extend their dominions, were always repulsed with loss; and the Russians were glad to enter into alliance with this all-powerful conqueror. Hitherto Nâdir had ruled with moderation and justice; but the latter part of his reign was disgraced by acts of the foulest tyranny and oppression. His conduct during this period has been described, even by a partial historian (Mirza Mabadi), as exceeding in cruelty and barbarity all that has been recorded in history of the most bloody tyrants. In 1743 his eldest son, Reza Kouli, who had distinguished himself by his bravery in many actions, was deprived of sight by order of his father. The possession of absolute power appears to have called forth in the mind of Nâdir, as it has often done in the minds of other absolute monarchs, some of the worst passions of human nature—avarice, jealousy, and cruelty. During the early part of his reign Nâdir was distinguished by the greatest liberality; and after he had obtained the immense wealth of the imperial house of Delhi, he at first remitted three years' taxes. But the possession of such enormous wealth appears to have excited in him the desire of accumulating more; and the taxes were increased to meet the insatiable demands of the royal treasury. It has been already stated that the presumption of the Shah had tended to render him unpopular. Nâdir, aware of this, ceased to trust any of the native Persians, who belonged almost entirely to the Shah's race, and placed his chief dependence on the Turks and Afghans in his army, who were Sunnees. So great was his suspicion of his own subjects, that he is said to have formed the design of putting to death every Persian in the army. Some of the principal officers of his court, having learnt that their names were included in the proposed massacre, endeavoured to save themselves by the assassination of the tyrant, and, having entered

his tent during the night, put him to death, on the 19th or 20th of June, 1747. Nâdir was succeeded by his nephew Ali.

'The character of Nâdir,' observes Sir John Malcolm, 'is perhaps exhibited in its truest colours in those impressions which the memory of his actions has left upon the minds of his countrymen. They speak of him as a deliverer and a destroyer; but while they expatiate with pride upon his deeds of glory, they dwell with more pity than horror upon the cruel enormities which disgraced the latter years of his reign; and neither his crimes nor the attempt he made to abolish their religion have subdued their gratitude and veneration for the hero, who revived in the breasts of his degraded countrymen a sense of their former fame, and restored Persia to her independence as a nation.' (*History of Persia*, vol. ii., p. 103.)

The life of Nâdir Shah was written in Persian by his secretary, Mirza Mohammed Mabadi Khan, who attended him in all his expeditions, and has been translated into French by Sir W. Jones. Fraser also published from Persian MSS., which he obtained in India, 'The History of Nâdir Shah, formerly called Thomas Kuli Khan, the present Emperor of Persia,' Lond., 1742. Many interesting particulars relating to Nâdir are given by Hanway, in his 'Historical Account of the British Trade over the Caspian Sea,' Lond., 1753-4, which have considerable value, since Hanway had personal knowledge of many of the facts which he has recorded. A detailed life of Nâdir is also given by Malcolm in his second volume of the 'History of Persia.'

NÆSA. [Isopona, vol. xiii., p. 53.]

NÆVIUS CNEIUS, a native of Campania, and one of the earliest Roman poets, was older than Ennius, and the contemporary of Livius Andronicus. He served in the first Punic war, and afterwards wrote an epic poem on the same, 'De Bello Punico,' and another called 'Ilias Cypria.' He also wrote several dramas in imitation of the Greek, and other comedies on national or Roman subjects, such as 'Macchus exul,' 'Vindemiatores,' &c. Of all these, the titles and a few scattered lines are all that have come down to us. ('Fragmenta Poetarum Latinorum, quorum Opera non extant,' by Stephanus, 1564, and also Maittaire, 'Corpus Poetarum.')

Cicero, 'De Oratore,' ii. 69, 70, and iii. 12, praises him for his unaffected simplicity and native humour. It appears that he had a genius for the satirical, which proved unlucky to him; for, having exposed in his plays some of the leading men at Rome, among others some of the Metelli family, he was imprisoned and banished as an alien. He is said to have retired to Utica in Africa, where he died about B.C. 204, according to the chronicle of Eusebius. Aulus Gellius (iii. 3) says, that being imprisoned at Rome, he composed two comedies in his prison, through which he was restored to liberty.

NÆVUS (*Nævus maternus*, *Mother Spot* or *Mole*) is a congenital mark or morbid growth on a part of the skin. Nævi are of various kinds; some are merely yellowish or brown discolorations of the skin without any evident alteration in its structure; but the greater number are composed of an excessively vascular tissue, or a dense network of arteries and veins forming a reddish or livid substance, more or less elevated above the surface of the surrounding skin. A third kind are like extensive warty excrescences, and many of them are covered with thick-set coarse hair.

The nævi of the first kind rarely require treatment. Those of the second are more important from their tendency to increase, or to ulcerate and slough, or to produce severe hæmorrhage by the rupture of some of their vessels. Many plans have been suggested for their removal. If they be not seated on an exposed part, or if they do not show a tendency to increase, they had better be left without treatment. In other cases, the simplest and sometimes a sufficient means is the continued application of cold with moderately firm pressure; but a more certain method is to produce such an inflammation in them as may obliterate their vessels and reduce them to the common substance of scars. In small superficial nævi this may be effected by vaccinating them so as to produce a number of pustules on their surface; and in larger ones, by cauterising a part of their surface with fused potash, or nitric acid, or nitrate of silver, or by injecting some stimulant (as dilute nitric acid) into their tissue, or by making small incisions into them, or by passing hare-lip pins and

sutures [HARE-LIP] through parts of their substance, or by placing setons in them. The circumstances of each case must decide the choice between these several means, and the mode in which that which is selected may be best applied. Should complete removal be deemed necessary, nævi may be either cut out, or made to slough by tying them round the base. For the third kind of warty nævi, excision is at once the simplest and the most secure means.

It is a popular belief that nævi and some other malformations in infants are consequent on an impression made on the mind of the mother during pregnancy, and that the mark always bears some resemblance to the object by which the impression was excited. It cannot be denied, that among the many cases of nævi, some singular coincidences of the kind have occurred, and that in some of these the malformation might be deemed to have some connection with the object of the mother's fear or anxiety; but till it be determined that the number of these coincidences is greater than would occur according to the common laws of chances (which is as yet far from being proved), the hypothesis of a connection between the state of the mother's mind and the local conformation of the child, which is totally opposed to all physiological probability, cannot be admitted.

NAGASAKI. [JAPAN.]

NAGORE. [MARWAR.]

NAGPORE. [BERAR.]

NAGPORE, a large town in the dominions of the Rajah of Berar, or Nagpore, situated in 21° 9' N. lat. and 79° 10' E. long. It stands on a plain 1100 feet above the level of the sea. The town, which is of very irregular form, is about 7 miles in circumference, the buildings being placed in a very straggling manner, as is often seen in India. The greater part of the dwellings are small thatched cottages. Some of the richer inhabitants have large brick-built houses with flat roofs, but the number of these is small, and is continually decreasing through the declining condition of the town. According to an enumeration made in 1825, Nagpore contained at that time,

Houses built of brick	1,301
Tiled houses	11,120
Thatched cottages or huts	14,680
Matted huts of the lowest description	48
Total	27,149

The population at the same time amounted to 115,228.

The palace of the rajah is a large, heavy, and very plain building of brick, and is surrounded by the lowest kind of houses or hovels: it has never been completely finished.

The trade of Nagpore, which was at no time very considerable, has declined since the fall of Appah Sahib, and the removal of the seat of government.

At the enumeration in 1825, it appeared that there were about 3500 domestic slaves, chiefly females, who had been purchased when children from their parents. The condition of slavery in this region does not bear much analogy to the state of degradation which is elsewhere implied in the name, since the severest punishment that can be inflicted for any crime committed by a slave is expulsion from the family of the master, and consequent manumission. On the other hand it would appear that the condition of free labourers is one of great hardship, so that life has little value in their eyes. Suicide is of very common occurrence, being resorted to upon the slightest occasions of domestic quarrel, or of real or supposed injury: the more usual modes employed for self-destruction are poison, drowning in wells, and hanging.

Nagpore is distant 733 miles from Calcutta, 577 miles from Bombay, 673 from Madras, 486 from Poonah, and 631 from Delhi, travelling distances. (*Report of Committee of House of Commons in 1832; Rennell's Memoir of a Map of Hindustan.*)

NAHUM (נְחֻם, נחום), one of the twelve minor Hebrew prophets, was called the Elkoshite (עֵלְכוֹשִׁי, Nahum, 1. 1), probably from the place of his birth, Elkosh, a village in Galilee (Hieronymus, *Proem in Nahum*; Eusebius, *Onomasticon*, art. 'Ελκωσι'). He prophesied in the kingdom of Judah, whither we may suppose he had gone after the overthrow of Israel. His age can only be conjectured from certain indications contained in his prophecy, from

which it appears that both the kingdoms of Israel and Judah had been subject to severe attacks from the Assyrians (chap. i.), and that the captivity of Israel had already taken place (chap. ii. 2). He is thought to allude to the destruction of Sennacherib's army (i. 11-14), as having occurred recently (ii. 1). He also prophesies the speedy restoration of Judah to prosperity (i. 15; ii. 7), which happened in the reign of Josiah. These circumstances would place his prophecy towards the close of Hezekiah's reign, about 705 B.C.

Some suppose that the destruction of Thebes and the captivity of the Egyptians and Ethiopians, spoken of in Nahum (ii. 8-10), are the same events to which Isaiah refers (chap. xx.); but this is uncertain.

His prophecy is a complete poem, the subject of which is 'the burden of Nineveh' (i. 1), that is, the destruction of Nineveh and the Assyrian empire, as the punishment of its wickedness and oppression. The prophecy commences with a sublime description of the power of Jehovah in punishing his enemies and protecting his people, and proceeds to foretell the impending destruction of Nineveh (chaps. i. ii.), which is described in the most vivid poetry in chap. iii. The event which he prophesies took place in the year 625 B.C., in the reign of Chyniladanus, king of Assyria, when Nineveh was destroyed and the Assyrian empire overthrown by Cyaxares I. and Nabopolassar.

'None of the minor prophets seem to equal Nahum in boldness, ardour, and sublimity. His prophecy too forms a regular and perfect poem; the exordium is not merely magnificent, it is truly majestic; the preparation for the destruction of Nineveh, and the description of its downfall and desolation, are expressed in the most vivid colours, and are bold and luminous in the highest degree.' (Bp. Lowth, *Praelect.*, xxi.) Some expressions and images, which are peculiar to him, occur in i. 10; ii. 4-9; iii. 17.

The canonical authority of Nahum's prophecy is undisputed.

(Rosenmüller, *Scholia in Vet. Test.*; Winer's *Biblisches Realwörterbuch*; the *Introductions* of Eichhorn, Bertholdt, Jahn, De Wette, and Horne.)

NAIA, Laurenti's name for a genus of highly venomous serpents, *Uraeus* and *Aspis* of Wagler.

Cuvier places the form next to the Vipers (*Vipera* of Daudin), and immediately preceding *Elaps* (Schn., part). Mr. Gray makes *Naiina* the second subfamily of his *Viperidae*, *Viperina* being the first. *Naiina*, which is characterised by Mr. Gray as having the 'head broad behind, with plates,' is immediately succeeded by *Elaphina*, and thus the genus *Naiia*, in his arrangement, stands between *Pelias* (Merrem) and *Sepidon* of the same author. (*On the Genera of Reptiles*, in *Annals of Phil.*, 1825.)

Mr. Swainson, in his 'Classification of Reptiles' (*Natural History of Fishes, Amphibians, and Reptiles*, vol. ii.), places the genus *Naiia* among the *Crotalidae*, his second family of *Ophides*, or serpents, and arranges it between *Cerastes* and *Platurus*. He gives the following as the subgenera:—*Naiia*, *Sepidon*, and *Elaps*, and thus characterises the subgenus *Naiia*:—Neck capable of being dilated; head narrow; dorsal scales linear; tail conical; subcaudal plates arranged in two rows.

Geographical Distribution.—This form appears to be confined to the Old World.

The Asiatic species, *Coluber Naja* of Linnæus, *Coluber cæcus* of Gmelin? *Vipera Naja* of Daudin, *Naja tripudians* of Merrem, *Naja lutescens* of Laurenti, *Cobra de Capello* (adder with a hood) of the Asiatic Portuguese, *Serpent à lunettes* of the French, *Spectacle-snake* of the English, *Nag* and *Chinta nagoo* of the natives, may be considered as the type of the genus.

Generic Character.—Head, with nine plates behind, broad; neck very expansile, covering the head like a hood; tail round. (Gray.)

The expansion of the neck and upper part of the body is effected by the anterior ribs, which the animal has the power of raising and bringing forward so as to dilate that portion into a disk more or less large. When this disk is thus dilated in the *Naiia tripudians*, it presents on the back part of it no bad representation of a pair of spectacles, or rather barnacles, reversed, for there is no trace of the lateral pieces by which spectacles are attached to the head of the wearer. The animal is brown above, and bluish-white beneath. The following cuts will convey some idea of the form of this snake, with the hood or disk expanded.

Head of Naja.
a, side view; b, seen from above.

a, view of the upper side of the disk or hood expanded, with the head on the same line with the body; b, view of the under side of the same; c, the disk or hood seen from behind, when the anterior portion of the excited serpent is in an erect posture.

Naja tripudians (reduced) in an erect and excited state.

Colonel Briggs informs us that this active and deadly serpent is sometimes worshiped in temples in India, where it is pampered with milk and sugar by the priests, and he notices it as a surprising instance of the effect of kind treatment in subduing the most irritable spirits. 'The Hindus,' says the Colonel, in continuation, 'have a notion that the sagacity and the long-cherished malice of this worm are equal to that of man. I have seen them come out from their holes in the temples, when a pipe has been played to them, and feed out of the hand as tamely as any domestic animal; and it is when in this state of docility, so opposite to their shy but impetuous nature, the common people believe that the Deity has condescended to adopt that form. It seems probable that this hooded snake was the dragon of the heathen worship; and the shape of its head and its activity when in a state of excitement probably gave rise to the fable of its being winged.'

It is pretended that the root of the *Ophiorrhiza mungos* is a specific against the bite of this serpent. The priests and jugglers however, who make them dance to astonish or amuse the people, make all sure, there is little doubt, by extracting the poison-fangs.

This formidable species, or at least some species of hooded snake, according to the records of travellers, grows to a considerable length. Captain Percival gives the following account of its size and habits, in his 'Account of the Island of Ceylon,' 4to., 1805.—

'The Cobra Capello, or hooded snake, is found here from six to fifteen feet long. Its bite is mortal. The natives find the herb pointed out by the ichneumon a remedy, if timely applied. When enraged and preparing to attack, it raises its head and body to the height of three or four feet in a spiral manner, while at the same time the remaining part of the body is coiled up to accelerate and give force to the spring. At this instant it distends from its head a membrane in the form of a hood, from which it receives its name. This membrane lies along the forehead and the sides of the neck, and is almost imperceptible till the animal gets into a state of irritation and is about to attack his foe. When the hood is erected it completely alters the appearance of the head, and discloses a curious streak in the shape of a pair of spectacles, and sometimes of a horse-shoe. The extension of this membrane seems intended by Providence to give warning to all those within this animal's reach that he is preparing to attack them. Without this signal he would be very dangerous indeed, as his motions afterwards are too rapid to be avoided. I have more than once been an eye-witness to instances where the fatal bite of this snake was escaped from merely by the object of his vengeance timely observing his preparations. One remarkable characteristic of those dangerous serpents is their fondness for music. Even when newly caught they seem to listen with pleasure to the notes, and even to writhe themselves into attitudes. The Indian jugglers improve greatly on this instinct, and, after taming them by degrees, instruct them even to keep time to their flageolet.'

The largest *Cobra de Capello* seen by Dr. Davy in Ceylon was nearly six feet long; and he adds that the general length is between two and four feet. The colour varied: those of a light colour were called high-caste snakes by the natives, and those of a dark colour low-caste. 'The natives,' says Dr. Davy, 'in general rather venerate this snake than dread it. They conceive that it belongs to another world,* and that when it appears in this it is merely as a visitor; they imagine that it possesses great power, that it is somewhat akin to the gods, and greatly superior to man. In consequence they superstitiously refrain from killing it, and always avoid it, if possible. Even when they find one in their house, they will not kill it, but, putting it into a bag, throw it into water. They believe that this snake has a good and generous disposition, and that it will do no harm to man, unless provoked.' Dr. Davy gives a pleasing picture of the irritations and soothing with which the snake-charmers excite and allay the temper of this serpent. He records several instances of the operation of the poison, the first arising from a serpent found in a bag floating down the Kalang-ganga. It was about five feet long, and about six inches in circumference in the broadest part. This snake bit a hen, fixing its fangs in the skin covering the lower

* Dr. Davy, in his chapter on the *Singalese System of the Universe*, has the following passage:—'The Naga-bhawoné, that lies under Ascora-bhawoné, is also 10,000 leagues in circumference. It is a hollow sphere, without mountains or hills, lakes or rivers, and entirely destitute of vegetation, with the exception of a single tree, called Parasattoo, that answers for all others, bearing not only an immense variety of flowers and fruits, but everything else that is desirable. The Naga-bhawoné is the abode of a numerous race of snakes, similar in kind to the hooded snake, and of great size, beauty, and power, capable of passing from one part of the world to another, and shining like gods; so that, though they have no light but that which emanates from their own bodies, they enjoy perpetual day infinitely brighter than ours. In their former lives on earth they were persons of remarkable purity and goodness, almost deserving of becoming gods; but their high virtues were sullied by some vice, particularly that of malice, to which they owe their present forms. Though snakes, they are Rhodist, and are in possession of a relic and worship in temples. They reside in well-furnished houses, and eat and drink, and enjoy society. By merely wishing, they immediately have any article of food they want; and whatever it may be, it always appears in the form of a frog. They are under a regal government, and are distributed into castes, like the Singalese. Their king, Mahakilla-naga-rajaya, is in every respect superior to the rest; it was with his assistance that the gods and Ascoras churned the milky sea; he wound himself round a rock, and they, pulling at his two extremities, set the mass in motion and accomplished their work. Were these snakes disposed, they could destroy the whole of the inhabitants of the earth by a single blast of their poisonous breath; but they are naturally mild and benevolent, and do harm only when provoked. In consequence, they are rather venerated than dreaded; and it is on this account that the common hooded snake is so much respected.'

part of the left pectoral muscle, and keeping its hold about two or three seconds, when Dr. Davy succeeded in shaking it off. The hen, which at first seemed to be little affected, died eight hours after she was bitten.

The reader will find other experiments recorded by the author; but the bite which was followed by the most speedy death was inflicted by another *Cobra de Capello* upon a young cock. 'The snake fastened on the thigh, and inflicted rather a severe wound, from which some blood flowed. The cock became instantly lame, and in less than a minute was unable to stand. In about five minutes his respiration became hurried and rather laborious; some alvine dejections took place. In about ten minutes he appeared to be in a comatose state, and for about five minutes he continued in this state, his respiration gradually becoming more feeble and laboured. In seventeen minutes, when his breathing was hardly perceptible, he was seized with a convulsive fit, which in the course of the next minute returned four or five times, each less violent than the former, and the last proved fatal.' (*An Account of the Interior of Ceylon, &c.*, by John Davy, M.D., F.R.S., 4to., London, 1821.)

We owe to Dr. Cantor, who has added so much to our knowledge of the natural history of Asiatic serpents, the introduction of a new genus of hooded snakes, *Hamadryas*, which will probably find its proper place in the series as a subgenus of *Naja*. The doctor himself gives it a position between that genus and *Bungarus* (Daudin), which two forms, in his opinion, it will be found to connect together

Hamadryas. (Cantor.)

Generic Character.—Head broad, subovate, deplanate, with a short obtuse rostrum, covered above with fifteen *scuta*. Cheeks tumid. Eyes large, prominent, pupil round. Nostrils widely opened within the confine of two *scuta*. Gape very ample, subundulated. Poison-fangs anterior, behind which are the maxillary teeth. Neck dilatible. Body thick, smooth, imbricated with smooth scales disposed in oblique rows. Tail short, covered with *scuta* and *scutella*, its apex acute. (Cantor.)

Example, *Hamadryas ophiophagus*. (Cantor.)

Description.—Above olive-green, girt with black sagittal striae, abdomen glaucous, marbled with black. The Hindustanee name is *Sunkr-Choar*.

Locality.—Bengal.

Habits, &c.—Dr. Cantor thus describes the habits, the effect of the poison, and the history of this serpent.

'The *Hamadryas*, like the *Bungarus*, *Hydrus*, and *Hydrophis*, has a few maxillary teeth behind the poison-fangs, and thus, like the latter, connects the venomous serpents with isolated poison-fangs to the harmless, which possess a complete row of maxillary teeth.

'Of the terrestrial venomous serpents, the *Bungarus* is chiefly characterised by a distribution of the teeth similar to that of the *Hamadryas*, which, also partaking of the chief characteristic of the genus *Naja*, viz. that of forming a hood or disc, constitutes an immediate link between the genera *Bungarus* and *Naja*.

'In consequence of the strong resemblance in the general appearance between the *Naja* and the *Hamadryas*, when first my attention became attracted to the latter, I thought I could refer this serpent to that genus; and it was not until I was able to examine a specimen whose poison-fangs were untouched (those of the first specimens I saw having been drawn by the natives, who are greatly afraid of this serpent), that I discovered the maxillary teeth behind the poison-fangs.

'*Hamadryas ophiophagus* differs from the *Naja tripudians*:

1. By its maxillary teeth.
2. By the strongly developed spines on the *os occipitale inferius*.
3. By the integuments covering the head.
4. By the integuments covering the abdominal surface of the tail.
5. By its colour.
6. By its size.

'According to the natives, the *Hamadryas* feeds chiefly upon other serpents: in one I dissected I found remains of a good-sized *Monitor*, which fact may account for its arboreal habits, as I have in Bengal, along the banks of the rivers, observed numbers of those large lizards among the branches of trees watching for birds.

'The power of abstaining from food, generally speaking,

so characteristic of the serpents, is but in a comparatively small degree possessed by this species; the most protracted starvation amounts to a period of about one month; while the *Vipera elegans*, the *Naja tripudians*, and the *Bungarus annularis*, have, without inconvenience, been confined in cages without any food for more than ten months. Two specimens of the *Hamadryas* in my possession were regularly fed by giving them a serpent, no matter whether venomous or not, every fortnight. As soon as this food is brought near, the serpent begins to hiss loudly, and, expanding the hood, rises two or three feet; and retaining this attitude, as if to take a sure aim, watching the movements of the prey, darts upon it in the same manner as the *Naja tripudians* does. When the victim is killed by poison, and by degrees swallowed, the act is followed by a lethargic state, lasting for about twelve hours. Such of the other Indian venomous serpents, the habits of which I have had opportunity to study from life, show themselves much inclined to avoid other serpents, however ready they are to attack men or animals when provoked or driven by hunger; and I am not aware of any other of those serpents being recorded as preying upon its own kind. A short time ago however, during my sojourn at the Cape of Good Hope, I received from high authority the following fact, which throws a light upon the habits of the *Naja* of Southern Africa, one of which, when being captured, threw up the body of a *Vipera arietans* (*Vip. brachyurus*, Cuvier), which bore marks of having been submitted to the process of digestion.

The *Hamadryas*, like the greater number of Indian serpents, evinces a great partiality to water; with the exception of the tree-serpents (*Leptophina*, Bell), they all not only drink, but also moisten the tongue, which, as this organ is not situated immediately in the cavity of the mouth, become in the serpents two different acts.* Specimens of this serpent in my possession changed the skin every third or fourth month, a process which takes place in all the Indian serpents several times during the year. The *Hamadryas* is very fierce, and is always ready not only to attack, but to pursue, when opposed; while the *Cophias*, the *Vipera*, the *Naja*, and the *Bungarus*, merely defend themselves; which done, they always retreat, provided no further provocation is offered. The natives of India assert that individuals are found upwards of twelve feet in length, a statement probably not exaggerated, as I have myself seen specimens from eight to ten feet in length, and from six to eight inches in circumference. I have often heard it asserted that "Cobras" (which name is naturally enough given to every hooded serpent) have been met with of an enormous size, but I strongly doubt their belonging to the genus *Naja*: among a considerable number which have come under my observation, I never saw any exceeding five to six feet in length, while the common size is about four feet. Some time before I discovered the *Hamadryas*, I was favoured by J. W. Grant, Esq., of the Hon. Company's Civil Service, with an interesting description of a gigantic hooded serpent he had observed in the upper provinces, and which, he remarked, was not a *Naja*. By inspection this gentleman denied the *Hamadryas* to be identical with the above-mentioned.

The natives describe another hooded serpent, which is said to attain a much larger size than the *Hamadryas*, and which, to conclude from the vernacular name, "*Mony Chour*," is perhaps another nearly allied species.†

The fresh poison of the *Hamadryas* is a pellucid tasteless fluid, in consistence like a thin solution of gum arabic in water; it reddens slightly litmus paper;‡ which is also the case with the fresh poison of the *Cophias viridis*, *Vipera elegans*, *Naja tripudians*, *Bungarus annularis*, and *Bung. caeruleus*: when kept for some time it acts much stronger upon litmus; but after being kept it loses considerably, if not entirely, its deleterious effects.

* M. Schlegel is of opinion that serpents never drink. (*Essai sur la Physiologie des Serpens, Partie Générale.*) As mentioned above, I have had opportunities of ascertaining that the greater number of Indian serpents are very fond of water, a fact which I am aware has also been observed in the African serpents by the eminent naturalist Dr. A. Smith, whose valuable discoveries, which he is at present engaged in publishing, will bring to light many facts, of which we are at present in almost total ignorance, concerning the habits of animals, particularly those of the Reptiles.

† The Cobra Capello described by Captain Perouval (ante, p. 69) may have been one of these gigantic hooded serpents.

‡ M. Schlegel asserts (loc. cit., p. 84) the venom is "ni alcalin ni acide." The only way in which I can account for this mistake from a man who ranks among the first Erpetologists, is by supposing that M. Schlegel himself never had an opportunity of testing the poison of a living serpent; for besides the five above-mentioned genera of Indian venomous serpents, I found the fresh

From a series of experiments upon living animals, the effects of this poison come nearest to those produced by that of the *Naja tripudians*, although it appears to act less quickly. The shortest period within which this poison proved fatal to a fowl was fourteen minutes, whilst a dog expired in two hours eighteen minutes after being bitten. It should however be observed that the experiments were made during the cold season of the year.

A specimen of the present genus (*Hamadryas*), in the Collection of the Society, was upon the table, having been presented to the Museum by Sir Stamford Raffles, but without any facts respecting its history, or the locality in which he had procured it. (*Zool. Proc.*, 1838.)

For an example of the African species see Asp. It is worthy of observation with reference to the contest in the presence of Pharaoh between Moses and Aaron and the magicians of Egypt (*Exodus*, vii. 9-12), that it is stated, on good authority, that the modern Egyptian jugglers possess the power of throwing the Asp (*Naja Haje*) into a state of catalepsy, and rendering it stiff and immovable, in other words, changing it into a rod, by pressing the nape with the fingers.

NAIADES, or NAYADES, Lamarck's name for a family of fresh-water conchifers (*Naiadae*), comprising the genera *Unio*, *Hyria*, *Anodonta*, and *Iridina*. The third of these genera has been of late years more correctly named *Anodon*. Dr. Leach and Mr. Bowdich first made this alteration, and they have been followed by most English zoologists. The genus *Unio* was first established by Bruguière.

The position which the genera constituting this family occupied in the systems of the leading zoologists will be seen by a reference to the article MALACOLOGY. Other genera were added by authors, to which it will not, at present, be necessary to advert. Mr. Swainson, in the first series of his interesting 'Zoological Illustrations,' some time ago observed, that having paid some attention to the fluviatile bivalves, and possessing a most extensive collection of specimens, he was clearly of opinion that no permanent characters will be found sufficient to retain either the genera *Dipsas*, Leach, *Hyria*, Lamarck, or *Alasmodonta*. Say, 'much less,' continues Mr. Swainson, 'that of *Damaris*, Leach, and another, whose name I forget, made by Dr. Turton* from the same shell as Leach's *Damaris*, viz. *Mya Margaritifera* of Linnæus. In fact, the line of demarcation between *Unio* and *Anodon* appears to rest on the first possessing cardinal teeth, and the latter having none.' In the second series of his 'Zoological Illustrations' Mr. Swainson gives the following synopsis of the genera—*Unio*, *Hyria*, *Iridina*, *Anodon*, *Alasmodon*.

The North American rivers abound with this family; and Mr. Lea of Philadelphia has contributed most largely to our knowledge of the habits of these animals, and has made great additions to the species. The result of his labours, as regards classification, we shall presently show.

Reproduction, Habits, Organization, &c.—Mr. Lea, in his 'Preliminary Remarks,' notices Lamarck's statement that the animal of *Anodon*, which is essentially the same with that of *Unio*, is hermaphrodite, and seems viviparous; for the eggs pass into the oviduct placed along the superior branch, where the young are found with their shells complete. Mr. Lea then tells us that he dissected a specimen of *Anodonta undulata* nearly three inches long, and found the oviducts charged with about 600,000 (as nearly as he could calculate) young shells perfectly formed, both valves being distinctly visible with the microscope. In his second volume bearing the title of 'Observations on the Genus *Unio*, &c.,' the same author informs us that, believing that the oviducts would present the means of discrimination in some species, he having found them to be so very different in *Unio irroratus*, his attention had been particularly addressed to these organs in the few and small species of his vicinity. Whilst engaged in this investigation, Dr. Kirtland, of Poland, Ohio, informed Mr. Lea of his ability to distinguish the female and male shells of the same species, without having recourse to the included animal; and, shortly afterwards, Dr. Kirtland's paper on the subject appeared in the 'American Journal of Science and Arts,' vol. xxvi. Mr. Lea's attention now became more addressed to sexual characters, and he states that a very short series of exami-

poison of different species of marine serpents (*Hydrus*) to possess the property of turning litmus paper red. The same fact with the *Crotalus* is noticed by Dr. Harlan, who says, "The poison of the living *Crotalus*, tested in numerous instances with litmus paper, invariably displayed acid properties." (*Vide Harlan, Medical and Physical Researches*, p. 501, sq.)

* *Myca?*

nation satisfied him fully as to the establishment of the difference of sexes. The female, sustaining her very large burthen, naturally requires, he observes, more space within the valves; hence an enlargement of the posterior portion of the shell is generally found, differing in its form in various species. The following figures, representing the oviducts of the species whose names are printed under the cuts, are given by Mr. Lea.

Unio Irroratus.

1, soft parts showing interior of oviduct; 2, showing exterior of oviduct, the mantle being removed; a, mouth; b, great anterior muscle; c, right superior branchia; d, great posterior muscle; e, inferior right branchia; f, right oviduct; g, foot; h, superior left branchia; i, interior view of oviduct; 3, 4, shell.

Appearances exhibited by female Naiades according to Mr. Lea, one of the valves removed and the oviducts exposed.

Unio Oohraceus.

Unio Carolus.

Anodonta Fluvialis.

In plate xx. (Mr. Garner's paper on the 'Lamellibranchiate Conchifera') will be found a figure of the animal from the ovary of an *Anodonta*, as seen in the field of the microscope ($\frac{1}{2}$ inch focus); and in pl. xviii. the disposition of the heart, pericardium, excretory organs, &c., of *Anodonta anatina* is shown.

Anodonta Undulata.

Apparently nearly ready to spawn.

Mr. Lea remarks that the mass of the lobes in this species differs from that of *A. fluvialis*, in presenting a darker appearance and a very curious arrangement of the oviducts. The ova are placed in a kind of sac lying across the lobe, and presenting one end to the stomach and the other to the mantle of the animal. They lie so close together, as to take the form on the exterior, like the cells of a honeycomb. This, Mr. Lea says, is of course produced by pressure. Some of these sacs, when carefully removed, were found to contain as many as twelve ova, each with a perfect living shell in it, having a brownish epidermis: a in the cut repre-

Two females of *Unio radiatus* as they were seen with the parts protruded as they lay at the bottom of a basin of water. Mr. Lea states that these females put on two quite different forms as regards the inferior portion of the mantle, as exhibited above.

sents a sac with its ova, *b* represents the ovum with its perfect young shell included, *c* represents the honeycomb appearance and is eight times magnified.

Mr. Lea (vol. i.) states that it seems to be a matter of doubt on what these animals subsist. He says that he has strong reasons for believing that they feed on animalcules which are ever found to exist in water, and which they might separate from the constant stream which they pass from the posterior part of the shell, and which must be taken in at another part. This operation he witnessed frequently in a vessel in which he kept the *Naiades* for some months. If the water was not changed for twenty-four hours, he uniformly found the animals quiet, but within a few minutes after it was changed they as uniformly commenced the passage of this constant stream. He adds that he cannot suppose this operation to be for the sole purpose of breathing, as there is no intermission in the stream of water, and the quantity thrown out is too great for this purpose only. He believes it to be the result of the action of the separation of the animalcules from the water.

In the Museum of the Royal College of Surgeons in London (*Physiological series*) are the following preparations. No. 1002, The soft parts of a fresh-water muscle (*Anodon cygneus*) injected and prepared to show the four branchiæ, which unite below the foot. The convolutions of intestine at the base of the foot and the passage of the rectum through the heart are also shown. No. 1003, The soft parts of a fresh water muscle, with both mantle-lobes and heart dissected away, so as clearly to display the branchiæ and labial processes. The orifice of the branchial vessels and water-tubes are well displayed at the base of the branchiæ. The first series of vessels, which run transversely across the branchiæ, give off lateral ramulets at right angles, and form a most delicate vascular net-work to receive the influence of the respiratory currents. No. 1004, A transverse section of the branchiæ of a fresh-water muscle, injected, dried, and preserved in oil of turpentine: a beautiful display of the vascularity and delicate structure of the respiratory organ. No. 66, A transverse section of the connecting ligament of the valves of a fresh-water muscle, showing that its structure is fibrous, the fibres being perpendicular to the plane of the shell, and converging towards the centre, so that when the shell is closed these fibres are in a state of compression, and consequently have a constant tendency to antagonize the adductor muscle, open the shell, and retain it in that state, independent of any muscular action. No. 67, A longitudinal section of the same ligament, made by dividing the valves from one another.

The brilliant and variously coloured nacre with which many of the species are lined and the extreme thickness of some of the shells are very remarkable. That pearls should be found in them will not surprise those whose attention has been drawn to their internal surface. Pennant remarks that *Mya Margaritifera* of Linnæus (*Unio elongatus*) is noted for producing quantities of pearls, and formerly there were regular fisheries in many of our rivers to obtain them. As many as sixteen have been taken from one shell. The Esk and the Conway were famous in this way. The latter river, in the days of Camden, was noted for them. Sir Richard Wynn of Gwydir, chamberlain to Catherine, queen to Charles II., is said to have presented her majesty with a Conway pearl which is to this day honoured with a place in the regal crown. Pennant, who states this, adds, that the shells are called by the Welsh, *Crigen Dituw*, or Deluge Shells, as if left there by the deluge. The river Irt in Cumberland also produced them; and Sir John Hawkins, the circumnavigator, had a patent for fishing that river. Britain indeed had early acquired a reputation for its pearls; for, according to Suetonius, they were Cæsar's inducement for undertaking his British expedition. (*Jul. Cæsar*, c. 47.) This however does not seem very probable. Pliny (ix. 36) indeed speaks of the pearls of our island as small and ill coloured, and refers to the breast-plate which Cæsar himself had brought home and dedicated to Venus Genetrix in her temple, adding that he wished it to be understood that the offering was formed of British pearls.

Ireland has produced pearls of considerable size and some value, especially in the rivers of Tyrone and Donegal. One weighed 36 carats, and was valued at 40*l.*, but it was foul, and so lost much of its worth. Other single pearls were sold for 4*l.* 10*s.*, and for as much as 10*l.* The last was sold a second time to Lady Glenlealy, who put it into a necklace, and refused 80*l.* for it from the duchess of Ormond. Pennant,

who quotes from the abridgement of the 'Phil. Trans.,' speaks of the last century as the time when these large Irish pearls were procured. We have seen some lately of considerable size, fair shape, and pretty good colour.

Mr. Lea, in his final arrangement, admits only two genera, *Margarita* and *Platiris*. The first of these has been pre-occupied by Leach to designate a genus of marine conchifers. [MARGARITA.] We shall however retain the name in this article, in order to present to the reader the leading features of Mr. Lea's arrangement and the forms of the shells.

MARGARITA. (Lea.)

1. Subgenus. Unio.

Having a cardinal and lateral tooth.

Symphynote.

Example, *Unio alatus*.

Unio alatus.

a, part of the wing of the valve broken off, showing the symphynote character reduced.

* *

Non-Symphynote.

Example, *Unio Pictorum*, common in our English rivers. shell and animal figured in the article CONCHIFERA, vol. vii., p. 433.

Unio pictorum. (From a young specimen.)

In Mr. Garner's memoir on the anatomy of the Lamellibranchiate Conchifera (pl. xx.) the ova of *Unio Pictorum* from the ovaries and branchiæ are represented (18*l.* of an inch focus). Also the valve of a young *Unio*, showing that its nucleus is of the same shape as the valves of the animals found in the branchiæ.

* *

2. Subgenus. Margaritana.

Having one tooth (cardinal).

* *

Non-Symphynote.

Example, *Alasmodonta undulata*. (Say.)

Alasmodonta undulata.

Symphynote.

Example, *Alasmodonta complanata*. (Barnes.)

Alasmodonta complanata.

3. Subgenus. *Dipsas*.

Having a linear tooth under the dorsal margin.

Symphynote only.

Example, *Dipsas plicatus*. (Leach.)

Dipsas plicatus.

4. Subgenus. *Anodonta*.

Having no teeth.

Symphynote.

Example, *Symphynota magnifica*. (Lea.)

Symphynota magnifica.

Non-Symphynote.

Example, *Anodonta fluviatilis* (*Mytilus fluviatilis* of Se-lander, Dillwyn, &c; *Anodonta catarracta* of Say).

Anodonta fluviatilis.

PLATYRIF. (Lea.)

1. Subgenus. *Iridina*.

Having a crenulate dorsal margin.

Non-Symphynote.

Example, *Iridina exotica*. [See CONCHACEA, vol. vii. p. 426.]

2. Subgenus. *Spatha*.

Having the dorsal margin non-crenulate.

Non-Symphynote.

Example, *Iridina Nilotica*. (Sowerby.)

Iridina Nilotica.

Plicate Shells.

Example, *Unio plicatus*. (Lesueur.)

Unio plicatus.

Nodulous Shells.

Example, *Unio pustulosus*. (Lea.)

Unio pustulosus.

Smooth Shells.

Example, *Unio complanatus* (*Unio purpureus*, Say).

Unio purpureus.

Spinous Shells.

Example, *Unio spinosus* (Lea). N.B. Bartram appears to have been the first who discovered this species. He, apparently, found it in the Mississippi. See his 'Travels,' p. 431.

Unio spinosus.

Mr. Lea, in his Tables, enumerates 323 recent species as admitted, and 29 as unknown to him or doubtful.

Of the subgenus *Unio*, 235 recent, and 20 which he has not been able to admit as certain. (Europe, Asia, Africa, North America, South America, New Holland. By far most abundant in North America.)

Margaritana, 20 admitted, 2 unknown. (Europe, North America, South America, and perhaps Africa.)

Dipsas, 2 recent. (Asia.)

Anodonta, 59 admitted; 7 unknown to Lea. (Europe, Asia, Africa, North America, South America, New Holland.)

Iridina, 2 recent. (Africa.)

Spatha, 6 recent. (Africa, South America.)

M. Deshayes (last edition of Lamarck), after reviewing the state of the question, comes to the conclusion that all the various genera cannot form and ought not to form more than one genus, constituting singly the family of the *Naiadae*. He refers to Mr. Lea's work favourably, but charges him with an omission which would have been almost unpardonable in an author who had undertaken a monograph of this extensive family. It is but common justice to Mr. Lea to insert his conclusive answer to this charge: 'I will be excused,' says Mr. Lea, 'in taking this opportunity to correct an erroneous impression on the mind of M. Deshayes. He says that I was not able to examine the collection of the museum of Paris. "Malgré cette imperfection qu'il ne pouvait empêcher, le travail de M. Lea se recommande à l'attention des naturalistes par des observations judicieuses, des descriptions exactes," &c. It would be strange indeed if, after spending so many years in the study of this family that I should neglect, while in Paris, to see the collections from which Lamarck made so many descriptions. I was frequently at the museum, and, on one particular occasion, by appointment of MM. Blainville and Férussac, arranged, in the presence of these and other gentlemen, all the species of the *Naiades* that were in the museum, and named them; and also presented to the museum about 15 species which were new to that great national institution. I also did the same thing for Baron Férussac, having designated every specimen in his cabinet belonging to this family.'

Fossil Naiade.

Speaking of *Anodon*, Mr. G. B. Sowerby (*Genera*) says that he does not know of any fossil species, unless we are justified in considering the bivalve from the coal-measures figured in Sowerby's 'British Mineralogy,' tab. 366, under the name of *Mytilus crassus*, as an *Anodon*. This Mr. G. B. Sowerby states he is unable, after examining the specimens, to demonstrate, though he finds strong reason for believing that it may prove so. When treating, in the same work, of the genus *Unio*, the author states that there are many fossil shells, particularly in the coal-measures, which are referred to this genus; and, he thinks, correctly so, though he has never been able to consult the characters of the hinge; but, judging from the cast of the inside, which is very common, he finds no difference between it and casts that he made from the inside of recent *Uniones*. He does not however feel authorised to pronounce the shell published in *Min. Con.*, t. 153 (*Unio crassissimus*), to be an *Unio*; for its hinge, he observes, is far from being characteristic, and it has not the compound muscular impression of that genus. He thinks that it agrees more nearly with some of the Lamarckian *Cypricardiae*; at the same time he confesses his doubts about the probability of that genus being ultimately adopted. His attention appears to have been next drawn to *Unio Listeri*, *U. hybridus*, *concinus*, and others figured in *Min. Con.*, and placed in the oolite series by Conybeare and Phillips; and, in confirmation of some of the observations recorded in their 'Outlines,' he remarks that these, together with *Unio crassiusculus* (*Min. Con.*, t. 185), all want some of the principal distinguishing marks of the *Unio*, and, judging even from their hinges, he remarks that we should certainly hesitate to place them with *Unio*. He adds that he has never seen any perfect specimen of the shell published as *Unio*, from the freshwater formation; but if he may be allowed to decide from such fragments as he had examined, and from its geological position, he should hardly feel a doubt upon the subject. Notwithstanding however what he has above advanced, he concludes by observing that he must still consider the existence either of *Unio* or *Anodon* in any bed below the chalk, except the coal-measures, as exceedingly problematical. M. Deshayes (*Tables*) makes the number of fossil species of *Unio* (tertiary), 2; of *Anodon*, 1; of *Hyria*, none; and of *Iridina*, none. In the last edition of Lamarck he records 2 of *Unio*—*U. concinns* (Sow.), from the inferior oolite near Banbury, in Oxfordshire, and *Unio hybridus* (Sow.) from the Nottinghamshire beds; both from *Min. Con.* Dr. Mantoll records a *Unio* (*Brit. Min.*, t. 500) from the

plastic clay (Castle Hill, near Newhaven), and *Uniones porrectus, compressus, antiquus, aduncus, and cordiformis*, from the Tilgate beds (middle division). Also *Unio antiquus* from the Ashburnham beds (lower division of the Hastings deposits). Professor Phillips (Yorkshire) enumerates *Uniones Listeri, concinnus, and crassiusculus*, from the lias; *peregrinus* from the cornbrash; and *abductus* from the inferior oolite and marlstone. Mr. Lonsdale (oolitic district of Bath) records *Unio concinnus* from the alluvium (Weston) and from the inferior oolite (Widcombe Hill); and an unnamed *Unio?* from the Kelloways rock (Christian Malsford). Dr. Fitton, in his table (*Strata below the Chalk*) notes *Uniones aduncus, antiquus, compressus, cordiformis, Gualterii, Mantellii, Martini, porrectus, subtruncatus*, a species not distinct, a large new species, and some other species probably new, from the Weald clay, Hastings sand, and Purbeck beds. Mr. Lea gives 21 as the number of fossil *Uniones*, and one (doubtful) of *Anodon*.

* * The last-named author, in his arrangement founded on the form of the hinge, has deemed it better not to adopt D'Orbigny's genus *Mycetopoda* [MYCETOPODA] established on the natural character of the animal. In its perforating habit it resembles, according to Mr. Lea, his *Unio oriens*, which buries itself about 12 inches below the surface of the sand in which it lives.

The genera *Diplodon, Triplodon, &c.* of Spix can hardly be allowed to stand.

NAIADES otherwise called *Naiadeæ* and *Fluviales*, are aquatic plants forming a small natural order of Endogens, remarkable for the unusual simplicity of their organization. As they live constantly below water, they require no epidermis, and therefore the leaves consist of nothing more than the mesophylæum, or central stratum of parenchyma. Their sexes are usually separate, and sometimes on different plants. Their floral envelopes are either deficient or in the form of a membranous tunic or cup, or consist of scales, to the face of which anthers or carpels adhere. The latter are either solitary or in pairs or fours, one-seeded, one-celled, with the ovule generally pendulous from the central suture. Their fruit is usually indehiscent and nut-like, but sometimes it is 2-valved or irregularly ruptured. The embryo has no albumen, and consists of a very large radicle, usually folded up, and containing a slender plumule lying in the cavity so formed.

These plants are inconspicuous objects, inhabiting both fresh and salt water in all parts of the world. In this country, the genera *Potamogeton*, a common inhabitant of rivers and ponds, elevating its little brown spikes of flowers above water during the time of fertilization; *Zannichellia*, a thread-shaped plant, with minute axillary flowers, constantly submersed; and *Zostera*, or sea-wrack, with long, narrow, riband-like leaves, inhabiting æstuaries of the sea, are the most common.

Zostera marina.

1, a spathe containing male and female flowers; 2, a female; 3, an anther; 4, an embryo.

NAIADS (*Naiades, Nnyides*) were female deities in the Greek and Roman mythology, who were supposed to preside over rivers, brooks, and springs. They are represented as young and beautiful nymphs (Hom., *Od.*, xiii. 103), of whom *Aglaë*, according to Virgil, was the most lovely (*Ecl.*, vi. 21). Many of the heroes of the Homeric poems are described as the offspring of Naiads.

According to Pausanias (viii. 4, § 2), the Naiads were called, by the Arcadians, *Dryades* and *Epimeliadæ*. [NYMPHS.]

NAIRN. [NAIRNSHIRE.]
NAIRNSHIRE, a small county in the northern highlands of Scotland. It is bounded on the north by Moray Frith, on the east by Elginshire, on the south-east by a detached portion of Inverness-shire, on the south by a detached portion of Elginshire, and on the south-west and west by Inverness-shire. It is situated between 57° 21' and 57° 39' N. lat., and between 3° 40' and 4° 5' W. long. Its form is irregular; the greatest length is, from north by east to south by west, from the eastern extremity of the coast to the neighbourhood of Cairn Glaschurn and the Leonach hills, 20 miles; the greatest breadth, at right angles to the length, is, from the neighbourhood of Culloden Muir to the neighbourhood of Loch-an-Tulloch in Elginshire, sixteen miles. The area of the county is given by Dr. Playfair (*Description of Scotland*) and by Mr. MacCulloch (*Statistical Account of the Brit. Empire*) at 198 square miles; the population, by the census of 1831, was 9354. Two detached portions belong to the county, the district of Ferintosh or Fairintosh, near Dingwall in Ross-shire, and Dunmaglass in Inverness-shire. These detached parts are not, we believe, comprehended in the measurements given above; but the population is included in the foregoing number. It is one of the least of the Scottish counties in extent, and is exceeded in population by all the others, except Kinross and Selkirk, and perhaps Cromarty, the population of which is not distinguished in the Return from that of Ross.

The southern part of the county is hilly; the hills form two irregular groups, separated by the river Findhorn, which flows through the county. The principal summits are Ben Bui, Cairn Our, Craigorachan, and the Leonach, all on the border towards Inverness-shire; Cairn Glaschurn and Cairn Dui, on the border toward Elginshire. The valley between the two groups of hills in which the Findhorn flows is called Strathdern. Along the coast, which extends about eight miles from east by north to west by south, is a narrow border of level country extending inland from one to six miles. The hill country belongs to one of the least interesting and least frequented parts of the highlands.

The principal rivers are the Findhorn and the Nairn, which both rise in Inverness-shire, and flow through the county in a north-east direction. The Nairn has about eleven miles of its course within or upon the border of Nairnshire, and falls into the Moray Frith at the burgh of Nairn. It is a stream of little consequence; its mouth forms an indifferent harbour, and the salmon-fishery in its waters is of no great value. Its name in the Celtic language is *Uisg Nearne*, 'the water of alders;' from this has been derived its usual designation, which it has communicated to the burgh, and through it to the shire. The Findhorn has about eleven miles of its course in this county, through which it passes to enter Elginshire, where it has its outfall. A number of small streams flow into these rivers, especially into the Findhorn. There are a few small lakes or lochs. The largest is the Lake of the Clans, about a mile long and half a mile broad, about four miles south-west of the burgh of Nairn; Cranloch, near the eastern extremity of the coast, is rather longer than the Lake of the Clans, but not quite so broad. The other lakes are much smaller.

The mineral treasures of the county are not great. There is abundance of marl, which is valuable for manure, but is little used. Expectations were once entertained of finding coal. A quarry of dark blue stone, which is inflammable, is worked; it neither loses bulk nor is pulverised by fire. There is freestone in Nairn parish, and a few men are employed in the quarries. Peat is dug.

The soil is diversified. In the eastern part of the level tract along the coast it is generally a rich loam on a sandy or gravelly bottom: in the western part it is either a stiff rich clay or a sharp gravelly mould. In the mountainous districts it is chiefly a sandy loam, full of gravel and small stones

The climate in this part is cold and stormy, and the crops are later than along the coast, where the temperature is more favourable. Yet the crops are rarely if ever cut off by frost, nor are they materially retarded by the autumnal rains.

The agriculture of Nairnshire is in a very backward state. About twenty or thirty years since the farms were small and the tenantry poor. Most of them held their farms without leases. These poorer tenants followed the routine of agricultural practice, which had been long established; but the richer tenants and the proprietors were more willing to break through the shackles of custom and to introduce improvements. The proportion of arable land was small, especially in the Highland district, and almost the whole county was unenclosed. Manure, formed of dung mixed with turf or sand, was accumulated by means of sheep, which on the small farms (on nearly all of which a small flock was kept) were housed every night; and also by means of some black cattle and horses. This manure was spread over a portion, perhaps a fourth, of the farm, which portion, after three ploughings, was sown with bear or big, and this crop was succeeded by two or three successive crops of oats. A small plot was allowed for potatoes, and occasionally a patch for growing flax for domestic use. When, as frequently happened, the land became too much overrun with weeds to afford an adequate return, it was left waste for one or two years, and the horses and cows were turned in to feed upon it; after which it was again brought into cultivation, as above described. The tenantry were allowed pasturage for their cattle, either in the open down along shore or in the unenclosed moors near the foot of the mountains. The more opulent farmers had introduced fallows into their practice, and cultivated the artificial grasses and other green crops. The poor farmers made their own carts and agricultural implements, which were consequently of very inferior construction.

There are in the county about 8000 acres of natural wood and 4000 acres of plantations. The woodlands are chiefly on the banks of the rivers and their tributary streams.

The population of the county in 1831 was thus classified: 2074 inhabited houses; 2246 families; of which 742 families were chiefly employed in agriculture; 487 families in trade, manufactures, and handicrafts; and 1017 families in other occupations: the population consisted of 4307 males and 5047 females; total, 9354.

There are no manufactures carried on in the county except that of woollen cloth, which in 1831 employed about 50 men, who converted yarn into cloth for family use. The coast fishery gave employment to 127 men in the parish of Nairn; and 532 men were engaged in retail trade or in handicrafts, chiefly carpenters, masons, shoemakers, tailors, and smiths.

The county has no other subdivisions than parishes, of which it contains three entire, and portions of seven others, the remaining parts of which are in Inverness, Elgin, Ross, or Cromartyshire, and most of them in the first.

There is only one town in the shire, the royal burgh of Nairn, situated on the west side of the river Nairn, near its mouth. It appears to have been founded by William the Lion (who reigned from 1165 to 1214), and was originally called Invernaren. The town was afterwards granted by Robert Bruce (who reigned from 1306 to 1329) to the earl of Ross, Lord of the Isles, under whose descendants it probably continued till A.D. 1473. The site of the more antient town was at some distance from that of the present town: this change has resulted from the gradual advance of the sea upon the land, and the shifting of the bed of the river. The ruins of the antient castle which defended the town have been long covered by the sea; but thirty years ago some of the older inhabitants remembered to have seen them at spring-tides. The present town consists of one principal street parallel to the river, and of a number of smaller streets or lanes branching from it at right angles. Some new streets of greater regularity have been laid out on the north side of the town, near the shore; but little progress, if any, has been made in building them. The kirk lies back from the main street near the river; the town-hall, a part of which is used as the burgh and county prison, is in the main street; it was rebuilt about twenty years since. There are two dissenting places of worship. There is a bridge over the Nairn.

Considerable expense was incurred, some time since, in forming a harbour; but the great floods of 1829 almost

ruined it, so that it is now only accessible to vessels of very small tonnage. The trade of the town, which never extended beyond the supply of a small district round, has been much injured by the ruin of the harbour. Nairn is a place of some resort as a bathing-place, and several villas have been erected in the neighbourhood. Some coal and lime are imported, and a number of boats are engaged in the herring fishery. The burgh and parish, which comprehends an extensive rural district, contained, by the census of 1821, 679 inhabited houses and 3228 inhabitants; by that of 1831, 721 inhabited houses and 3266 inhabitants: 38 of the houses were assessed at 10% a year value or upwards, and more than 60 were estimated to be worth 10% a year or more. There is a weekly market: and six stated fairs are held in the year.

The burgh of Nairn belongs to the Inverness district of burghs, which comprehends Inverness, Fortrose, Forres, and Nairn, and returns one member. The number of councillors, as determined by act 3 & 4 Will. IV., c. 76, is 9; the number of registered voters is above 60. The yearly revenue of the corporation is upwards of 140%.; the expenditure about 10% more. The whole of the trades make but one corporation. The jurisdiction of the burgh magistrates has dwindled to the cognizance of petty thefts and assaults.

Several Roman coins have been discovered at Nairn. (*Carlisle, Top. Dict. of Scotland.*)

Auldearn, a parish, the kirk of which is about two miles south-east of Nairn, is a burgh of barony. The parish had, in 1831, 330 inhabited houses and 1613 inhabitants.

Nairnshire is united under one sheriff with Elginshire: the sheriff, as in the other counties of Scotland, is a paid legal functionary or judge, with extensive jurisdiction in civil cases and more restricted jurisdiction in criminal cases. (*MacCulloch's Statistical Account of the British Empire.*)

There is little crime in the county, and that little is decreasing, from greater decision in enforcing the laws against smuggling, and from the growth of self-respect, the result of the increased civilization of the people. Petty assaults and other breaches of the peace, almost all arising from drunkenness, are the most common offences. Drunkenness is however diminishing; but the condition of the people is much depressed. Most of the adults are able to read, and the men can generally write. (*Second Report of Inspectors of Prisons.*)

There is much suffering among the people from poverty: in the parish of Nairn alone, in 1836, 200 persons were on the poor-roll. The condition of the able-bodied labourer has however improved. There is a savings' bank near Nairn. Potatoes and herrings form a considerable portion of the food of the poorer classes.

The three parishes which are wholly within the county, and two of those which are partly within it, are in the presbytery of Nairn; the remainder of those which are partly in the county are severally in the presbyteries of Inverness, Forres, and Dingwall. The presbytery of Dingwall is in the synod of Ross; the other presbyteries are in the synod of Moray.

For parliamentary purposes the county is united with that of Elgin: the two return one member. Before the Reform Act, Nairnshire returned a member alternately with Cromartyshire.

This county was formerly included in the district of Moray. It contains some antiquities, of which the most interesting is Calder or Cawdor Castle, the antient seat of the thanes of Cawdor. In this building tradition has fixed the scene of the murder of Duncan by Macbeth, and the very bed in which he was murdered is professedly shown; but the tower, which alone remains of the old castle, and to which is attached a more modern building, is obviously of later date than the transaction connected with it. In the parish of Nairn are the vestiges of an antient fortress, called *Caistle Fionlah*, i.e. Finlay's Castle; and at no great distance are the remains of the castle of Rait, the seat of the Cummins. Below this castle there is a place called *Knock-na-Gillan* or *Knoch-na-Gillaw*, i.e. 'the hill where the young men were killed.' It takes its name from the slaughter, by the Cummins, of eighteen of the clan MacIntosh with whom they had a feud.

In the year 1645 the low country, the people of which favoured the Covenanters, was ravaged by Montrose, who destroyed the fishermen's boats and nets. The Covenanters, under General Hurry or Urry, attacked him at Auldearn

near Nairn, but were beaten with the loss of 2000 men. Montrose burnt the towns of Elgin and Nairn.

In the Rebellion of 1745-46 the royal army in pursuit of the Pretender's forces crossed the county. The battle of Culloden was fought just beyond the boundary, in the county of Inverness.

(Playfair's *Description of Scotland; Beauties of Scotland; MacCulloch's Statistical Account of the British Empire; Municipal and Boundary Commissioners' Reports* and other Parliamentary Papers; Carlisle's *Top. Dict. of Scotland*.)

NAKED SEEDS. This name was applied by Linnæus to a small form of fruit which does not directly bear a style at the apex, and which has the appearance of a seed, as in the Sage, the Dead-nettle, the Borage, &c.: such fruits are now called *spermidia* by many writers. Naked seeds strictly so named are seeds which are fertilised by immediate contact with pollen, and which have no pericarpial covering: they are at present known only in the great class of Gymnosperms, that is to say, in Coniferæ, Cycadaceæ, and Loranthaceæ. It however sometimes happens that seeds burst through their pericarp, after the influence of the pollen has been communicated to them, and long before their maturation, as in *Leontice thalictroides*. In such cases they are, strictly speaking, naked, but not in the sense in which the term is usually applied.

NAKHICHEVAN. [GEORGIA.]

NAKHIMOV, AKIM NIKOLAEVITCH, a Russian poet, was born at Kharkov, of wealthy parents, in 1782, and educated at the university of Moscow. According to the usual custom of that period, he entered the military service at an early age, but did not long continue in it; for, on the new university being opened at Kharkov, he enrolled himself among the students, and applied himself to literature with such zeal and diligence as to excite general astonishment. Having taken his degree, he retired to his own estate to indulge in that fulness of literary enjoyment which his fortune permitted him, and in that domestic society which he shortly after secured to himself by his union with a very amiable young lady. Thus eminently favoured in every respect, the tranquil felicity of his life met with no other interruption than that of a premature death, for he was suddenly carried off by a fever, July 17-29, 1814, in the 32nd year of his age, leaving behind him two infant children, to whom he had looked as pledges of the increasing happiness in store for him.

Though of amiable disposition and possessed of a fund of good sense and philosophy, Nakhimov had many singularities, and was at times morbidly shy even among his most intimate acquaintance. Another trait in his character was his singular diffidence of his own literary talents, notwithstanding that his favourite subjects, and those in which he best succeeded, were of a satirical cast. This turn for caustic observation displays itself also in his 'Fables,' which are remarkable for their epigrammatic point. Besides his satires in verse, he wrote many pieces in prose that partake more or less of the same spirit, more particularly that entitled 'The Speaking Monkeys,' which was composed in derision of the attempted conquest of Russia by Napoleon, and which may challenge comparison with Voltaire's 'Micromogas.' A short memoir of him, with a critical notice of his chief productions, was published at St. Petersburg in 1818, by Dr. Maslovitch.

NAME. [NOUN.]

NAMEN. [NAMUR.]

NAMES, PROPER, are words by which single objects are denoted, as countries, rivers, towns, men, &c.

But when we speak of proper names, we mean, more usually, the names of men; and on this subject, to which little attention has hitherto been paid, and especially such proper names as appear among ourselves, it is our intention to offer a few observations.

In the primitive state of society, as soon as men were so far advanced as to find the convenience of having a verbal denotation of the individuals who composed a tribe, the rule would undoubtedly be, 'one man, one word:' we see this to be the case in the uncivilized tribes; and as man is presented to us in very early historic periods, we still see the same system prevailing. In the Hebrew genealogies, which ascend much higher than any which possess the slightest claim to our respect in any other nation, we find a single word, as *Terah, Abraham, Reuben, Aaron, David, Solomon*, the only designation of the persons whom those words call up before

us; and if in any instance there is any deviation from the rule, it is for some special reason, and we see it to be an exception to what was the usual practice.

In the other nations, the fathers of European civilization, it was the same, Egypt, Syria, Persia, and Greece; one person, one word: and so in the earliest periods to which we can ascend in the history of the Latin nation, we have rarely more than one word to denote one individual, or if there is a second word employed, it bespeaks an origin in something which is apart from the simple, colloquial, and usual designation of him.

In the Celtic and German nations it appears to have been the same; *Arminius, Ariovistus*, and the like: and in Britain, *Caractacus*. The Saxons were a nation in whom this, the primitive system, was still prevalent, not only when they first established a colony in Britain, but during the whole period when the descendants of Hengist held the supreme authority in this island. Persons do, to be sure, present themselves in the pages of historians with such additions as *Harefoot, Ironside*, but it may be reasonably doubted whether these terms can be properly regarded as names, and if it is admitted that they may be such, still these are only exceptions, the great mass of the Saxon population, of whatever rank, having but one single word by which the individual was denoted, such as *Edwin, Alfred, Gurth, Ulf, Tosti, Harold*, and the like.

As nations advanced in refinement, the names of the individuals comprising them became more complex. Amongst the Romans, for instance, we have *Publius Cornelius Scipio Africanus, Caius Julius Cæsar, Publius Ovidius Naso*; and names of this class formed the rule, at least in families which were free. The slaves probably remained with the single word only.

We have not room to enter into an examination of the principle on which this new form of personal denomination was constructed. A uniform principle, like that very valuable one on which our own personal nomenclature is at present constructed, perhaps did not exist, so that our present system is rather to be regarded as the invention of modern nations, than as borrowed by them from any of the nations of more ancient civilization.

The principle of the modern system of personal nomenclature in our own nation is this: to have one name for the individual, joined to a second name, which is common to some particular stirps in the great English family to which he belongs. We call the two the *name* and the *surname*. We think in these days much more of the latter than of the former. But in the more solemn acts of our lives, we find the proper consequence given to that which is indeed the name; in baptism, in elementary Christian instruction, at marriage, when the name is the thing in question, it is that which is properly the name, and not the surname, which is pronounced; *John, Richard, Anne*. We may find in books, even down to the close of the seventeenth century, that catalogues and indexes are sometimes so constructed, that the names, and not the surnames, are ranged in alphabetical order. Philips's 'Theatrum Poetarum' presents a late instance.

The value of this principle lies here: that it is a simple and easy mode of showing, to some extent, to what family an individual belongs; it promotes family union; but its chief advantage lies in the facilities which it affords for conducting inquiries into the condition of the ancestors of persons who may feel any curiosity on the subject, which, without the indications afforded by identity of surname, could be attended with very little success, when it was attempted to ascend beyond the recollections of persons still living.

This mode of designation, we believe, prevails in most other countries of modern Europe. In England it is almost the universal plan. The royal house of England forms an exception, an unchangeable surname having never been adopted by them. In this respect the house of Brunswick is like the houses of Saxa, Nassau, Bourbon, Orleans, and a few others, springing from the persons who were of prime note in that state of society when the rule was, 'one person, one word,' and being afterwards too conspicuous by rank and station to need any such ordinary mode of distinction as that which the adoption of an invariable addition to the name would have given them. This was once not peculiar to the royal house of England in this island (the Stuarts, it may be observed, and perhaps the Tudors, but not the Plantagenets, were a temporary exception, being families of inferior rank, who were raised by circumstances to the possession of the

regal dignity), for the earls, in the first two or three centuries, seem also to have disdained a practice which assimilated them too nearly to the classes next below them. Thus the persons distinguished in Domesday Book as *Comites*, are *Comes Hugo*, *Comes Rogerus*; and never, we believe, with names of addition which descended to their posterity. But all these great houses have become long ago extinct.

There is also an exception to the modern rule, of another kind. There are still some remote and rudely-cultivated districts, in which the inhabitants are better known by some *by name*, as of the house in which they live, or as the son of some person well-known, than by any unvarying addition to their name properly so called. This is said still (or at least very lately) to be the case in some parts of Yorkshire and Lancashire, and is certainly the case in parts of Wales, but it is probable that the extension of education will bring all parts of this island into subjugation to a plan which has such obvious convenience.

If it is inquired when the system on which we now proceed was first adopted, the fact which has just been stated, that even now the system is not universally prevalent, will show, what is indeed the fact, that, like many other things, it has made its way by degrees. There is not, we believe, a single instance before the Conquest of persons in genealogical succession bearing the same surname; and it is also quite certain that in the mass of the population of England after the Conquest, the descendants of the Saxon population, there can rarely, if ever, be shown an instance of successive individuals of the same family being distinguished by the same surname in the two centuries immediately succeeding the Conquest. We have indeed but imperfect means of pursuing the inquiry for those two centuries. The names of the people of those centuries lie buried in unprinted records and chartularies. But if there are exceptions, and Saxon families in these centuries to be traced using an invariable as well as a variable name, it is in that remarkable class, who still exist in no very small number, who have one of the old Saxon appellatives in the place of the surname, such as *Thorold*, *Swaine*, *Aldrea*, *Thoroughgood* (*Turgot*), *Godwin*, and the like.

But we find in Domesday Book that several of the Normans and other people from the Continent, who became settled in England at the Conquest, and soon after that event, are distinguished by names of addition, which are not merely personal, but names which were borne by themselves and their posterity after them. Such are *Darcy*, *Arundel*, *Devereux*, *Balliol*, *Burton*, *Laci*, *Perci*, and others, people just below the rank of the comites, and who, gaining great possessions and great power, were afterwards very conspicuous in English history. These are the persons, we conceive, who first set the example of the practice which has since become all but universal among us.

The disposition which always more or less exists to imitate what is done by a superior, is probably the principle to which we are to refer the change in this point which we find to have taken place by the middle of the fourteenth century.

By that time the present system may be said to have been pretty generally established in all the well-settled portions of the island. The statute of additions of the 1st Henry V., by requiring that the name and description of the party should be exactly set forth in any writ or indenture, would do something to consolidate the system: and when it was required that in all parishes a register should be kept of baptisms, marriages, and burials, which was one of the acts of the Reformers, there was a new check presented to any attempts at relaxation in the practice.

But even at the beginning of the fifteenth century there was much that was unsettled in the personal nomenclature of England even in families to whom pertained portions of the soil. Thus in 1406 a person describes himself as *Willielmus filius Ada Emmotson*, who in 1476 is *Willielmus Entmotson*; and more remarkably about the same time, a person who is described as *Johannes filius Willielmi filii Johannis de Hunshelf* appears soon after as *Johannes Wilson*. About the same time we had *Willielmus Johnson Wilkinson*, *Willielmus Adamson Magotson*, and *Thomas Henson Magot*, showing the present system then in its rudiments.

As the system at present existing made its way by degrees, and with much of casualty, so there seems to have been much also of accident in respect of the name of addition which marked the distinction of the stirpes. There are some of the surnames in common use among us for the

adoption of which it is difficult now to assign any satisfactory reason. This is partly to be attributed to the corruption which many names have undergone, and partly to the strange additions which we find in the place of surnames in early documents of undoubted authenticity. One of these is *Adam that God made*, whose addition, if he lived at the period when his race first began to conform themselves to the system, would appear now in some form which would probably foil the sagacity of the most skillful inquirer. Sometimes there is a difficulty arising out of a wrong apprehension of the origin. Thus we have the names *Spring*, *Summer*, *Winter*; there is no *Autumn*. It is difficult to conceive how the names of the seasons should become the names of families; but in fact it is not so, *Spring* being a word denoting a small grove of trees, so that the name classes with *Wood*, *Holt*, and others concerning which there is no difficulty; while *Summer* and *Winter* are *Summoner* and *Vintner*, names derived from occupations.

But the great mass of our surnames may be easily explained. We cannot enter here at large into the subject; but it may be useful to those who are inclined to prosecute it, to say that nearly the whole of them may be referred to one of the five following classes:—

1. Foreign names brought in by settlers from other countries, including the Scotch and Irish names. These designate a very large section of the whole population; and there is a constant accession being made to them by the tide of population setting towards England. Very few of the names of this class introduced in the early periods remain: the great majority being of families who have become settled in England in the course of the last century and a half.

2. Names of locality.—These are divisible into two great portions: those which are derived from places of generic names only, such as *Hill*, *Dale*, *Cliff*, *Slack*, *Combe*, *Grove*, *Shaw*, *Frith*, and many others, mostly monosyllabic, which would originally appear as *John de la Hill*, &c.; and those which are derived from some specific place, as *Atherton*, *Burton*, *Denby*, and thousands of others, there being scarcely a town, village, or hamlet which has not given its name to some English family.

3. Names of occupation.—Of this class the number is very great. We have *Brewer*, *Barber*, *Smith*, *Mason*, in short every trade and every other occupation in which men engage. Lost trades or trades which have changed their names are preserved in the names of families whose ancestor was engaged in them at the time when his family fell into the system. Thus we have *Fletcher*, *Girdler*, *Furbisher*, *Stringfellow*, *Lister*, *Walker*, *Pargiter*, *Webster*, *Taverner*, and the like. We have also *Palliser*, *Lunder*, *Foster*, *Palfreyman*, *Page*, *Woodruffe*, *Reeve*, *Hunter*, which were evidently at the beginning names of occupation. It is difficult to account for such names as *Bishop*, *Baron*, *Karl*, *Lord*, *Priest*, *King*.

4. A large portion of our personal nomenclature is made up of surnames which are formed upon those which we call Christian names. Nearly all these appeared originally in the form of *Filius*, &c., as John son of William. This mode of designation has taken various forms. Thus on this name of *William*, there are founded *Williams*, *Williamson*, *Wills*, *Wilson*, *Wilks*, *Wilkins*, *Wilkinson*, *Willis*, *Willison*, *Bill*, *Bilson*, *Willet*, *Willimot*, *Willmot*, *Till*, *Tilly*, *Tillot*, *Tilson*, *Tillotson*, *Willy*, each of which, if written by a scribe of the middle ages in Latin, would be expressed by the same phrase, *Filius Willielmi*. Other names have an equally numerous progeny. To this class may be referred *Ives* and *Iveson* which are *Filius Judei*; *Clarkson*, *Cookson*, *Wrightson*, which are names formed not indeed on the name, but the profession of the parents.

It would however be to extend this article to an inordinate length, even to touch upon the subordinate classes to the five great classes.

5. The fifth and last is that of names which indicate something peculiar in the personal appearance or mental qualities of the person to whom they are first given. Such are *Swift*, *Long*, *White*, *Black*, *Crumpp*, *Rouse*, *Wise*, *Good*, &c.

Of the proportions in which names of the five classes enter into the composition of English society, some idea may be formed by the following analysis of 896 names, found in what was called the 'Fashionable' class of the inhabitants of Bath. Throwing out 162 as of uncertain origin, there remained 734 surnames, which give the following results:—

1. Foreign names, 142.
2. Names of locality. Generic, 57; specific, 249. Total, 306.
3. Names of occupation, 79.
4. Patronymical, 172, of which 43 were Saxon names.
5. Descriptive, 35.

The results would be somewhat different in a population of a different kind. There are six families who have names of occupation in the English peerage. The number of the individuals bearing the names varies greatly in the five classes. The ratio of the number of persons bearing the name to the name itself is the lowest in the first and second classes.

The nations who contributed the 142 foreign names were these:—

Scots, 44	German, 9	Italian, 2	Poles, 1
French, 39	Dutch, 6	Portuguese, 2	
Irish, 32	Welsh, 5	Cornish, 2	

Thus much for the *surname*.

The names of the ancient Saxon population of England were nearly all descriptive of some quality of mind or body. Thus *Edward* is truth-keeper; *Winfred*, win-peace; *Alfred*, all-peace; *Edmund*, truth-mouth; *Ailwin*, of all beloved; *Ulf*, wolf. But a great change took place soon after the Conquest. We see in the names of the Normans who became settled in England many which continued for ages favourite names of the English nation; *Roger*, *Ralph*, *Hugh*, *Humphrey*, *Geffrey*, *Gilbert*. To them also we owe the introduction amongst us of names of religion. If these names existed at all in England before the Conquest, they were exceedingly rare. In the catalogues of Saxon bishops, not one occurs. Even amongst the first race of Normans they did not abound. We find *Adam*, *John*, *Stephen*, *David*, *Peter*, *Matthew*, and perhaps a few others. But in the century and a half after that event, names of this class began to prevail in a great degree. It was a period of extraordinary Christian devotion: the exertions in founding monasteries, building churches, and maintaining the war against the infidels show it. In this state of the public mind the new system of taking names of religion spread and strengthened. The names of religion were almost wholly from the Old and New Testament, a few only being taken from the names of persons who have been eminent in later times for their Christian virtues.

Since then little change has taken place. A few names once common have lost their popularity; a few others have been introduced. There have been periods when names somewhat fantastic have had a popularity; such as the names of the virtues, as *Patience*, *Truth*, *Prudence*, *Faith*, by which women have been named; *Thankful*, *Faithful*, *Sabbath*, and others more extraordinary, have been given to men. Some went for a time into another extreme, and we had *Hannibal*, *Scipio*, *Cæsar*, and *Hercules*.

We have however not been sufficiently attentive to the importance of keeping up a stock of what we call Christian names. Our population has increased to a very great extent, while our surnames have rather diminished than the contrary. We should therefore, if we wish that names should be what they are intended to be, *Notamina*, increase the number of those names out of which we have the power ourselves of selection. As it is, with a population of 20 or 30 millions, we have but 53 names of men which can be used without some appearance of singularity. Of these 12 are in more frequent use than the rest:—

John William Henry George James Robert
Thomas Francis Charles Edward Richard Samuel

Of these, 4 are names of religion; 4 are names introduced at the Conquest; 3 names introduced at a later period from the nomenclature of other countries; 1 is pure Saxon. Of the 41 names of secondary frequency, 28 are names of religion; so that of the 53 names of men in ordinary use, 32 are names of religion, or considerably more than one-half, and they are all taken from the Scriptures.

Again, looking at the 53 names in respect of the languages from which they are derived, it appears that

- 25 are of Hebrew origin,
- 19 from the various dialects of Western Europe,
- 5 from the Greek, and
- 4 from the Latin.

There are a multitude of names, once in use in England, which might easily be revived, and it would be a matter of some public convenience to do so. Few persons have not found inconvenience in some form or other from the want of sufficient distinctness in the name he bears. Thus a little time ago there were two antiquarian Chalmers; two Parkes upon the bench; two Whitakers, both clergymen, and both writers on Lancashire topography: some time ago there were two Dr. John Thomas's, both chaplains to the king, and both bishops; and two Dr. Grays, both divines, both writers in their own profession, both connected with historic literature and poetry, and both engaged in controversies with Warburton. This occasions confusion. To change a surname is a difficult and expensive process; the cheapest and simplest remedy is to give a name at baptism which will be marked and remembered, as *Basil Hall*. Of neglected names there are, *Austin*, *Allan*, *Aubrey*, *Arnold*, *Baldwin*, *Blase*, *Barnard*, *Fabian*, *Ferdinand*, *Josceline*, *Miles*, *Sylvester*, *Theobald*, *Theodore*, and a host of others. But it might be worth the consideration of government, whether some facilities should not be afforded for increasing our very scanty stock of surnames by the revival of many which are now extinct and lost in persons who descend from those who bore them.

NAMUR, the French name for NAMEN, a province of the kingdom of Belgium, bounded on the north by Brabant, on the north-east and east by Liège, on the south-east by Luxemburg, on the south by France (department of Ardenes), and on the east by Hainault. Its greatest length from north to south is 55 English miles, and its greatest breadth 42 miles; its area is 366,181 hectares, equal to 901,467 English acres, or 1413 square miles, and is thus employed

In cultivation	181,306	hectares.
Marshes and waste land	48,343	"
Woods and forests	125,541	"
Sites of buildings	1,277	"
Roads and streets	7,523	"
Rivers and streams	1,658	"
Undescribed	533	"

366,181 hectares.

The province is watered by the Maas, the Sambre, the Lesse, and several small streams, by which it is traversed in all directions. The Maas enters Namur from France, near the town of Givet, and runs north-north-east about 9 miles to Dinant, when it flows to the north-north-west for 17 miles to the city of Namur, and turning to the east-north-east, enters the province of Liège at the distance of six miles from Namur. The Sambre enters the province from Hainault about 10 miles east of Namur, at which city it falls into the Maas. The Lesse enters Namur from Luxemburg at Palizeul, and flowing first to the north, and then to the north-east, falls into the Maas a short distance south of Dinant.

The soil of the province is generally fertile, consisting for the most part of an unctuous marl, but without any great depth. Of the three *arrondissemens* or districts into which the province is divided, viz. Namur, Dinant, and Philippeville, that of Namur is the most productive, the other two being more stoney. The principal agricultural products are wheat, rye, oats, barley, hemp, flax, and chicory. The grain harvests do not more than suffice for the consumption of the province. There are few natural meadows in the district of Namur, but in the other parts of the province the meadows are the most profitable of the lands. Artificial grasses are also much cultivated, especially trefoil in the district of Namur. Wood grows abundantly in the province. The trees are principally oak (the bark of which forms an article of export), beech, ash, hornbeam, birch, and hazel. With the exception of the oak trees, which are used for building purposes, the wood which is cut is converted into charcoal for the use of smelting furnaces. A great many plantations have been made of late years, especially in places where, through a want of depth in the soil, its cultivation cannot be profitably conducted. The breeding of draught horses forms an important branch of rural occupation; they are at once strong and active, and the farmers are careful to preserve the breed unmixed. Great numbers of swine are bred, and are mostly sold to itinerant dealers. Near to Dinant some are killed and salted for exportation. The farmers occasionally suffer from the visits of wolves, and there are great numbers of foxes, rats, weazles, and polecats.

The mineral productions of the province are iron, lead, coal, marble, and potters' clay. The quantity of iron made in the course of a year is stated to be 30,250 tons, nearly the whole of which is smelted with wood charcoal, requiring annually the produce of 6000 to 7000 hectares (16,000 acres). The number of people employed in the iron-works is 913, in addition to miners, wood-cutters, charcoal-burners, waggons, &c., amounting to 13,700 persons. The lead-mines which are near the city of Namur have been open since 1619, but their working has been discontinued at various times. These mines are worked by a company, who employ in them about 200 men. No return of the produce has been given. The coal-field of this province has already been sufficiently described. [BELGIUM.] The marble quarried in Namur is found in various parts of the province, and gives employment in sawing and polishing it to a great number of persons. It is of various colours, red, grey, blue, and black; the greatest part of what is raised is exported to France. The potters' clay found in the province is used chiefly at Namur and Ardenne.

In addition to the branches of industry already mentioned, Namur contains the only copper-works in Belgium. The raw material is procured chiefly from Sweden, and the principal market for the manufactured goods is found in France.

The province of Namur contains only five towns, Namur, Ardenne, Dinant, Fosse, and Philippeville. With the exception of the capital, they are all inconsiderable places. Ardenne is situated on the right bank of the Maas, near to the border of Liège, in 50° 30' N. lat. and 5° 4' E. long. Its population in 1837 was 4314. Various kinds of earthenware are made in the town, and there is a paper-mill in which 140 workmen are employed. Dinant is likewise situated on the Maas, in 50° 17' N. lat. and 4° 54' E. long. Its population in 1837 was 5033. They are engaged in manufacturing woollen cloths, paper, and hats, and in cutting and polishing marble. Fosse, a small town with 2722 inhabitants, is situated in 50° 22' N. lat. and 4° 42' E. long., about 9 miles south-west of Namur. The coal-mines and marble-quarries in the vicinity give employment to many of the inhabitants. Philippeville, in 50° 12' N. lat. and 4° 32' E. long., although the capital of an arrondissement, has only 1127 inhabitants. It is built on an eminence and fortified: the walls form an irregular pentagon. The town is composed of ten wide well-paved streets.

The population of the province, on January 1, 1838, was 229,665. The movement of the population during 1837 was as follows:—

	Males.	Females.	Total.
Born—in towns . . .	567	622	1189
„ in the country . . .	3211	3046	6257
	3778	3668	7446
Died—in towns . . .	514	491	1005
„ in the country . . .	2002	1902	3904
	2516	2393	4909
Marriages			1673

The number of houses in the province was then 43,096, and of separate families 46,995. With the exception of about 400, the whole population profess the Roman Catholic religion.

NAMUR (in Flemish, *Namen*), the capital of the province of that name, is situated in 50° 28' N. lat. and 4° 48' E. long., at the confluence of the Sambre and the Maas. It is considered to be the strongest fortress in Belgium. It is entered by eleven gates; the streets are wide and clean; the houses are mostly built of a bluish stone and are slated. There are several squares; two bridges, one over the Maas, the other over the Sambre; and six churches, one of which is the cathedral dedicated to St. Aubin. This is a fine building of modern architecture; the front is ornamented with twenty Corinthian columns, sustaining a cornice which bears several statues of white marble. On either side of the great altar are fine statues in Carrara marble, representing St. Peter and St. Paul. This building was begun in 1750, and finished in 1767.

The situation of Namur, at the confluence of two navigable rivers, is favourable to commerce. The two chief branches of industry are the manufacture of cutlery and tanning. Great numbers of workmen are employed in the neighbouring collieries, marble-quarries, and mines of iron

and lead. There are four cattle-fairs held in the year, in February, May, July, and November. The great fair begins the 2nd of July, and lasts fifteen days.

The castle of Namur is said to have been built at the end of the sixth century, and for more than four centuries thereafter the city was of very insignificant dimensions. Early in the eleventh century, under the reigns of Albert I. and II., it was much enlarged, and by the beginning of the fifteenth century Namur had attained its present dimensions.

This fortress has sustained several sieges, the most celebrated of which was successfully undertaken by Louis XIV., assisted by the renowned Vauban, in 1692. The French maintained themselves for three years in the fortress, to the defences of which they made several additions. On the 3rd July, 1695, the town was invested by the English under William III. The garrison, under the Marshal de Boufflers, consisted of 14,000 men, but the attack was so fierce, that the marshal capitulated on the 4th of August. Namur was unsuccessfully attacked by the count of Nassau in 1704; it was ceded to Austria, in 1713, and put under the care of Holland in 1715. In 1746 it was taken by France, but was restored to Austria, under the treaty of Aix-la-Chapelle, in 1748. The fortifications were demolished by Joseph II. in 1784, but were afterwards restored. It was taken by the French in 1792, retaken by the Austrians in the following year, and falling again into the hands of France in 1794, was constituted the capital of the department of the Sambre and Meuse, and so continued until 1814, when the Netherlands threw off the yoke of France. Namur was the scene of an obstinate battle in 1815, between the French and Prussians.

The population of the city, on January 1, 1838, was 20,480.

NANCY, or NANCI, an important town of France, capital of the department of Meurthe, situated on the left bank of the Meurthe, 172 miles east of Paris in a direct line, or 206 miles by the road through Epernay, Châlons-sur-Marne, and Bar-le-Duc; in 48° 41' N. lat. and 6° 12' E. long.

Nancy is not known to have existed before the twelfth century. In the middle ages it was the capital of Lorraine, and was several times taken and retaken, especially in the struggle in which René II., duke of Lorraine, had to engage with Charles le Temeraire, duke of Bourgogne [BOURGOGNE], for the possession of his duchy. It was under the walls of this town (Jan., 1477) that Charles experienced his last fatal defeat, in which he fell. In the reign of Louis XIII. (A.D. 1633) it was taken by that prince from Charles III. or IV., the then reigning duke of Lorraine. The fortifications were demolished on the restoration of the town to the dukes of Lorraine.

The town is situated in a fertile and pleasant plain at the foot of wooded and vine-covered hills. It consists of two parts, the old town on the north and the new town on the south. The old town retains some portions of the old fortifications: the streets are narrow and crooked. The new town, commenced in the beginning of the seventeenth century, has wide and straight streets, lined with good houses: the stateliness of its public buildings, and the extent and beauty of its squares and public walks, render Nancy one of the handsomest, though it is one of the dullest, of the great towns of France. La Place Royale is the finest of the squares: one side is formed by the town-hall (one of the handsomest in France), containing a gallery of pictures; two other sides are occupied by the office of the prefect, the custom-house, the theatre, and some private houses. In the angles of the square are four fountains, and in front of the town-hall a triumphal arch, erected by Stanislas Leckzinsky, duke of Lorraine, to Louis XV. Two streets run in a direct line from this square to two of the town-gates, built like triumphal arches. The cathedral is not remarkable, except for a portal with a triple row of columns, and for the high altar. The little church of Bon Secours, in the suburb of St. Pierre, is adorned by the monuments of Stanislas Leckzinsky and his wife. This church was erected by Stanislas to replace one built by René II., on the spot where Charles of Bourgogne fell. There are fine barracks both for cavalry and infantry, an Exchange, and other public buildings. In the old town is the ancient Gothic castle, the former residence of the dukes of Lorraine; and adjacent to it is a small church of Gothic architecture, the burial-place of the ducal family. The tomb of René II. and some

others are in the church itself; others are in a round chapel attached to the choir. This chapel was restored in 1822, at the joint expense of the French and Austrian governments: it is lighted by some stained-glass windows in the cupola by which it is surmounted, and contains seven marble tombs erected to the memory of the dukes of Lorraine or members of their family, a marble altar on which is a sculpture of Christ in his grave-clothes, and other ornaments. The remains of several of the princes of Lorraine lie in the vault beneath.

The population of Nancy, in 1826, was 29,122 for the commune; in 1831 it was 29,001 for the town, and 29,783 for the whole commune; in 1836 it was 31,445 for the commune. The inhabitants manufacture hosiery, hats, and gloves; and embroider muslin. This latter branch of industry employs many hands; the embroidery is sent to Paris and to the colonies. They spin cotton yarn by the agency of steam; and make coarse woollen cloth, calico, muslin, and other cotton goods. Some chemical preparations are manufactured; also vermicelli, liqueurs, paper-hangings, and earthenware. There are several establishments in the town or neighbourhood for spinning woollen yarn and weaving muslin and calico; besides tan-mills, tanyards, dye-houses, breweries, and oil-presses. There is near the town a large bed of stone well adapted for lithographic printing. Trade is carried on in the various manufactured articles; and in grain, wine, brandy, wool, and iron. There are two yearly fairs, one of twenty days.

Nancy is the seat of a bishop, whose diocese comprehends the department of Meurthe, and who is a suffragan of the archbishop of Besaçon; of a Cour Royale, whose jurisdiction comprehends the departments of Meurthe, Meuse, and Vosges; of a subordinate justice court and a commercial tribunal; and of several fiscal or administrative government offices. There are several hospitals and charitable institutions, and a house of correction.

There is a public library of 23,000 volumes; and there are libraries attached to the bishopric, the Cour Royale, and the high school. There are a rich museum, a cabinet of natural history, and a botanic garden; an académie universitaire, a high school, and a seminary for the priesthood; a school of design, and a secondary school of medicine; a central agricultural society, a royal society of sciences and arts, an elementary Protestant school, a Bible society, and a society formed by the wealthier Jews of the department for the instruction of the poor children of their nation in the useful arts.

Nancy was the native town of Marshal Bassompierre, of Claude Lorraine the painter, of Calmet the Benedictine, and other eminent men.

The arrondissement of Nancy has an area of 551 square miles, and contains 187 communes; the population, in 1831, was 127,944; in 1836 it was 129,841.

NANGASAKI. [JAPAN.]

NANINA, Mr. Gray's name for a genus consisting of the phanorbicular species of *Helix*, with large umbilici, included in the subgenus *Helicella* of De Férussac. The animal was first discovered and figured by General Hardwicke in 1797. Mr. Gray characterizes the genus, and enumerates the species in the 'Zoological Proceedings for 1834.'

NANING is the name of a country which up to 1832 was possessed by a Malay chief, who was tributary to the British province of Malacca. In the year 1832 Naning was annexed to that province, the chief having risen in rebellion against the East Indian government. It lies at the back of the other territories, and separates them from the small kingdoms of Rumbowé and Johole. It extends north and south about 40 miles, with an average breadth of 10 miles, which gives an area of 400 square miles, or nearly the extent of the county of Bedford. The surface is undulating, interspersed with high knolls thickly clothed with jungle; the hollows or flats, between the undulations, where the water lodges in the rainy season, average seventy or eighty yards in width, and either form a swamp or paddy ground. The soil on the high grounds is red and generally gravelly; on the flats it is soft and whitish. Water is plentiful, and may easily be got two or three feet below the surface, on the slopes of the rising grounds. The chief products are rice, timber, and fruits; pepper and gamboge are cultivated. Among the fruits are mangosteens, pine-apples, jack-trees, and many other kinds. There are forty-five species of trees in the jungle, of which the fruit is edible.

A small portion of gold is found, and tin in considerable quantities. According to a census taken in 1829, the population amounted to 3458, probably males, as it is added that 1809 were capable of bearing arms. They are Malays, profess the Mohammedan faith, and live in villages, of which the largest, called Sabany, contains 148 houses. (Moor's *Notices of the Indian Archipelago*, Singapore, 1837.)

NANKKEEN, a description of cotton cloths, usually of a yellow colour, imported from China, and taking their name from the city of Nankin, in which great quantities of them are made. The peculiar colour of these cloths is natural to the cotton-wool of which they are made, and not the effect of any dye. White cloths of similar texture are imported from China, and these, to distinguish them from the yellow cloths, are called white nankeens. Nankeen cloths were formerly very much used in England for gentlemen's summer clothing, but better fabrics of home manufacture being now procurable at lower prices, these have taken the place of the Chinese goods. Within the last ten years the annual importation of nankeen cloths into the United Kingdom, from China, has exceeded 900,000 pieces; but the quantity brought in 1838 was under 60,000 pieces, and the greater part of these was re-exported.

NANKIN, a town in China, on the south bank of the river Yantse-kiang, near 32° N. lat. and 117° E. long., and about 120 miles from the mouth of the river. It is said that at some remote period sea-vessels were able to ascend the river to the town, but the very low and swampy shore which extends in these parts along the Hoang-Hay (Yellow Sea) renders this statement improbable. This town was the capital of the empire to the end of the thirteenth century, and at that time the largest town on the globe. To give an idea of its then extent, the Chinese historical records say, that if two horsemen were to go out in the morning at the same gate, and were to gallop round by opposite ways, they would not meet before night. This is certainly an exaggeration. The Jesuits, when surveying the town for the purpose of making a plan of it, found that the circuit of the exterior walls was 37 *lies*, or nearly 20 miles; and this agrees pretty well with the description given by Ellis, who estimates the distance between the gate near the river and the Porcelain Tower at about six miles, and says that an area of not less than thirty miles was diversified with groves, houses, cultivation, and hills, and enclosed within the exterior wall, which forms an irregular polygon. But the whole of this area is not covered with houses built in regular streets; only about one-fourth of it at present is covered by the town, which occupies that part which is farthest from the river, and is about six miles from its banks.

The town began to decrease when Kublai-khan removed the Imperial residence to Pokin, and still more rapidly when the six great tribunals, which for some time were kept at Peking and Nankin, were attached to the court at Peking. When this took place the name of the town Nankin (the southern court) was changed into that of Kian-ning-foo, as it is now always called in public documents, though the people continue to call it Nankin.

The present town consists of four principal streets, running parallel to one another, and intersected at right angles by smaller ones. Through one of the larger streets a narrow channel flows, which is crossed at intervals by bridges of a single arch. The streets are not spacious, but have the appearance of unusual cleanliness. The part within the walls, which is now only occupied by gardens and bamboo-groves, is still crossed by paved roads, a fact which seems to indicate that the whole area was once built upon.

None of the buildings of Nankin are distinguished by their architecture, except some of the gates, and the famous Porcelain Tower, which is attached to one of the pagodas or temples. This building is octagonal, and of a considerable height in proportion to its base, the height being more than 200 feet, while each side of the base measures only 40 feet. It consists of nine stories, all of equal height, except the ground-floor, which is somewhat higher than the rest. Each story consists of one saloon, with painted ceilings; inside along the walls statues are placed. Nearly the whole of the interior is gilded. The material of the wall seems to be a highly polished stone; but probably it is composed of bricks made of a fine clay, susceptible of impressions, as the figures show which appear on them. On the outer side of the wall they are white, and, according to Ellis, are merely the white bricks frequently used in China. At the termination of

every story, a roof built in the Chinese fashion projects some feet on the outside, and under it is a passage round the tower. At the projecting corners of these roofs small bells are fastened, which sound with the slightest breeze. On the summit of the tower is an ornament in the form of the cone of a fir-tree: it is said to be of gold, but probably is only gilt; it rests immediately upon a pinnacle, with several rings round it. This tower is said to have been nineteen years in building, and to have cost 400,000 taels.

The population of Nankin, which is said to have been once four millions, is now probably reduced to 800,000. It still has a great number of manufactures, especially silk and crapes, and carries on a very considerable commerce, being situated in the most populous part of the empire. Through the ports of Soo-cheou-foo and Shang-hae it receives great quantities of corn and other articles. They are brought by water to Nankin, as there are several canals which connect the town with the river, which is five or six miles from it in a straight line. According to the statements of the Jesuits this city is also famous as the seat of arts and sciences, and furnishes more doctors and great mandarins than many more populous cities together. It has also the greatest number of libraries, and the numerous booksellers' shops are well stocked with the best publications. The paper made here is considered the best in the empire.

(Du Halde's *History of China*; Ellis's *Journal of the late Embassy to China*.)

NANNI, GIOVANNI, called Giovanni di Udine, was born at Udine, in 1490. He studied first in the school of Giorgione, and afterwards passed to that of Raphael, under whose direction he executed the greater part of the stuccoes and grotesque ornaments in the loggie and other apartments of the Vatican. He is considered as the most eminent in this branch of the art. His bowers, plants, and foliage, his aviaries, with birds of every description, are so true to nature as almost to deceive the eye by the closeness of the imitation. After the sack of Rome he visited other parts of Italy, and many of his works are at Florence, Genoa, and Udine. He died in 1464, at the age of 70. Vasari frequently calls him 'Ricamatore.'

NANO'DES. [PSITTACIDÆ.]

NANTES, a town in France, capital of the department of Loire Inférieure, situated on the north bank of the Loire, in 47° 13' N. lat. and 1° 34' W. long.; 208 miles from Paris in a direct line west-south-west, or 231 miles by the road through Versailles, Chartres, Le Mans, and Angers.

Nantes is a very ancient town: it is mentioned by Ptolemy as the capital of the Nannetes, a Celtic people, under the name of Condevicnum, a name which was superseded about the time of the downfall of the Roman empire by that of Nannetes, whence the modern Nantes. In the ninth and tenth centuries it was six times pillaged and burnt by the Northmen, and continued desolate for thirty years. In A.D. 1598 Henri IV., who had come into Bretagne to appease the troubles excited by the duke of Mercœur [BRETAGNE], issued from this town an edict granting various privileges to his Protestant subjects. This edict, commonly known as the edict of Nantes, was revoked by Louis XIV. In the Vendean war, the town was attacked by a body of insurgents computed to amount to 80,000: the inhabitants, with some troops of the line in the town, succeeded in repelling them. Nantes was afterwards the scene of the cruelties of Carrier, the most ferocious of the agents employed at that time by the revolutionary government. Madame La Roche Jacquelin estimates the number of those who were drowned or shot or died in prison at 25,000.

The old town of Nantes was almost entirely comprehended in the angle formed by the north bank of the Loire and the east bank of its tributary the Erdre: a small part of the old town near the junction of the rivers extended across the Erdre to the opposite bank, on which the suburb of Le Marchys is situated. The suburbs of St. Clement and Richelbourg are east of the town in the angle of the rivers, the latter extending along the bank of the Loire. The suburb of Les Ponts (the bridges) comprehends the islands of the Loire opposite the town, across which islands a chain of bridges and causeways communicates with the suburb of St. Jacques, on the south side of the river. The quay of La Fosse extends along the north bank of the Loire, west of the town: it is planted with trees for a considerable part of the length, and is lined with handsome houses with

balconies, which may be considered as forming another suburb. The ramparts of Nantes have been almost entirely removed: the two promenades of St. André and St. Pierre, which form one line extending from the Erdre to the Loire, are on or near the site of one portion; and the boulevard, a public walk, west of the Erdre, is on or near the site of another portion. The ancient castle of the dukes of Bretagne, a stately and massive building, is at the south-eastern point of the old town, on the Loire. By the destruction of the fortifications, Nantes and its suburbs have become one town: the space between the quay of La Fosse and the suburb Le Marchys has been filled with streets and squares, forming Le Quartier Neuf, or New Quarter; and various other improvements have been effected and are still going on.

The streets are generally well laid out and paved; and the houses well built, chiefly of stone, and roofed with slate. There are about twenty places or squares, which are regularly laid out: the Place Royale and the Place Graslin are adorned with handsome houses of uniform design. Part of the old town however yet retains the narrow, dark, and dirty streets, and the old black-looking houses, faced in some instances with a sombre covering of slates, which were formerly characteristic of the whole place. The street La Poissonnerie (Fish-street) is the most remarkable of these relics of the olden time: the upper parts of the houses project so as nearly to meet across the street.

The principal public buildings are the cathedral and the episcopal palace; the prefect's office (formerly the Chambre des Comptes), the Hôtel de Ville, the Bourse or Exchange, the theatre, the mint, the prison of Bouffay, the hospitals of Le Sanitat and the Hôtel Dieu, the Salorges (now used as a dépôt for merchandise of all sorts), the corn-market, &c.

The cathedral is just within the line of the ancient ramparts on the east side of the town: it has never been finished; the nave only was erected: the west front has three doorways, and is adorned with sculptures in high relief, which were much defaced during the Revolution; it is of the fifteenth century. It has two towers, which have never been finished; they rise little above the level of the roof: one of them is crowned with a lantern or turret built for the purpose of keeping watch on the movements of the Vendean insurgents. The interior of the nave is fine: it is not of great extent, but is very lofty: the transepts and choir were never built to correspond with the nave; but the heavy, low, and dark choir of a much more ancient building of the sixth century was adjusted to the nave in the seventeenth century: the communication is by a modern portico. The cathedral contains the tomb of François II., last duke of Bretagne. The episcopal palace, which adjoins the cathedral, has the appearance of a common parsonage-house. The prefect's office has two good fronts, the principal towards the cathedral, the other towards the river; each front is adorned with an Ionic portico of four columns. The corn-market is a large, modern, and tolerably handsome building: above it is the public library of 30,000 volumes. The exchange is adorned with Ionic columns, with the statues of four of the most eminent seamen whom France has produced, viz, Duquesne, Jean Bart, Duquay-Trouin, and Cassard; and with a number of allegorical statues. The hospital of Le Sanitat is partly a receptacle for decayed townsmen, who here obtain lodging and board at a very low rate, and partly a lunatic asylum. There are no fountains in Nantes; but the town is adorned by several public walks; there is a departmental column 70 feet high, and in the Place Louis XVI. is a column surmounted by a statue of that king. There are a number of bridges, some of them over the fosse of the ancient ramparts, now forming a ravine or deep valley in the town; others across the Erdre or the arms of the Loire. There are several low islands in this latter river opposite Nantes; that of Feydeau is nearest to the town, of which indeed it forms part; the others are the Ile Gloriette and the Ile de la Biessé, divided by the arms of the river into three parts. Communication is maintained between the opposite banks of the river by bridges from one island to another.

The population of Nantes, in 1826, was 71,739 for the commune; in 1831 it was 77,992 for the town, or 87,191 for the commune; in 1836 it was 75,895 for the commune. It derives its importance and prosperity from its situation on the Loire, which forms its port. The tide flows up to Nantes, but its rise in ordinary tides is only about 5 feet; and in winter it is imperceptible, being then counteracted

by the force of the stream. Vessels of 200 tons come up to Nantes at spring-tides; at other times only vessels of 100 tons or less can get up. Larger vessels either remain at Paimbœuf, 25 miles lower down, or at least discharge part of their cargo there. The quays at Nantes extend along the river side from the eastern extremity of the suburb Richebourg to the western or lower extremity of the quarter of La Fosse.

There are quays all round the Ile Feydeau and in one part of the Ile Gloriette, and along the bank of the Erdre, which expands into a fine sheet of water, resembling a lake, with its banks adorned with country-houses: it is navigable to Nort, 12 or 13 miles above Nantes. The merchants of Nantes enjoy a high reputation for the punctual fulfilment of their commercial engagements: they were formerly extensively engaged in the slave-trade; and during the last general war a hundred privateers were fitted out here. The manufactures are considerable, and include coarse woollen cloth and flannel, calico, handkerchiefs, fustian, bed-ticking, and other cotton or linen fabrics. There are copper-foundries, and iron-works for making chain-cables, casting cannon, and furnishing other articles for the equipment of vessels; ship-building yards (at which corvettes and other small ships of war are built) and ropewalks; breweries, brandy-distilleries, vinegar-yards, refining-houses for colonial and beet-root sugar, a glass-house for bottles, tan-yards, currying establishments, &c. Pottery, tobacco-pipes, chemical products, brushes, corks, and fishing-nets are also made. There is a victualling establishment for the navy, from which Brest, Lorient, and Rochefort are supplied. Provisions are very cheap. The trade of the port is not limited to any particular part of the world: the principal articles of export and import are grain, flour, ship-biscuit, butter, dried pulse, hides, morocco leather, timber, agricultural implements, Spanish and Portuguese wine, liqueurs, colonial produce, and French manufactures. Vessels are fitted out for the Newfoundland cod-fishery, and the fishery of the sardine, or pilchard, is actively carried on. The navigation of the river facilitates communication with the interior of France, and the dangerous navigation of one part of the coast is superseded by the canal from Nantes to Brest. The salt from the salt-pans of the coast about Noirmoutier and Le Croisic is in great part conveyed into the interior by Nantes. There are two weekly markets and twelve yearly fairs.

Nantes is the seat of a bishopric, the foundation of which some carry back to the third century: the diocese comprehends the department of Loire Inférieure: the bishop is a suffragan of the archbishop of Tours. It is also the seat of a Lutheran consistory. There are nine churches, six nunneries, and four hospitals. There are a subordinate court of justice and a commercial tribunal, a custom-house, a mint, and a variety of other fiscal or administrative government offices. There are a high school, two seminaries for the priesthood, a school of design, a free school for navigation, a secondary medical school, and one or two courses of lectures. Besides the public library of 30,000 volumes, there are a library at the episcopal palace, museums of paintings, natural history, and physical science, a botanic garden, an observatory, public baths, and a theatre. There are various societies for literary and charitable purposes.

The arrondissement of Nantes has an area of 685 square miles, and comprehends sixty-six communes: the population, in 1831, was 205,627; in 1836 it was 205,892.

NANTUA. [AIN.]

NANTUCKET BAY. [MASSACHUSETTS.]

NANTWICH, or **NAMPTWICH**, a market-town in the hundred of Nantwich, in Cheshire, on the river Weaver, 192 miles from London on the road through Lichfield and Stafford to Chester. The first part of the name is said to be derived from *nant*, a British word signifying a brook or valley; the second part is an Anglo-Saxon corruption of the Roman *vicus*; and though locally assumed to be the appropriate designation of a salt-work, is in reality a general designation of a group of habitations, whether in town or country. The termination *wick* or *wich*, for it is written both ways, and is sometimes separate from the other part of the name, is found in the names of places (e.g. Green-wick, Wool-wick, Nor-wick, Ips-wick, War-wick, Aln-wick, &c.) which have no peculiar connection with the manufacture of salt.

Nantwich is mentioned in 'Domesday' by the simple designation *Wich*, and the salt-works are there mentioned.

It was then enclosed by the river Weaver on one side, and on the other by a ditch. In 1069 Nantwich was the scene of an unsuccessful attempt by the Cheshiremen to resist the advance of the Normans under Hugh Lupus, earl of Chester. It was afterwards made the head of a Norman lordship, and the lords had a castle here, of which there are no remains. In 1438 and 1583 the town suffered considerably from fire. The damage on the last occasion was estimated at 30,000*l.* In the civil war of Charles I. the town was occupied by the Parliamentarians, from whom it was taken by Lord Grandison just before the battle of Edge Hill. Sir William Brereton, the parliamentary general, afterwards re-occupied it, and made it his head-quarters during the war. It was besieged (January, 1643-44) by a body of the king's troops, partly Irish, under Lord Byron; but though defended only by works hastily raised round the town, was gallantly held by the townsmen and others under Sir George Booth until the siege was raised, and the enemy entirely defeated by Sir Thomas Fairfax and Sir William Brereton.

The town is in a low flat situation, on the right or east bank of the Weaver. It is irregularly laid out, and consists of three principal streets, which unite near the church, and some others. The streets are indifferently paved, and the houses are commonly old, built of timber and plaster, with large bay windows and projecting upper stories. The church is a cross church, with a mixture of various styles of architecture. The west door is early English; the rest of the church decorated English or perpendicular, with some portions of a transition character between them. The nave has flying buttresses within, and is marked by some other peculiarities. The north transept has a fine decorated window; and the south transept and the choir or chancel, some fine perpendicular windows. The tower, which rises from the intersection of the nave and transepts, is an octagon of perpendicular date, with small crocketed pinnacles. It is small in proportion to the other parts of the church. The whole is of red-sandstone of friable texture. In the churchyard is an antient timber building, formerly the town-hall, but now used as a free-school. There is a market-house and town-hall, built in the last century, and a stone bridge over the Weaver. The dissenters have several meeting-houses, and there are several ranges of almshouses.

The parish has an area of more than 3490 acres, with a population, in 1831, of 5357: it comprehends the whole townships of Alvaston, Leighton, Nantwich, Woolstanwood, and part of that of Willaston. Nantwich township comprehends 780 acres, with a population of 4886, scarcely any part of it agricultural. The prosperity of the town was formerly owing to its brine-springs and salt-works, which were of great celebrity and antiquity. Only one spring is now worked. The chief manufactures are of shoes, gloves, and cotton goods. The Chester, the Ellesmere, the Liverpool and Birmingham Junction canals, and the Middlewich branch canal, unite in the neighbourhood of the town; and the Grand Junction Railway passes at no great distance. The market is on Saturday, and there are three yearly fairs. The cheese made in the neighbourhood is highly esteemed. Petty-sessions for the hundred are held here; general quarter-sessions were formerly held here, but were removed to Knutsford in 1760. The town was once governed by a guild, but this was suppressed by Edward VI. The living is a rectory, in the diocese and archdeaconry of Chester, of the clear yearly value of 269*l.*, with a glebe-house.

There were in the township, in 1833, a day-school, with 65 boys, partly supported by endowment; another day-school, with 68 boys and 8 girls, partly supported by endowment and partly by payments from the children; fourteen other day-schools, with 431 children; and four Sunday-schools, with 636 children. The other townships contain only one day-school, with 30 children.

Major-general Harrison, one of the Regicides, who was put to death on the restoration of Charles II., was a native of Nantwich. Milton's widow was born in the neighbourhood, and died here at an advanced age in 1726.

(Ormerod's *Cheshire*; *Beauties of England and Wales*; *Parliamentary Papers*.)

NAPHTHA. [HYDROGEN-CARBURET.]

NAPHTHALAMIDE. This compound is formed by heating naphthalate of ammonia in a retort; ammonia and water are disengaged, and naphthalamide sublimes, without

leaving any residue. This substance is colourless, inodorous, and insipid. It fuses when heated, and on cooling becomes a fibrous mass. When strongly heated it boils, emitting vapour, which condenses in crystalline plates. It is nearly insoluble in cold water, and but slightly soluble in hot; the solution deposits acicular crystals as it cools.

Chlorine does not act upon naphthalamide; heated concentrated sulphuric acid dissolves it, but when cooled and diluted, crystals of naphthalamide are deposited. Dilute acids do not act upon it; when boiled in a strong solution of potash, ammonia is disengaged; sulphuric acid separates the naphthalamide from the alkali.

According to M. Laurent this substance consists o-

Hydrogen . . .	3.10
Carbon . . .	64.65
Oxygen . . .	23.35
Azote . . .	8.90

100

NAPHTHALASE, a compound discovered by M. Laurent in 1835. It is prepared by mixing nitronaphthalase with about ten times its weight of lime, slightly moistened in a retort filled to the neck; when heat is applied, a brown oil is formed, containing much naphthalin, some ammonia and undecomposed naphthalase, and in the neck of the retort a thick oil is condensed, which on cooling becomes solid; this is separated by cutting off the neck of the retort, and when washed with æther, the foreign matter is dissolved and the naphthalase remains.

Its properties are, that it is pulverulent, of a yellow colour, insoluble in water and alcohol, and nearly so in æther. At 482° it begins to sublime but does not melt; at a higher temperature it fuses and boils; the vapour is of a yellow colour, and it condenses either in yellow scales or needles. A small quantity dissolved in cold sulphuric acid imparts to it a fine deep violet-blue colour, and water precipitates it unaltered.

According to Laurent, it consists of

Hydrogen . . .	4.9
Carbon . . .	87.
Oxygen . . .	8.2

100

M. Laurent considers it as nitronaphthalase minus an equivalent of hyponitrous acid.

NAPHTHALIC ACID, a compound obtained by a very tedious and complicated process from naphthalin by Laurent. Its properties are, that it is white, brilliant, and in long feathery crystals, which are four-sided prisms; it considerably resembles benzoic acid. It melts at 221°, and on cooling concretes into a fibrous mass, and when more strongly heated, it volatilizes without decomposition in a pungent white vapour, which is readily combustible.

This acid is devoid of smell, has little taste, is unaltered by exposure to the air, reddens moist litmus paper, is only slightly soluble in cold water, but dissolves to a considerable extent in hot water; alcohol and æther dissolve it readily. Chlorine has no action upon it, but hydrochloric, nitric, and sulphuric acid dissolve it while hot without decomposition.

According to M. Laurent, it consists of nearly

Two equivalents of Hydrogen . . .	2	or	2.13
Ten equivalents of Carbon . . .	60		63.83
Four equivalents of Oxygen . . .	32		34.04
Equivalent . . .	94		100

The crystals contain one equivalent of water. Its saline compounds are called naphthalates, but they are not important.

NAPHTHALIN. [Hydrogen-Carburets.]

NAPIER, JOHN, baron of Merchiston, was born at Merchiston Castle, near Edinburgh, in the year 1550, at which time his father was but sixteen years old. His lineage is traced from John de Napier, who, in 1296, swore allegiance to Edward I. of England: and among his more immediate ancestors are mentioned William Napier, governor of the castle of Edinburgh, and Alexander Napier, vice-admiral of Scotland. His father, Sir Archibald Napier, was master of the mint of Scotland. Napier was never raised to the peerage, as might be inferred from the writings

of some authors, Briggs among others. (*Letter to Archbishop Usher*, vol. v., p. 422.) His name has been variously written. Besides the Latinized forms Neper and Neperus, we meet with Naper, Napier, and Nepair. The last is the orthography adopted in the title-page of Wright's translation of the logarithmic canon, which work was revised by Napier himself the year before his death. The name at the head of this article appears to have been the family name, and is certainly that by which he is now generally known.

Napier's matriculation into the university of St. Andrew took place in the year 1562-3, as appears from the books of the university. (See the 'Pursuit of Knowledge,' in the *Library of Entertaining Knowledge*, and the subsequently published *Life of Napier*, by Mark Napier, 4to., Lond., 1834.) That it took place early also appears from the following passage in the preface to his 'Plain Discovery of the Revelation of Saint John,' published at Edinburgh in 1593, 4to. Speaking of the university, he says, 'In my tender years and bairn age at schools, having on the one part contracted a loving familiaritie with a certain gentleman, a papist, and on the other part being attentive to the sermons of that worthy man of God, maister Christopher Goodman, teaching upon the Apocalypse, I was moved in admiration against the blindness of papists, that could not most evidentlie see their seven-hilled citie of Rome pointed out there so lively by St. John as the mother of all spiritual whoredom: that not only bursted I oute in continuall reasoning against my said familiar, but also from thenceforth I determined with myself, by the assistance of God's spirit, to employ my study and diligence to search out the remanent mysteries of that holy booke, as to this houre, praised be the Lord, I have bin doing at all such times as convenientlie I might have occasion.' One object of the 'Plain Discovery' was to show that the doctrines of the pope were antichristian, which so accorded with the views of the French Huguenots, that a translation of the work, stated in the title-page to have been revised by Napier, appeared at Rochelle in 1603, and the same year the council of Gap formerly declared the pope to be Antichrist. In the same work he fancies he has determined the dates at which the completion of the prophecies will take place, and he assigns the destruction of the world to the year 1786.

From the time of his entering the university to the publication of the above work, scarcely any thing is known concerning him. His biographers, David Stewart, earl of Buchan, and Walter Minto, about the close of the last century made inquiries among the descendants of Napier for letters or other documents which might throw light on his history during this long interval. Their exertions in this respect seem to have been attended with little success. MacKenzie, in his 'Lives and Characters of the most eminent Writers of the Scottish Nation,' fol., published at Edinburgh in 1708-22, informs us, but without mentioning any authority, that Napier passed some years in France, the Netherlands, and Italy, and that while absent he applied himself to the study of the mathematics. This is confirmed by his biographer, Mark Napier, who supposes him to have left Scotland as early as the year 1566, and adds that his college residence had been too short to entitle him even to the degree of B. A. In 1571 he had returned to Scotland. In 1593 he was chosen by the General Assembly one of the commissioners appointed to assemble at Edinburgh to counteract the attempts of the Roman Catholics to put aside Protestantism, then recently established. We are left to conjecture at what time prior to the year 1594 the mind of Napier first became occupied with the discovery of a method which should supersede the long and laborious arithmetical operations which the solution of the most simple trigonometrical problems then exacted. That he was thus occupied in the year 1594 is probable from a letter written by Kepler to Crugerus, dated 1624, wherein, speaking of Napier's logarithmic tables, which had then been published ten years, he says, 'Nihil autem supra Naperianam rationem esse puto: etsi quidem, Scotus quidam, literis ad Tychonem anno 1594 scriptis, jam speciem fecit canonis illius mirifici.' (Kepl., *Epist.*, Lips., 1718, fol., p. 460.) The Scotchman here alluded to was Dr. Craig, of whom a circumstance is related by Wood, in his 'Athens Oxonienses,' under the article 'Briggs,' upon the authority of Oughtred and Wingate, and cited by several authors with reference to Napier's invention. The substance is this:—Craig, coming out of Denmark, called on Napier at Merchiston

and informed him, among other things, of a rumoured discovery by Longomontanus, 'as 'tis said,' whereby the tedious operations of multiplication and division in astronomical calculations were avoided; and intimated that this was effected by means of proportional numbers, of which information Napier availed himself so skilfully, that upon Craig repeating his visit a few weeks after, he showed him a draught of what he called canon mirabilis logarithmorum. The correctness of this story, as regards Longomontanus, is disproved by the fact that Longomontanus attributes the invention to Napier. (*Astronomica Danica*, p. 7, &c., quoted by Dr. Hutton.) There appears however to be no doubt that Craig did write to Tycho Brahe at the time stated, acquainting him with the progress which Napier had then already made.

Besides Longomontanus, several authors have been mentioned, and their works referred to, with a view to detract from the merit of Napier by bringing him in debtor to some of his contemporaries. All these attempts appear to proceed more or less on the supposition that the principle of logarithms was in Napier's time a novelty. The fame of Napier however does not rest on the discovery of that property of numbers upon which all the advantages of logarithms depend. Long before his time it was known that if the terms of an arithmetical and geometrical series were placed in juxta position, the multiplication, division, involution, and evolution of the latter would answer to and might actually be effected by a corresponding addition, subtraction, multiplication, and division of the former. To a certain extent this property was employed by Archimedes, in his 'Arenarius,' or treatise on the number of the sands. Stifel also, in his 'Arithmetica Integra,' Nürnberg, 1544, p. 35, exhibits its principal uses, and evinces so clear a conception of the nature of logarithms, only not under that name, that had he been furnished with a table of such numbers, he would doubtless have been able to make use of them. He might even have constructed a table, but the natural numbers would not have been consecutive, and the omissions would have been by far more numerous than the insertions, and this would have happened simply because he, in common with all other mathematicians previous to Napier, possessed no means of determining the logarithm corresponding to any proposed number, but merely those corresponding to particular numbers. Until such means were supplied, no table of any practical utility could have been constructed. Napier discovered the means, but had he not been of a peculiarly ardent disposition, he would have shrunk from the labour which their application required, and his discovery would perhaps have remained a mere sterile truth. It happened to him, as it has happened to most original discoverers, that the view which he took of the problem was not the most natural, and consequently not the most simple. The problem itself was purely arithmetical; Napier arrived at its solution through geometrical considerations. But notwithstanding this circumstance and the disadvantages he must have laboured under, arising from the imperfect methods of analysis then in use, and the almost total absence of notation, his processes even now are to a certain extent the most eligible, and are analogous to those employed in the construction of the great 'Tables du Cadastre.' 'Modern formulæ,' says Delambre, 'have furnished processes more sure and exact, but not more convenient.' (*Astronomie Moderne*.) Concerning Napier's principles we have not further to speak; the reader will find them explained in the article LOGARITHMS.

With regard to the importance of the invention, and the claim of its author on the gratitude of his successors, we may cite the words of Laplace. (*Exposition du Système du Monde*.) 'By reducing to a few days the labour of many months, it doubles, as it were, the life of an astronomer, besides freeing him from the errors and disgust inseparable from long calculations. As an invention it is particularly gratifying to the human mind, emanating as it does exclusively from within itself. In the arts man avails himself of the materials and forces of nature; in this instance the work is wholly his.'

His tables were published in 1614, by the title of 'Mirifici Logarithmorum Canonis Descriptio,' Edinb., 4to. As their principal object was to facilitate trigonometrical computations, they contained only the logarithms of the natural sines corresponding to each minute of the quadrant and to radius = 10'. The principle of their construction Napier

at first withheld, 'waiving the judgment and censure of mathematicians before exposing the remainder to the malignity of the envious.' This explanation was given in a posthumous work, edited by his son, and published in 1619, Edinb., 4to. It is entitled 'Mirifici Logarithmorum Canonis Constructio: una cum annotationibus aliquot Doctissimi D. Henrici Briggsii.' The two works were reprinted at Lyon in 1620.

From the date of the publication of the logarithmic canon until the death of Napier, which took place the following year, there is little recorded of him which demands particular notice, except his connection with Briggs, already noticed. [BRIGGS.] His 'Rabdologia, seu Numerationis per Virgulas, libri duo,' Edinb., 1617, 12mo., was the last of his literary productions. [NAPIER'S BONES.]

Napier died at Merchiston on the 3rd or 4th of April, 1617 (not 1618), old style, and was interred in the cathedral church of St. Giles at Edinburgh. On the eastern side of the cathedral is a stone tablet with a Latin inscription, indicating the spot of his interment. He was twice married. By his first wife, the daughter of Sir James Stirling of Kier, or Keir, he had one child, Archibald, who became privy-counsellor to James VI., and was raised by Charles I. to the peerage in 1627, by the title of Lord Napier. By his second wife, the daughter of Sir James Chisholm of Crombie, he had five sons and five daughters. To his third son Robert, to whom he had taught the mathematics, he confided the care of publishing his posthumous works.

Of Napier's improvements in trigonometry it is sufficient to refer to the elegant theorems known as Napier's 'Analogies' [TRIGONOMETRY], and to his theorem of the 'five circular parts,' which furnishes a ready solution of all the cases of right angled spherical triangles.

The only work of Napier not already mentioned is a letter to Anthony Bacon, entitled 'Secret inventions profitable and necessary in these days for the defence of the island, and withstanding strangers, enemies to God's truth and religion' (the original is in the archbishop's library, Lambeth; two copies are in the British Museum; it is also printed in Tilloch's 'Philosophical Magazine,' vol. xviii.). Watt, in his 'Bibliotheca Britannica,' adds 'Arithmetica Logarithmica,' Lond., 1624, fol.; but this is a mistake, Briggs being the author of that work.

(*Life, Writings, and Inventions of John Napier*, by David Stewart, earl of Buchan, and Walter Minto, LL.D., Perth, 1787, 4to.; Hutton's *Tracts*, &c.)

NAPIER'S BONES, or RODS, a contrivance of Napier to facilitate the performance of multiplication and division, explained by him in his 'Rabdologia,' published in 1617. The invention would have been perhaps more employed, but for his discovery of logarithms: and even yet it might be used with advantage by young arithmeticians in verification of their work. We shall therefore describe it, with a very slight modification, which somewhat facilitates its use.

The preceding cut represents one of the rods belonging to the number 3. It is a parallelogram with an angle of 45°, containing nine equilateral parallelograms, with one vertical diagonal in each. In these are distributed, in a manner which will be visible at a glance, the multiples of the number which stands at the head, up to nine times. A sufficient number of rods must be provided for each of the headings 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, so that by placing the proper rods side by side, any number may be seen at the head, as in the following diagram, which represents rods in juxta-position ready for the multiplication of 70955

If we wish to multiply by 32978 we look at the eighth column of multiples, in which we see the following disposition of figures (which however it is not necessary to write down afresh)

602204
 507746

These may be added on the rods, and the result 5079664 written down in its proper place. The same is done with the other digits, and the results are added in the usual manner.

The only difference between the preceding description and Napier's rods is, that in the latter the rods are upright, and the additions that are made from the rods are therefore made diagonally. The compartments should be made large enough to allow of the figures which are to be added standing directly under one another.

Napier's bones, as they were called, have been much more often described in historical works than in those intended for use. Sir Walter Scott must have had an indistinct remembrance of them, without however knowing what the phrase meant, when he made David Ramsay, in the 'Fortunes of Nigel,' swear by 'the bones of the immortal Napier.'

NAPLES, KINGDOM OF, REGNO DI NAPOLI, is the name commonly given to the Continental part of the united kingdom of the two Sicilies, which, in the administrative language of the country, is styled 'Sicilia Citeriore' (hither Sicily), or 'Dominij di quà dal Faro' (territories on this side of the Straits of Messina). This fine region occupies the southern half of the Italian peninsula, being bounded on the north-west by the Papal State, and on every other side by the sea. The frontier line between the kingdom of Naples and the Papal State begins on the coast of the Mediterranean, at the tower 'Dei Confini,' which is a mile or two south-east of Terracina, where the mountains recede from the sea, and at the opening of the basin of the lake of Fondi. The boundary-line then follows an offset of the ridge of the Lepini mountains as far as the valley of the river Sacco, an affluent of the Liris, which opens a natural road into the kingdom. Crossing that valley, the line proceeds first in a northern and afterwards in a north-north-western direction, along several ramifications of the Apennines, which divide the waters of the Liris from those of the Anio; then ascending the loftier group which, to the west, bounds the basin of the lake Fucino, it descends by following the downward course of the river Salto into the valley of the Volturno, crosses that river a little to the east of Rieti, which belongs to the Papal State, and then again ascends, crossing the backbone or central ridge of the Apennines between the sources of the Nera and those of the Tronto. Descending along the eastern slope of the central ridge, the line follows an offset which skirts the right bank of the Tronto, and afterwards, below Ascoli, the river itself forms the boundary down to the Adriatic. The whole of this tortuous boundary-line is about 160 English miles, but the direct distance, from its extreme point on the Mediterranean to the corresponding point on the Adriatic coast, is not quite 120 miles. Four roads, which

are ultimately reduced to two, lead into the kingdom: one by Terracina to Fondi, along the coast of the Mediterranean; the second from Rome, by Palestrina and the valley of the Sacco, into the valley of the Liris, and from thence into the valley of the Volturno, where it joins the former; the third, by Rieti, Civita Ducale, and Antrodoco, to Aquila and the valley of the Pescara; and the fourth by Ascoli to Teramo, and along the coast of the Adriatic to the banks of the Pescara likewise. It is a remarkable fact that the boundaries of the kingdom of Naples, since the foundation of the Sicilian monarchy by the Normans, about eight centuries ago, have not varied throughout all the political vicissitudes of the country.

The greatest length of the kingdom of Naples, from the Tronto to Capo Spartivento at the southern extremity of Calabria, is about 400 miles, in a curved line running through the centre of the peninsula. Its breadth from sea to sea varies greatly. In its northern part, from the mouth of the Garigliano to that of the Pescara, it is about 85 miles wide: farther south, from Cape Misenum near Naples, to the mouth of the Fortore, on the Adriatic coast, it is 100 miles; and from Naples to Vietri, on the promontory of Mount Gargano, it is 125 miles. From Naples to Manfredonia it is about 100 miles. South of Naples the gulf of Salerno on one side, and that of Manfredonia on the other, reduce the breadth of the peninsula to 83 miles; but farther south it again widens from the point of Licosa near Paestum, to Mola di Bari, on the Adriatic, a distance of 130 miles, which is the utmost breadth which the kingdom of Naples attains, but in which we do not include the length of the Iapygian peninsula, which projects in an oblique direction to the line of breadth measured across the main body of the peninsula of Italy. The length of the Iapygian projection is nearly 90 miles, with a mean breadth of 30 miles: the description of this district is given under **OTRANTO, TERRA DI.**

The breadth of the kingdom again becomes contracted between the deep gulf of Taranto on one side and that of Policastro on the other, it being about 65 miles from the mouth of the Bradano to that of the Trecchina. [BASILICATA.] It becomes still narrower as we advance southwards into Calabria: it is 45 miles between the gulf of Lao and that of Taranto, and 35 from the mouth of the Cratis to Cape Cetraro, after which it widens again to near 60 miles for a length of about 50 miles. South of the Lacinium promontory, now Capo delle Colonne, the land becomes contracted into a narrow isthmus about 14 miles across, between the gulfs of Squillace and Sant Eufemia, beyond which it spreads again to a breadth of 25 to 35 miles throughout the length of the province of Calabria Ultra. [CALABRIA.]

The area of the kingdom of Naples is estimated at about 31,600 square miles, or about 2700 square miles more than the area of Ireland. The population consisted in 1815 of 5,059,000 inhabitants; in 1825 it had increased to 5,456,664; in 1832 it was 5,809,000; and in 1837 it ascended to 6,021,284. (Petroni, *Censimento dei Reali Dominij di quà dal Faro*, 1826; Serristori, *Saggio Statistico dell' Italia*, 1833; *Bollettino Statistico di Milano* for January, 1839.) Of this population more than two-thirds, or about four millions, live by agriculture, about half a million by manufactures and other mechanical labour, another half million by trade, including sailors and fishermen; the priests, monks, and nuns amount to about 40,000; lawyers 8000; medical men 9000; persons employed under government 30,000; the military amount to 40,000; household servants to 50,000. The illegitimate children are to those born in wedlock as 1 to 22; but in the capital they are as 2 to 13.

The main features of the physical geography of the kingdom are—1, the Apennines, which run through the centre of the country, forming in several parts large masses and high table-lands, which, with their numerous offsets, occupy, especially in the southern part, the whole breadth of the peninsula [APENNINES]; 2, two extensive plains, Apulia and Campania, the former to the east and the other to the west of the Apennines; 3, numerous valleys between the offsets of the Apennines, of which those on the side of the Adriatic are mostly transverse, while on the side of the Mediterranean the valleys of the Volturno, and its affluents the Calore, Sabate, and Tamaro, and the valley of the Tanagro, an affluent of the Sole, and some others, are longitudinal, running between ridges parallel to the central chain; 4, a strip of

low land along the coast between the base of the mountains and the sea, varying in width from ten miles to one mile, and in some places even less, especially in Eastern Calabria, and some parts of Abruzzo, where the mountains advance close upon the sea. This low region is hot and naturally fertile, but unwholesome in many parts and exposed to inundations from the mountain-torrents.

The principal basins or water-systems are—1, that of the Liris, or Garigliano, which is about 60 miles long, not reckoning the windings of the river, from its source at Mount Camicciola, in the Abruzzo, to its estuary near the site of antient Minturnæ. The breadth of the basin in the upper course of the river is much contracted between the central Apennines to the east and the Sabine mountains to the west, which latter divide it from the basin of the Anio, but after passing Sora it spreads to about 20 miles in breadth, including the courses of the Fibreno, Melfa, Rapido, Frigido, and other affluents. It also drains part of the Papal province of Campagna through the channel of the river Sacco. The Garigliano is a deep river, always full of water, and is navigable for boats in the lower part of its course. West of the basin of the Garigliano, and separated from it by the mountains of Itri, is the small basin of Fondi, containing a low plain of about 50 square miles in extent and drained by the small river Vetere. 2. The basin of the Volturno is the largest and most important in the kingdom. The Volturno drains the greater part of the province of Terra di Lavoro, and its affluent the Calore is the drain of Principato Ultra, making in all an area of nearly 3000 square miles. The Volturno has a tortuous course of nearly 100 miles, and the Calore runs for about 60 miles before its junction with the Volturno. 3. The fertile plain east of Mount Vesuvius and between it and the Apennines forms a small basin, which is drained by the river Sarno. 4. The basin of the Sele and its affluent the Tanagro includes the greater part of the province of Principato Citra and a part of that of Basilicata which lies west of the central ridge. The Sele has a course of about 60 miles altogether, and the Tanagro a course of about 35 above its junction. South of the basin of the Sele, the peninsula becomes narrow, the Apennines come close upon the sea, and the course of the rivers towards both coasts is very short. In fact Calabria has numerous mountain-torrents, each of which drains its narrow valley. An exception however is found in 5. The basin of the Crati in Calabria Citra. The Crati has its source south of Cosenza, in the high lands of La Sila, a vast group projecting east of the main ridge of the Apennines and extending towards the coast of the gulfs of Taranto and Squillace. The Crati flows in a north direction between the main ridge to the west and the mountains of La Sila to the east, draining the fine valley of Cosenza; turning eastwards after passing the town of Tarsia, it enters the gulf of Taranto. Its whole course is about 60 miles, and it is the largest river of Calabria. 6. The basin of Basilicata, with its four parallel rivers, the Agri, Sinno, Bradano, and Basiento, is fully described in the article BASILICATA. East of Basilicata, the narrow Iapygian peninsula, which is intersected in its length by a low barren ridge, has no water-courses of any importance; and this is also the case with the province of Terra di Bari. 7. The Ofanto, one of the principal rivers of the kingdom, rises in the Apennines of Conza within the boundaries of Principato Ultra; it drains the part of that province which lies east of the Apennines, and also the northern part of Basilicata, as well as a part of Capitanata and Terra di Bari, and after a course of above 70 miles enters the Adriatic. It receives no affluents of any importance. 8. The great plain of Apulia is drained by the Carpella, Cervaro, and Candelaro, the courses of which are nearly parallel, and run from the central Apennines to the sea. The Candelaro has several affluents, and drains a considerable tract of country between the group of Mount Gargano and the Apennines of Lucera and San Severo. 9. The Abruzzi contain numerous and rapid streams which run direct to the sea along deep valleys between lofty parallel ridges; but there are no extensive basins, with the exception of that of the river Pescara, which has a course of above 80 miles, and receives on one side the waters of the central chain of the Apennines, including Mount Velino, which runs north of Lake Fucino, and on the other those of the lofty mass of Monte Corno, which projects eastwards towards the Adriatic coast and has snow on its summit almost the whole year. The Pescara above the middle of its course passes through a narrow defile near the town of Popoli and turns

eastwards towards the Adriatic, receiving from the south the waters of another great outlying group of Apennines, called Mount Majella, in the province of Chieti. 10. The basin of Lake Fucino, or Celano, in the centre of the peninsula, is surrounded by mountains on every side. The lake, which is 16 miles long and nine miles broad, receives the waters of about 400 square miles, mostly of high lands covered with snow for a great part of the year, and yet it has no visible outlet. But there are subterraneous drains from the bottom of the lake, which is much higher than the neighbouring valleys of the Liris on one side and the upper Pescara on the other. On the side of the Liris the intervening ridge about Capistrello is much depressed, and there the 'emissary' or tunnel was made in the time of the emperor Claudius, which is now in course of repair. The Liris runs in a deep narrow valley about three miles from the lake. [CELANO.]

The kingdom of Naples has a coast-line of about 1500 miles in length, two-fifths of which lie on the west or Mediterranean sea, and the rest on the Ionian and Adriatic seas. The Ionian sea, according to the Italian denomination, extends from the Straits of Messina to Cape Leuca, at the extremity of the Iapygian peninsula. Unfortunately this very extensive line of coast has few harbours. The deficiency of tides in the Mediterranean renders the estuaries of rivers useless for the purpose of navigation; and this is a great and lasting disadvantage to the countries round that sea, which alone would determine their maritime inferiority to the countries bordering upon the ocean. The Garigliano, Volturno, Sele, Crati, Ofanto, Pescara, and other rivers of the kingdom of Naples, if they were tide rivers, would afford good natural harbours for large vessels, whilst, as it is, the bars at their entrance are impassable except for very small craft. The only harbours on the Mediterranean coasts are those of Gaëta and Naples, and even these are not safe at all times, and do not admit of large vessels. But the Gulf of Baïre, in the Bay of Naples, affords a safe anchorage for the largest men of war. The natural port of Misenum, although not used now, is still capable of receiving large merchant vessels. South of Naples, as far as the Straits of Messina, there is no harbour. The artificial port of Salerno is filled up with sand, which has been the fate of most harbours on the coast of the kingdom, wherever a mole has been constructed. To prevent this evil, it has been proposed to raise, instead of continuous moles, piers made of arches, as the antients did at Puteoli, which, by leaving free ingress and egress to the waters, would prevent the constant accumulation of the sand. (De Fazio, *Nuove Osservazioni sopra i Pregj Architettonici dei Porti degli Antichi*, 1832.) On the eastern coast are the ports of Taranto and Brindisi; Gallipoli has merely a roadstead; the ports of Trani and Barletta are filled up, but Manfredonia has a very good road. A new harbour has been begun at Bari. On all the coast of Abruzzo there is no harbour; the mouth of the Pescara and the mole of Ortona afford shelter only for small craft. A new harbour is in course of construction at Ortona. The coast of the Abruzzo is generally shallow, except at the point of Formoli, where there is deep water, and the position is favourable to the construction of a harbour which has been projected. (Afan di Rivera, *Considerazioni su i mezzi di restituire il valore proprio ai domi che la natura ha largamente concesso al Regno delle due Sicilie*, 2 vols., 1833.)

The productions of the soil throughout the kingdom are various. The staple products are corn, wine, oil, wool, and silk. The plains of Apulia produce vast quantities of corn for exportation. A quantity of wool is exported from the same province, where about two millions and a half of sheep are fed. [CAPITANATA.] Oil is likewise exported from the eastern provinces and from Calabria, to the amount of about nineteen millions of Italian livres, or about 750,000 sterling. Gallipoli is the great oil mart. Silk is made in Calabria, in Abruzzo Citra, Terra di Lavoro, and Principato. Cotton is produced in the provinces of Bari, Principato, near Castellamare, and other places. Wine is made all over the kingdom, and in great abundance and variety, but most of it is consumed in the country and within the year; and although some of the wine, especially that of Calabria, is as full bodied and generous as any Portuguese and Spanish wine, yet little of it is kept or sent to the northern parts of Europe. Naples however exports wine to Rome, Genoa, and other parts of Italy. Some brandy is made and exported to America. Some of the wines made in the

neighbourhood of Naples, at Piedimonte, Procida, Capri, Gragnano, and at the foot of Mount Vesuvius (the latter is known by the name of 'Lachryma Christi'), are very fine and well flavoured. The country produces most kinds of fruit, such as figs, chestnuts, almonds, oranges, lemons, pomegranates, melons, peaches, and apricots. The Indian fig comes to maturity in Sicily, but not in the continental part of the kingdom. Tobacco is cultivated chiefly near Lecce, saffron in Abruzzo, and the sugar-cane in Calabria. Flax, hemp, and rice are also raised in considerable quantity in the low grounds. Indian corn is also much cultivated. Cheese is made chiefly in Abruzzo and Apulia. In some favoured spots, such as in the neighbourhood of Naples, at the foot of Mount Vesuvius, near Mostafione and Reggio in Calabria, the fertility of the soil seems inexhaustible.

There is a rich iron-mine near Stilo in the farthest Calabria, which is worked for the government. Coal is found also in Calabria near Briatico (Vivenzio, *Relazione dei Terrimenti di Calabria*, Naples, 1788; Savaresi, *Viaggio in Calabria*, 1801-2; Tenore, *Essai sur la Géographie physique et botanique du Royaume de Naples*, 1827.)

The forests with which the Apennines were once clothed have in great part disappeared through the waste, improvidence, and neglect of the people and the various governments which have succeeded each other in the country. This is a very serious evil, for not only fuel and timber have become scarce, but the destruction of the forests has caused the springs to be dried up and occasioned summer droughts in the subjacent lands, whilst the winter rains have washed away the vegetable earth from the mountain sides and exposed the bare rock, and the torrents carrying down alluvial matter into the valleys and plains have damaged whole tracts of country, choked up the beds of rivers, and occasioned the formation of pestilential marshes. Afan di Rivera, already quoted, has shown at great length the calamitous effects of the destruction of the Apennine forests. By a law concerning the forests, promulgated on the 21st August, 1826, an attempt has been made to arrest the progress of the evil.

The strip of maritime low land which skirts the sea-coast is in many places marshy and covered with underwood. Herds of black cattle, buffaloes, and pigs live in that unwholesome region. Something has been done of late years towards draining the marshes, especially between the mouth of the Volturno and Cuma, and on the opposite coast of Apulia. [BRINDISI; CAPITANATA.]

At the beginning of the present century there was no carriage-road through the kingdom, with the exception of the high road from Rome to Naples. Since that time roads have been made from Naples to Reggio at the extremity of Calabria, to Bari, Manfredonia, and Taranto in Apulia, to Chieti, Teramo, and Aquila in Abruzzo, to Potenza in Basilicata, to Campobasso in the province of Sannio, and other roads are in course of being constructed. A handsome suspension-bridge has been thrown across the Garigliano, which, although on the high road from Rome to Naples, had been crossed for centuries before only by a miserable ferry.

The kingdom is divided for administrative purposes into 13 provinces. We subjoin the population of each, as it was by the last authentic returns which we have seen, of 1837, which, compared with those of Petroni for 1825, show that the population has been gradually increasing at the average rate of about 1 per cent. annually: Provincia di Napoli, 720,796 inhabitants; Terra di Lavoro, head town Caserta, 664,138 inhabitants; Principato Citra, head town Salerno, 539,227; Principato Ultra, head town Avellino, 379,999; Sannio, formerly called Contado di Molise, head town Campobasso, 339,882; Abruzzo Citra, head town Chieti, 284,482; Abruzzo Ultra Primo, head town Teramo, 294,092; Abruzzo Ultra Secondo, head town Aquila, 299,543; Campania, head town Foggia, 273,489; Terra di Bari, head town Bari, 441,969; Terra d'Otranto, head town Lecce, 282,814; Basilicata, head town Potenza, 437,529; Calabria Citra, head town Cosenza, 424,622; Calabria Ultra Prima, head town Reggio, 298,886; Calabria Ultra Seconda, head town Catanzaro, 325,124. In common discourse, these divisions are often called by the name of the head-towns, such as Provincia di Salerno, Provincia di Lecce, Provincia di Teramo, &c. The provinces are divided into districts, and the districts into communes. Each province is administered by an intendant, or king's lieutenant appointed by the king, and changed every three

years. In every province there is a 'Consiglio provinciale, or a council of notables, proposed by the communal councils, and appointed by the king, which assembles once a year, and examines the provincial accounts and proposes local improvements. Keppel Craven, the latest authority on the subject, who has visited at leisure every province of the kingdom speaks favourably of the character, qualifications, and general behaviour of the intendants. The same praise however ought not perhaps to be extended to the subaltern or district and police authorities. Every commune has a sindaco, who corresponds to the maire of the French communes. A communal council, called 'Decurionato,' chosen by ballot from among the notables or proprietors, fixes the local rates, administers the revenue, and appoints the municipal officers, subject however to the sanction of the intendant. One of these officers is called 'conciliatore,' and acts as umpire between parties at variance, for the purpose of preventing them from going to law upon trifling grounds. (Serristori; Colletta, *Storia del Reame di Napoli*; Orloff, *Mémoires sur le Royaume de Naples*.)

The judicial department consists of four 'Gran Corti Civili,' which sit at Naples, Aquila, Trani, and Catanzaro; a criminal court, and a civil court in every head town of a province; and a judge of instruction in every district, and a justice of peace, 'giudice di circondario,' in every 'giudicatura inferiore,' of which there are 525 in the whole kingdom. A supreme court of cassation, 'Corte Suprema di Giustizia,' sits at Naples. Trials are public in the kingdom of Naples, as in France. The French civil code, with some modifications, has been retained, as well as the French commercial code.

For the purposes of public instruction, there is an elementary school in every commune; grammar schools, 'scuole secondarie,' in most towns; a royal college in every head town of a province; five lycea at Naples, Salerno, Aquila, Bari, Catanzaro; and, lastly, the university of Naples. There is a very good institution at Naples for the education of young ladies, founded by Caroline, Murat's wife, and since patronised and increased by Queen Isabella, the wife of Francis I.; but the education of females in general is much neglected.

The ecclesiastical establishment consists of 20 archbishops and 65 bishops, 72 clerical seminaries, and 3767 rectors of parishes. The number of priests, monks, and nuns has been stated above. Serristori, in 1833, reckons the monks at 11,000, and the nuns at 9000; but Petroni, in 1826, reckoned the former only at 8455, and the nuns at 8185. It is possible that the monks may have increased since the former date. The ecclesiastical jurisdiction and discipline were defined by a concordat agreed upon between Cardinal Consalvi on the part of the pope Pius VII. and the Cavaliere de' Medici for king Ferdinand I., in March, 1818. The Roman Catholic is the exclusive religion of the country; a Protestant chapel has been of late years tolerated in the capital, for the accommodation of foreigners. Several communes in Calabria, Apulia, and Abruzzi follow the Greek ritual, but they belong to the Latin communion, and acknowledge the pope as their spiritual-head.

The history of the kingdom and the present constitution of the monarchy are given under SICILY, TWO, KINGDOM OF THE.

The inhabitants of the countries composing the kingdom of Naples are derived from various and mixed races. The descendants of the ancient Samnites, Peligni, Marsi, Frontani, Lucanians, and other people of old Italian origin; the Etruscan Campanians, the wild Bruttii, the Greek population of the coasts—of Magna Græcia, of Cuma and Neapolis—after having been fearfully thinned during their contest with Rome, the war of Pyrrhus, the second Punic war, the social war, and the civil war of Marius and Sulla, became mixed with numerous Roman and Latin colonies. The ancient Oscan and Samnite languages were gradually lost, but the Greek still remained a spoken language over a great part of the maritime districts. At the fall of the empire, the country was overrun rather than occupied by the northern tribes, but afterwards returned to the allegiance of the Byzantine emperors, when it received a fresh admixture of Greek blood and Greek language and Greek usages. In the sixth century the Longobards took possession of Beneventum, and founded there a powerful duchy, which survived the fall of their power in North Italy. In the eleventh century the Normans came, who conquered both the Longobards and the Greeks, and founded the

monarchy of the two Sicilies upon the base of feudal institutions. Then came in succession the Suabians, the French or Provençals, the Aragonese, and the Spaniards. All these nations have left traces of their residence. A dash of Greek character is still observable in the temper, customs, and dialect of several parts of the country. Some families trace their descent from the Normans and the Angevins or Provençals. Lastly, Spanish family names, Spanish habits, and Spanish words often occur, especially in the capital. Considerable shades of variety are observable among the inhabitants of different parts of the kingdom [ARRUZZO; CALABRIA]; whilst the capital, from the constant influx of provincials, contains specimens of them all. But notwithstanding these varieties, the long habits of amalgamation produced by a central administration and a large capital during eight centuries have created a lasting feeling of common nationality, which is perhaps stronger in the kingdom of Naples than in any other Italian state. Neapolitan, not Italian, is the national appellation. Generally speaking, the Neapolitan is quick, shrewd, humorous, fond of music and dancing, rather inclined to bombast and hyperbole, fiery but changeable, inclined to pleasure and ease, hospitable, susceptible of generous feelings, and also of a high social polish.

Notwithstanding the common prejudice to the contrary, the Neapolitan is by no means deficient in personal courage. During the last wars, Neapolitan troops fought well as auxiliaries in the ranks of the French, Austrian, and English armies; the people also fought desperately in defence of their capital in 1799; and the long and obstinate war in Calabria, from 1806 to 1810, was only put down by extermination. If the regular troops have not shown the same spirit in defence of the kingdom, this has proceeded from various peculiar circumstances which are fairly explained by Colletta in his 'History' already quoted, and likewise by the author of a work lately published at Florence, 'Fasti e Vicende dei Popoli Italiani, dal 1801 al 1815.' See also the *Antologia Militare*, of which the sixth volume has been lately published at Naples.

NAPLES, PROVINCE OF (Provincia di Napoli), is the name of the metropolitan province of the kingdom of the two Sicilies, which includes the capital [NAPLES, CITY OR] and the territory round the bay from Cape Misenum and Cuma on the west to Castellamare and Sorrento on the south-east. The islands of Ischia and Procida belong also to the province of Naples. The province is divided into four districts: 1, Naples; 2, Pozzuoli, which includes the whole western division and the islands; 3, Castellamare, which comprises the territory at the base of Mount Vesuvius, and the coast opposite Naples as far as Sorrento; 4, Casoria, which comprehends a tract of the Campanian plain stretching north of the range of hills behind the city of Naples. This tract extends as far as a line which, beginning on the sea-coast half way between the lakes of Licola and Patria, runs in an eastern direction to Caivano, not including the town of Aversa, which belongs to the province of Terra di Lavoro: it then runs south-east skirting the north base of Mount Vesuvius, and not including the towns of Acerra, Nola, and Nocera: it next follows the ridge of hills which runs through the peninsula of Sorrento at the back of Castellamare, including the towns of Castellamare, Vico, and Sorrento. The summit of the ridge divides the province of Naples from that of Principato Citra, or province of Salerno. The whole of this territory formed until lately part of the larger division of Terra di Lavoro, from which it is not geographically separated; but owing to the great population of the capital and surrounding territory, it has been found convenient for administrative purposes to constitute it into a distinct province. The province of Naples, exclusive of the capital, contained, according to the returns of 1837, 374,194 inhabitants.

The principal towns of the province of Naples, exclusive of the capital, are: 1, Pozzuoli, the ancient Puteoli, situated on the east side of the gulf of the same name, and opposite to Baia, originally a colony of Cuma, called Dicæarchia, founded in the sixth century B.C., and now a bishop's see and a poor-looking town, with 10,000 inhabitants. [POZZUOLI.] The whole surrounding country is of a volcanic character. The hill called Solfatara, which is the crater of a volcano not yet extinct, rises to the east above the town. 2, Afragola, a large village or town of 13,000 inhabitants, north-east of Naples in the Campanian plain, has some hat manufactories. 3, Fratta Maggiore, near the ancient Atella, is

famous for its strawberry beds, which supply the markets of Naples. 4, Somma, at the north base of Mount Vesuvius, has 7000 inhabitants. 5, Sant' Anastasia, near Somma, has 6000 inhabitants. The whole neighbourhood produces the luscious wine known by the name of 'Lachryma Christi.' 6, Portici and Resina, two adjoining towns built on the south-west slope of Vesuvius, on the site of Herculaneum, contain together about 14,000 inhabitants. Visitors who ascend Mount Vesuvius pass through Resina. Portici has a royal palace; its museum of antiquities obtained from Herculaneum and Pompeii has been lately removed to the Museo Borbonico at Naples. East of Resina is another pretty royal villa called La Favorita, in a lovely situation near the sea-shore. 7, Torre del Greco, about two miles south-east of Portici, at the foot of Vesuvius, a town of 12,000 inhabitants, has been repeatedly destroyed by the lava and earthquakes, but rebuilt over and over again. The inhabitants are mostly addicted to a seafaring life. 8, Torre dell' Annunziata, about four miles south-east of Torre del Greco, and near the site of Pompeii, has 9000 inhabitants, a manufactory of muskets for the royal service, and a large gunpowder magazine. It is also known for its great manufactory of macaroni, which is the best in Naples, and known by the name of 'Macaroni della Costa.' North of Torre dell' Annunziata is the large village of Bosco tré Case, and further north, on the east slope of Vesuvius, is the town of Ottajano, with 15,000 inhabitants. 9, Castellamare, at the south-east extremity of the Bay of Naples, near the site of Stabia, is in a delightful situation on the sea-coast, at the foot of the lofty mountain St. Angelo, the Mons Lactarius of the ancients, nearly 5000 feet high: it has docks for the royal navy, several sources of mineral water in the neighbourhood, a royal villa called 'Quisisana' and park, and about 10,000 inhabitants. Castellamare is much frequented by the Neapolitans during the summer heats. In the neighbouring district of Gragnano a wine is made which is among the best in the neighbourhood of Naples. 10, Vico (Vicus Æquanus), a small town perched upon the cliffs above the coast, about 4 miles south-west of Castellamare, was the birth-place of the metaphysician and historian Gianbattista di Vico. 11, Sorrento is in a delightful valley surrounded by hills, which is a complete grove of orange and mulberry trees, and contains several villages and numerous country-houses. The town of Sorrento has 5000 inhabitants, is a bishop's see, and the birth-place of Tasso. The plain of Sorrento is much frequented by the wealthy Neapolitans during summer. There are boats which cross daily from Naples to Sorrento, and return loaded with oranges and other fruit. Silk is also produced here.

The country round Naples is the most populous neighbourhood belonging to any capital in Europe, excepting perhaps that of Paris. For particular descriptions of it see **AGNANO; AVERNO; BAIA; CUMA; HERCULANEUM; ISCHIA; POMPEII; POZZUOLI; VESUVIUS.**

NAPLES (*Nápolis*, in Italian), the capital of the kingdom of the Two Sicilies, and the fourth in population among the European cities, is situated in 40° 50' N. lat. and 14° 18' E. long., on the northern coast of the fine bay of the same name, and partly at the foot and partly on the slope of a range of hills which runs obliquely to the shore. On the south-east is Mount Vesuvius, from which it is divided by a fertile plain watered by the small river Sebeto, and opposite to it, across the bay, are the mountains of Castellamare, Vico, and Sorrento, with the island of Capri due south, at the entrance of the bay, on the side of Stilly.

Seen from the sea Naples appears in the form of two crescents, of very unequal depth, one on the east, and the other on the west, divided by the point of Castel dell' Uovo and the hill of Pizzofalcone, which is behind it. The eastern crescent, which includes the great bulk of the city, faces the south-east, and is bounded by the hill of Capodimonte to the north, and Sant' Elmo or Ermo to the west, crowned by the castle of that name, which commands the town. Between these two hills is a considerable depression, on which the suburbs of La Sanità and L'Intoscata are built. The slope of the hill of Capodimonte is likewise covered with houses, forming the suburbs called Miracoli and Le Vergini. To the eastward the town is open to the plain of Campania. From the barrier of Capo di Chino, at the entrance from Rome, a succession of fine streets run through the body of the town to the sea, the principal of which, called Toledo, about a mile in length, runs due south, and divides the old city, which is east of it, from the new districts. The street of Toledo terminates in the place

before the royal palace. The old city forms a closely built square of about a mile on each side: part of its walls, towers, and ditches still remain, and several of the gates are standing, namely, *Porta Nolana*, on the road to Nola, *Porta Capuana*, on the road to Apulia, and *Porta S. Gennaro*, and *Porta S. Maria di Constantinopoli*, towards the north. This part of the town, which is in a plain, has narrow streets and lofty massive houses, many of them six or seven stories high; it is very thickly inhabited, and contains more than one half of the whole population of the capital. West of Toledo numerous streets run up the hill of *Sant'Elmo*, which is covered with houses for two-thirds of its height. South of the hill of *Sant'Elmo*, and between it and the point of *Pizzofalcone*, is another depression, which affords a carriage communication between Toledo and the western crescent, or new part of the town, which is called by the general name of *Chiaja*, 'the quay.' This part, which is much contracted between the hills and the sea, extends in length about a mile and a half between the hill of *Pizzofalcone* to the east and that of *Posilipo* to the west. A fine road runs all this length, parallel to the sea-shore, and between the public gardens on one side and a row of fine houses on the other; it then turns along the base of *Mount Posilipo*, and gradually ascending it, leads to the other side of it towards *Pozzuoli*. There is another and straighter road to *Pozzuoli* by the tunnel called *Grotta di Posilipo*, which is cut through the mountain for about three-quarters of a mile.

Naples is an open city like London, but it has a sort of barriers or custom-house posts at the principal avenues leading into the town, for the purpose of collecting the 'gabella,' or duty upon provisions, corresponding to the 'octroi' of the French and other continental towns. The extreme length of Naples, measured along the sea-coast, but without following its sinuosities, is about three miles and a half from the *Ponte della Maddalena*, on the road to Calabria, to the grotto of *Posilipo*: the greatest depth, from the suburb of *La Sanità*, at the foot of *Capodimonte*, to the shore of *Santa Lucia*, is about two miles; but in other directions it is much less.

Few buildings at Naples are in a good architectural style; they are either overloaded with ornaments or disproportionate in their parts. The most remarkable are—

1. The royal palace, '*La Reggia*,' a large mass of buildings, constructed at two different times, first by the viceroy *Pedro de Toledo*, which part goes by the name of *Palazzo Vecchio*; and the second, after the design of the architect *Fontana*, under the Spanish viceroy *Count De Lemos*, in the seventeenth century. This new palace has a front of nearly 400 feet in length, with three orders of pillars, one above the other, *Doric*, *Ionian*, and *Corinthian*. The great court has two rows of arcades, one above the other, supported by granite columns; the grand staircase is ample and commodious. The apartments are adorned with valuable paintings of the old Italian masters. The great gallery contains the portraits of all the Spanish viceroys who presided over Naples for more than two centuries. At the back of the palace, along the first floor, facing the sea, is a handsome terrace paved with marble and shaded with trees, from which there is a delightful view of the bay. On the ground-floor are the royal printing-press and the royal china manufactory. Facing the palace is a semicircular colonnade, with a pantheon-shaped church in the centre, raised by the late king *Ferdinand I.*

Adjoining the palace, and between it and the sea, are the arsenal, the cannon-foundry, and basin, or wet-dock, for the king's barges or yachts. On the eastern side the palace adjoins the theatre of *San Carlo*, which is one of the remarkable structures of Naples. It was rebuilt after the fire of 1815, and is one of the largest theatres in Europe; it has six tiers of boxes, each box capable of containing from ten to twelve persons. Farther on the old palace adjoins the *Castel Nuovo*, a massive and extensive castle, with towers and a ditch around, begun in the thirteenth century, by *Charles of Anjou*, and successively increased. Fronting the castle is the finest square in Naples, called *Largo del Castello*. East of *Castel Nuovo* is the mole, with the lighthouse at the end of it. The harbour, which it is intended to shelter, is small, and not always safe.

The mole affords a promenade, which is much frequented by the citizens, and on which Punch and a story-teller, who recites the romantic deeds of *Ruggiero*, are generally stationed in the afternoon.

2. The palace, museum, and library, called '*degl. Studi*,'

are in the northern part of the town, at the foot of the hill of *Capodimonte*. The museum, styled '*Museo Borbonico*,' is one of the richest in Europe. Among the numerous masterpieces of ancient sculpture which it contains, the *Hercules Farnese*, the *Venus Callipyge*, the *Apollo Citharædus*, the *Bacchus*, and the statue of an orator called *Aristides* [*Ἀριστιδης*], deserve especial mention. The museum is also rich in ancient bronzes; the *Mercury*, the *Satyrs*, a horse's head, &c. are much admired. The collection of ancient instruments, utensils, female ornaments, and other household articles found at *Herculaneum* and *Pompeii*, is unique. It contains also a vast number of articles of glass, mostly Egyptian. The collection of *Campanian*, *Greek*, and *Sicilian* vases, as well as the numismatic cabinet, is also very rich. That of ancient paintings is very remarkable, although most of them are evidently the work of secondary artists. There are also some fine ancient mosaics. The tables found at *Heracles*, in *Magna Græcia*, are valuable as specimens of *Greek palæography*. A good description of the museum, with plates, has been recently published by the government, '*Il Reale Museo Borbonico*,' 16 vols. 4to.

The Gallery of Modern Paintings contains many good works of the Neapolitan, Flemish, Venetian, and Bolognese schools. The collection of papyri found at *Herculaneum* has hitherto disclosed few works of any importance. [*HERCULANEUM*.] The Royal Library contains 150,000 printed volumes, and about 3000 MSS. A catalogue of it was published in 1830, in 2 vols. fol. Besides this library, which is open to the public, there are two or three other public libraries at Naples, such as that of *S. Angelo à Nido*, and that of the convent of *S. Filippo Neri*.

3. The churches of Naples amount to about two hundred; but in general they are remarkable for their monuments, paintings, and other accessories, rather than for their architecture. The cathedral, begun by *Masuccio*, a Neapolitan architect and sculptor of the thirteenth century, has been since repeatedly altered, ornamented, and spoiled. The interior is rich in ancient columns of valuable marbles; it also contains a splendid mausoleum of *Charles I. of Anjou*, the conqueror of Naples. The adjoining chapel of *San Gennaro* is rich in paintings: the ceremony of the liquefaction of the blood of *St. Januarius* continues to be performed there annually. *Valéry*, in his '*Voyages Historiques et Littéraires en Italie*,' has described it as he saw it in September, 1826. The front of the church of *S. Paolo*, built on the site of a temple of *Castor and Pollux*, contains some fluted columns of marble, the remains of the ancient structure.

The church of *San Lorenzo*, founded by *Charles of Anjou*, on the site of the town-house, where the municipal council of the city formerly used to assemble, contains several royal tombs and some good paintings. The church of *S. Filippo Neri* is built in better taste than most of the churches of Naples; it is rich in paintings, and contains the tomb of *Vico*, an original Neapolitan thinker and writer in the early part of the eighteenth century. The church sacristy and convent of *S. Domenico* constitute a real museum of the middle ages, on account of the numerous monuments of kings, literary men, and other distinguished personages of the times of the *Anjous* and *Aragonese*; and for the cell, lecture-room, and chair of *Thomas Aquinas*, who resided, wrote, and taught in this convent. The interior of *Santa Chiara* is elegant and rich: it contains the monuments of *Robert of Anjou*, the friend of *Petrarch*; of his son, the duke of Calabria; of *Joanna I.*; and of *Raimondo Capanno*, a Moorish slave, who became great seneschal of the kingdom, and acted a part in the murder of *Joanna's* husband, *Andreas of Hungary*. The neighbouring church of *Gesù Nuovo*, the façade of which has been compared to that of a prison, has in the interior the appearance of a splendid ball-room. It now belongs to the *Jesuits*, who were re-established at Naples in 1816. The church of *Monte Oliveto* is rich in sculptures by *Giovanni di Nola*, *Donatello*, *Benedetto da Majano*, and other celebrated artists. The vast adjoining convent, which once afforded an asylum to *Italy*, has been suppressed, and is now occupied by several offices of the municipal administration. *San Giacomo dei Spagnoli* contains the magnificent tomb of *Don Pedro de Toledo*, one of the best Spanish viceroys of Naples. The small neglected church of *S. Giovanni à Carbonara* is remarkable for the monuments of *King Ladislaus* and his sister *Joanna II.*; and in the chapel behind the altar, that of her favourite,

Ser Gianni Caracciolo, who was murdered at last through a court intrigue. The walls of this chapel are painted with frescoes, now much impaired and defaced, which have reference to the history of Joanna and Caracciolo. The convent of San Giovanni had once a library rich in MSS., founded by Parrhasius and Cardinal Seripandi; but about a century since, the emperor Charles VI. having sent some learned Germans to examine the MSS. and make extracts from them, the monks felt so wearied by their obligatory attendance on the foreign scholars, that they preferred making an offer of the MSS. in question to the emperor, in order to avoid being exposed to any further trouble about them. (Valéry.) The church Del Carmine, with its lofty steeple, is chiefly noticed for its neighbourhood to the great market, the scene of Masaniello's insurrection, and also of the desperate defence of the populace against the French in 1799; and likewise for the modest tomb of the unfortunate Corradino and his cousin Frederic of Austria, who were beheaded near this spot by order of Charles of Anjou. The church of L'Annunziata, by the architect Vanvitelli, is one of the best churches of Naples: adjoining to it is a foundling hospital and a Magdalen. The church of San Martino, near the castle of Sant' Elmo, from which there is a most magnificent view of Naples and the bay, is richly painted by Lanfranco, Spagnoletto, and D'Arpino: the adjoining convent is now occupied by invalids from the army, of whom many are blind. The church of Santa Maria del Parto, founded by Sannazaro, in a delightful spot, near the shore of Mergullina, has a fine mausoleum of the poet. San Gennaro dei Poveri is remarkable for its vast catacombs, which extend under the hill of Capodimonte.

4. The royal palace of Capodimonte is a heavy structure, but is remarkable for its fine situation, the excellent road leading to it, constructed by the French, its extensive park and hunting grounds, and the adjoining observatory. On the slope of the hill is the Chinese College, for the education of young Chinese, who, after taking holy orders, return to their country as missionaries. The number of Chinese students seldom exceeds six. An account of this remarkable institution is given in 'Italy and the Italians in the Nineteenth Century,' by A. Vieusseux, which work contains also many particulars concerning the peculiar sights of Naples and the manners and habits of the people.

On another part of the hill of Capodimonte is the botanical garden, formed in 1818, and placed under the direction of the Neapolitan professor of botany, M. Tenore. Not far from thence, in a secluded valley at the foot of the hill, are the remains of an aqueduct constructed by Augustus, which is called Ponti Rossi, 'red bridges or arches,' from the colour of the stone.

Naples has many charitable institutions, such as the great hospital Degli Incurabili, the foundling hospital already mentioned, the school of the deaf and dumb, the asylum for the blind, under the direction of the distinguished oculist Quadri; the Reclusorio, or general workhouse for able-bodied poor, with a school annexed to it, and which contains about 3000 poor; San Gennaro dei Poveri, for the poor who are unable to work, San Francesco di Sales, and several other minor hospitals and houses of refuge. Valéry seems to think that the administration of the workhouse might be susceptible of much improvement, especially with regard to moral discipline. Mendicity is forbidden by law; but the law is often evaded. There are no poor-rates at Naples.

The university is well provided with professors. It has a good library and a cabinet of natural history annexed to it. Some account of the state of education in the Neapolitan kingdom is given in Nos. 5 and 16 of the 'Quarterly Journal of Education.' Among the special schools are a medical college, a veterinary college, two military schools, a college of pilots, and the 'Conservatorio,' or school of music, which has produced many illustrious composers, has some good professors, and a rich musical library, containing among others the autographs of Paisiello's works. Besides San Carlo, Naples has half a dozen minor theatres, Il Fondo, i Fiorentini, Teatro Nuovo, La Fenice, San Carlino, &c. In the last two, plays, or rather farces, are performed in the Neapolitan dialect, which is full of humour and naïve expression.

The Neapolitan or Apulian dialect is very old; it was spoken at the court of Frederic II. and his son Manfred, and their contemporary, the chronicler Matteo Spinello, wrote in it the annals of those two princes. The

popular songs or ballads, of which every now and then new ones are produced by obscure poets and sung about the streets, generally run upon love matters, which furnish the principal incidents in the existence of the people of this country. Some of these songs are full of pathos. The following are specimens—

Albero piccirillo te chinata;
 Lo s' adacqua col li miel ardere;
 Vuone lo viento, e ne rompe no ramo;
 La fronda verde ha signato colore;
 Lo frutto doce è diventato amaro;
 Addò è ghinto la bello sapora?
 Viene, morte, arremmilla a chitate guajo,
 Giacche unuillo m'è ha signato amore.

('I planted a small tree, and watered it with the sweat of my brow; but the wind came and broke a branch of it, the green leaf became withered, and the fruit, once sweet, grew bitter: Oh, where is its sweet flavour gone? Come, O death, and put an end to my distress, since my love has left me for another.')

We extract the next, which is conceived in a wilder spirit, from Valéry, who heard it about the streets of Naples in 1826-27:—

Cha bella cosa è de morire acciso
 Nnanze a la porta de la nuaminorata,
 L'uenema se ne suglie in paradiso
 E lo corpo lo obliagne la scasata.

('A desirable fate, to be stabbed to death at the door of one's love! The soul then ascends to paradise, while the forsaken beauty bathes the bleeding body with her tears.')

For a further account of the Neapolitan dialect, see ITALY—*Italian Language and Literature*, and the references in that article.

The population of Naples, which in 1835 amounted to about 350,000, was reduced by the cholera in the two following years to 336,300, according to the returns of the end of 1837, exclusive of the garrison and non-resident foreigners. (*Bollettino Statistico di Milano*, January, 1839.) Of this population, about 1700 are priests, 700 monks, and 800 nuns; 9400 are employed under the government, and 18,000 are pensioners, 3000 lawyers, 26,000 are men-servants, 3400 coachmen, 8000 sailors, boatmen, and fishermen, 3500 porters, 5200 shop-boys, 3700 gardeners and greengrocers, 2500 tailors, 2400 shoemakers, 800 cobblers, 1450 barbers and hairdressers, 1500 cooks, 500 printers, 59 booksellers, 58 bookbinders, 146 physicians, 105 surgeons, and 186 apothecaries, 900 sellers of wine, 303 coffee-house-keepers, 350 tavern and eating-house keepers, 310 inn-keepers, 800 fruiterers, 800 goldsmiths, 1000 smiths, 2400 carpenters, 1600 builders and masons, &c. Naples has manufactures of hats, straw-hats, gloves, leather, earthenware, coral, and jewellery. There are about 700 hackney-coaches, 600 cabriolets, 1600 boats, and about 500 vessels, belonging to the town of Naples. There are 809 inns and lodging-houses. The town is divided into twelve 'quartieri,' or districts, of which five and the most populous are in the old or eastern part of the town, namely, Mercato, Pendino, Porto, S. Lorenzo, and Vicaria; one in the middle, S. Ferdinando, in the neighbourhood of the royal palace; two at the west end, Chiaja and S. Giuseppe; one, S. Carlo all' Arena, at the north end towards the road to Rome; and three, Stella, Avvocata, and Monte Calvario, include the upper part of the town, which is built on the hills of Capodimonte and S. Elmo. Every district has a commissary of police, whose office is open at all hours of the day. There are sixty-six military posts in the whole town, four castles, S. Elmo, Castel Nuovo, Castel dell' Uovo, and Castello del Carmine, besides extensive barracks both for infantry and cavalry. The town has six prisons, one of which is for debtors. The vast and massive structure called 'La Vicaria,' at the east end of Naples near Porta Capuana, which was once a castle and the residence of the Norman kings, now contains various courts of justice, and also the archives of the kingdom, an immense collection of documents, divided into four sections, historical, financial, judicial, and communal. The acts, edicts, &c. of the sovereigns of the Anjou dynasty alone fill 368 thick folio volumes. The 'Constitutiones' of Frederic II., the oldest code of the kingdom, written by his chancellor Pietro della Vigne, are also there.

The Lazzaroni, so often mentioned by travellers, and so confusedly described, included the lowest orders of the inhabitants or populace, the porters, the hawkers of fish, vegetables, and other eatables, the boatmen, journeymen out of place, and numerous vagrants, and other low and loose characters. Many of these classes in former times had no regular domicile, and lived chiefly in the open air, or were huddled together at night under some porch or

vestibule, in narrow alleys, in their boats, and wherever they could find shelter. To these were added indiscriminately the numerous class of fishermen, an industrious race, whose habits have always been more domestic and orderly than those of the common *lazzaroni*. All these people were vaguely reckoned, with probably some exaggeration, at 40,000 individuals, a muscular, brawny, and erect set of men, but totally uneducated and little civilised, very abstemious and frugal in their habits, mostly barefooted, living from day to day on their casual earnings, their dress consisting merely of a shirt and a pair of loose trowsers; very good-tempered in quiet times, but apt to run riot on the first political excitement or tumult. The name *lazzaro* is said to have been derived from the numerous lepers who once abounded on the coasts of the Mediterranean, and who invoked as their patron the Lazarus who is mentioned in the Gospel. A charitable order, or fraternity, which was instituted in the middle ages for their relief, assumed the name of 'Order of St. Lazarus.' The lepers were obliged to wear a peculiar dress, consisting of white shirt and trowsers and hood. After the leprosy became extinct, the same garb continued to be worn by the lower orders for the sake of cheapness and convenience in the warm climate of Naples, and the name *lazzari* was retained and applied to that class. This is the etymology given by Galiani and others, in the 'Vocabolario del Dialetto Napolitano,' published at Naples in 1789. But the author adds that already in his time the number of the *lazzari* had much decreased, owing to the progress of civilization, and that 'many among the people who had the appearance of *lazzari* during the week-days, looked very different when dressed in their Sunday-clothes.' As a peculiar class, the *lazzari* may be said to be now extinct: the lower orders live like those of other cities; they are all duly registered in their respective parishes, they have all a domicile of some sort, and the police regulations, enforced for the last thirty years, have produced a material alteration in their habits, though the every-day clothing of many of them continues to be the same as before.

The nobility at Naples are very numerous, but, excepting their titles, they enjoy no privilege or influence above the rest of their countrymen. The alterations made in the law of inheritance, by which all the children succeed in equal or nearly equal portions, as in France, have broken down the fortunes of most families, which were already encumbered by debts, the consequence of want of order, of indolence, and expensive habits of living. The most important and interesting class at Naples at present consists of the higher ranks of the middle orders, including lawyers, physicians, professors, and men of other liberal professions, some native merchants, the higher officers under government, and the better sort of the clergy. Among these are found considerable information, much civility united to frankness, great sociability, and respect for decency and morality. Those who wish to know more particularly the present state of Neapolitan society and the changes which it has undergone during the last half century, may consult Colletta, *Storia del Reame di Napoli*, a work of great moral penetration, extensive observation, and written with remarkable impartiality.

The palaces of the nobility are spacious and massive, but few of them are in a good architectural style. The most remarkable are the palazzo Gravina or Orsini, the palace Maddaloni, that of Sansevero, remarkable for its chapel, adorned with some good statues, that of Della Rocca, those of Francavilla, Stigliano, Berio, &c. The building which has been raised between the streets Toledo and S. Giacomo, for the offices of the financial department and for the bank of the Two Sicilies, is one of the finest structures in Naples.

Naples is not so well supplied with water as Rome, and has not such handsome fountains; those of Fontana Medina and Monte Oliveto are the best. Several aqueducts from the neighbouring mountains supply the water, besides which most houses have cisterns. There is a sulphureous spring of water on the shore of Santa Lucia, which is much drunk by the inhabitants in the spring.

The neighbourhood of Naples abounds in delightful walks. The public gardens, or 'Villa Reale,' extending along the shore of Chiaia for nearly a mile, enjoy the advantages of the sea-breeze, and of a view unrivalled in the world. The new road over the hill of Posilipo is a beautiful drive. The hills of Capodimonte and S. Elmo, and the suburbs of Infrescati and Arenella, at the back of Sant' Elmo, abound with pleasant walks and a variety of scenery.

These, as well as the other neighbouring hills of Vomero, Posilipo, &c., are covered with country-houses and gardens of all sizes. But the hills are mostly destitute of trees, and appear barren and parched, especially in summer.

Naples is an archbishop's see, and is divided into fifty parishes, including the neighbouring villages.

The town is abundantly supplied with provisions of every kind; fish and shell-fish are plentiful, as well as vegetables and fruits. Snow, of which a great quantity is used, especially in summer, for cooling the drink and for ices, is brought from the mountain of Castellamare, where it is kept in large reservoirs.

The great street of Toledo is thronged with people and carriages at all times of the day, and until very late at night, or rather until two or three o'clock in the morning, when fashionable people retire to rest. It is decidedly the noisiest street in Europe, as the people are in the habit of vociferating at the top of their voice; and others must do the same in order to be heard. The motley groups which are seen mixing pell-mell in the street, the crowded balconies above, the numerous vendors of provisions, the *acquaiuoli*, or sellers of ice-water, at the corners of the bye-streets, the life out of doors, which is a general habit in this country, all render the streets of Naples, and especially that of Toledo, most curious to a foreigner.

Naples, or Neapolis, that is, 'New City,' was a Greek colony from Cumæ; the date of its origin is not known. The story of its first foundation, under the name of Parthenope, is a mythic tradition. Livy (b. viii. 22) says that there were once two towns near each other, Palæopolis and Neapolis, the inhabitants of both being from Cumæ, but Palæopolis had, long before Livy's time, merged into the new town, or Neapolis.

Neapolis, after its first foundation by the Cumæans, received colonists from Chalcis, Pithocusa, and Athens; and subsequently admitted some Campanians also among the body of citizens. (Strabo, p. 246. *Casaub.*) It became allied to the Samnites, but after their subjugation by Rome it maintained its independence as a republic, and during the second Punic war sent ambassadors to Rome to propose an alliance against Hannibal, and with it a rich present in golden vases, which the people took from their temples to defray the expenses of the war. (Livy, xxii. 32.) It continued afterwards an ally to Rome and became a municipium. After the fall of the empire Neapolis was taken by the Goths, retaken by Belisarius, and lastly destroyed by Totila, A. D. 543. It was afterwards rebuilt, and annexed to the Longobard duchy of Beneventum, but after the decline of the Longobard power, when the Byzantine emperors asserted a kind of supremacy over southern Italy, Naples had its dukes, who were chosen by the inhabitants. In the ninth century the dukes of Beneventum obliged it to pay tribute. When the duchy of Beneventum was split into three principalities, Benevento, Capua, and Salerno, Landulf, count of Capua, in order to maintain its independence of the other two, called in the Saracens, who devastated the shores of Campania. The Norman adventurers lent their assistance to the prince of Salerno against these piratical hordes, and afterwards by degrees established their own power in Apulia and Sicily. Naples was one of the last towns which submitted to the Normans; it acknowledged king Roger I., of Sicily, as its sovereign, about A. D. 1137. The subsequent history of Naples, both political and literary, is given under the head of SICILIES, TWO, KINGDOM OF THE.

The following are the principal works concerning the town of Naples, besides those which have been mentioned in this article:—Celano, *Notizie del bello, dell' antico, e del curioso della Città di Napoli*, 4 vols. 8vo., 1792; Romanelli, *Napoli antica e moderna*, 3 vols. 8vo., 1815; Vargas, *Ragguagli storici dell' Origine di Napoli*, 4to., 1754; and also *Dissertazioni storico-legali sull' Antichità, Sito, ed Ampiezza della Liburia Ducale, o stasi dell' Agro e Territorio di Napoli*, 4to., 1756, by the same; Giraffi, *Le Rivoluzioni di Napoli*, 8vo., 1647; Chioccarelli, *Antistitum Neapolitanæ Ecclesiæ Catalogus ab Apostolorum temporibus ad annum 1643*, fol.; Stefano (Pietro di), *Descrizione dei Luoghi Sacri di Napoli*, 4to., 1560; Caracciolo (Eugenio), *Napoli Sacra*, 4to., 1623; Luscina (Pietro), *Dell' antico Ginnasio Napolitano*, 4to., 1641, 1688; Origlio, *Istoria dello Studio di Napoli*, 2 vols. 4to. 1754; Signorelli, *Storia della Reale Accademia delle Scienze e Belle Lettere à Napoli*, 1787; Attu monelli, *Delle Acque Minerali di Napoli*, 8vo., 1808; Ricci, *Analisi chimica dell' Acqua Ferrata e Sulfurea di Napoli*

8vo., 1821; Vetrano, *Sebethi Vindiciae, sive Dissertatio de Sebethi antiquitate nomine, &c.*, 8vo. 1767.

Coin of Naples.

NAPOLEON. [BONAPARTE.]

NAPOLEON, CODE. [CODES, LES CINQ.]

NA'POLI DI MALVASIA, or **MONEMBASIA**, a town built on an island on the east coast of Laconia, and connected with the mainland by a bridge about 540 feet in length. Its situation gave rise to its name Monembasia (single entrance). About four miles north of the bridge, along the coast of the mainland, are some ruins which Leake considers to be those of Epidaurus Limeria, while Monembasia is the Minoa of Pausanias, which was a small place in his time. As Epidaurus fell into decay, the town on the island grew into importance, and it then probably assumed the name of Neapolis, or new town, in addition to that of Monembasia. It was a place of some consequence under the Byzantine emperors, and Andronicus Comnenus in the twelfth century founded here a monastery, which still exists, and the church of which is one of the largest in Greece. The Franks when they conquered a great part of the empire in the thirteenth century corrupted the name of Monembasia into that of Malvasia. The country in the neighbouring district formerly produced a luscious wine, to which the Venetians gave the name of Malvasia from the town at which it was shipped, and the name has been since applied as a generic appellation to wine of the same quality made in other parts of the Mediterranean, as at Lipari, in Sardinia, Spain, &c. This is the kind of wine called in English *malmsey*.

The island of Monembasia is hilly, about half a mile in length, and one third of a mile in breadth. The castle is on the summit of the hill, and the town, which is built below it, extends to the sea on the south side of the island. The streets are narrow and steep; the place contains about 300 houses, besides 50 more in the castle. The ramparts and several other buildings were constructed by the Venetians, who took possession of the place in the thirteenth century and kept it till 1540, when it was given up to the Turks by a treaty. On this occasion most of the inhabitants left it along with the Venetian garrison and found an asylum in the other Venetian possessions. It now forms part of the new kingdom of Greece.

The bishop of Monembasia, a metropolitan of high rank in the Greek church, has seven suffragan bishops under him, including those of the neighbouring district of Maina. (Coronelli; Leake.)

NA'POLI DI ROMANIA, **NAU'PLIA**, **ANAPLI**, a town of the Morea, built on a rocky promontory at the north-east extremity of the Argolic Gulf. The harbour between this promontory and the north coast is large and tolerably safe, but has become too shallow to admit large ships. A small fortified island lies at the entrance of the harbour. The town stands on the north-east slope of the hill facing the mainland, and is fortified; the hill has a tabular summit, which is unoccupied with houses, and from which abrupt cliffs descend to the open sea at the back of the promontory. A steep and rocky mountain rises above it to the south-east called Palamedi, a very ancient appellation derived from Palamedes, the son of Nauplias, the reputed son of Neptune and founder of the town. On this cliff is the castle, which is very strong owing to its almost inaccessible situation.

Nauplia was once the port and arsenal of Argos, but in the time of Pausanias it was deserted. It revived under the Byzantine emperors, was occupied by the Venetians in the thirteenth century, and became their chief settlement in the Morea, until it was taken from them by Sultan Solyman in 1537. The fortifications are of Venetian construction, but the ramparts towards the east are partly composed of the ancient walls of the town, which are of a similar construction with and probably of the same date as those of the Acropolis of Argos. Other and later remains of Hellenic

construction are seen on the brow of the tabular summit above the town.

Nauplia, after the Greek insurrection, remained for several years the head town of Greece, until it was superseded by Athens. Its population, which had risen to about 12,000 inhabitants, has recently declined. The streets are irregular and dirty, and the air is not wholesome. A few of the houses and the barracks are of a superior description to the rest of the buildings. The bishop, of the Eastern communion, is styled bishop of Argos and Anapli. There is also a Latin church. An aqueduct of good water from the rocky ridge near Tiryns supplies the town. (Spon; Coronelli; Leake; Gell.) From the old Greek name of Nauplia the Franks made by corruption that of Napoli, to which they added 'Di Romania' to distinguish it from the Italian Napoli.

NARBONNE, a city in France, in the department of Aude, near the coast of the Mediterranean, in 43° 11' N. lat. and 3° 0' E. long., 539 miles from Paris by Orléans, Châteauroux, Limoges, Cahors, Montauban, and Toulouse.

Narbonne (the Roman Narbo, or Narbo Martius) is one of the oldest cities of France. A Roman colony was planted here about B.C. 116, and it had been one of the chief towns of the Volcæ Arecomici, a Celtic people, long before that time. Cæsar sent additional colonists to Narbonne, the veterans of the tenth legion. Cicero (*Pro Fonteio*, c. i.) speaks of Narbo as 'a watch-tower and bulwark of Rome.' Mela (ii. 7) speaks of Narbo as being in his time the chief town of that province of Gaul, in which it was situated, and to which it gave the title of Gallia Narbonensis. Strabo (p. 101. *Casaub.*), describes it as the emporium of all Gaul; and, at a later period, Sidonius Apollinaris and Ausonius have borne testimony to the number of its structures or the extent of its wealth. The course of the Atax, or Aude, through the adjacent lake of Rubresus, or Rubrensis (*étang de Sigean*), was facilitated by an artificial channel 100 feet wide and 30 feet deep; and the navigation of the river, though of small extent, promoted the commerce of the town. The history of Narbonne under the Romans has been minutely given by Expilly, in his 'Dictionnaire des Gaules,' &c.

In A.D. 413, Ataulphus, king of the Visigoths, surprised Narbonne, where he shortly after celebrated his marriage with Placidia, sister of Honorius. He was however soon obliged to abandon the city; but in A.D. 462 the Visigoths obtained possession again by treachery, and retained it. After the taking of Toulouse by Clovis and the Franks, Narbonne became the Visigothic capital: it was repeatedly taken by Franks and Burgundians, and early in the eighth century fell into the hands of the Saracens [Morus, p. 385], from whom it was taken (A.D. 759) by Pepin le Bref, and annexed to the Frankish monarchy. Narbonne was subsequently pillaged by the Northmen. In the ninth and tenth centuries it was the capital of the marquisate of Gothia, or Septimania, which was afterwards merged in the county of Toulouse. Under the marquises of Septimania, Narbonne was governed by vidames, or viscounts, who were at first removable, but afterwards became hereditary, and were feudatories of the counts of Toulouse and (for a portion of the town) of the archbishops of Narbonne. Aymeri III, viscount of Narbonne, was engaged in the crusade against the Albigenses: the Inquisition was established at Narbonne in his time, but not without occasioning considerable disturbances. The inhabitants were at this time extensively engaged in commerce, and had alliances and treaties with Marseille, Nice, Genoa, Pisa, and other trading towns on the Mediterranean. In 1348 the plague carried off 30,000 of the inhabitants of Narbonne, a loss which attests the greatness of the population. In 1355 Aymeri IX, viscount of Narbonne, defended the place successfully against the attacks of the Black Prince, but was taken prisoner next year at the battle of Maupertuis, or Poitiers. In 1407 Guillaume, or William II, viscount of Narbonne, contested the possession of Sardinia (whither he had been invited by the natives) with the kings of Sicily; he was ultimately however obliged to yield. He was one of the supporters of the Dauphin, afterwards Charles VII.; and took part in the murder of Jean, duke of Bourgogne, at Montereau (A.D. 1418). He fell (A.D. 1424) in the battle of Verneuil against the English. The viscounty afterwards passed by sale to the counts of Foix. The last viscount was Gaston de Foix, nephew of Louis XII., king of France, who fell in the battle of Ra-

venna (A.D. 1612). He had before his death exchanged his viscounty, which was annexed to the crown, for the duchy of Nemours. In the religious wars of the sixteenth century, Narbonne embraced the party of the League; but in 1596 the inhabitants submitted to Henri IV.

There do not appear to be at Narbonne any edifices of Roman erection; but a number of fragments of Roman architecture are incorporated in the walls of the town, which were erected in the reign of François I.; and a number of inscriptions exist in excellent preservation. A few years ago, many thousand silver coins of the Roman emperors were found at Narbonne.

The town is situated upon the Canal Robine de Narbonne, by which a portion of the waters of the Aude flow into the Mediterranean. It is a fortress, but not of the first class, surrounded by an old wall, with several bastions and towers. The Canal Robine divides it into two parts, respectively distinguished as Le Bourg and La Ville, between which there is communication by three bridges. Along the bank of the canal is a public walk planted with trees. There are a cathedral and two other churches. The cathedral is a Gothic building, with a fine nave. It contains the mouldering tomb of Philippe III., le Hardi, king of France. The archbishop's palace is an antient building, having much the appearance of a fortress, and is defended by square towers. There are barracks, an arsenal, a military hospital, two other hospitals, and a prison. The population, in 1826, was 10,097 for the commune; in 1831 it was 9281 for the town, or 10,246 for the whole commune; in 1836 it was 10,792 for the commune, showing a steady but not rapid increase. The country about Narbonne is fertile in corn, but the neighbouring marshes render the place unhealthy. The inhabitants make brandy and other distilled spirits, verdigris, bricks, tiles, pottery, and paper, and are engaged in throwing silk, dyeing, and tanning. They carry on trade in corn, red and white wine, brandy, oil, salt, soda, wax, and excellent honey, which is collected in the arrondissement. There are two yearly fairs. There are marble quarries and salterns near the town. There are several fiscal government offices, an Exchange, a subordinate court of justice, and a commercial court; a society of agriculture, a society of emulation, a school of hydrography, and a seminary for the priesthood; a museum, a theatre, and public baths. The village of La Nouvelle, at the mouth of the Canal Robine, is the port of Narbonne. The learned Benedictine Montfaucon was a native of Narbonne.

The archbishopric of Narbonne is very antient: the foundation of the see has been carried by some as far back as the first century of the Christian era. It is now united to the archbishopric of Toulouse.

The arrondissement of Narbonne has an area of 581 square miles, and comprehends seventy communes. It is divided into six cantons or divisions, each under a justice of the peace. The population, in 1831, was 54,101; in 1836 it was 56,965.

NARBOROUGH, SIR JOHN, an English naval commander of some distinction, was descended from an old family in Norfolk, and received his first commission, as lieutenant of the *Portland*, in the year 1664. In the ensuing Dutch war, his bravery and good services soon became so conspicuous that, within two years, after the long and desperate action, in June, 1666, between the English fleet, under Prince Rupert, and Monk, duke of Albemarle, and the Dutch under De Ruyter and Van Tromp, he was promoted to the command of the *Assurance*, a fourth rate. After the conclusion of peace, he was selected to conduct a voyage of discovery to the South Seas, for which destination he sailed 1680, in the *Sweepstakes*, of 36 guns, attended by the *Bachelor* pilot. In the following year, he passed the Strait of Magalhaens, and, after being impeded, in the ports of the Pacific, by the jealousy of the Spanish authorities, with the usual obstacles to either intercourse or research, from which he extricated himself with remarkable prudence, he returned home in 1671. Captain Philip Parker King, in speaking of the early navigators who explored the Strait of Magalhaens, observes that among the numerous plans of it that are extant, those of Sir John Narborough and Cordova are the most correct.

On the breaking out of the second Dutch war, in 1672, he was taken by the lord-high-admiral, the duke of York, into his own ship, the *Prince*, as second captain; and in the obstinately contested battle of Solebay with the Dutch fleet under De Ruyter, in which the first captain of the *Prince*, Sir John Cox, was killed, and the vessel so disabled that the

Duke of York was compelled to shift his flag into the *St. Michael*, Narborough's energy and ability in resisting the ship for action in a few hours, as well as his courage during the fight, were deemed sufficiently meritorious to be made the subject of special commendation in the account of the action published by authority of government. After being, next, successfully employed in convoys and other duties, he was raised, in 1673, to the rank of rear-admiral, and received the honour of knighthood. In 1674 he was appointed commander-in-chief of a fleet sent to the Mediterranean, for the purpose of overawing the Tripolines and other piratical states, and obtaining redress for their depredations upon the national commerce; and he acquitted himself with so much spirit, address, and success in this duty, that he compelled the Bey of Tripoli to release all his British captives, to pay 80,000 dollars in reparation for injuries to the British trade, and to grant to British subjects more honourable and valuable privileges than any other nation had before possessed or claimed. Having achieved these objects, Sir John Narborough returned to England with his squadron in 1677: but the skill and gallantry with which he had fulfilled his instructions caused him, almost immediately, to be despatched again to the Mediterranean, in command of another fleet, with a similar commission to chastise the piracies of the Algerines. In this expedition he acted with his accustomed vigour; burnt or sunk many Algerine vessels of war; cannonaded the city of Algiers itself with good effect, though without being able to bring the pirates to terms; and concluded his operations by capturing and carrying into Cadiz a whole squadron of five Algerine frigates, which the Dey had equipped to obtain satisfaction for his previous losses. This exploit, after which he returned home in 1679, was Sir John Narborough's last important service at sea; but in the following year he was made a commissioner of the navy, and continued to hold that office both during the remainder of the reign of Charles II., and throughout the whole of that of his patron James II., until his death, which occurred towards the close of 1688. (Charnock, *Biographia Navalis*; Captain P. P. King, in the *London Geographical Journal*, vol. i.; and Sir John Narborough's *Journal*.)

NARCEIA, an alkali procured from opium by Pelletier in 1832. To prepare this substance opium is to be digested in repeated portions of cold water until the soluble part is dissolved. The mixed solutions are to be evaporated to the consistence of an extract, and when this is treated with boiling water, a brilliant crystalline substance is left, which is the narcotina of the opium; this is to be separated. The clear liquid is then to be heated to ebullition, and ammonia added slightly in excess to precipitate the morphia; expel the excess of ammonia by heat; the liquor being then evaporated to one half, more morphia is separated, and barytes water mixed with it throws down meconate of barytes; carbonate of ammonia then added precipitates the excess of barytes, and heat expels the superabundant ammoniacal salt. The liquor being again filtered, evaporated to the consistence of a thick syrup, and set aside in a cool place for some days, yields a pulpy mass which contains crystals; this is to be drained, dried by strong pressure, and digested in boiling alcohol; the solution obtained, when the spirit is distilled, yields a crystalline substance, which, when repeatedly dissolved and crystallized, is narceia in a state of purity.

The properties of narceia are, that it crystallizes in colourless acicular four-sided prisms, is inodorous, has a slightly bitter taste, dissolves in 375 times its weight of cold and 230 times its weight of boiling water; alcohol dissolves it, but ether does not. At about 195° it melts, and on cooling it concretes into a white translucent mass, exhibiting appearances of crystallization. At 230° it becomes yellow, and at a higher temperature it is decomposed.

Dilute acids combine with narceia, but they continue to redden vegetable blues; when hydrochloric acid diluted with one-third of its weight of water is put into contact with narceia, it becomes of a fine blue colour; but the addition of more water renders it colourless; it may be precipitated from the blue solution by an alkali with its properties unchanged. The stronger and concentrated acids decompose narceia; the persalts of iron are not rendered blue by this alkali. According to Pelletier's analysis, narceia consists of—

Hydrogen . . .	6.52	or nearly 20 equivalents.
Carbon . . .	54.73	„ 32 equivalents.
Oxygen . . .	34.42	„ 16 equivalents.
Azote . . .	4.33	„ 1 equivalent.

NARCISSUS is a genus of Endogens belonging to the natural order Amaryllidaceæ, among which it is known by its flowers growing upon a scape, and having a cup at their mouth; the stamens which are opposite the sepals being longer than the others. It consists of bulbous plants principally inhabiting the warmer parts of Europe, only one species, *N. pseudo-narcissus*, or the Common Daffodil, being found plentifully so far north as Great Britain, with two others, *N. biflorus* and *poeticus*, in an apparently wild state, and a very few advancing into Africa.

The species are numerous, and from their hardiness or gay colours, or sweet smell, have long been favourite objects of cultivation, especially the Daffodils, Jonquils, and Taz-zettas. A very full account of them will be found in the 'Amaryllidaceæ' of the Honourable and Reverend William Herbert, p. 292 (8vo., London, 1837), who however divides the genus into six others, after the example of Salisbury and Haworth; but as those genera are not likely to be adopted by botanists, with the exception perhaps of the genus *Corbularia*, no account need be given of them. With regard to *Corbularia*, to which the name of Hoop-petticoat Narcissus is given, and of which five supposed species are enumerated, the peculiar form of the flower and the delicate stamens of that plant may perhaps entitle it to be regarded as a peculiar genus: the species are pretty, all yellow flowered, with the single exception of *C. cantabrica*, a little plant with white flowers found on the mountains of Biscay and the Pyrenees, but now lost in our gardens.

NARCOTICS (from the Greek adjective *ναρκωτικός*, which is from *ναρκή*, a stiffening, stupor, or insensibility), a class of medicines which may be defined—agents which, in moderate doses, cause a temporary increase of the action of the nervous and also of the vascular system, followed more or less speedily by a marked diminution of this action, terminating generally in sleep. When the dose is large, the excitement is scarcely perceptible; while the diminished power of the nervous system is so manifest, that an appearance of coma or apoplexy is induced. All the agents included in this class are capable of producing a state termed narcosis, or narcotism, which, if not quickly removed by a natural subsiding of their influence, or by artificial means, may terminate in death. Many of them are therefore as familiarly known as poisons as therapeutic agents. It is the consideration of them however in this latter quality which is to be entered on in this place. Their power of inducing sleep has procured for them the name of hypnotics, or soporifics; and the property which many of them possess of alleviating pain, by blunting the sensibility, has obtained for them the appellation of anodynes [*ANODYNES*], or, from one of the best known among them, simply of opiates.

The most important consideration respecting them is the circumstance of their depressing action being always preceded by a stimulant. This peculiarity renders their employment difficult in some cases and improper in others. 'Narcotics must be distinguished from stimulants on the one hand, and from sedatives on the other; and the distinction is the more necessary, because in nature the narcotic principle is generally combined with one or other of these: hence the contradictory and unsatisfactory reports of the value of different narcotic remedies, and the difficulty experienced in their application by those who do not know the reason why opium suits one case, hyoscyamus another.' (Billing's *First Principles of Medicine*, 3rd edit.) The progress of chemistry, by isolating the various active principles existing in the same natural compound, has lessened the difficulty attendant on their administration; still, as no one can be said to act in a manner precisely similar to another, a correct knowledge of each is desirable in order to ensure the selection of that which is best suited to the case. Diversified as they are in their nature and modes of action, there is this common property, that they all make a direct impression on the extremities of the nerves (to whatever part of the body, with few exceptions, they are applied); but their full and ultimate effects do not take place till they are absorbed, and mingled with the circulating fluid.

A slight glance at their action on the different systems of the body will furnish a useful guide in their administration. A full dose of a narcotic introduced into the stomach will, if that organ be empty, destroy the desire for food, while, if it contain food, the digestive process is suspended or rendered slower. Their frequent or continued use is therefore very injurious to that function, on which all the others depend, viz. nutrition; as is displayed in the persons of opium-

eaters of the East. Further, should any considerable irritation or subacute inflammatory condition of the mucous coat of the stomach exist, they cause an aggravation of the febrile symptoms, and either in common or cancerous ulceration of that organ they cause great uneasiness. Though their primary effect on the vascular system be stimulating, and many of them send thereby a large quantity of blood to the brain (probably the source of their soporific property), their secondary effect is depressing; and in this the respiratory organs participate. This is at once a source of utility and of danger, for by moderating the action of the heart and lungs, the respiration is rendered slower, an advantage in most inflammatory complaints; but when pushed too far, the blood is not sufficiently aerated, and partaking too much of the nature of venous blood, it does not prove a sufficient stimulus to the brain and other organs.

Their action upon the secreting system is not very uniform, nor are all writers agreed as to its nature. Opium generally checks most of the secretions, except that of the skin, and causes heat, thirst, and constipation. Hyoscyamus rarely causes any of these states, but on the contrary is rather laxative, and aconite greatly increases the secretion of the bile and also of the skin. Many natural compounds have an acrid principle combined with the narcotic, and hence are termed *narcotico-acrids*, such as aconite, squil, colchicum, hellebore, &c.; these generally augment the mucous and other secretions, though they produce narcotism in excessive doses.

Lastly, some of them possess greater influence over one set of nerves than the other, and expend their energy on the nerves of motion, or of sensation, according to their nature.

No set of medicines have their action more modified by a variety of circumstances—such as the quantity given, or the frequency of repetition, also the force of habit, climate, or season, but above all by idiosyncrasy. Age also has an important share in determining the amount of action. Children do not in general bear them well, and therefore though they are very subject to convulsive and spasmodic diseases, other means should be employed, especially the removal of the source of irritation, when practicable. The various nostrums recommended for children generally contain some narcotic, and prove a fertile cause of the mortality of early life. [*ANTISPASMODICS*.] The administration of narcotics requires more knowledge and judgment than that of any other class of remedies, and should only be had recourse to under competent advice.

In case of over-dose or accidental poisoning, the following observations may be useful. The stomach being rendered insensible to the irritation of emetics, these are generally useless, and much valuable time is lost by administering them. Where better means cannot be had, sulphate of zinc (white vitriol) dissolved in water, or a table-spoonful of flour of mustard diffused through a pint of warm water, may be given, accompanied with pressure on the pit of the stomach, and at the same time tickling the throat with a feather. Neither ipecacuan nor tartar emetic should be used; the latter is particularly unfit. [*BELLADONNA*.] The stomach-pump is the surest means of emptying the stomach, and should be used as soon as possible. If the brain appear much oppressed, the countenance flushed, and the pulse full, moderate blood-letting will be serviceable, especially if artificial respiration be subsequently employed. When the water brought up by the stomach-pump is clear and devoid of any smell of the poison, which will prove that all the hurtful material has been evacuated, then, and not till then, vinegar may be given to the patient, who should also be kept moving about, and not suffered, if possible, to sink into a state of slumber. Coffee is a very useful beverage, and still more a drink made by boiling twelve ounces of vinegar, and pouring it immediately on three ounces of roasted and ground coffee, or by boiling the coffee in the vinegar, straining it, then adding half an ounce of sugar, and giving it in small quantities to the patient every quarter or half hour. This can be prepared while the stomach-pump is being used, and is one of the most efficacious means of counteracting the narcotic principle. Vinegar given while any of the poisonous substance is in the stomach only increases its deleterious property. [*ANTRIDORS*.] See Pereira's *Materia Medica* for the mode of action of the different narcotic substances, i., p. 66, and Christison *On Poisons*.

NARCOTINA, one of the peculiar and alkaline principles of opium which was discovered by Derosue about 1804; its true nature and alkaline properties were however first

ascertained by Robiquet in 1817. Various processes have been proposed for obtaining narcotina; the easiest method is stated to be that of digesting opium in water, filtering the solution, evaporating it to the consistence of an extract, and digesting this in æther, which dissolves the narcotina and some other substances. The æther being distilled off, the residual matter, which has a brown colour and is acid, is to be dissolved in hot water or boiling alcohol; the solution, after decolorizing with animal charcoal, is to be treated with ammonia, which precipitates the narcotina, and if it be not white, it is to be dissolved in hydrochloric acid, again treated with animal charcoal, precipitated by ammonia, washed, and dried; thus obtained, it is in the state of light white flocks, but when dissolved in boiling alcohol or æther it is deposited from them, on cooling, in pearly acicular crystals.

The properties of narcotina are, that it is insoluble in cold and very sparingly soluble in hot water; æther and the fixed oils readily dissolve it; its taste is not bitter; it does not restore the blue colour of reddened litmus, but as it combines readily with dilute acids, and forms salts which are made to crystallize, though with difficulty, it is classed with the alkalis; the hydrochlorate crystallizes in radiating groups; the sulphate does not crystallize, and the acetate is decomposed by heat: these salts have a taste which is more strongly bitter than those of morphia.

Narcotina has been repeatedly analyzed; the results do not exactly agree, but its composition is not far removed from—

Hydrogen . . .	5.32 or 20 equivalents
Carbon . . .	65.27 or 40 equivalents
Oxygen . . .	25.63 or 12 equivalents
Azote . . .	3.78 or 1 equivalent

100.

NARCOTINE. [PAPAYER.]

NARDI, JA'COPO, born at Florence in 1476, served first in the troops of the republic, and afterwards in a civil capacity. He was sent in 1527 as ambassador to Venice. He died at a very advanced age, after the fall of the republic. He wrote 'Storia della Città di Firenze dell' anno 1494 al 1531,' published at Lyon in France, 4to., 1582: another edition was published at Florence in 1584. Some passages which were expunged in both editions, but especially in that of Florence, on account of the political feelings of the author, are found in the MSS. in the libraries of Strozzi of Florence and Nani of Venice. Nardi was warmly attached to the republican constitution of his country, of which he witnessed and described the overthrow, whilst his contemporary Nerli, who composed a general history of Florence including the same period ('Commentarii dei Fatti Civili occorsi in Firenze dall' anno 1215 all' anno 1537,' fol., Augsburg, 1728), wrote in a manner favourable to the Medici, and accepted office under the grand-duke Cosmo I. The history of Nardi forms a sequel to that of Machiavelli, which ends with the death of Lorenzo the Magnificent in 1492, and the two together form a complete history of the Florentine republic from its rise till the overthrow of its independence.

Nardi wrote also 'Vita di Antonio Giacomini,' 4to., 1597. Giacomini was one of the most distinguished captains of the Florentine republic. He was also the author of an Italian translation of Livy, and a comedy, 'L'Amicizia,' one of the earliest comedies in Italian verse.

NARDUS. [SPIKENARD.]

NARES, JAMES, Mus. Doc., was born at Stanwell in Middlesex, in 1715, and received his musical education first as a chorister in the King's Chapel, under Bernard Gates, and afterwards under the celebrated Dr. Pepusch. At an early age he was chosen organist of the cathedral of York, and in 1756 was appointed organist and composer to George II., on the decease of Dr. Greene; and about the same time the degree of Doctor in Music was conferred on him by the University of Cambridge. In 1757 he succeeded Mr. Gates as master of the children of the Chapels-Royal, which office he held till 1780, when declining health induced him to resign it to his friend Dr. Ayrton, who had been his pupil. He died in 1783, 'regretted,' says his eldest son, the late Archdeacon Nares, 'not only by the family he left, but in a proportionate degree by all related to or connected with him.' Among these were, his younger brother, Sir George Nares, one of the judges of the Court of Common Pleas, and his nephew, the Rev. Edward Nares, D.D., author of the 'Life and Administration of Cecil, lord Burleigh;' also of Sermons and other works.

P. C., No. 988.

Dr. Nares published several musical works, the most important of which are: 'Twenty Anthems in Score, composed for the use of the Chapels-Royal,' and now constantly heard in every cathedral in England and Ireland; 'A Collection of Catches, Canons, and Glee,' dedicated to the Earl of Mornington, including the prize-gee, 'To all Lovers of Harmony,' and 'Fear no more the Heat of the Sun;' 'A Treatise on Singing,' with a set of English duets; and 'The Royal Pastoral, a Dramatic Ode.' After his death a second set of anthems, six in number, together with his popular Service, were, as he had directed, published by his son; and though these anthems have not obtained the same celebrity as those in the former set, they are not inferior in merit, and ought to be brought into notice by the influential persons in our choirs.

Of Dr. Nares it is most justly remarked in the *Harmonicon*, that 'his numerous productions for the church are rich in beautiful air as well as in harmony, not elaborate, but of the purest kind; and his judgment in setting our Liturgy has been equalled by few, exceeded by none; for his natural good sense and cultivated understanding led him not only to avoid the errors too apparent in the works of many ecclesiastical composers who preceded him, but also qualified him to become the guide of those who followed and had discernment and wisdom enough to profit by his examples.'

NARNI, a town of the Papal State, in the fine valley of the Nera, an affluent of the Tiber, and in the administrative province of Spoleto e Rieti, is situated on a hill which forms part of the mountains of Sabina, is a bishop's see, and has about 2500 inhabitants. (Calindri, *Saggio Statistico dello Stato Pontificio*.) It is an ill-built old-looking town; but it has several churches and convents, besides the cathedral, and in the neighbourhood are the remains of a very handsome bridge on the Nera, the antient Nar, said to have been built by Augustus. The antient Nequinum, a strong town of the Umbri, which stood on the present site of Narni, being taken by the Romans, 299 B.C., a Latin colony was sent there, which assumed the name of Narnia, from the neighbouring river. (Livy, x. 9, 10.) Narnia was one of the twelve Latin colonies which, after the battle of Cannæ, refused to give any further assistance to Rome. (Livy, xxix. 15.)

NARRAGANSET BAY. [RHODE ISLAND.]

NARROWS, The. [NEW YORK.]

NARSES, the name of a eunuch who became one of the most successful generals of the emperor Justinian I, and rivalled Belisarius in his military triumphs. His origin and parentage are unknown. He was probably by birth an Asiatic, emasculated, and sold, according to the old barbarous custom of that part of the world, and employed in his youth in menial services in the imperial household of Constantinople. His natural abilities and insinuating manners attracted the attention of Justinian, who had certainly the tact of discerning merit in those about him. Justinian employed Narses about his person, and raised him successively to the office of 'cubicularius,' or 'groom of the bedchamber,' and afterwards to that of keeper of the emperor's privy purse. Narses seems to have known and practised the arts of a courtier, but at the same time he was also capable of better things. He was sent on several missions, and at last, in A.D. 538, he was appointed to the command of a body of troops which were sent to Italy to act under Belisarius. [BELISARIUS.] The two generals acted in concert at first, and obliged the Goths to raise the siege of Ariminum; but they soon quarrelled, and Narses, who was supported by a party at the court of Justinian, chose to act for himself: the consequence was, that Belisarius was cramped in his operations, and meanwhile the Goths and Burgundians took and ravaged Milan. (Procopius, *De Bello Gothico*, xi. 21.) In the year 539 Justinian recalled Narses, who resumed his places at the imperial palace. Several years after, Belisarius having been recalled from Italy, the state of that country fell again into utter confusion; the Goths under Totila overran the whole country; and Germanus, a nephew of the emperor, being sent with an army to prevent the total loss of Italy, fell ill in Dalmatia and died. In the year 552, Justinian determined to make a last effort: he appointed Narses commander-in-chief of the Italian expedition, and supplied him plentifully with money, with which he collected a number of auxiliaries, Heruli, Longobardi, Gepidæ, and others, whom he united with the army of Germanus, and assembled them all near Salona. Not having sufficient vessels

VOL. XVI.—N

to embark his troops, he marched along the shores of the Adriatic, through Dalmatia, Istria, and Venetia, and thus arrived at Ravenna, from whence, after some days' rest, he moved on across the Apennines, and met Totila, who was advancing from Rome, at a place called Tagina, or Tadinæ, where a desperate battle took place, in which the Goths were completely defeated and Totila was killed. Narses advanced to Rome, which he took, whilst the Goths, having retired to Pavia, elected for their king Teias, who moved with a fresh army to encounter Narses. The two armies met on the banks of the river Sarno, near Nocera in Campania: Teias was killed in the fight, and the remaining Goths entered into a convention with Narses, by which they laid down their arms and withdrew to North Italy, where they dispersed in various parts of the country. Not long after however part of them joined a host of Franks and Alemanni who had crossed the Alps, under two brothers, called Lothar and Bucelin, and the whole made an irruption into South Italy whilst Narses was besieging Lucca. The barbarian host advanced as far as Calabria, plundering and committing all sorts of excesses; but on returning northwards loaded with booty, they were met by Narses on the banks of the Volturno, and totally destroyed. The Gothic kingdom in Italy was now at an end, and the whole country acknowledged the authority of Justinian, who appointed Narses exarch of Italy, A.D. 553. Narses fixed his residence at Ravenna, as the most convenient place for a prompt communication with Constantinople. During his fifteen years' administration, he did much to re-establish order throughout Italy; he checked the licentiousness of his troops, dismissed the most turbulent of his barbarian auxiliaries, appointed governors, with the title of dukes, to the different provinces, and repressed faction and religious schism. He has been accused of only one vice, avarice: he is charged with accumulating a large treasure during his residence in Italy. After the death of Justinian, A.D. 565, the enemies of Narses obtained his recall from the emperor Justinus II., who sent Longinus to supersede him as exarch of Ravenna. It is said that Sophia, the wife of Justinus, added to the letters of recall an insulting message to the purport that he ought to leave to men the command over other men, and return to the use of the distaff among the women of the palace; to which Narses is said to have retorted, that he would spin her a thread that she should not be able to unravel. He is accused of having entered into a correspondence with Alboin, king of the Longobards, inviting him to invade Italy. This however rests upon dubious report. Narses, after giving up his command, withdrew to Naples, but soon after, upon the urgent application of the Roman people, forwarded through their bishop, he removed to Rome, where he died at a very advanced age, A.D. 568. About the same time Alboin was crossing the Noric Alps to invade Italy. (Agathias; Paulus Diaconus; Gibbon.)

NARUSZEWICZ, ADAM STANISLAUS, a voluminous Polish writer, was born October 20th, 1733, and at the age of fifteen entered a seminary of the Jesuits, where his abilities and application so greatly recommended him to his instructors, that he was sent to the college of Jesuits at Lyon, and on quitting it was enabled, by the liberality of his patron, prince Czartorysky, to travel through Italy, France, and Germany. Having employed the opportunity thus afforded him in acquiring information and perfecting himself in various branches of study, on his return to his native country he was appointed professor of poetry at the university of Wilna. Within a short time afterwards he was promoted to a similar professorship in the College of Nobles at Warsaw. The reputation his talents now procured for him also the notice of the king Stanislaus Augustus, who, besides other repeated marks of his favour, conferred upon him the bishopric of Smolensk after the suppression of the order of the Jesuits, and in 1790 that of Lukow. He died July 6th, 1796, in his 63rd year.

Besides his poems, which consist of fables, satires, pastorals, and several books of odes and other lyrical pieces, including several imitated from Anacreon and Horace, he wrote a 'History of Poland,' in six volumes, a translation of Tacitus, a description of Taurida or history of the Crim Tartars, a translation of all the odes of Horace, and Stanislaus Augustus' Journey to Kaniow in 1786, which contains an account of the origin of the Kosacks.

NARVA, the capital town of the circle of the same name in the government of St. Petersburg, is situated in $59^{\circ} 24'$

N. lat. and $28^{\circ} 10'$ E. long., on the west bank of the river Narowa, which comes from Lake Peipus and falls into the Gulf of Finland about ten miles below the town. It is surrounded with a rampart, and in the suburb of Ivan-gorod, on the other side of the river, there are the remains of a large fortress built by the czar Ivan Wassiliowitsch. Narva is divided into the old and new town, which are separated by a rampart. The houses are well built of brick, and stuccoed white. There are 7 stone and 2 wooden Greek churches, and 2 stone Lutheran churches, an Exchange, and a good German school. The inhabitants, about 4500 in number, are for the most part of German descent, and Narva looks more like a German than a Russian town. It was a member of the Hanseatic League, and has still a very considerable export trade in balks, planks, flax, hemp, corn, and furs. The fishery in the Baltic is very productive, and the lampreys and smoked salmon of Narva are celebrated. About 100 merchantmen, chiefly in ballast (the imports being much less than the exports), arrive every year, and can come up to the town; but the barks which come down the Narowa from Lake Peipus are unloaded about a mile from the town, at the island of Kragholm, where there is a fall in the river about twelve feet perpendicular.

Narva was built in the year 1213 by King Waldemar, taken in 1553 by the grand-duke Ivan Wassiliowitsch, and re-taken by the Swedes in 1581. In 1590 and 1658 it was besieged by the Russians. On the 30th November, 1700, King Charles XII., with 8200 Swedes, totally defeated 80,000 Russians under Peter the Great and the duke of Croy, and stormed their intrenched camp near the town. In 1704 however Peter the Great took it by storm, and it has ever since remained in the possession of Russia.

NARWHAL. [WHALES]

NASA'LIS, M. Geoffroy's name for a remarkable genus of Monkeys established on the 'Guenon à long nez' of Buffon, the *Proboscis Monkey* of Shaw, *Simia Nasica* of Schreber, *Nasalis larvatus* of Geoffroy, *The Kahau*.

ORGANIZATION AND HISTORY.

The enormous development of the nose in the *Kahau* is not dependent on bone. The nasal bones are no more elevated than they are in the rest of the *Simiada*, as will be perceived from the following cut of the skull of a *Proboscis Monkey* in the museum of the Zoological Society of London.

Skull of Kahau

The figure given below was reduced from the drawing of a female, when newly taken from the cask of spirit in which the body was preserved: the specimen came from Borneo, and is now to be seen, but with the nose deteriorated by drying, in the museum of that Society. It is

Face of Kahau (Female).

said that the animal has the power of dilating this organ to an enormous size by inflation.

Audebert gives the following view of the nose, as seen from beneath.

Nose of Kahau, seen from beneath.

In July, 1837, Mr. Martin laid before the Zoological Society the following observations on this Monkey:—

'The genus *Nasalis*, of which the "*Guenon à long nez*" of Buffon (*Suppl.*, vii.) or Proboscis Monkey of Shaw, is the type, was founded by Geoffroy St. Hilaire in his '*Tableau des Quadrumanes*,' published in the '*Annales du Muséum d'Histoire Naturelle*' for 1812. In this outline of the *Simiadae* the genera *Semnopithecus* and *Cercopithecus* are blended together under the latter title; but from this group are excluded two Monkeys, the *Douc*, constituting the type of the genus *Pygathrix* (*Lasiopyga*, Ill.) and the "*Guenon à long nez*." With respect to the genus *Pygathrix* or *Lasiopyga*, founded upon the alleged want of callosities, most naturalists, I believe (aware of the error committed both by Geoffroy and Illiger, in describing from an imperfect skin), have regarded it as merging into the genus *Semnopithecus*, at least provisionally, until the internal anatomy of its assumed representative be known.

'The characters of the genus *Nasalis*, formed for the reception of the "*Guenon à long nez*" (*Simia Nasica*, Schreb.; *Cercopithecus larvatus*, Wurm), are laid down as follows:—

"Muzzle short, forehead projecting, but little elevated; facial angle 50°; nose prominent, and extremely elongated; ears small and round; body stout; cheek-pouches; anterior hands, with four long fingers and a short thumb, ending where the index-finger begins; posterior hands very large, with fingers stout, especially the thumb; callosities large; tail longer than the body."

'At a subsequent period, however, in his '*Cours de l'Histoire Naturelle*,' published in 1828, Geoffroy, adopting the genus *Semnopithecus*, established by Fred. Cuvier, places the "*Guenon à long nez*" within its limits, doubtfully, it is true, and with the acknowledgment that his genus *Nasalis* has not been generally adopted, but at the same time with a bias in its favour; for, observing that the manners of these Monkeys are those of the *Semnopithecus*, he adds, "Cependant, il ne nous paraît encore démontré que le singe nasique soit une véritable semnopitheque, et il est fort possible que lorsque l'espèce sera moins imparfaitement connue, on soit obligé de rétablir le genre *Nasalis*, dans lequel on l'isolait autrefois, mais qui n'est pas été admis par la plupart des auteurs modernes."

'Setting aside the singular conformation of the nose, so remarkable in the *Simia Nasalis*, its external characters are not different from those of the *Semnopithecus* in general; and it is to be observed that in a second species, lately added by Mr. Vigors and Dr. Horsfield, under the title of *Nasalis recurvus*, the proportions of this part of the face are much diminished, and its form also modified. This species (which, though doubted by some as being distinct, is, we believe, truly so) takes an intermediate station between the *Simia Nasalis* and the ordinary *Semnopithecus* with flat noses, thereby showing that the transition in this particular character is not abrupt; even were it so, an isolated point of this nature does not form a philosophical basis upon which to ground a generic distinction.

'So far I have alluded to external characters only; it remains for me to give some account of the anatomical characters of this singular Monkey, of which, as far as I can learn, modern naturalists do not appear to be aware.

'It would seem that M. Otto,* who described the sacculated form of the stomach in one of the Monkeys of the genus *Semnopithecus*, is not the first observer of this pecu-

* See his paper in the '*Nova Acta Academiae Cæsareæ*,' vol. xii.

liarity, for I find that Wurm, in the '*Memoirs of the Society of Batavia*,' notices this point in the anatomy of an individual of the *Simia Nasalis*. After giving some interesting details respecting the habits and manners of the species, he proceeds as follows:—"The brain resembles that of man; the lungs are of a snow-white colour; the heart is covered with fat, and this is the only part in which fat is found. The stomach is extraordinarily large, and of an irregular form; and there is beneath the skin a sac which extends from the lower jaw to the clavicles." Audebert (with whose work, '*Histoire des Singes*,' Geoffroy St. Hilaire was well acquainted) refers to this account of Wurm; yet Geoffroy does not, as far as I can find, advert to these points, unless indeed his statement of the presence of cheek-pouches be founded on the observation of a sac extending from the lower jaw to the clavicles; and if so, he has made a singular mistake, for the sac in question is laryngeal, and the words as they stand cannot be supposed to mean anything else. I know of no Monkey whose cheek-pouches extend beneath the skin to the clavicles; but the laryngeal sacs in the *Orang* and *Gibbons*, and also in the *Semnopithecus* themselves, are remarkable for development. It is evident however, from the silence of M. Geoffroy St. Hilaire respecting the laryngeal sacculus in the Proboscis Monkey, that he was not aware of the real character of the structure to which Wurm had alluded. With respect to the structure of the stomach, neither Wurm nor M. Otto drew any general inferences from it; they described it as it presented itself in single species, and regarded it in an isolated point of view; it is, if I mistake not, to Mr. Owen that we owe its reception as an anatomical character extant throughout the *Semnopithecus*. (See his paper on the subject, in the *Proceedings for 1833*, and in the *Transactions of the Zoological Society*.)

'This is perhaps scarcely the place in which to introduce any speculations, but I cannot help observing that the same structure may be expected in the genus *Colobus*, which in form is a mere repetition of the genus *Semnopithecus*, except that the thumb of the fore-hands, which in the latter begins to assume a rudimentary character, is in the former reduced to its lowest stage of development. In both genera the teeth precisely agree, and present early that worn surface which is the consequence of a continued grinding rodent-like action upon the leaves and herbaceous matter which constitute the chief diet of the animals.

'The statement of Wurm respecting the stomach and laryngeal apparatus of the Proboscis Monkey I have lately been enabled to confirm.

'Among the specimens in store brought within the last few months from the Gardens to the Museum occurred an example of the Proboscis Monkey, in brine, but in a state of decomposition which induced me to lose no time in making such an examination as its condition would admit, being indeed extremely anxious to ascertain the relationship of this curious Monkey to the other groups of Indian *Simiadae*, groups to which I have been lately directing my attention.

'The specimen in question was a female, measuring, from the vertex to the ischiatic callosities, one foot nine inches.

'The body was meagre and slender, and the limbs long and slim; the contour of the animal being very unlike that displayed in the mounted specimen in the Museum of the Society, which gives the idea of great robustness.

'The abdominal cavity had at some former period been opened and the liver removed, in doing which the stomach had been cut, but not so much as to spoil it entirely. In every essential point this viscus is the same as in all the *Semnopithecus* hitherto examined: it consists of a large cardiac pouch, with a strong muscular band running as it were around it so as to divide it into two compartments, an upper and lower, slightly corrugated into sacculi; the cardiac apex of the upper pouch projects as a distinct sacculus of an oval form, and is not bifid. From this upper pouch runs a long and gradually narrowing pyloric portion, corrugated into sacculi by means of three muscular bands, of which one is continued from the band dividing the cardiac pouch into two compartments. The elongated pyloric portion sweeps around the lower cardiac pouch.

'The oesophagus enters the first compartment about four inches from its terminal apex, giving off a radiation of longitudinal muscular fibres over the central portion of the first compartment. The second or lower compartment is the largest and deepest, and is embraced by longitudinal

muscular fibres from the œsophagus to the division-band, but, unlike the same compartment in the stomach of the *Semnopithecus Entellus*, it is very slightly sacculated; indeed it can scarcely be said to be so at all. The admeasurements are as follow:—

	feet.	inches.
1st compartment, round the greater curve . . .	1	6
2nd compartment, measured in the same manner . . .	1	8½
From the entrance of the œsophagus, round the 2nd compartment, to the division-band . . .	1	1
The same measurement, round the 1st compartment . . .	0	8½
Length of pyloric portion . . .	2	1
Circumference at base . . .	0	9½
Circumference just above pyloric orifice . . .	0	5½
Length of small intestines . . .	18	0
Length of large intestines . . .	6	2

The average diameter of the small intestines, lying flat, was ¾ of an inch; the ileum however was rather more, but not quite an inch.

The *cœcum* is of a pyramidal figure, 5 inches in length, pointed, and somewhat sacculated by three slight muscular bands. Circumference at the base, 5½ inches.

The large intestines are puckered into *sacculi* by two longitudinal bands; they commence large, becoming gradually smaller, the bands in the mean time gradually disappearing. Advancing towards the *rectum* the intestine again enlarges; and here, to the extent of 2½ feet from the anus, all trace of bands is lost.

The circumference of the large intestines, at their commencement, is 3½ inches.

The lungs consisted of two lobes on each side, the fissure dividing the lobes on the right side being the most complete.

The laryngeal sac was of enormous size, and single. It extended over the whole of the throat, and advanced below the clavicles, communicating by means of a single but large opening with the larynx. This opening is on the left side, between the *larynx* and the *os hyoides*, and is capable of being closed by means of a muscle arising from the anterior apex of the *os hyoides*, and running down the central aspect of the *trachea* to the *sternum*. The contraction of this muscle draws the *os hyoides* down, so as to press upon the edge of the thyroid cartilage.

There were no cheek-pouches, nor any traces of them.

The teeth were much worn, but the fifth tubercle of the last molar tooth of the lower jaw was very distinct.—(*Zool. Proc.*, 1837.)

The Kahau. (Audebert.)

Description.—Reddish brown, except the light-coloured tail, lower part of the back, and some light-coloured markings on the arms. Height about three feet, when nearly erect. Female rather less, and destitute of the light markings on the back, &c. Nose and face darkish brown.

Geographical Distribution, Habits, &c.—This species is a native of Borneo. Their habits are gregarious, and they

are said to collect in great troops upon the trees bordering the rivers at sunrise, darting from tree to tree with great activity, sometimes springing a distance of fifteen feet. Their name, *Kahau*, is supposed to be given to them from their continued cries, which are considered to resemble that word in their expression. Their disposition is said to be bad. M. Lesson notices the 'on dit' that the species is also a native of Cochin China; but he gives no authority for this locality.

Mr. Vigors and Dr. Horsfield, in their paper 'On the Mammalia in the Zoological Museum,' after noticing the species above described, mention another form, of which two specimens, almost equally distinguished by the extension of the nose, but having that member turned up instead of being recumbent, brought also from Borneo, are in the same collection. This is the form alluded to above by Mr. Martin, and is thus characterised by Mr. Vigors and Dr. Horsfield, under the name of *Nasalis recurvus*. It is to be remarked that they were also preserved in spirit, and consequently were not subject to the same contraction of the soft parts of the nose as might have occurred in dried skins:—

Description.—Head, neck, shoulders, and thighs rufous above; abdomen paler; middle of the back reddish grey; inside of arms and thighs, lower part of the back, and tail, grey; tail below, white. Size about one-third less than the Kahau.

Mr. Vigors and Dr. Horsfield observe that the general colour and markings of this animal correspond with those of the Kahau. The skin of the face however, they remark, is reddish in *N. recurvus*, where in the other species it is black. In *N. recurvus*, they add, the beard is very prominent; but in the Kahau the hairs on the chin scarcely assume the appearance of a beard.

Profile of *N. recurvus*.

Mr. Vigors and Dr. Horsfield state that it has been suggested that this may be the young of the Kahau; but they state that they cannot allow themselves to come to the conclusion that they are the same, with so great a disproportion of the facial angles, in the absence of some stronger grounds than mere conjecture. Its teeth, they remark, showed no signs of being otherwise than adult.

Mr. Swainson appears to agree with Mr. Vigors and Dr. Horsfield and Mr. Martin, in considering *N. recurvus* distinct; for he gives the number of species of *Nasalis* as two. (*Natural Hist. and Classification of Quadrupeds.*)

NASAMONES (*Νασαμώνες*), a barbarous people in Libya, who dwelt on the coasts of the Greater Syrtis. According to Strabo they were bounded on the west by the *Psylli*, and extended westward as far as the *Philœnian Altars*, which were at the southern extremity of the Greater Syrtis (xvii., p. 836, 838, Casaub.). Herodotus places them further to the west, and states that they occupied the country of the *Psylli* (iv. 173). On the east they extended beyond the Syrtis, and were bounded by the *Auschisæ*, a small tribe, who dwelt to the west of the *Cyrenaica* (Herod., ii. 32; iv. 172). Inland they had dominion as far as the oasis of *Augila*, in the great desert of *Barca*, which is 180 miles south-east of *Barca*, and is at the present day one of the resting-places of the caravans which trade between *Cairo* and *Fezzan*. [**AUGILA.**] The *Nasamones* were accustomed to leave their cattle on the coast in the summer season, and go to *Augila* to gather dates (Herod., iv. 172).

Pliny (v. 5) also places the *Nasamones* on the Syrtis, and says that they were antiently called *Mesammones* by the Greeks, because they were situated between two quicksands (*μέσος, ἄμμος*); meaning perhaps the two Syrtis, which however is not the case.

The Nasamones are described by Herodotus (iv. 172, 190) as a numerous nomade people, who had a community of wives, were accustomed to swear by the tombs of the bravest and justest of their ancestors, and pledged their faith by drinking out of the hands of one another, or by licking dust out of one another's hands, if they had no water.

They are described by Lucan (*Phars.*, ix. 404) and Q. Curtius (iv. 7) as a barbarous tribe, who lived by the plunder of the vessels shipwrecked on their coast. Bruce, who was shipwrecked on this coast, found that the present inhabitants followed the same practice. (Reynell's *Geography of Herod.*, ii., p. 270.)

The Nasamones were driven into the interior of the country by the Romans in the time of Domitian. (Dionys. Perieg., ed Hudson, iv. 208; Eusebii *Chron.*, Ol. cexvi.; Joseph., *Bell. Jud.*, ii. 16, § 4.) Ptolemy places them as far inland as Augila.

Herodotus gives (ii. 32) an interesting account of an exploring expedition, undertaken by five young men of this country, who crossed the great Libyan desert, and, after traversing extensive marshes, came to a large river flowing from west to east, with crocodiles in it, which many commentators have supposed to be the Niger. [NIGER.]

NASCENT STATE, a term proposed by Dr. Priestley to express the moment at which a gaseous body is liberated from previous combination and before it has assumed the gaseous form. The nascent state has a powerful effect in occasioning chemical combination, which could not occur without it. If, for example, azotic and hydrogen gases be mixed in any proportions whatever, and be subjected either to heat or electricity, which are so efficacious in causing many other gases to combine, no union takes place between them, and consequently no ammonia is formed. If however we decompose nitric acid and water by means of tin, the azote of one and the hydrogen of the other come into contact in their *nascent state*, and before they have even assumed the form of gases, and they combine to form ammonia. Other examples of similar action might be adduced, but no one more strikingly exemplifies the meaning of the term and the efficacy of the action which it is intended to describe.

NASEBY. [CHARLES I.]

NASH, THOMAS, was born in the year 1558, at Lowestoft, in Suffolk, and closed a calamitous life of authorship in his forty-third year. Dr. Beloe has given a list of his works, and Mr. D'Israeli an account of his privations and miseries. As a wit and a satirist, he seems to have been superior to all his contemporaries; but as a dramatic poet, much below most of them. He has left only one dramatic performance entirely of his own composition, 'Summer's Last Will and Testament,' which is not to be regarded so much in the light of a play as of a spectacle. It was exhibited before Queen Elizabeth at Nonsuch in the autumn of the year 1592, but not printed till eight years afterwards. Nash was concerned with Marlow in writing 'Dido, Queen of Carthage,' 1594, which was also acted before the queen by the children of her chapel.

He had a vigorous understanding, well stored with learning, and was capable of giving powerful descriptions of things and striking characters of persons, as will be found by his 'Supplication of Pierce Penniless to the Devil,' 1592: this latter work was followed up, though with less effect, by his 'Christ's Tears over Jerusalem,' 1593. 'Summer's Last Will and Testament' has been reprinted in the last edition of Dodsley's 'Old Plays.' It has no pretention to diversity of character in the persons, nor to interest in the plot, the only part that approaches to anything like individuality being that of Will Summers (or Sommers), the jester of Henry VIII.: the piece depends upon a sort of pun between the name of the jester and the division of the year which corresponds with that name.

(*Collier's Annals of the Stage.*)

NASH, JOHN, was born in 1752, and is said to have been of Welsh extraction, but few particulars are known of his early life, or when he first began to apply himself to architecture as a profession, previously to which he followed portrait, or rather miniature painting. Perhaps it was in an evil hour for architecture, that he devoted himself to it as practitioner; for though he thereby acquired a popular reputation for himself, as the author or promoter of the very extensive improvements in the metropolis, arising out of the formation of Regent Street and the Regent's Park, the taste there displayed most certainly has not contributed to

raise our national character in regard to architecture, but has rather tended to bring into vogue a sketchy, showy, and meretricious style, wherein, though richness is affected, poverty and meanness are the prevailing qualities. Notwithstanding all their pretension and finery, the terraces in the Regent's Park have more the look of barracks than of palaces;—are mere stretched-out ranges of common-place houses, garnished with columns and pilasters, insipid enough in themselves, and rendering the poverty of all the rest absolutely offensive. It has been said that for the bad taste of many of the designs both in Regent Street and the Park, he is not answerable, they being the productions of the different architects, or rather builders, who erected them; yet besides that such excuse reduces Nash to little more than the surveyor employed on that occasion, it is no excuse whatever for the paltry taste of his own designs, which, so far from being decidedly superior to all the rest, exhibit some of the very worst specimens among them. Neither is he at all entitled to the originality claimed for him as having set a new fashion in street architecture, by combining several houses into one façade, since the same thing had been done about a century before by Wood of Bath. Whatever allowance however may be made for works of that class, we may fairly take Buckingham Palace as proof of his talent; and that costly structure is a decided and most deplorable architectural failure; hardly at all superior in style and quality to the average of the designs above referred to. Here and there are some bits of prettiness, but nowhere does it manifest the slightest approach to grandeur or to real architectural taste; neither is there any redeeming point in the general conception. In the Pavilion at Brighton he succeeded better, although it is but a poor and sketchy imitation of the style attempted; he seems never to have given any study to detail, but to have contented himself with the mere generalities of form. The United Service Club-house, the Haymarket Theatre, and the Terraces in St. James's Park, and indeed almost all his works, sufficiently attest this, nor is the variety displayed in them more than a very commonplace sort of fertility. The entrance to the Queen's Mews, another of his works, is remarkable only for its barbarous ugliness.

Mr. Nash died at his villa near East Cowes in the Isle of Wight, May 13, 1835, in his 83rd year, and is said to have left very little property, notwithstanding the vast sums of money he had derived from his profession.

NASIR-ED-DIN, MOHAMMED BEN HUSSEIN AL THUSSI, a Persian and an astronomer, who died A.D. 1276, aged about 70. Having met with some slight from Al Mustasseni, the kalif, he left his country and went into Tartary. Here he obtained the friendship of Hulaku (commonly written Holagu), surnamed Ikhan, the brother of the reigning prince. It is said that Hulaku, being on the point of leading an army against Constantinople, was deterred by Nasir-ed-din, and induced to prefer an invasion of Persia. D'Herbelot treats this as a fiction, so far as the astronomer is concerned; but whether this be so or not, Hulaku overran Persia, put Mustasseni to death, and fixed his seat of government at Maragha, in Azerbaijan, where he collected men of science, built an observatory, and placed Nasir-ed-din at the head of both. The instruments there used are described by Delambre, from an Arabic manuscript, in the 'Hist. de l'Astron. du Moyen Age,' page 199, &c. The tables made at this observatory are called the Ichame Tables, from the name of their author's patron. They enjoyed great reputation in the East, and are known in Europe from the 'Synopsis Tabul. Astron. Persicarum' of George Chrysococca, printed by Bouillaud in 1645, and the Commentary of a Persian, whose Latinised name is Slab Cholgius, printed by Greaves, in 1642. The Ichame Tables, according to Delambre, differ from those of Ptolemy only in the correction of some of the mean motions.

Nasir-ed-din also wrote a work on geography, which was printed by Greaves in 1652, and which we believe was long the authority for many Asiatic longitudes and latitudes; also a work on ethics, and several other writings.

NASSA. [ENTOMOSTOMATA, vol. ix., p. 455.]

NASSAU or POGGY ISLANDS, THE, form a part of a chain of islands which lie off the whole length of the west coast of Sumatra, at a distance of 60 or 80 miles. There are two islands which bear this name: they lie between 2° 30' and 3° 16' S. lat., and are separated from each other by a strait called Si-kakap, which is about two miles long and a quarter of a mile across. This strait

forms an excellent harbour for ships of any size. It is surrounded by mountains, so that the water is literally as smooth as in a pond; and there are twenty-five fathoms of water close in-shore, and forty-five in the mid-channel. There are also some high rocks in the strait.

The surface of the islands is rough and irregular, consisting of high hills or mountains of sudden and steep ascents. The mountains are covered to their summits with trees, many of which supply excellent timber. The sago-tree grows in abundance, and affords the chief article of food to the inhabitants, who cultivate no rice. The cocoa-nut tree and the bamboo also abound. The fruits common in the islands of the Indian archipelago, such as mangosteens, plantains, &c., are numerous. The woods in their natural condition are impervious to man, and harbour various wild animals, as deer, hogs, and several kinds of monkeys. Fowl and pigs are raised, and fish are plentiful.

The inhabitants of these islands are few in number; they are divided into small tribes, each tribe occupying a little river, and living in one village. On the Northern Pogy there are seven villages, and on the southern five. The population amounted in 1792 to about 1400 individuals. In colour and stature they resemble the Malays, but they speak a language quite different from those used on the coast of Sumatra. There is some resemblance between them and the inhabitants of the islands of the Pacific in their practice of tattooing their body. They are still strangers to the use of coin of any kind. A sort of iron hatchet serves as a standard for the value of various commodities among them. They neither export nor import any article. Some Malays have settled among them for the purpose of building large boats, timber for which is found close at hand. (Crisp, in *Asiatic Researches*, vol. vi.)

NASSAU. [BAHAMAS.]

NASSAU, THE DUCHY OF, derives its name from the mountain castle of Nassau, the original seat of the Nassau family, of which only the ruins now remain, near the small town of Nassau. The extent of this duchy and its territories have undergone numberless changes in consequence of partitions, re-unions, cessions, and acquisitions. It is at present composed of 23 different territories, including all those which formerly belonged to the several branches of the family. It is comprised between 49° 55' and 50° 50' N. lat. and 7° 31' 50" and 8° 45' E. long., and is bounded by the Prussian Rhenish provinces and by the different states of Hesse. The area is variously stated, 2226 square miles being the highest and 1743 the lowest estimate. According to the best maps, it seems to be 1900 square miles. The duchy is divided into three provinces, Wiesbaden, Weilburg, and Dillenburg, and subdivided into 28 bailliwicks. There are no large towns, Wiesbaden having only 9000 and Biberich 3000 inhabitants. The country is generally mountainous or hilly, and there is no part that can be called plain. The mountains follow the Rhine and the Lahn in their whole course through the duchy, and form delightful valleys, which are among the most romantic parts of Germany; the most picturesque is the Rheingau from Biberich to Lorchhausen, celebrated for its fine wines. This beautiful valley is protected by the Taunus from the north wind, and bounded on the south by the Rhine. There are two principal chains of mountains; on the north the wild and wooded Westerwald, and on the south east the Taunus or the Höhe, the most elevated summit of which is the Fuldberg, 2605 feet, and the Altkönig, 2400 feet above the level of the sea. The climate is on the whole temperate and healthy; it is mildest in the parts about the Main; on the highest summits of the Taunus and the Westerwald, it is rather bleak and cold. Of the rivers the chief is the Rhine, which bounds the duchy on the south and west, and at Lahnstein receives the Lahn, which is navigable 14 leagues from its junction with the Rhine at Weilburg. The Main forms the boundary to the south-east. There are several smaller rivers and mountain streams, such as the Embs, Aar, Sieg, Wiedbach, Weilbach, and Niester. There are no canals and no lakes. On the other hand the country has numerous Spas and mineral springs, which are among the most celebrated in Germany: of the former we may mention Ems, Wiesbaden, Langenschwalbach, and Schlangenbad, which are annually frequented by above 10,000 visitors; and of the latter Nieder-Selters, Fachingen, and Geilenau, from which about three millions of bottles are annually exported, of which 2½ millions are Selters water. The natural productions are various and valuable. Though the farmers are very industrious, the corn raised is

in general not sufficient for the consumption of the country. The fertile bailliwick of Höchst is indeed a granary to the city of Frankfurt, and considerable quantities of the fine wheat and rye grown on the banks of the Aar and the Lahn are exported by means of the latter river; the wheat is of such superior quality that it fetches in Holland 25 or 30 florins per last more than that of the other countries on the Rhine and Main. Peas and beans, linseed, potatoes, flax, hemp, and tobacco are cultivated. Fruit is raised in great perfection, and large quantities are exported. But the boast of Nassau is its wine, of which that produced about Hochheim is well known by the name of *hoch*; there are likewise the wines of Markebrunn, Asmannshausen, and Johannisberg; the last is the property of Prince Metternich, which the emperor Francis conferred on him in 1816 as a reward for his eminent services to the cause of Germany, the emperor retaining the feudal rights, and receiving the tithe on the wine. The prince derives from the estate an annual revenue of about 40000 sterling. The breeding of cattle (especially horned cattle) is a chief source of wealth: there are about 200,000 horned cattle, 70,000 swine, 180,000 sheep, 10,000 horses, and 10,000 goats. The minerals are silver, lead, iron, copper, marble, freestone, limestone, basalt, slate, fullers' earth, and potters' pipe, and porcelain clay. There are also some salt-springs. The forests, which abound in game, supply vast quantities of timber and firewood. The smelting and manufacturing of metals are carried on to a considerable extent; there are also paper-mills, tanneries, distilleries, tobacco, vinegar, and potash works, and some woollen, leather, and linen manufactures, but on a small scale. The trade is almost wholly limited to the exportation of the produce of the country. With respect to religion, the inhabitants, who at the beginning of 1838 amounted to 379,272, are pretty equally divided between the Roman Catholic and the Protestant churches. In the year 1817 the Lutherans and Calvinists agreed to unite in one body under the denomination of Evangelical Christians. There are nearly 6000 Jews. There is a gymnasium, a military school, a seminary for teachers, a deaf and dumb institution, an agricultural school, and 658 district schools. There is no university, but the young men study at Göttingen, where there is a professor who lectures on the laws of Nassau.

The duke was formerly an absolute sovereign, but in 1817 a representative constitution was introduced, with two chambers, which have larger powers than those of some other German states. The military force amounts to 4000 men. The revenue is 1,810,000 florins: but there are debts to the amount of twelve millions of florins. The duchy has been composed of so many different territories, and the exchanges and partitions, have been so numerous, that a regular history of the country is out of the question. Otho, brother of king Conrad I., in the tenth century, is considered as the founder of the Nassau family, which after the death of Henry II. was divided into two branches, of which his sons, Wabram and Otho, were the heads. The dukes of Nassau are descended from the elder, and the house of Orange-Nassau (king of the Netherlands) from the younger branch.

Nassau together with Brunswick has the thirteenth vote in the diet of the German Confederation; in full council Nassau has two votes of its own. Its contingent to the army of the Confederation is 3028 men.

NASSAU, HOUSE OF, an ancient and illustrious German family, which, having distinguished itself throughout Europe, during the sixteenth and seventeenth centuries, in the cause of civil and religious liberty, has in our own times attained the regal title with the sovereignty of the Netherlands. The counts of Nassau on the Rhine had, in the middle ages, acquired sufficient power at one period to dispute the pre-eminence with the House of Austria, and to give a sovereign (Adolphus of Nassau, elected emperor A.D. 1292) and five ecclesiastical electors to the German empire. Early in the sixteenth century the family of Nassau obtained, through marriage and bequest, the French principality of Orange in Provence, from whence their most celebrated title has been derived: but the possession of several large domains and hereditary dignities in the Netherlands had meanwhile numbered the counts of Nassau among the vassals whom the House of Austria gained by the marriage of Maximilian with Mary of Burgundy; and William I. of Nassau, prince of Orange, the true founder of the glories of his race, was the subject of the emperor Charles V. Besides William I., the most remarkable per-

sonages of his house were his son Maurice, the ablest general of his age, and his great-grandson William III., stadtholder of the United Provinces and king of England; the lives of each of these three individuals will claim a separate notice.

I. WILLIAM I. OF ORANGE was born in the year 1533, at Dillenburg in Nassau. His father having embraced the reformed doctrines, he was at first educated in those principles; but the emperor Charles V., who early interested himself in his fate, removed him to his court, and had him brought up in the Roman Catholic faith. The emperor, who is said to have foreseen and predicted the great statesman in the boy, placed him about his person, allowed him alone to be present when he gave audience to foreign ambassadors, and soon honoured him with a confidence far above his years. William merited his favour by a discretion which had already obtained for him his famous surname of 'The Silent;' and the emperor did not blush publicly to avow, that to so young a man he had often been indebted for suggestions which had escaped his own sagacity. In the last solemn act of his public life, when he abdicated his throne to his son Philip II., Charles leant on the shoulder of William of Orange; and to him also, still only in his twenty-third year, the retiring monarch committed the honourable mission of delivering over his imperial crown to his brother Ferdinand.

The esteem of Charles seems to have been sufficient of itself to excite the jealousy and distrust of his son; and, from the commencement of Philip's reign, William became to that gloomy and suspicious despot an object of hatred and fear, which he repaid with deep though dissembled indignation. The state of religion in the Netherlands enabled him to convert those provinces into a theatre of action for projects which have been variously attributed to his patriotism or revenge, but which perhaps may with more probability be ascribed to the mixed motives that usually influence human conduct. While his benefactor Charles was on the throne, William had adhered to the Imperial creed; but after the abdication of that monarch we find him embracing Calvinism with the same facility with which he had in earlier years deserted the Lutheran for the Roman Catholic faith. This last transition was yet undecided or unknown when he was resident at the court of France as a hostage for the peace of Cateau-Cambresis; and the French king, Henry II., believing him to be as deep in the confidence of Philip II., as he had been in that of Charles V., incautiously spoke to him of the secret treaty which the crowns of France and Spain had recently concluded for the extirpation of the Protestants in the dominions of both.

This disclosure had a double consequence; for William hastened to communicate it to the leaders of the Protestant party in Brussels, and Philip II. discovered that he had given the information. The existence of this treaty and its detection served to increase the antipathy between William and his sovereign; but the dissimulation which belonged to their characters in common long prevented any open rupture, and for several years, while the Netherlands remained under the feeble administration of Margaret of Parma, the Prince of Orange, as a member of the Flemish council of state, and as stadtholder of Holland, Zealand, and Utrecht, covertly but indefatigably employed himself in undermining the tyrannical designs of Philip. The tortuous and often treacherous policy pursued by William during all this period can only be approved by that class of politicians in whose estimation the means are justified by the end. At length the approach of the energetic and sanguinary duke of Alva, to whom Philip had transferred the government of the Netherlands from the hands of Margaret of Parma, warned William that it was time to throw off the mask; and he avoided the tragical fate of his friends, the counts Egmont and Hoorne, by retiring from the Low Countries to his paternal domains of Nassau.

In the following year, 1568, the detestable tyranny and inhuman cruelties of Alva against the Protestants in the Netherlands, his own wrongs, and the appalling sufferings of a people whom he loved, roused William from his retreat, and thenceforward he stood forth the fearless and zealous champion of the great cause, which he is supposed to have embraced less from religious than from political motives. His efforts in arms were for the most part unsuccessful; for the raw and heterogeneous levies which he was enabled to make among the German and French Protestants for the succour of the unwieldy people of the Netherlands were no match for the veteran Spanish and

Italian bands which Alva had led into the Low Countries. But every disadvantage under which William contended in the field with Alva and his skilful successors, Don John of Austria and Alessandro Farnese of Parma, was more than counterbalanced by his consummate abilities as a statesman, which enabled him finally to triumph, not only over his Spanish enemies, but over every rival in the councils of the revolted provinces. The archduke Mathias of Austria and the duke of Anjou, both of whom had been invited by the party opposed to William to assume the government of the insurgent states, found their authority less durable than his influence; and it was by his suggestions and under his auspices that the seven Protestant provinces of Holland, Zealand, Utrecht, Friesland, Groningen, Overijssel, and Guelderland, concluded, in 1576, the famous Union of Utrecht, which formed the lasting basis of the Dutch republic. [NETHERLANDS]

Philip II. no sooner heard of this decisive measure than he showed his sense of its importance and his dread of its author by setting a price upon his head. So atrocious a temptation, combined with fanatical zeal, soon produced two attempts upon the life of William, from the first of which he escaped with a wound. The second was more successful, and he fell at Delft, in the year 1584, by a pistol-shot from the hand of one Balthazar Gerard, a Burgundian, who had been instigated or encouraged to the deed by Roman Catholic priests. William was four times married, and left, besides daughters, three sons, of whom Philip William, the eldest, having been seized in his youth by Alva, sent to Spain, and educated in that country in the Roman Catholic faith, was ultimately restored to the principality of Orange, and the two others, Maurice and Frederic Henry, successively attained the dignity of stadtholder of the United Provinces.

II. MAURICE OF NASSAU, the second surviving son of William I., was born in 1567, and named after his maternal grandfather, the celebrated elector Maurice of Saxony, whose military genius he inherited. Although only seventeen years of age when his father was assassinated, the states of Holland and Zealand showed their gratitude to the memory of their deliverer by immediately electing young Maurice their governor or stadtholder; and though the count of Hobenloo was at first appointed his lieutenant to aid his inexperience, he soon proved himself capable of the unassisted conduct of military affairs. For a time indeed his further rise was impeded by his extreme youth, and by the desire of the States to gratify Queen Elizabeth of England through the elevation of her unworthy favourite, the earl of Leicester, to the supreme command of their forces. The proceedings of that nobleman however soon gave them just grounds of suspicion and disgust, and in 1587 they solemnly elected Maurice to fill, in his absence, the office of captain-general of the whole Seven United Provinces, a dignity which accordingly devolved altogether upon him, when the misconduct of Leicester had at length compelled the queen of England to relieve the Netherlands of his presence. At this epoch a great part of the territory of the Seven United Provinces was still in the hands of the Spaniards; but Maurice began vigorously though gradually to make head against them. In 1591 he displayed his skill and activity by the capture of Zutphen, Deventer, Nimeguen, and other important places; and his successes had now infused such confidence into the States and people, that he was received at the Hague with transports of public joy. In 1593 he took Gertruydenberg, after a memorable siege, and Groningen in the following campaign. The progress of the republican arms was marked during some years principally by the reduction of those and other fortified places; but in 1597 Maurice, with the aid of the English auxiliaries under Sir Francis Vere, completely defeated the Spaniards in his first ranged battle at Turnhout in Brabant; and three years later, in 1600, he obtained at Nieuport, with the same confederates, a second and more brilliant victory over the archduke Albert of Austria.

Thenceforth, until the recognition by Spain of the independence of the Seven United Provinces in the truce for twelve years, which was concluded in 1609, Maurice continued to extend the successes of the states, and to raise the glory of their arms. The undoubted talents of the great generals to whom he was opposed, and over whom he gained many advantages, signally enhanced his own reputation; for, after having baffled in his youth the enterprises of the renowned duke of Parma, Alessandro Farnese he found,

in his later career, another worthy opponent, in the equally famous Italian, Spinola, who had succeeded to the command of the Spanish forces. Under such leaders, the operations of the hostile armies in the Netherlands riveted the attention of the world; and the camp of Maurice, as well as that of Parma and Spinola, being thronged with volunteers of distinction from every quarter of Europe, became the great school of military instruction.

The cessation of hostilities exhibited the qualities of Maurice in a less favourable light. He had laboured from selfish views to obstruct the conclusion of the truce with Spain, and was successfully opposed in these and other ambitious designs upon the liberties of the republic, by the pensionary Barneveldt, a man of real patriotism, eminent ability, and incorruptible integrity. But the religious disputes, which arose in the republic at this juncture between the Calvinists and Arminians, enabled Maurice to revenge himself upon the pensionary. Barneveldt being attached to the Arminian opinions, Maurice placed himself at the head of the opposite faction, the Calvinists, or Gomarists, as they were called after Gomar, the professor of theology at Leyden, who had been the antagonist of Arminius. As the Gomarists composed the great mass of the people, that party at length prevailed; the Arminian preachers were banished; and, in 1619, at the age of seventy-two years, the virtuous and venerable Barneveldt, who had for nearly half a century served the republic as successfully in the cabinet as Maurice had done in the field, was, by the machinations, and to the eternal dishonour of that prince, brought to the scaffold after being convicted on various false charges, of which the principal was, that he had 'troubled the state and religion.'

[BARNEVELDT]

The stadtholder, who by the decease of his elder brother had succeeded, in 1618, to the principality of Orange, gained little by his persecution of Barneveldt. After the death of the pensionary, the people awoke to a sense of their injustice and ingratitude to that patriot; and his oppressor Maurice suddenly became as hateful and suspected in their eyes, as he had hitherto been popular. His designs of acquiring the sovereignty of the states were perceived and frustrated; and whenever he appeared in public, groans and execrations pursued him as the murderer of Barneveldt.

The resumption of hostilities with Spain, at the expiration of the truce in 1621, turned the tide of public indignation; and Maurice again appeared in arms to measure himself against his old antagonist Spinola. The fortune of the contest however between these two great commanders was now so nicely balanced, that it would be difficult to assign the palm of victory to either. In 1622 Maurice compelled the wily Genoese to raise the siege of Bergen-op-Zoon, after having expended on it the lives of ten thousand of his veteran troops: but three years later, Spinola succeeded in reducing Breda, notwithstanding all the efforts of Maurice, and so much to his mortification, that the circumstance is believed to have produced or hastened his death, which occurred on the 23rd of April, 1625, and in the fifty-eighth year of his age. He left no legitimate offspring, and was succeeded, both in the principality of Orange and stadtholdership of the United Provinces, by his half-brother, Frederic Henry.

The character of Maurice of Nassau was favourably distinguished only by military genius. As a statesman he was without the sagacity and prudence of his father; as a man, in his treatment of Barneveldt and his family, he showed himself devoid of honour and humanity; and the violence and grossness of his nature were redeemed by no virtue of private life. But, as a general, he must ever be numbered among the greatest masters of his art, and may, in fact, be regarded as the founder of the military science of modern Europe. He was at least the earliest restorer among the moderns of the true principles of warfare, which he had deeply studied in the enduring lessons of classical antiquity, and as carefully applied to the exigencies of his own times. He was the first to methodise the practice of sieges, encampments, and marches; and he introduced numberless reforms in the armament, training, and formation of troops. He taught a cavalry of inferior physical weight to engage in close encounter, and to overthrow the ponderous masses of the old general armie; he first accustomed the infantry to a systematic management of their arms; and to his institutions must be referred that uniformity of exercise and regularity of movement which have become the simplest elements of martial discipline. To this may be added, that

the celerity, as well as good order of his marches, the able arrangements by which he husbanded the lives and health of his troops, and the felicitous skill with which his camps were chosen and secured from assault, are the constant subjects of contemporary eulogy. He excelled particularly in the art of fortifying, besieging, and defending places; and, as the circumstances and localities of the contest in which he was engaged rendered such operations less perilous for the States than the hazard of decisive encounters in the field, his successes were gained more by a war of sieges, marches, and entrenched camps, than of great battles. But the victories of Turnhout and Nieuport were not the less the triumphs of his tactical system. Those actions were the first important defeats inflicted upon the Spanish bands, who had so long been the terror of Europe; and it was in the school of Nassau that the fundamental rules of military science were established, which, within less than half a century, finally prevailed over the slow and cumbrous array of the Imperial and Spanish service, in the plains of Lutzen and Rocroi.

III.—WILLIAM III. of NASSAU, Prince of Orange, stadtholder of the United Provinces, and ultimately king of England,—the great champion of the civil and religious liberties of Protestant Europe,—was born in the year 1650, and was the posthumous son of William II. of Orange, by Mary, daughter of Charles I., king of England. As William II. was the eldest son of the stadtholder Frederic Henry, who was the youngest son of William the Silent, by Louisa, daughter of the famous admiral Coligni, William III. was great-grandson of the founder of the Dutch republic, and was also lineally descended, in the female line, from the renowned leader of the Huguenots. Not only had a father's care been denied to the birth and infancy of William III., but his youth was destined to suffer for the errors of his parent. The stadtholder Frederic Henry, unlike his brother Maurice, had administered his office without attempting to violate the liberties of the republic, or giving umbrage to the jealousy of the States: but his son William II., even in the brief career which was cut short by death in his twenty-fourth year, contrived, by his violence and infringement of constitutional rights, to revive public suspicion of the designs of his house against the freedom of the commonwealth; and the party opposed to the Orange interest took advantage of the helplessness of his infant son to prevent his succeeding by election to the dignity of stadtholder, which had become, as it were, hereditary in the line of Nassau. The alliance of that family with the house of Stuart had also excited the jealousy of Cromwell, whose power was now in the ascendant; and, when peace was concluded between the two republics of England and the United Provinces, in 1654, the imperious demand of the protector, that all the states should solemnly engage to exclude the infant prince of Orange and his descendants prospectively from the stadtholdership, was only satisfied by a secret engagement to the same effect, to which Holland, as the leading province of the Union, disgracefully acceded.

The restoration of the Stuarts to the British throne, in a few years, tended however at once to raise the hopes of the adherents of the house of Orange, and to increase the inquietude of their opponents; and, in 1667, the republican or aristocratic party, headed by the two celebrated brothers, John and Cornelius de Witt, succeeded in inducing the States to pass the 'Perpetual Edict,' for ever abolishing the office of stadtholder. But the iniquitous aggression of the French king, Louis XIV., upon the republic in 1672, soon put an end to the operation of this edict. However pure might have been the intentions of the De Witts, their measures had left the republic defenceless. Confiding in the friendship of France, and distrusting the best officers of the army, as devoted to the House of Orange, they had, by reductions and neglect, so weakened the land forces of the republic, that resistance to the invaders seemed hopeless. The Orange party were loud in their clamours against the administration of their rivals; and the populace, who had always been favourable to the family of Nassau, were instigated to revolt. Their fury was directed against the De Witts, whom they murdered with horrid barbarity; and the young prince of Orange was tumultuously raised to the proscribed dignity of stadtholder.

William III. was only in the twenty-second year of his age when he was thus suddenly called to the government of a factious and distracted state, a lawless populace, and a dispirited and disorganized army. With such means was

he required to arrest the progress of the victorious king of France at the head of a veteran army of 100,000 men, aided by the best generals of the age, and supported by the whole power both of his own crown and of that of England, which the baseness of Charles II. had rendered subservient to his ambition. But, happily for his country and the world, William at once displayed the same characteristics of a firmness and sagacity far beyond his youthful years, which seem to have been the heir-looms of his race, and equally to have distinguished him with his great ancestors William the Silent and Maurice. He indignantly repelled all the efforts of the combined kings of England and France to seduce him from the cause of the republic; and when Buckingham, the favourite of Charles II., asked him if he did not see that the destruction of the commonwealth was inevitable, he replied, 'There is one means by which I at least shall be sure not to witness the ruin of my country: I will die in the last ditch.' His magnanimous spirit he knew how to infuse also into his despairing countrymen, who cut the dikes of their lands, and resigned the fertile fields, which their ancestors had rescued from the sea, to the ravages of that element, rather than yield them to their invaders. The example of their young leader taught them to spurn the insolent demands of their enemies; and it appears among the miracles of history, that, in two short campaigns, the French armies, which had overrun the United Provinces, and penetrated almost to the gates of Amsterdam, were entirely driven out of the territory of the republic. In 1674, the young prince of Orange even dared every measure to bring the veteran Condé to a battle; and, though he suffered for his temerity at Seneffe, he so nobly conducted himself in that defeat as to extort from his illustrious opponent the generous avowal that 'he had acted in everything like an old captain, except in venturing his life too much like a young soldier.'

During the remainder of the war, which, after a separate peace between England and the States, was protracted with France for four years, and concluded by the peace of Nimeguen in 1678, William continued to give abundant proofs both of his political and military talents; and, shortly before the close of hostilities, he had effected a personal alliance, which largely influenced the fortunes of his subsequent life. This was his marriage with his cousin Mary, eldest daughter of James, duke of York, and heiress presumptive to the British crown. It is not easy to comprehend the readiness of Charles II. to adopt a measure so contrary to his usual policy and inclinations as this union of the princess with William, who, though his nephew, had thwarted his designs and offended his wishes by his maintenance of the republican cause. But dread of the growing discontents of his people, and a belief that the marriage would dispel the suspicions excited by his brother's religion, are supposed to have been motives sufficient to obtain his consent; and he invited or permitted his nephew to pay him the visit in England during which the alliance was concluded. To William the union presented obvious advantages: yet he honourably declined any proposals on the subject until he should be allowed to make the acquaintance and ascertain the inclinations of the princess; and this disinterestedness was not without its reward in the harmony which distinguished the course of his domestic life with his consort.

Neither the prince of Orange nor Charles II. and his brother probably foresaw all the consequences of this union to the politics of Europe. But no event of William's fortune contributed so essentially to the furtherance of that great design which had become the master passion of his mind—the reduction of the tyrannical power of Louis XIV. and the security of the liberties of the Protestant world. To these great objects, from the first hour in which he had been called to the defence of his country, his whole life was consistent; and in whatever degree motives of personal ambition, whether unconsciously to himself or otherwise, were mingled in his plans, he never appears to have suffered any consideration for an instant to interfere with his pursuit of the great cause to which he had devoted himself. Many circumstances contributed to place him at the head of the general league, provoked by the aggressive power of Louis XIV., in resistance to which his first glory had been won. The revocation of the Edict of Nantes, in 1685, by that monarch, and his persecution of his Protestant subjects, had justly alarmed and outraged all their European brethren of the same faith; the insolent pretensions of Louis

had given mortal offence to the emperor and king of Spain; the apprehensions which experience had taught the United Provinces to entertain of the projects of the French king naturally rendered the court of their stadtholder the centre of negotiations against him; and various causes of hatred and fear enabled William to combine the States themselves and the Protestant princes of Germany, with the two Roman Catholic monarchs of the house of Austria and other powers, in the celebrated league which was concluded against Louis XIV. at Augsburg, in 1687. To the completeness of that great European confederacy nothing was wanting but the accession of England; and this was obtained, in the only manner which the alliance of her new king, James II., with France rendered practicable, by his insane attempt to overthrow the national faith.

Ever since his marriage, William had studiously abstained from taking part in the struggle of parties in England; and though, through his activity in thwarting the schemes of the French king, he had not been able to escape the displeasure of his uncle Charles II., he had lived on decent terms with his father-in-law, and since his accession had proffered him aid in suppressing the rebellion of the duke of Monmouth. But when he publicly refused to support the repeal of the Test Act, James began both to treat him as an enemy and to take injurious measures against the United Provinces; and, on the other hand, all the English Protestants turned their eyes to the prince of Orange for the protection of their liberties and faith. On the invitation of the principal persons both of the Whig and Tory parties, William was at length induced to undertake an expedition into England for the restoration of the national rights; and having arranged his preparations with consummate skill, he sailed from Holland with an army of about 14,000 men, composed partly of Dutch troops and partly of English regiments in the service of the States, and landed at Torbay, on the 5th of November, 1688.

This interference of William in the domestic politics of England has been variously viewed by opposite parties, as the most glorious, or the most questionable act of his life. But it cannot be denied that it was in perfect consonance with the whole tenor of his principles and his policy. The measures of James II. struck at the very existence of the Protestant faith; and their success might have been fatal also to the cause of civil freedom in Europe, to which William was equally attached. The birth of a male heir to the crown of England, by James's marriage with a princess of the Roman Catholic communion, may have quickened the zeal of William; and the double injury to his wife's title, consequent upon a prior right and a Roman Catholic succession, doubtless had its influence upon his mind. Yet there is no reason to discredit his sincere anxiety for the Protestant cause, which without these interested motives might assuredly have prompted his enterprise. The dethronement of a father-in-law has sometimes been imputed to him as a deed of unnatural guilt; and, if the affections of private life were usually permitted to have sway in the breasts of princes, it would not be easy to justify William in having made his wife an accomplice in the expulsion of her father. But he had himself personally little reason to love James, who had reluctantly received him as a son-in-law, and never cordially courted his friendship or gratitude; nor had there at any time been circumstances of private regard between them to outweigh considerations of public duty or personal interest.

The landing of William in Torbay was followed, after a few days of hesitation, by an almost total defection of James's English subjects from their allegiance; and with unparalleled ease and rapidity was that memorable and bloodless revolution effected which changed the royal line and firmly established the constitution of these realms. For once all parties and orders of men in the nation, except a very small minority of Roman Catholics, peaceably concurred in the necessity for a change of government; and when the betrayed and misguided king fled to France, the most opposite principles of passive obedience and popular rights were strained to the same practical conclusion, that James II. had either deserted or forfeited the throne. The all-important question, in what manner the vacant regal seat should be occupied, terminated the short-lived concord of factions. But William, whether moved in part by a mere selfish ambition, or wholly by a better conviction of the public exigencies of the crisis, at once cut short all schemes of the high monarchical party for restricting his functions to

a regency, either on behalf of his wife or her infant brother. He declared that, except as king, he would not remain in the country. This decisive language hastened the proceedings of the convention parliament, which William had composed of the peers, the surviving members of the three last houses of commons, and the corporation of London; and in the famous Act of Settlement passed by that body, the crown, with constitutional limitations to its power, was conferred jointly upon the prince and princess of Orange, with remainder successively to the issue of the latter, to the princess Anne and her children, and to the heirs of William by any other wife.

Notwithstanding the ease with which William III. thus acquired the British crown, he was soon compelled to contend in arms for its preservation. In Scotland the cause of James was upheld by the gallant viscount Dundee, but perished with his fall in the brief moment of victory. In Ireland, the struggle maintained by James's Roman Catholic adherents was more obstinate; but William in person inflicted on them a memorable defeat at the passage of the Boyne in 1690; and the capitulation of Limerick in the following year completed the submission of Ireland. Meanwhile William had the satisfaction, the greatest probably which his new dignity gave him, of engaging England in the League of Augsburg. The war of that confederacy against Louis XIV., of which the principal conduct was intrusted to William, had indeed little success; for though possessed of considerable military talents, he wanted that good fortune which the ancients numbered among the most indispensable attributes of a great general; and he sustained in the course of this struggle two severe defeats from the French under the duke of Luxemburg at Steenkirk and Neerwinden. By the peace of Ryswick, which terminated the war in 1697, little more was gained from the French monarch by the allies than the recognition of William III. as king of England.

The possession of that throne had meanwhile given him little happiness. Though almost all the nation had at first concurred in the Revolution of 1688, the tory and high church party were in general indisposed to the pretensions and person of the new king. The Whigs were still full of jealousy of the royal power; and the cold reserved temper and ungracious manner of William disgusted and alienated the minds of his subjects in general. His most favourite schemes were continually thwarted in parliament; his whole reign was harassed with intrigues of faction and plans of insurrection at home; and his life and throne were assailed from abroad with base plots of assassination by the adherents of James II., and with projects of invasion undertaken by Louis XIV. for the restoration of the dethroned king. To add to the distresses of William, he experienced in 1695 a severe domestic calamity in the loss of his queen-consort Mary, to whom he was deeply attached. Her decease, as she left no issue, terminated all claim of her husband to the crown in the eyes of that part of the nation who had been reconciled to his government by the semblance of hereditary right in her participation of the throne. His measures now experienced systematic opposition from all parties: from the Jacobites, as the partisans of the exiled monarch were termed, who of course regarded him as a usurper; from the Tories in general, to whom he was personally obnoxious; and from the Whigs and republicans, who desired in various degrees to lower or annul the royal power. The first use therefore which was made in parliament of the peace of Ryswick was to compel him to reduce the army to an insignificant remnant of guards and garrisons, and to send out of the kingdom the regiments of French Protestant refugees, as well as his own Dutch guards; and these and other mortifications had such an effect upon his mind as to extort from him a passionate expression of his regret that he had interfered in the affairs of a nation at once so ungrateful and so suspicious.

From the annoyances of his position in England, he sought relief by renewing with more ardour than ever his attention to the affairs of Europe, and by pursuing his favourite project for humbling the power of the French king, which the precarious health of Charles II., the childless monarch of Spain, and the pretensions of the house of Bourbon to the inheritance of his dominions, threatened to render more dangerous than ever. To avert these impending evils to the balance of power in Europe, William successively negotiated two treaties of partition for the Spanish monarchy, to both of which Louis XIV. was an artful and

faithless subscriber; for when the Spanish king, in indignation that other powers should dismember and distribute his dominions, bequeathed them at his death, in 1700, to Philip duke of Anjou, second son of the dauphin, Louis XIV., in spite of every obligation of treaties, accepted the testament for his grandson.

William III., now in declining health, was sensibly affected by this defeat of all his labours: but he applied himself with his usual energy to form a new league against France; and the insulting conduct of Louis XIV. at this crisis, in giving the son of James II., on the death of that prince, the title of king of England, so exasperated the British nation, that they eagerly seconded William's wishes for a war. But, in the midst of eager preparations for the commencement of hostilities, William's life was suddenly brought to a close. His constitution, originally frail and sickly, had now been completely exhausted by a career of incessant and harassing anxieties. An accidental fall from his horse, by which he broke his collar-bone, gave a fatal shock to his worn-out frame; and he expired at Kensington palace, on the 8th of March, 1702, in the fifty-second year of his age.

With the death of William III. the male line of William the Silent became extinct; and the states-general were not sorry to leave the stadtholdership vacant, and tacitly abolished. But William had named for his personal heir his cousin John William Friso, prince of Nassau-Dietz (grandson of his aunt Albertina Agnes by William Frederic of Nassau-Dietz), from whom the present royal line of Orange is descended. The following has been the succession of the princes of this house:—

William (IV.) Henry Friso, son of John William Friso, born in 1711; married Anne, daughter of George II. of England; was raised by the Orange party to the stadtholdership in 1747, and died in 1751.

William (V.) Batavus, son of William IV., born in 1748, was declared stadtholder (under the guardianship of his mother) in 1751; was expelled by the French in 1795, renounced the dignity of stadtholder by treaty with France in 1802, and died in 1806.

William (VI.) Frederic, son of William V., born in 1772, was restored to the dignities of his family in 1813, was proclaimed king of the Netherlands under the auspices of the Congress of Vienna in 1815, and still survives; having two sons, the eldest of whom, William Frederic Charles, prince of Orange, has also male issue.

(The principal authorities consulted for the preceding sketch of the most illustrious members of the house of Nassau are—*La Généalogie des Illustres Comtes de Nassau*, Amst., 1624; *Commentaries of Sir Francis Vere*, Cambridge, 1657; *Grotius, Annales et Historiæ de rebus Belgicis*, Amst., 1658; *Le Clerc, Histoire des Provinces Unies*, Amst., 1723-28; *Burnet's History of his own Time*; *Hume and Smollett's History of England*, &c.; and *L'Art de Vérifier les Dates*, Paris, 1818-19.)

NASTURTIUM, an old word applied to some kind of pungent herb, such as cress. By the English of the present day it is given to the *Tropæolum majus*, an American annual with pungent fruit; by botanists, to the *Watercress* and plants allied to it; by the Romans it was applied to a plant resembling Mustard in its qualities.

NA'SUA. [URSIDÆ; VIVERRIDÆ.]

NATAL, THE COAST OF, extends along the eastern side of Africa from the boundary-line of the Cape Colony, which, since the last war with the Amakosas, is formed by the Kei river (32° 30' S. lat.), to Dalagoa Bay (26° S. lat.), and constitutes the shores of Kafferland. Along the sea it is low, and in many parts swampy. Some of these swampy grounds extend far inland, especially towards Dalagoa Bay; but in general the country begins to rise within a few miles from the sea. The rise is rather rapid, for some miles farther inland the country is said to have an average elevation of 500 or 1000 feet above the sea level, and to present the appearance of a hilly plain, here and there covered with swamps, but mostly intersected by narrow deep valleys, through which the rivers run to the sea. The declivities of the hills are partly covered with forests and bushes, and partly bare and red owing to the iron ore which they contain. The numerous rivers and mountain torrents after rains sometimes rise to an astonishing height, and their waters fill up the narrow valleys through which they rush with terrific violence. As all the rivers abound in cataracts, and alternate depths and shallows, they are

not navigable except for a few miles from the mouth. Nearly all of them have a huge sand-bank at their entrance, which prevents all access, and renders them useless as harbours even for small vessels. Most of the rivers have also a comparatively short course, as they rise in a high and continuous ridge of mountains, which runs parallel to the shores of the sea at the distance of about 80 miles. The elevated country mostly serves as pasture-ground, and is always covered with grass, as a want of rain is seldom experienced there, except towards the southern extremity, where the country frequently suffers from continual drought. During the summer months the grass is generally brown and dry, and towards the end of the dry season it is burnt by the natives, in order that the cattle may enjoy the new and tender herbage which comes after the first rains. On these elevated grounds there is generally a cool and refreshing breeze, but in the villages which are built in the deep valleys the heat in the dry season is extremely oppressive. The soil is rich, especially on the flats near the margin of the rivers, and along the hill-sides, where the natives cultivate pumpkins, melons, a species of millet, maize, sweet potatoes, and tobacco. The missionaries have introduced grapes, figs, oranges, lemons, apricots, peaches, nectarines, and some other fruits, as well as several kinds of vegetables, which in many places grow luxuriantly. The domestic animals are horned cattle, goats, and a few horses; some tribes possess also sheep. For further particulars see CAFFRARIA. (Stedman's *Southern Africa*.)

NATIONAL ASSEMBLY. [MIRABEAU.]

NATIONAL DEBT. It will hardly be questioned that if we were to bring into account the wealth possessed by her citizens individually, England would be found, beyond all comparison, the richest country in Europe. The amount of her public debt, on the other hand, so infinitely beyond the public engagements of any other state, would seem to indicate that, considered apart from that individual wealth, England is poorer than the poorest among nations. It must not however be for one moment admitted that the public burthens of the country are ever to be considered in that light. The debt is owing by the aggregate of the people—*by the nation*—for whose benefit, real or supposed, it was legally contracted. It suits the general convenience, including that of the public creditor, that the nation, in its aggregate sense, should thus continue to exhibit signs of poverty in contrast with the evidences of enormous wealth; but if it were otherwise—if the public convenience, still more if the public safety, demanded such a course, the same authority which sanctioned the contracting of the debt could also oblige each individual in the country to contribute according to his fair proportion and his means towards its extinction. It would be difficult to imagine any circumstances that could render such a course expedient, and the position has been here advanced solely with the object of explaining, in a familiar way, the nature of the debt, and the manner in which the obligation to bear the burthen and contribute towards upholding the national faith presses upon every individual in the community. There is in truth no one, however high or however low his station in the country, excepting only those whose whole subsistence is drawn from *elemosynary* sources, who can be said not to bear a part towards this upholding of the public faith. Every one therefore is interested in forming a correct idea concerning a matter which exercises an influence upon every act and circumstance that affects his social position and progress. This being the case, one cannot help feeling surprised at the crude and fallacious ideas that are generally entertained on the subject. It is by no means uncommon to find, among even educated persons, the impression that the national debt is a fund, a deposit of treasure, a sign of national riches; anything in short opposed to that which it really is, namely, a drawback upon the national wealth, a mortgage of the national industry for the payment of a perpetual annuity in return for capital advanced to meet the national exigencies, and which has been expended or consumed for national objects. It has been said, that as this debt, or by far the largest part of it, is owing among ourselves, it cannot have any prejudicial effect upon the national interest, since that which a body owes to its own members cannot be held in the light of a

debt, and may be considered as though it had no existence. It certainly says more for the national resources that its public expenditure, including its debt, has been furnished by its own citizens rather than borrowed from strangers, and that our future industry is therefore not mortgaged to strangers, but that the portion of its fruits which must be set apart for the public creditors will remain at home to afford a fresh stimulus to that industry in time to come. It will nevertheless easily be made apparent how the successive absorption of private capital for public purposes must prove injurious to a country, if we consider what must have been the condition of England, if, instead of thus absorbing a part only, the whole of the disposable wealth of her individual citizens had been so expended. It might still have been said, that as what was taken from all in the form of taxes was returned to a part in the form of dividends, the money did not leave the country; and that although of course it must affect the condition of individuals, it would not affect the condition of the aggregate. But, it must be asked, where, in the case supposed, would have been the capital that must set in motion the springs of industry and enable the payment of taxes? It is indeed evident that in such case the country must have long ago become bankrupt, and have been unable to hold any rank among independent nations.

It is not intended further to pursue the inquiry as to what might have been the result to the nation of any circumstances different from those actually existing, but rather to explain what those actual circumstances are, and to suggest rather than to follow out to their ultimate effects their bearing upon the public prosperity. It seemed necessary however to mention and to combat some of the fallacies by which the question of our public debt is beset, and to show wherein it agrees and on what points it differs in its nature from the debt of an individual. That difference in fact consists in the compound character of the creditors, who as members of the nation are legally and morally bound to contribute towards the maintenance of the public faith, while they have each a personal interest in its preservation. In its practical operation, there is this further distinction to be drawn between the debts of the nation and those of individuals, that the state has at all times the right to pay off its creditors at par, while the latter have no right to demand repayment of the principal money they have advanced, but must content themselves with receiving half-yearly the amount of their annuity.

Before proceeding to give an historical sketch of the progress of the national debt, it may be as well to mention one other fallacy which has been often broached of late years by a small and happily an unimportant party in the country, namely, that the general prosperity of the state would be advanced by the abolition (unsatisfied) of the public debt; and as in all matters of public policy the prosperity of a great majority should be considered before that of a part, a sound policy requires that faith should no longer be kept with the public creditor. The proposition is here put in plainer terms perhaps than its advocates would use, but this is the substance of their argument.

It has been shown that the money in respect of which the claims of the public creditors have arisen is spent, and that those creditors being part of ourselves, living and expending their incomes among us, the evil effects of the debt are limited to the loss of the capital which otherwise would have formed part of the national wealth, giving additional rewards to industry, and adding in various ways to the sum of our material enjoyments. But the capital thus lost has all been advanced in times of necessity, in full faith that the conditions promised would be performed by the borrowers under all possible circumstances; and it would indeed be a day of disgrace that should sanction the securing of any advantage, however great, through the dishonest breach of those conditions. But would any such advantage as has been supposed follow from so dishonest a step? Those who contend that the great majority of the nation would be benefited by the unsatisfied extinction of the national debt, and would urge its extinction on this ground, as being precisely the same ground on which many enactments are made, ought to show that the loss occasioned by such extinction will be confined to the immediate losers, to the comparatively small number of public creditors. But it is easy to show that the loss would not be confined to the immediate losers; and this being the case, it is impossible to prove that such extinction will really benefit a great

majority. It might happen that it would in its results benefit only a small minority of the actual generation, or even nobody at all; and the allegation of this possible result is a sufficient answer to the assumption made by the advocate of unsatisfied extinction, that the loss incurred would be confined to the immediate losers, and that there would be a real gain to the great majority of the nation. Such an unsatisfied extinction would in effect be a dissolution of innumerable contracts, on the faithful performance of which depends the happiness of many thousands who are not public creditors. It is hardly necessary to remark that the nation would not afterwards find it easy to borrow money from individuals on any reasonable terms for any purpose, however generally useful, or any public necessity, however urgent.

The contracting of the National Debt cannot be said to have been begun before the Revolution of 1688. The kings of England had indeed been accustomed from a remote date to borrow money upon emergencies, but on such occasions the revenues of the crown were pawned for the amount, which was seldom beyond what could by that means be repaid in a few years. The earliest instance of this borrowing which we have on record was in the reign of Richard I., when money was wanted to defray the expense of his crusade to the Holy Land. Even for some few years after the accession of William and Mary the borrowings of the government were for short periods only. The first transaction of this kind of a permanent character arose out of the chartering of the Bank of England in 1693, when its capital of 1,200,000*l.* was lent to the public at 8 per cent. interest. A power of repayment was reserved on this occasion by the crown, but no corresponding right of demanding payment existed on the part of the bank.

So cautious was the parliament in those days of burthening future generations for the exigencies of the present moment, that when the annual income was inadequate to meet the charges of the foreign wars in which the country was engaged, and it became necessary to borrow the deficiency, annuities were granted, not in perpetuity, but for lives and terms of years, the produce of certain duties being mortgaged for their discharge.

This cautious proceeding could not be long continued. The expensiveness of the wars in which the nation was engaged at the end of the seventeenth century made it necessary to incur debts beyond the means of their prompt redemption, and at the peace of Ryswick, in 1697, the debt amounted to 21½ millions. During the next ten years, although the country was again involved in a continental war, its amount was reduced to little more than 16 millions, and the greatest efforts were made to raise money without imposing any lasting burthen on the people. These efforts indeed soon found their limit, and at the accession of George I. in 1714, the debt had accumulated to the amount of 54 millions, an amount which excited great uneasiness and caused the House of Commons to declare itself under the necessity of making efforts for its reduction. In 1717 the debt amounted to 48½ millions, and the annual charge in respect of the same to 3,117,296*l.* A great part of this debt consisted of annuities granted for 99 years, the money obtained for which had varied from 15 to 16 years' purchase.

In the year 1720 the South-Sea Act was passed, authorising the company to take in, by subscription or purchase, the redeemable and unredeemable debts of the nation, the object being to reduce all the debts under one head of account at one uniform rate of interest. In the accomplishment of this scheme the projectors only partially succeeded, while the disgraceful frauds by which the proceedings of the company at that time were marked, led to a parliamentary investigation which caused the disgrace of some of the ministers, the chancellor of the exchequer being expelled the House, and committed to the Tower for his share in the plot. It is not the least remarkable circumstance attending this scheme that it was attempted at the same time with the equally famous Mississippi scheme, which, with a similar object, was projected in France by John Law, under the sanction of the Regent Duke of Orleans. [LAW, JOHN.]

In 1736 the public debt of England amounted to about 50 millions, but the annual charge had been reduced below two millions. At the peace of Aix-la-Chapelle, in 1748, the national debt exceeded 78 millions, but in the following year the public obtained some relief from the burthen through the lowering of the rate of interest. Little else was done in

the way of alleviation at this time, and at the breaking out of the Seven Years' War, in 1756, the debt still amounted to 75 millions. A public writer of some repute, Mr. S. Hannay, says, at that date, 'It has been a generally received notion among political arithmeticians, that we may increase our debt to 100,000,000*l.*, but they acknowledge that it must then cease by the debtor becoming bankrupt.' Those who in more recent times have witnessed the addition year after year to the debt of sums equal to more than the difference between its then amount and its declared limit, may smile at this prediction, and learn to put little faith in opinions which are not based upon previous experience.

When the Seven Years' War was ended by the peace of Paris, the debt reached 139 millions and the annual charge was 4,600,000*l.* During the twelve following years, a period of profound peace, only 10,400,000*l.* of the debt was discharged. The war of the American Independence raised the debt from 129 to 268 millions, and the annual charge in respect of the same to 9,512,232*l.* So little was done in the way of liquidation during the following ten years, that at the beginning of the war of the French Revolution the debt still amounted to 260,000,000*l.*, and its annual charge to 9,437,862*l.* The outlay occasioned by the prosecution of that war was great beyond all precedent. Between 1793 and the peace of Amiens the addition made to the capital of the debt amounted to 360 millions and the annual burthen was increased from 9,437,862*l.* to 19,945,624*l.* Between the recommencement of the war in 1803 and its termination after the battle of Waterloo in 1815, there were added 420 millions to the capital of the debt, which then amounted, including the unfunded debt, to 885 millions, and the annual charge upon the public exceeded 32 millions of money. This enormous, this frightful rate of progression, appears to have excited far less alarm than was expressed at the comparatively trifling additions made at the beginning of the funding system, a consequence which probably must be in great part attributed to the establishment of the sinking fund, and to the hope which it held out of cancelling at no very distant period each amount of debt successively increased.

A plan for the gradual extinction of the national debt by the establishment of a sinking fund was proposed and partially applied in 1716 by Sir R. Walpole. The scheme for that purpose proposed under the same name by Mr. Pitt in 1786 had a greater show of reality about it. By this scheme the sum of one million was annually set apart from the income of the country towards the extinction of its debt. Other sums were rendered accessory to the plan, and it was supposed that at the expiration of 28 years the annual income of the sinking fund would amount to four millions, a part of which might then be applied towards relieving the burthen of the public. So far the project bore the stamp of reasonableness and prudence: had the fund of one million annually assigned to commissioners been an actual surplus of income over expenditure, its operation must speedily have been highly advantageous to the country. The fallacy consisted in this, that the sums devoted to it were borrowed for the purpose. The only real advantage secured by this means arose from the unfounded confidence which it imparted to the public, under which they willingly bore a higher rate of taxation than might have been tolerable but for the expectation of future relief through its means. Now that the absurdity is acknowledged of borrowing in order to pay off debt, which absurdity would in the case of an individual always have been apparent, it is difficult to account for the blindness with which the whole nation clung to this so-called fund as the certain means of extinguishing the debt which in effect it contributed to augment through the less advantageous terms upon which the money was borrowed than those upon which an equivalent amount of debt was afterwards redeemed. The difference between the average rates at which money was borrowed and at which purchases were made by the Commissioners who managed the sinking fund between 1793 and 1814 was such, that through the operations of the fund, upon which such confident hopes of relief was placed, the country owed upwards of 11 millions more at the end of the war than it would have owed but for those operations. At the period just mentioned the annual income of the sinking fund amounted to 13,400,000*l.*, arising from dividends on stock purchased by the commissioners with funds borrowed at a higher rate of interest for the purpose. It was impossible however during a time of peace to

raise by means of taxes so large an amount, in addition to the actual current expenditure of the country and the interest upon the unredeemed portion of the debt. During the war, when the deficiency of income was covered by yearly loans, the fallacy was not quite so apparent as it now soon became, for a few years after the peace the deficiency in the public income was borrowed from the sinking fund commissioners by parliament, a course which served to render the absurdity only the more apparent, and in 1824 the plan of keeping up a large nominal sinking fund in the absence of actual surplus income was abandoned.

The amount of the National Debt unredeemed on the 5th of January, 1816, was stated to be as follows in the fourth Report of the select committee of the House of Commons on public income and expenditure:—

3 per cent. stock	£580,916,019
3½	10,740,013
4	75,725,504
5	148,930,403
Perpetual annuities	816,311,939
Terminable annuities, 1,894,612 <i>l.</i> , equal to an estimated capital of	30,080,347
Unfunded debt	38,794,038
Total of unredeemed debt	£885,186,324

The annual charge upon which was:—

Interest upon perpetual annuities	£28,278,919
Terminable annuities	1,894,612
Interest on unfunded debt	1,998,937
Charge for management paid Bank of England	284,673

Total annual charge £32,457,141

The experience of the last twenty-five years has proved that the only important relief from the pressure of debt to be obtained, even during a profound and long-continued peace, will probably be derived from the lowering of the rate of interest. The price of 5 per cent. stock at the beginning of 1822 was advanced to 6 or 8 per cent. above par, and advantage was taken of this circumstance to induce the holders to exchange each 100*l.* of 5 per cent. annuities for 105*l.* of 4 per cent. annuities. On this occasion 140,250,828*l.* of 5 per cent. stock was cancelled, and 147,263,328*l.* of 4 per cent. stock was created, the annual charge being by this means reduced by the sum of 1,122,000*l.* In 1824 a further saving of 361,034*l.* per annum was effected by reducing to 3½ per cent. the interest payable on 76,206,882*l.* of 4 per cent. stock; and in 1830 a further abatement of one-half per cent. was effected on the 4 per cent. stock created in 1822, whereby the sum of 700,000*l.* per annum was saved to the public.

Some little progress has been made since 1816 in the reduction of debt by the employment for that purpose of actual surplus revenue. An addition has on the other hand been made to the public burthens by means of the grant of 20,000,000*l.* voted by parliament for compensation to the owners of slaves in the British colonies who were emancipated by the act of 1833. The unredeemed funded and unfunded debt which existed on the 5th January, 1839, and the annual charge thereon, was as follows:—

3 per cent. annuities	£508,360,605
3½	249,922,566
4	1,615,385
5	1,449,134
Perpetual annuities	761,347,690
Terminable annuities, 4,292,173 <i>l.</i> , equal to an estimated capital of	68,145,907
Unfunded debt	24,026,050

Total of unredeemed debt £853,519,647

The annual charge upon which was:—

Interest on perpetual annuities	£24,136,180
Terminable annuities	4,292,173
Interest on unfunded debt	720,928
Charge for management	158,150

Total annual charge £29,306,431

The diminution of the annual burthen in the course of twenty-three years, from 1816 to 1839, has thus been

3,150,710*l.*, at which rate the total extinction of the debt would not be effected until the year 2053. The slow progress made in this direction stands in striking contrast to the rapidity with which the load was accumulated, the entire diminution effected during twenty-three years of peace being scarcely equal to the additions made during some of the individual years of the war.

It will be seen, on comparing the above statements for 1815 and 1839, that the terminable annuities have increased from 1,894,612*l.* to 4,292,173*l.* By the act 48 Geo. III. and several subsequent acts, the commissioners for the reduction of the National Debt were empowered to grant annuities, either for lives or for certain terms of years, the payment for such annuities being made in equivalent portions of permanent annuities, which were therefore to be given up and cancelled. By this course, which it will be seen has been acted upon to some extent since the peace, some future relief will be obtained at the expense of a present sacrifice. This plan, provided it be not carried so far as to interfere with the onward progress of the country, through an overload of taxation, appears to be dictated by sound prudence. A part of the terminable annuities (nearly one-half their present amount) will expire in 1860, and after that time portions will rapidly fall in; so that without looking to any redemption of debt from surplus income, or to any further reductions in the rate of interest, the next twenty-three years will be productive of nearly as much relief as has been obtained since 1816.

If this course of proceeding is justly characterised as prudent, what must be said of the scheme of a directly opposite tendency which was brought forward and partially carried into effect by the government in 1822? When the measure for commuting the half-pay and pensions usually denominated the 'dead weight' was adopted in that year, the annual charge to which those obligations amounted was about five millions. From year to year the public would have been relieved from a part of this burthen through the falling in of lives, until, according to the most accurate computation, the whole would have ceased in forty-five years. The measure above alluded to was an attempt to commute these diminishing payments into an unvarying annuity of forty-five years certain; and the calculation which was made assumed that by the sale of such a fixed annuity of 2,800,000*l.*, funds might be procured enough to meet the diminishing demands of the claimants. Only a part of this annuity was sold. The Bank of England purchased an annuity, payable half-yearly until 1867, for 585,740*l.*, and paid for the same between 1823 and 1828, in nearly equal quarterly instalments, the sum of 13,089,419*l.* For the sake of obtaining a partial relief during those six years, to the amount of 9½ millions, we have thus had fixed upon the country for thirty-nine subsequent years an annual payment of 585,740*l.* It is not possible to allow that both these courses, so directly opposed to each other, could have been wise. Without inquiring further into the matter, it may be said that the plan of taking a larger burthen upon ourselves, that we may relieve those who come after us, has at least the recommendation of being the most generous; and considering that our successors will have had no hand in the contracting of the debts, the burthen of which they will have to bear, it might also be said that such a course is the most just.

It will be seen that some saving has been effected between 1816 and 1839 in the charges of management. This saving was part of the bargain made by the government with the Bank of England on the renewal of its charter in 1833, and may be considered as a part of the price paid by that establishment for the prolongation of certain of its privileges then on the point of expiring. The system employed for the management of the public debt by that corporation is explained elsewhere in this work. [BANK, BANKER, BANKING.] The functions intrusted to the Bank of England with reference to the National Debt do not extend to the transaction of any matter connected with its reduction. Such business is placed under the control of a body of commissioners, who act *ex officio* under the provisions of an act of parliament. This board is composed of the speaker of the House of Commons, the chancellor of the exchequer, the master of the rolls, the lord-chief-baron of the Court of Exchequer, the accountant-general of the Court of Chancery, and the governor and deputy-governor of the Bank of England. The greater part of these commissioners do not take any part in the management of the

business, the details of which are attended to by permanent officers, viz. a secretary and comptroller-general, and an actuary, with an adequate establishment of assistants and clerks: the ultimate control is exercised by the chancellor of the exchequer for the time being, assisted by the governor and deputy-governor of the Bank of England.

NATIONAL GALLERY. Of the origin of this public collection of paintings mention has already been made at the end of the article on the British Museum. Previously to the purchase of the Angerstein pictures, the gallery at Dulwich was almost the only one in the whole country, excepting the royal collections at Windsor and Hampton Court, to which the public had anything like free if not gratuitous access; for wealthy as England is in masterpieces of painting, they are dispersed through a great number of private galleries and cabinets, to which, if access is to be had at all, it is only occasionally. Consequently those stores of art have had little influence upon our national taste, but the public generally have been left to pick up their acquaintance with art at our annual exhibitions, where of course there is always a great preponderance of mediocrity. The exhibitions of the works of the old masters at the British Institution constituted almost the only opportunity of seeing works of that class which was afforded to artists and the public. Still, however desirable in themselves, such temporary exhibitions were insufficient. Hitherto government had scarcely ever done anything directly for art; and if it was to do so at all, no better beginning could be made than by securing for the nation the Angerstein collection, it being, although not very extensive, of choice quality, and containing some first-rate specimens. For the Sebastian del Piombo alone 20,000*l.* had been offered (by Mr. Beckford) and refused; therefore, 57,000*l.* for the whole was by no means an extravagant price, particularly if compared with what has since been given for single paintings, namely, 5000*l.* for Titian's Bacchus and Ariadne; 3800*l.* for the Virgin *au Panier*, by Correggio; 11,500*l.* for the two larger specimens of the same master (the Ecce Homo and the Education of Cupid), sold to the Gallery in 1834 by the marquis of Londonderry; and about 4000*l.* for Raphael's St. Catherine, a single half-length figure.

The original collection consisted of about forty pictures, chiefly of the Italian school, but is now (1839) augmented to more than treble that number, by purchases, donations, and bequests. The directors of the British Institution have liberally presented at different times five works, namely, the Parmegiano and Paul Veronese, and three specimens of the English school, Reynolds's Holy Family, Gainsborough's Market-Card, and West's large picture of Christ healing the Sick. Sir George Beaumont's noble gift of his collection, in 1826, enriched the Gallery soon after its establishment with several choice specimens, particularly in the department of landscape, with the very fine one by Rubens, four Claudes, and two Wilsons: the others are, a Descent from the Cross (sketch) by Rembrandt, the portrait of a Jew, by the same master, a landscape by Both, West's Pylades and Orestes, and Wilkie's Blind Fiddler. The bequest of the Rev. William Holwell Carr constituted a very numerous and important accession of works of the Italian school, besides some others, as will appear from the following list:—Leonardo da Vinci—Christ disputing with the Doctors in the Temple; Michael Angelo's Dream; Andrea del Sarto—a Holy Family; Bronzino—a female portrait; Garofalo—Vision of St. Augustin; Giulio Romano—a Charity; Titian—an Adoration of the Shepherds; Sebastian del Piombo—Portrait of Cardinal Hippolito de' Medici, and another, supposed to be that of Giulia Gonzaga; Tintoretto—St. George; Paul Veronese—Europa; Domenichino—Tobias and the Angel; Ditto—Landscape, with St. George and the Dragon; Guercino—a Christ and two Angels; Claude—Landscape, with the story of Sinon; Gaspar Poussin—three landscapes, one of them with the Adventure of Dido and Aeneas; Rubens—St. Bavon relieving the Poor; Rembrandt—a landscape, with Tobias and the Angel; also a female wading through a stream, which last, though disagreeable as a subject, is for its execution a superior specimen of that master.

Among other donations the principal are the two Guidos, Perseus and Andromeda, and Venus attired by the Graces, presented by William IV.; the allegorical subject, by Rubens, entitled Peace and War, given by the late duke of Sutherland; the two Cartoons, by Annibale Caracci, the gift of Lord Francis Egerton; and the picture representing the

story of Phineus, presented by Lieutenant-general Thornton, called in the catalogue a Poussin, but asserted by some to be the production of Romanelli. The most considerable of the later bequests is that of Lord Farnborough, which has added fifteen pictures to the Gallery, nearly all by Flemish and Dutch artists, including three by Teniers and two by Vandervelde; therefore furnishing specimens of that school, of which there were previously scarcely any, excepting those of Rubens and Rembrandt. The same number of paintings have been bequeathed by Lieutenant-colonel Harvey Ollney, most of which also belong to the above school, except four small ones, originally described as Watteau's, but now recognised as being by Lancret, an inferior artist.

From the great increase which has thus taken place within the course of a very few years, there is room for supposing that the liberality of private possessors will in time augment the collection very materially; still, if it be desirable on the one hand that such disposition should be encouraged, it is equally necessary on the other to guard against the indiscriminate acceptance of whatever may be gratuitously offered; since if due regard be not had to quality, the character of the entire collection will be endangered by the influx of mediocre and indifferent works, inferior specimens of the masters whose names they bear. The three pictures, for instance, presented by the duke of Northumberland are certainly not of that rank which would have procured their admission into the original Angerstein collection. It has also been complained that sufficient discretion has not been exercised with respect to purchases; for while extravagant sums have been paid in some instances, many works of equal or even greater merit have been rejected, although offered at reasonable prices. 'No specified sum is placed at the disposal of the trustees every year; but if any work of art is strongly recommended, a memorial must be sent to the Treasury, which is followed up by an application for the amount to parliament: the delay and the system effectually prevent merchants and others from negotiating with the trustees, as the doubt and perplexity are not to be compensated by the price demanded. In some instances pictures of the highest quality have been peremptorily refused, for what reasons we are unable to say. Two of the finest works by Salvator Rosa (Diogenes casting away his Cup, and Heraclitus sitting among the remnants of Mortality) were offered by the earl of Lauderdale, on the part of the late dowager-marchioness of Lansdowne, and refused: the individual who had the chief voice in rejecting them afterwards purchased them for the marquis of Westminster, for 1400*l.* If they were worthy to be placed in the Grosvenor Gallery, they would have been ornaments to the national collection.' (*Brit. and For. Rev.*, No. 17, 'Works of Art, &c. in England.') The writer just quoted asserts that the prices of all the subsequent purchases after that of the first collection have been extravagant, with the exception of those for the two Londonderry Correggios and the Murillo (the Holy Family), added to the Gallery in 1837. The three pictures more recently purchased of Mr. Beckford, viz. the Raphael (St. Catherine), the Garofalo, and the Perruzzi, originally cost that gentleman 3628*l.*, but have cost the nation 7000*l.*, or nearly double that sum, a price greatly disproportionate to their worth; which may also be said of that given for the Titian (Bacchus and Ariadne), purchased of Mr. Hamlet for 5000*l.* The same authority further assures us that, besides the instances above given, several opportunities of obtaining superior specimens at very moderate rates have been very inconsiderately neglected, in consequence of which many fine pictures, that might have been procured for the Gallery at a much lower cost than some of inferior rank have been, have either been sent out of the country or disposed of to private collectors. Among them was a fine specimen of Guercino (the Beheading of St. Catherine), purchased by Mr. Higginson for 350*l.*; a Bellini, Carlo Dolce, and a Correggio (greatly superior, it is stated, to the Virgin *au Panier* in the Gallery), which, with another picture, were sold to Mr. Wynne Ellis for only 1200*l.*, though the Correggio alone was worth double that amount. Again, an exceedingly fine work by Bonafacio (the Adoration of the Magi), almost equal to Titian, might have been had for the inconsiderable price of 200*l.* It further appears that notwithstanding the exceedingly large sums they have cost, some of the pictures are not in that high condition which they ought to be. The Correggio (Virgin *au Panier*) has suffered very materially, and the Raphael (St. Catherine) has undergone much repairing by

stippling in the flesh parts. Even the Raising of Lazarus, by Sebastian del Piombo, had in some places been damaged by time, but were so finely restored by West as almost to defy detection. With regard to the authenticity of some of the pictures there is also considerable doubt: Dr. Waagen pronounces the Lionardo da Vinci to be not by that master, but by Bernardino Luini; while, according to the writer in the 'British and Foreign Review,' it is by Andrea Solario; nor is the subject Christ disputing in the Temple with the Doctors, but Joseph interpreting Pharaoh's dream. Again, though so assigned in the catalogue, the story of Phineus is not by Niccolo Poussin, but Romanelli.

The following is a numerical synopsis of the collection at present (1839), arranged according to the principal schools:—

Italian:—Baroccio, 1; L. Bassano, 1; Bronzino, 1; A. Caracci, 9; L. Caracci, 3; Claude, 10; Correggio, 4; Canaletto, 3; Domenichino, 4; Ercole da Ferrara, 1; Mazzolino da Ferrara, 1; Garofalo, 1; Giorgione, 1; Guercino, 1; Guido, 3; Michael Angelo, 1; Mola, 3; Paduanino, 1; Parmegiano, 1; Pannini, 1; S. del Piombo, 3; N. Poussin, 8; G. Poussin, 6; Raphael, 2; Giul. Romano, 1; Sal. Rosa, 1; A. del Sarto, 1; Titian, 5; Tintoretto, 1; A. Veronese, 1; P. Veronese, 2; Da Vinci, 1:—(85). *Spanish*:—Murillo, 2; Velasquez, 1. *Flemish and Dutch*:—Both, 1; Cuyp, 1; Decker, 1; Van Goyen, 1; Van der Helst, 2; Jordans, 1; Mues, 2; Van der Neer, 1; Pether, 1; Rombrandt, 7; Rubens, 7; Storck, 1; Steinwick, 1; Vander-velde, 2; Vandyck, 4:—(33). *French*:—S. Bourdon, 1; Lancret, 4. *English*:—Beaumont, 2; Beechey, 1; Constable, 1; Copley, 1; Gainsborough, 2; Hogarth, 7; Hoppner, 1; Housman, 1; Jackson, 1; A. Kauffmann, 1; Lawrence, 4; Reynolds, 8; West, 4; Wilkie, 2; Wilson, 2:—(38).

The specimens of the English school are far from numerous, and some of them by no means *chefs-d'œuvre* of the artists to whom they belong; but it is to be hoped that the Gallery will in time deserve the epithet of National, by exhibiting proofs of native and national talent. It would be well therefore if, by the occasional purchase of the finest productions of living talent, our artists were incited to apply themselves to works of higher aim and more sterling character than are required for distinction at an exhibition-room, and to look forward to a place in the Gallery as to a monumental niche in the temple of Fame. It will however soon become necessary to consider how space is to be provided for fresh acquisitions, since, although the collection can even now be considered only as the nucleus of what it eventually will and ought to become, the increase has been such that the portion of the building allotted to the Gallery is already filled with as many pictures as it can properly contain, since it consists of no more than five rooms altogether, and two of them of very moderate dimensions.

This brings us to speak of the edifice itself, which has been more severely and more illiberally censured, both for its external appearance and interior accommodation, than almost any other architectural work. In either respect it is undoubtedly very far from what it ought to be; yet although the censure has fallen almost entirely upon the architect alone, many of the defects complained of were forced upon him by the inconveniences attending the site, and other unfortunate circumstances, and it is therefore very doubtful whether, fettered by the same untoward conditions, any one else would have been able to do much better, at least as far as accommodation is concerned. Not only was the plan restricted to an inconveniently narrow slip of ground, but the alleged, yet by no means apparent, necessity of keeping as public thoroughfares two passages through the lower part of the building, has caused the ground-floor to be so divided that should occasion for so doing arise, it will be found impossible to form a spacious gallery of any kind, either for sculpture or paintings, in that part of the building. Again, the necessity for providing two distinct entrances and staircases, without the means of projecting out the latter at the rear of the building, has unavoidably caused all the centre portion, amounting to about one-third of the interior, to be so appropriated, which of course seems a very great loss of space, although the same space would not have been at all extravagant if the Gallery itself had been in proportion to it. Such a building as St. Martin's workhouse ought never to have been allowed to be any obstacle in the way of a suitable plan for the Gallery, more especially as it

could easily be foreseen that though the accommodation at first provided might be amply sufficient, the time would arrive when it would be found altogether inadequate. Consequently what is now erected should have been understood to be only provisional, and Mr. Wilkins should have been instructed to have formed his plans with the view of the building being extended northwards, both at its east and west ends. How additions may be made is shown in one of the plans of the Gallery accompanying the 'Report from the Select Committee of Arts,' &c., viz. by continuing the present suite of rooms westward, at the rear of the houses on the north side of Pall-Mall East, where there might be a building upwards of 100 feet square, enclosing an inner court. But were government to give up the site of the adjacent barracks, the plan might be much more extensively enlarged, as there would then be space for erecting, in continuation of the present edifice, a series of galleries upwards of 300 feet in length, by nearly 200 in depth, which would give a line equal to about 1000 feet, doubled by the walls on each side. Even this might be still further extended by building other galleries intersecting the square or quadrangle enclosed by the outer ones; for supposing these latter 30 feet wide, they would leave an internal space or court 200 feet one way and 100 the other. (*Public Buildings of London*, by W. H. Leeds, vol. ii.)

There may be difficulties, but surely not insuperable ones attending the scheme here proposed, which while it would provide sufficiently numerous and spacious galleries, that would lose nothing of their effect by being approached through the present rooms, would be recommended by economy, because all such additional buildings would be entirely shut out from view externally, and therefore require no finish or regard to design on their outside. The increase of space so obtained would, besides, be double what is above stated, since that refers only to the upper floor, whereas there would be equal additional extent gained beneath it; which might be appropriated to a gallery of modern sculpture, there being nothing of the kind at the British Museum. Such a plan might be carried on by degrees, a single room or gallery on each floor being erected as it should become necessary to do so; and some classification as to schools, and also subjects and sizes, might be observed, which, if not of much importance at present, will require to be attended to when the collection shall have become much more numerous. There would then be opportunity for introducing in such new galleries that greater attention to architectural splendour and decoration which the public seem to demand; for almost every one has spoken most contemptuously of the present rooms, not only as insufficient in size, but as mean in appearance. One writer calls them 'little poking boxes,' another ('Br. and For. Rev.') says, 'they are beneath contempt: they display neither grandeur nor style.' Undoubtedly not, but then neither does anything of the sort appear to have been contemplated; and, at all events, the architect is not to be reproached for not having attempted more than he was allowed to perform. The architecture of the rooms is quite subordinate, almost negative; there is nothing whatever in them to please as mere architecture, nor is there anything whatever to offend; while the principal object, that of showing the pictures, has been satisfactorily accomplished.

The exterior of the building has been criticised, or rather summarily condemned, with equal severity; and without any allowance being made for the difficulty thrown in the architect's way by his being under the necessity of making use of the columns formerly belonging to the portico of Carlton House. This seems to have cramped his design by limiting him as to the height of his portico, which he would else most probably have rendered a far more imposing and dignified feature by employing for it an order of larger dimensions, rising above the general height of the elevation as in the façade of the London University College; and had he done so, bestowing on that order a richer entablature than on the rest, together with a rather loftier pediment enriched with sculpture, and with statues on its acroteria, the dome, which is more of a blemish than an ornament in the design, might have been dispensed with, as the centre would have been sufficiently and more effectively distinguished, by its greater loftiness, without it. The entire extent of front is 460 feet, but this length is too much broken up into separate parts, and more so than would else probably have been done, it being required of the architect to set back the extremities in order that the east end of his

building should not at all intercept the view of the portico of St. Martin's from Pall-Mall East; whereas had he been allowed to bring those parts as forward as the background of his portico, very much more space would have been obtained internally, and the end facing the church, which is now a very narrow and insignificant-looking bit, would have been considerably augmented. It is to be regretted, too, that the small windows at the sides of the entrances to the two thoroughfares were not got rid off, by being turned towards those passages; and perhaps a little more study and contrivance would have enabled the architect to dispense with those in that division of the façade from which the portico projects, and where they sadly cut up that mass. At all events, there would have been no difficulty whatever in entirely concealing the windows in the basement story, by merely continuing the podium as a low screen before them, with breaks forming pedestals for statues at intervals. By that means a deformity would have been got rid off, the ordinary dwelling-house look attending those kitchen-windows have been avoided, and an air of nobleness and richness, with some degree of novelty of design also, have been imparted to the whole façade. It is true, the rooms in the offices below would not have commanded the view they now do, yet that is a very minor consideration, and ought not to have been allowed to stand in the way of its being done. Fortunately however for such improvement it is even now not too late, since it may be carried into effect at any time without the slightest trouble or inconvenience. So also may the now empty niches be filled with statues; but there is no hope that anything will ever be done to remedy one prevalent and very serious defect, namely, the excessive poverty of the whole entablature, which renders it not only at variance with the richness of the columns, but insignificant in the general effect, whereas even some little exaggeration with respect to the depth of its members would have been allowable, if merely because a little more height might thus have been given. Notwithstanding these and other defects, some of which appear to have been forced upon the architect, there is much beauty in particular parts, especially the portico: but for further criticism on the building we must refer to the work above quoted, where elevations and plans of it will also be found. Plans of it have also been given in the 'Companion to the Almanac for 1837,' and the 'Penny Magazine,' No. 299. The latter publication also contains (Nos. 8, 12, 24, and 47) notices of some of the principal pictures. The building was begun in 1833 from the designs of W. Wilkins, R.A. (died August 31, 1839), and completed in 1837; and the first exhibition of the Royal Academy within its walls took place in 1838.

NATIONS, LAW OF. [LAW, p. 361.]

NATOLIA. [ANATOLIA.]

NATRIX, Laurenti's name for a genus of *Colubridæ*, a family of snakes destitute of poison-fangs, and of which the common snake, *Natrix torquata* of Ray, may be taken as the example.

Generic Character.—Head distinct, oblong-ovate, depressed, covered with scuta; gape wide, body very long, nearly cylindrical, slender, scales imbricated, placed in longitudinal series, lanceolate, generally carinated, abdominal shields simple, arched at the margin, caudal shields biserial. (Bell.)

Head and tail of *Natrix*. Head seen from above; tail from below.

The Common or Ringed Snake is too well known to require description: the female is larger than the male. Its food consists of lizards, young birds, birds' eggs, mice, and more particularly frogs. The latter are generally captured by one of the hind legs, and in that case the prey is swal-

lowed alive, and with the lower limbs and parts foremost, the head still continuing in its proper position, and disappearing last. During the operation of deglutition the cries of the frog are very distressing, and we have delivered more than one from its enemy—unfairly perhaps, in consequence of being attracted by the cries of the sufferer. The frog evidently remains alive for some time after it has been swallowed, in the course of which the jaws are dilated, and, so to speak, dislocated in order to allow of the passage of the disproportioned body to be conveyed into the stomach. Mr. Bell, who gives in his 'British Reptiles' a very accurate and clear account of the manner in which this operation is performed and the dilatation effected, states that he has heard a frog distinctly utter its peculiar cry several minutes after it had been swallowed by the snake. The same zoologist observes that the frog is generally taken by one of the hinder extremities, because the latter is most frequently in the act of fleeing from its pursuer when taken; and in that case, the prey, according to his experience, is swallowed as we have above described; but he adds, that if the frog be taken by the middle of the body, the snake invariably turns it by several movements of the jaws, until the head is directed towards the throat of the snake, when it is swallowed head-foremost. In taking lizards or birds, the snake, as far as Mr. Bell's observation goes, always swallows them head first. The same author gives a curious but painful description of an instance where two snakes had seized the same wretched frog, which, after a long and painful struggle, and some fighting between the snakes, was swallowed by the victor.

When the skin of the common snake has been just cast, it is a very beautiful serpent, and those who have seen it, as we have, gracefully swimming with elevated head and neck, and with the sun shining on its 'enamelled skin,' as it crossed the limpid water of some clear stream or little lake, will acknowledge its elegance and beauty. Mr. Bell has the following observations upon the subject of this change of the skin, which, as some misapprehension has existed on the subject, we proceed to lay before our readers. 'Snakes, like most other reptilia, shed their cuticle or outer skin at greater or less intervals. It is a mistake to assign a particular period to this process; some have stated it to occur once, some twice in the summer; but I have found it to depend upon the temperature of the atmosphere, and on the state of health, and the more or less frequent feeding of the animal. I have known the skin shed four or five times during the year. It is always thrown off by reversing it; so that the transparent covering of the eyes, and that of the scales also, are always found in the exuvie. Previously to this curious circumstance taking place, the whole cuticle becomes somewhat opaque, the eyes are dim, and the animal is evidently blind. It also becomes more or less inactive, until at length, when the skin is ready to be removed, being everywhere detached, and the new skin perfectly hard underneath, the animal bursts it at the neck, and creeping through some dense herbage, or low brushwood, leaves it attached, and comes forth in far brighter and clearer colours than before.'

White and others have remarked an offensive power in this creature, that of 'stinking se defendendo,' as White describes it. He adds, 'I knew a gentleman who kept a tame snake, which was in its person as sweet as any animal while in good humour and unalarmed; but as soon as a stranger or a dog or cat came in, it fell to hissing, and filled the room with such nauseous effluvia as rendered it hardly supportable.' But this offensive odour, which is expelled from certain glands, is not emitted in self-defence alone. It is also said to be the concomitant of sexual excitement.

Reproduction.—Oviparous, as in the rest of the genus. The eggs, to the number of sixteen or twenty, are deposited in a connected chain in some dung-heap or warm situation, the connection being effected by a glutinous substance, and there left till the heat of the place or of the sun calls the young into life. In the museum of the Royal College of Surgeons (*Physiological Series*, No. 2708) is a preparation of a species of coluber, in which the ova in the ovaria are in an advanced state of development; the ovisac nearest the expanded anterior orifice of the left oviduct is near the period of discharging its contained ovum, and the longitudinal line is discernible, which indicates the place of the future rent by which it would have escaped. The cloaca is laid open; a bristle is placed in the termination of the rectum, behind which may be observed the semilunar fissure

in which the oviducts terminate, and the bilobed prominence on which the ureters open. No. 2417 (the first illustration of the Ametabolian subclass, in which copulation is attended with intromission) exhibits the posterior part of the body of the *Common Snake* with the ventral integuments dissected off from the abdomen and tail, to show the testes and two penes *in situ*. The testes are small, slightly compressed, oblong bodies, situated anterior to the kidneys, the right about an inch in advance of the left, corresponding to the difference in the relative position of the kidneys; the penes, which consist almost wholly of a præputium or invertible sheath, and a small glans, are retracted within their subcaudal cells; bristles are inserted into the outlets of these receptacles, and pass into the cavities of the inverted præputia. The muscles which retract the penes and invert the sheaths are exposed as they pass backwards to their origins from the inferior spinos of the caudal vertebrae. No. 2418 exhibits the termination of the abdomen and tail of a large *Coluber*, also prepared to show the male sexual organs. (*Catalogue*, vol. iv.)

Habits, &c.—The common snake commences its hibernation in some warm hedge, under the root of a tree, or other sheltered situation, about the end of autumn; and then they coil themselves up, sometimes in numbers, till the spring again brings them forth. Many instances of tame snakes have been recorded, and more than one has come under our immediate observation. Mr. Bell gives the following account, showing that these snakes may be made to distinguish those who caress and feed them. 'I had one many years since, which knew me from all other persons; and when let out of his box would immediately come to me, and crawl under the sleeve of my coat, where he was fond of lying perfectly still, and enjoying the warmth. He was accustomed to come to my hand for a draught of milk every morning at breakfast, which he always did of his own accord, but he would fly from strangers and hiss if they meddled with him.'

The following are the synonyms collected by the last-mentioned author:—*Natrix torquata*, Ray, Fleming, Jenyns, Bonaparte. *Coluber Natrix*, Linn., Shaw, Daudin, Turton. *Coluber torquatus*, Lacépède; *Natrix vulgaris*, Laurenti. *Tropidonotus Natrix*, Kuhl, Gray. *Ringed Snake*, Pennant. *Couleuvre à Collier*, Lacépède. It is the *Ringelnatter* of the Germans, and *Tomt-Orm*, *Snok*, and *Ring-Orm* of the *Fauna Suecica*.

The editor of the last edition of Pennant's 'British Zoology,' the Rev. L. Jenyns, and Mr. Bell, are all of opinion that the *Dumfriesshire Snake* of Sowerby's 'British Miscellany' is probably an immature variety of this species. The editor of Pennant seems however to be in doubt whether it is the young of the *Aberdeen Snake*, *Anguis Eryx*, or of the *Natrix* here treated of. But there can, we apprehend, be hardly any doubt that the *Dumfriesshire Snake* is the young of *Natrix torquata*. The *Aberdeen Snake* is nothing more than the *Slow-worm* or *Blind-worm*. [BLIND-WORM.]

Geographical Distribution.—Europe, 'from Scotland and the corresponding latitude of the Continent, to Italy and Sicily.' (Bell.)

With reference to the alleged inability of reptiles to live in Ireland, Mr. Bell says, 'I have already mentioned the existence of *Lacerta agilis* there, and with respect to the present species, the following is the result of my inquiries. It would appear not only that the common Snake is not indigenous to Ireland, but that several attempts to introduce it have totally failed. Mr. Ball some time since informed me of some trials of this kind.' Mr. Bell then prints the following letter from Mr. Thompson, which he had recently received, and which, as Mr. Bell observes, gives a very detailed and clear account of the actual facts.

'In this order (*Ophidia*) there is not now, nor, I believe, ever was there, any species indigenous to Ireland. In the Edinburgh "New Philosophical Journal," for April, 1835, it is remarked: "We have learned from good authority that a recent importation of snakes has been made into Ireland, and that at present they are multiplying rapidly within a few miles of the tomb of St. Patrick." I never, proceeds Mr. Thompson, 'heard of this circumstance until it was published, and subsequently endeavoured to ascertain its truth, by inquiring of the persons about Downpatrick (where the tomb of St. Patrick is) who are best acquainted with these subjects, not one of whom had ever heard of snakes being in the neighbourhood. Recollecting that about the year 1831, a snake (*Natrix torquata*), im-

P. C., No. 990.

mediately after being killed at Milecross, was brought by some country-people in great consternation to my friend Dr. J. L. Drummond, I thought this might be one of those alluded to; and recently made inquiry of James Cleland, Esq. of Ruth Gael House (county Down), twenty-five miles distant in a direct line from Downpatrick, respecting snakes said to have been turned out by him. I was favoured by that gentleman with the following satisfactory reply:—"The report of my having introduced snakes into this country is correct. Being curious to ascertain whether the climate of Ireland was destructive to that class of reptiles, about six years ago I purchased half a dozen of them in Covent Garden market in London; they had been taken some time, and were quite tame and familiar. I turned them out in my garden; they immediately rambed away; one of them was killed at Milecross,"—that alluded to as having been brought to Dr. Drummond,—"three miles distant, in about a week after its liberation; and three others were shortly afterwards killed within that distance of the place where they were turned out; and it is highly probable that the remaining two met with a similar fate, falling victims to a reward which it appears was offered for their destruction."

To this Mr. Bell adds, that it certainly does not appear that the failure of these attempts to introduce snakes into Ireland is to be attributed to anything connected with the climate, or other local circumstances, but rather to the prejudices of the inhabitants; nor is there reason to believe that their absence from Ireland is other than purely accidental. (*British Reptiles*.)

Natrix torquata: Common or Ringed Snake.

NATROLITE. [MESOTYPE]

NATRON, native sesquicarbonate of soda. [SODIUM.]

NATRON LAKES are in a valley in the western desert which borders upon Lower Egypt running south east and north-west between the calcareous ridge that skirts the western edge of the Delta and another parallel range which divides it from the BAHR-BELA-MA. The Natron valley contains six lakes, remarkable for the great quantity of salt which they produce. The crystallizations are both of muriate of soda, or common salt, and of carbonate of soda, called natron or trona. The lakes are ranged in succession along the length of the valley, being separated from each other by barren sands; the whole occupy a length of about sixteen miles. The size of the respective lakes varies according to the season, and they are very shallow; the bottom is muddy, of mixed sand and clay. The lakes are supplied by water, which oozes out of the banks, chiefly on the side which is towards the Nile. It appears that the water flows abundantly when the Nile is high, and decreases with its decrease, until some of the lakes become quite dry. The banks of the lakes below the springs are covered with crystallizations. The natron is collected once a year, and is used both in Egypt and Syria, as also in Europe, for manufacturing glass and soap, and for bleaching linen.

There are three or four convents in the valley of the Natron lakes; their foundation is said to date from the fourth century of our æra; they are inhabited by Copt and Syrian monks, who are very poor and very ignorant. The valley itself is a barren desert.

(Andreossi, *Mémoire sur la Vallée des Lacs de Natron*.)

VOL. XVI.—P

NATTER-JACK, or **NATTER-JACK TOAD**, the English name for the *Bufo Calamita* of Laurenti. Its colour is light-yellowish inclining to brown and clouded with dull olive; but its most distinguishing mark is the bright-yellow line running along the middle of the back. The warts or glands on the body and the large glands behind the head are reddish; the under parts yellowish spotted with black, and the legs banded with black.

Sir Joseph Banks was the first who drew Pennant's attention to it as a British species: and the latter notices it as frequenting dry and sandy places, and as having been found on Putney Common and also near Revesby Abbey in Lincolnshire. The Rev. L. Jenyns records it as occurring in plenty on many of the heaths about London, as well as on Gaimingay Heath in Cambridgeshire, and in two or three localities in Norfolk. Mr. Bell (*British Reptiles*) states that he has found them in considerable numbers near ponds and ditches not far from Deptford, where they appeared to have congregated for the purpose of breeding. He observes that Dr. Fleming was not apparently aware of its being an inhabitant of Scotland, but Sir W. Jardine informed Mr. Bell that it is 'taken in a marsh on the coasts of the Solway Frith, almost brackish (certainly so in winter), and within a hundred yards of spring-tide high-water mark. It lies,' continues Sir William, 'between the village of Carse and Saturnes- (Southernness) Point, where I have found them for six or seven miles along the coast. They are very abundant.' The specimens sent to Mr. Bell by Sir W. Jardine were in every respect the same as those found in the neighbourhood of London. We long ago saw them frequently at Hillingdon near Uxbridge (Middlesex).

Pennant well describes the movements of the Natter-Jack. 'It never leaps, neither does it crawl with the slow pace of a toad, but its motion is more like running.' He says that its deep and hollow voice is heard to a great distance. Mr. Jenyns states that it spawns later in the season than the common toad. Mr. Bell gives the following dimensions:—

	Inches.	Lines.
Total length . . .	2	8
Length of fore leg .	1	3
Length of hinder leg	2	2

Natter-Jack.

NATURAL, a musical character, thus formed-

the use of which is, to make a sharpened note a semitone lower, and a flattened note a semitone higher; or, in other words, it brings into the scale of the natural key of c any note which had been made sharp or flat. But it must be observed, that the power of this character does not extend beyond the bar in which it appears, except where a lasting change of key is intended, in which case each natural placed at the clef removes a corresponding sharp or flat permanently, or until such sharp or flat shall be restored in like manner.

NATURAL ORDERS OF PLANTS. In classifying the vegetable kingdom according to the affinities of the species, it has been found necessary to collect together into groups such genera as have more resemblance to each other than they have to anything else, and to these the name of

natural orders has been given. They constitute the foundation of all arrangements, and are wholly independent of the peculiar views which different writers have taken of the manner in which the vegetable kingdom should be otherwise classified; thus, while one author advocates the propriety of arranging Exogens by the modifications of their corolla, another by the insertion of their stamens, a third by what is supposed to be the progressive order of their development, and so on, the result of each of which methods is a different sequence of matter, the natural orders themselves remain unchanged. This being so, the study of their true limitation, and of the characters by which they are essentially distinguished, constitutes by far the most important branch of systematical botany, and accordingly we find that a large proportion of the natural orders yet founded are admitted without much difference of opinion. It must be obvious also to any one at all acquainted with such subjects, that in many cases there is in fact no room for discussion; as in the Apiaceous, Asteraceous, and Brassicaceous orders, or in Grasses, Sedges, and Orchidaceæ.

It is however sufficiently singular, that notwithstanding the general accordance of opinion that may be said to exist upon this subject in the majority of cases, no one should, as yet, have undertaken to prove what are really the essential characters by which natural orders ought to be distinguished, and what are unimportant or inapplicable to the limitation of such groups. In the absence of a settlement of this point, all that has yet been effected is, in its very nature, arbitrary and unsatisfactory, notwithstanding that it does appear to be, to a great extent, right; and there is an inconsistency and want of harmony in the different divisions of the natural system, which is most perplexing to the student. Up to the present time botanists have occupied themselves much more with searching for differences by which genera may be divided, than for resemblances by which they may be combined, a state of things which has proved advantageous to the science of botanical classification in its infancy, but which, if not corrected, will prevent its ever attaining maturity.

It is probable that such characters as the number of parts, the regularity or irregularity of flowers, the insertion of stamens, direction of ovules, and the presence or absence of particular organs, all which are at present considered of great importance, are so far from serving to separate plants into different orders, that they may be mere indications of a peculiar state of development in plants of the same order. Such orders as Myrtaceæ and Onagraceæ serve to place this in a striking point of view. In Myrtaceæ the stamens vary from an indefinite number in *Myrtus* to only 5 in the genus *Bæckea*; and from being polyadelphous in *Calothamnus*, to being distinct in *Myrtus* itself; the flowers are polypetalous in *Myrtus*, and apetalous in *Eucalyptus*; regular in the mass of the order, but irregular in *Lecythis* and its allies; the ovary is many-celled and many-seeded in *Leptospermum*, and one-celled with two seeds in *Calytrix*; altogether inferior in *Eugenia*, &c., and superior in the whole of the *Leptospermeous* division. In like manner in Onagraceæ, *Oenothera* has 8 stamens, and *Hippuris* one only; the flowers are polypetalous in the mass of the order, but apetalous in some *Fuchsias*; regular in the mass of the order, but irregular in *Chamænerium*; and the ovary is 2- or 4-celled in the greater number of genera, but 1-celled in *Trapa*, and in some plants referred to *Haloragis*. So, in like manner, is the position of the ovule within the ovary a character liable to much variation; for instance, among *Urticaceæ*, it is erect in *Urtica*, and pendulous in *Dorstenia* and *Humulus*; among *Myrtaceæ*, it is erect in *Verticordia*, peltate in *Beaufortia*; and among *Onagraceæ*, it is peltate in *Epilobium*, &c., erect in *Circæa*, and pendulous in *Haloragis*.

We ought therefore, in sound philosophy, to disallow all the differences just enumerated, as available for the discrimination of natural orders, and yet they are of constant employment. If they were disallowed, the effect would be to reduce very considerably the number of natural orders, and to limit the remainder in a more positive manner; an advantage of no little moment in the existing state of systematical botany, in as much as it would tend to simplify the distinctions of the orders, and to remove the numerous inconsistencies whose existence it is at present impossible to deny. Many prejudices would be violently shocked, but an entirely new light would be thrown upon the real nature of vegetable affinities; *Corylaceæ* would be brought into the vicinity of *Combretaceæ*, and *Tamaricaceæ* of *Sali-*

cacæ; Begoniacæ would be associated with Melastomacæ; Solanacæ and Scrophulariacæ, Geraniacæ, Tropeolæ, and Limnanthacæ, would be respectively consolidated, and many more such changes might be expected.

For the natural orders now admitted in the writings of botanists the reader is referred to EXOGENS and ENDOGENS and to the numerous names of orders introduced in their places in the alphabetical arrangement of this work.

NATURAL PHILOSOPHY. [PHYSICS.]

NATURALIZATION. [ALIEN; DENIZEN.]

NATURE, LAW OF. [LAW, p. 361.]

NAUCLE'RUS. [FALCONIDÆ, vol. x., p. 186.]

NAUDE', GABRIEL, born at Paris in the year 1600, displayed at an early age a great aptitude for philological and critical studies. In 1622-3 he studied medicine, but it was not till several years later that he took his doctor's degree in that science at Padua. In 1624 he made his first journey into Italy, and on his return to Paris he published his work, 'Apologie pour les grandes Personnages fausement accusés de Magie,' 1625. In 1631 he accompanied the papal nuncio Cardinal de' Bagni on his return to Rome, and was appointed his librarian. While he was at Rome the controversy concerning the authorship of the book 'De Imitatione Christi' began. [KEMPIS, THOMAS A.] The Benedictines claimed the authorship for one of their order, John Gersen, abbot of Vercelli; whilst the regular canons of St. Génévieve claimed it for Thomas à Kempis. Naudé, being in Italy, was requested to examine several MSS. of the work in question. His report was unfavourable to the claims of the Benedictines, who were much incensed against him, and accused him of bad faith. The affair then came before the courts in the shape of a charge of defamation; the suit lasted for years, and was at last compromised. In 1640 Cardinal de' Bagni died, and Naudé, after remaining some time with Cardinal Barberini, the nephew of the reigning pope Urban VIII., was recalled to Paris in 1642, and appointed librarian to Cardinal Mazarin. In this capacity he travelled through several parts of Europe to collect books and MSS. to enrich his patron's library, which was afterwards sold according to a sentence of the parliament of Paris, during the civil war of La Fronde, to the great sorrow of Naudé, who attempted to prevent what he considered an act of barbarism, 'Avis à Nosseigneurs du Parlement sur la Vente de la Bibliothèque du Cardinal Mazarin,' 1652. On receiving an invitation from queen Christina of Sweden, to be her librarian, Naudé went to Stockholm in 1652, where he was very well received. The climate of Sweden not agreeing with his health, he set out to return to Paris, but died on his way, at Abbeville, in July, 1653.

Naudé wrote numerous works in French and Latin, a catalogue of which is annexed to the 'Naudæana, ou Singularités remarquables prises des Conversations de M. Naudé,' 1701 and 1703; the latter edition is by Bayle. His principal works are—1, 'Instruction à la Franco sur la Verité de l'Histoire des Freres de la Rose Croix,' 1623, in which he shows the absurdity of the wonderful stories concerning the Rosicrucians, which had begun in Germany, and were then spreading into France. 2, 'Bibliographia Politica,' being a list of the principal writers upon politics, with his own remarks. 3, 'Avis pour dresser une Bibliothèque,' 1627. 4, 'Additions à l'Histoire de Louis XI.,' 1630. 5, 'De Studio Militari Syntagma,' 6, 'Jugement de tout ce qui a été imprimé contre le Cardinal Mazarin,' 4to., 1650. 7, 'La Marfore, ou discours contre les Libelles.' 8, 'Considérations politiques sur les Coups d'Etat,' Rome, 1639. Naudé says that he wrote this work at the request of and for the private perusal of his patron Cardinal de' Bagni, who however for his own convenience had twelve copies of it printed. The work was afterwards reprinted in Holland in 1667, and again in 1673, with comments by way of refutation, by L.D.M. (Louis Dumaz). The principles broached in this book are of a similar nature with those of the 'Principe' of Machiavelli. Among other things Naudé (in ch. iii.) approves of the massacre of St. Bartholomew, not on religious but on political grounds, considering the Huguenots as obstinate rebels, and says that the obloquy which has been thrown upon it is, 'because it was done only by half; for had all the heretics in France been cut off, the country would afterwards have enjoyed perfect tranquillity.'

Naudé was a man of irreproachable morals, of great learning, but self-opinionated and somewhat paradoxical. Father Jacob, in his 'Gabrielle Naudéi Tutulus,' 1659, has

collected all the eulogies and epitaphs that have been written in his honour.

NAUMA'CHIA, the representation of a sea-fight among the Romans, which was sometimes performed in the Circus Maximus or amphitheatre, water being introduced sufficient to float ships, but more frequently in places made especially for the purpose, which were called Naumachia. Julius Cæsar appears to have been the first who gave a representation of a sea-fight on an extensive scale. He dug a lake in the Campus Martius for the purpose, which however was filled up in his life-time (Dion Cass., xl. 23; Suet., *Jul.*, c. 39, with Casaubon's note, and c. 43). Augustus also dug a lake near the Tiber for the same purpose, which was afterwards turned into a park or plantation ('*nemus*;' Suet., *Oct.*, 43; Tac., *Ann.*, xii. 56). Another lake was dug in the Campus Martius by Caligula (Dion Cass., lix. 10); but Claudius exhibited a naumachia on the lake Fucinus, now Celano. (Suet., *Claud.*, 21; Dion, ix. 33; Tac., *Ann.*, xii. 56.) The old naumachia (*vetus naumachia*), in which Titus is said by Suetonius (*Tit.*, 7) to have exhibited a sea-fight, has occasioned some dispute among the learned; some understanding it to be the Circus Maximus, and others the lake dug by order of Augustus (Ernesti on Suet., *Tib.*, 72). Domitian appears to have been the first who erected a building of stone around these artificial lakes (Suet., *Dom.*, 4, 5). Previous to his time the spectators appear to have sat upon wooden benches, which might be easily made to rise gradually above one another with the earth which had been dug out of the artificial lake. In later times the naumachia were usually surrounded with buildings like the amphitheatre or circus.

The ships which were engaged in these sea-fights were divided into two parties, which were called respectively by the names of different maritime nations, as the Tyrian and Egyptian fleets (Suet., *Jul.*, 39), the Sicilian and Rhodian (Suet., *Claud.*, 21), &c. The combatants, who were called Naumachiarum (Suet., *Claud.*, 21), were usually composed of captives or criminals, who fought to death, unless saved by the clemency of the emperor. These sea fights were said to have been exhibited on such a scale of magnificence and splendour as almost to surpass our belief. In the naumachia exhibited by Nero there were sea-monsters swimming about in the artificial lake (Suet., *Nero.*, 12), and Claudius caused a Triton, made of silver, to be placed in the middle of the lake Fucinus, who was made, by machinery, to give the signal for attack with a trumpet. (Suet., *Claud.*, 21.) In Domitian's naumachia the number of ships engaged was almost equal to two real fleets (*præne justæ classes*, Suet., *Dom.*, 4); and in the sea-fight on the lake Fucinus, there are said to have been no fewer than 19,000 combatants. (Tac., *Ann.*, xii. 56.)

NAUMBURG, on the Saale, a very considerable town of Prussian Saxony, in the government of Merseburg, is situated in 51° 9' N. lat. and 11° 40' E. long., at a short distance from the junction of the Unstrutt with the Saale. It consists of the town itself, the liberties, and three suburbs. There are several remarkable buildings in this city, especially the churches. The cathedral (in the liberties), founded in 1028, is an interesting specimen of old German architecture; its ancient monuments, altars, statues, carved work, paintings, are well worthy of observation. Connected with the cathedral are residences of the canons. The church of St. Wendel (which has a celebrated organ, and many fine paintings, one of which is by L. Cranach, 'Christ blessing the little Children') and the church of St. Maurice, with the monument of bishop Richwins, are likewise interesting. Among the other public buildings, the principal are the court of justice, the town hall, the gymnasium (or cathedral school), and the city school. Besides the above, there are two churches, two orphan houses, six hospitals, and several schools.

Naumburg is the seat of the chapter, of the supreme tribunal for the governments of Merseburg and Erfurt, of several supreme courts of justice, a tribunal of commerce, &c. Naumburg is a very thriving town; the inhabitants, now above 12,000, carry on manufactures of woollens, linen, stockings, gloves, and leather; starch, white-lead, soap, vitriol, aquafortis, vinegar, beer, and brandy are made both for the consumption of the surrounding country and for exportation to foreign parts. Wine produced in the vicinity is a considerable article of trade; the red is better than the white, and is often sold as French. There are a few houses that carry on very extensive dealings

'n wool. There are two annual fairs, one in June, instituted in 1514, by the emperor Maximilian I.; the other, in December, instituted in 1818, by the king of Prussia. These, and three other annual cattle and horse fairs, contribute greatly to the prosperity of the town. An interesting ceremony, called the Kinderfest (i.e. the children's fête), is annually celebrated in commemoration of an attack made on the town on the 28th of July, 1482, by the Hussites under Procopius. On that day, by the advice of a citizen named Wolf, all the children, dressed in shrouds, each carrying a lemon and a green bough, went out of the city to beg mercy for their parents and for the city. Procopius, who had threatened utterly to destroy the town and the inhabitants, because the late bishop had voted at the synod of Köstnitz for the death of John Huss, was so affected that he raised the siege. Though the memory of this event has been handed down for above 300 years, some modern historians have doubted the fact. On the 5th of November, 1632, the great Gustavus Adolphus here took his final leave of his queen before the battle of Lützen.

(Müller, *Handbuch*; also local descriptions by Lopsius, 1822; and Kratsch, 1827.)

NAUPACTUS. [LOCRI.]

NAU'PLIA. [NAPOLI DI ROMANIA.]

NAU'PLIUS. [BRANCHIOPODA, vol. v., p. 340.]

NAU'TILIDÆ, or NAUTILA'CEA, according to Lamarck, the sixth family of his *Polythalamous Cephalopoda*, consisting of the genera *Discorbites*, *Siderolites*, *Polystomella*, *Vorticialis*, *Nummulites*, and *Nautilus*. To these Mr. G. B. Sowerby, jun. adds *Simplegas* and *Endosiphonites*. In the system of M. de Blainville it is the fifth family of his *Polythalamacea*, and comprises the genera *Orbulites*, *Nautilus*, *Polystomella*, and *Lenticulina*.

NAU'TILUS, a genus of cephalopods with polythalamous or chambered shells, established by Linnæus, who gave the following as the generic character: 'Animal ('Rumph. Mus.,' t. 17, f. D) *Testa univalvis, isthmis perforatis concaemerata, polythalamia.*' And he divided the genus into

Spiral rounded.

In which section he placed the species *N. Pompilius*, *Calcar*, *Crispus*, *Beccarii*, *rugosus*, *umbilicatus*, *Spirula*, and *semilitus*. Of these, all, except *Nautilus Pompilius*, and *N. Spirula*, the latter of which is separated as a cephalopodous genus under the name of *Spirula*, are minute chambered shells, for the most part from the Adriatic Sea.

* *

Elongated, suberect (erectiusculi).

In this section the species are *obliquus*, *Raphanistrum*, *Raphanus*, *Granum*, *Radicala*, *Fascia*, *Sipunculus*, *Legumen*, *Orthocera*. Of these, all but *Orthocera* are minute, and from the Adriatic and Mediterranean. *Orthocera*, now established as a fossil genus of cephalopods under the name of *Orthoceras*, though described by Linnæus as fossil, seems to have been considered by him as not without a living analogue; for he writes,—'Habitat in alto Pelago; Fossilis;' and he has the following observation:—'*Testa frequentissima petrificata in montibus nostris calcareis, inter omnia fossilia nobis nota sæpe longissima, non dum visa immutata.*'

Lamarck thus characterises the genus *Nautilus*—

Shell discoid, spiral, multilocular; with simple walls (à parois simples). Whorls contiguous; the last enveloping the others. Chambers numerous, formed by transverse partitions (cloisons), which are concave towards the side next to the aperture; their disk perforated by a tube, and their edges very simple.

Lamarck records only two species, *Nautilus Pompilius* and *N. umbilicatus*. For the animal he refers to Rumphius and Denys de Montfort.

Cuvier observes, in his last edition of the 'Règne Animal,' that Linnæus united in his genus *Nautilus* the genera *Spirula* of Lamarck, and the *Nautili*, properly so called. Of the latter he remarks that they have a shell differing from that of the *Spirulæ*, inasmuch as the laminae increase very rapidly, and the last whorls touch, but envelop the preceding whorls. The siphon, he adds, is in the middle of each septum. He refers to the *Nautilus Pompilius* of Linnæus as the species most known, and he refers to Rumphius for the animal, observing however, in a note, that the figure of Rumphius is not to be deciphered (indé-

chiffable), and that it is matter of wonder that the numerous naturalists who have visited the Indian Seas have not examined or captured so curious an animal, and one which belongs to so common a shell.

M. de Blainville thus describes the genus:—

Animal having the body rounded, and terminated behind by a tendinous or muscular filament, which attaches itself in the siphon with which the chambers of the shell are pierced; mantle open obliquely, and prolonging itself into a sort of hood above, the head provided with tentacular appendages, which are, as it were, digitated, and surrounding the aperture of the mouth.

Shell discoid, but little compressed, with the back rounded or subcarinated, umbilicated or not, but never mammellated (mamelonnée); the chambers simple, invisible externally; the last deeply hollowed and pierced by one or two siphons.

The same zoologist thus divides the genus.

A.

Species not umbilicated; back rounded; aperture round a single, subcentral siphon.

Example, *Nautilus Pompilius*, Linn.

B.

Species not umbilicated, with a carinated back and angular opening. (*Angulithes*, De Montf.)

Example, *Nautilus triangularis*.

C.

Umbilicated species, with the back rounded and a single siphon. (*Oceanus*, De Montf.)

Example, *Nautilus umbilicatus*.

D.

Umbilicated species, with the back rounded and two siphons. (*Bisiphites*, De Montf.)

Example, *Nautilus Bisiphites*.

M. Rang, under the genus *Nautilus* of Linnæus, places also *Aganides*, *Angulithes*, *Canthropes*, *Oceanus*, *Bisiphites*, and *Ammonites* of De Montfort. All De Montfort's genera, except *Oceanus* and *Ammonites*, are fossil only: the former he describes as coming from the Moluccas. It is, as far as one can judge from the figure, a very young shell, possibly the young of *Nautilus Pompilius*. *Ammonites* is described as coming from the China Seas, and is, apparently, a specimen of *Nautilus umbilicatus*. De Montfort considers it as the type of a species of *Ammonites* analogous to the *Ammonites*, or *Cornua Ammonis* 'à cloisons unies.' He further says that he possessed a superb petrification of this *Ammonite* a foot in diameter.

M. Rang gives the following generic character of *Nautilus*:—

Animal bursiform, lodged partially in the last chamber of the shell, furnished posteriorly with an appendage or particular organ, destined to traverse all the chambers, and placed in a siphon, which serves it as a sheath; mantle prolonged above the head, which is furnished with a great number of sessile arms surrounding the mouth.

Shell discoid, regularly spiral, rolled on the same plane, embracing or not, with contiguous whorls; siphon central, or placed 'contre le retour de la spire.'

The animal, he says, is only known from the figure of Rumphius, which leaves so much to be desired. He divides the genus into two subgenera.

I. Subgenus. *Nautili*, properly so called.

Animal, as described in the generic character.

Shell with a spire either embracing or not; chambers united (unies); siphon central, or approximated to the penultimate whorl of the spire, without being contiguous to it.

1st group.

Spire embracing (Genera—*Nautilus*, *Angulithes*, *Oceanus*, De Montf.).

Nautilus Pompilius, &c.

2nd group.

Spire exposed (à découvert)—(*Ammonites*, De Montf.).

Nautilus umbilicatus, &c.

II. Subgenus (*Aganides*, De Montf.).

Animal unknown.

Shell with an embracing spire; partition disunited by two interior prolongations of its borders; siphon touching the penultimate whorl of the spire.

All the descriptions of the animal above given seem to have been taken from the figure of Rumphius. We therefore give a copy of this figure, which represents the animal in a supine position. The general form is not inaccurate, but the details are confused; and many of them incorrect, the funnel

for instance, which is erroneously represented as round. That which an ordinary spectator would take for the eye, is merely an opening between the digitations: the mantle is torn, and so represented as to mislead the spectator.

Animal of Nautilus Pompilius, from Rumphius.

The following is the description of Rumphius, and it has much more merit than his figure:—

'The fish that inhabits this shell (the Nautilus) is a species of Polypus (i.e. Cephalopod; *πολύπους*, Aristotle; *Poulpe*, French), but of a particular aspect, moulded according to the concavity of the shell, which it does not quite fill when it holds itself retracted therein.

'The posterior part of the body fits into the bottom of the cavity, while the superior parts (which are inferior when the animal drags itself along the bottom) are flattened, but also rounded off, plaited, and of cartilaginous texture; coloured with brown or washed with red; spotted with blackish marks, which run one into another, as in the Cuttle-fish (*Veelvoet*). The posterior part of the body, which presses against the shell below the convexity (kick), and which, in its progression, becomes the superior part, is also a little cartilaginous, but not so much as the anterior parts, which are covered with a number of cavities (wratten).

In the middle of these parts, in front of the head, there is a considerable lump of little feet, which terminate in fleshy processes laying one over another, and which cover the mouth on each side: these processes are formed like the hand of a child. The largest, or those which are exterior, are terminated by twenty of these fingers or little feet, each as long as half a finger, as thick as a straw, round, smooth, having none of those suckers we see on the feet of the Cuttles, but a little flattened or divided at the end. The great fleshy processes are succeeded by others, which are shorter, and have only sixteen fingers, and these are followed successively by others still shorter, which go on covering even to the mouth.

'The animal can retract or elongate these fingers at will, for they not only serve as feet to creep withal, but also as hands to seize his prey and carry it to the mouth. This mouth is armed by a very hooked beak, formed like that of a Cooatoo or a Seacat (*Sepia*?). The upper beak is large, hooked, dentated on the edge; the lower beak is small, concealed, or, as it were, shut up in the upper. Both sharp, and calculated to pierce flesh (*vleesch*). This beak is hard as bone, and its colour of a blackish-blue, surrounded by circular lips of a white colour, fleshy or parchment-like. These are produced sometimes so as to cover entirely the beak, which at other times is almost entirely concealed by a gelatinous deposition, and by the multitude of feet which surround it, so that it cannot be seen without violent means being used.

'The eyes are placed a little low down, laterally disposed, very large, large as beans, without an inferior eyelid, pierced in the middle; but we cannot find the lens (*oogappel*), they are filled with dark-brown blood.

'From the hinder part of the body, to wit, that which rests upon the last partition, goes a long artery (*ader*) through all the partitions and through all the chambers, even unto the extremity of the spire, the middle hole to which the fish hangs fast to the shell: excepting this part, the chambers are entirely empty, and it breaks readily when the fish is drawn out. Under the beak (*snuif*) is a half pipe (*canal*) of a rounded form, one side rolled over the other, of a whitish flesh, like as in the Sea-cat (*Sepia*), and in this is concealed a sort of tongue. It is most likely the same canal as that by which the *Zeekat* ejects its black blood.' (*Rariteit-Kamer*, book ii.)

This figure and description warmed the imagination of Denys de Montfort, who published a ludicrous representation of the supposed animal seated in its shell, and expanding its hand or sail. This has been copied by Shaw; and as it has been published by that zoologist in his Lectures, we give a copy of the monster, which was meant to pass current for the inhabitant of the shell.

Supposed animal of Nautilus Pompilius. (Denys de Montfort and Shaw.)

It will be now necessary to go back to the earlier authors, and to inquire whether this animal was known to them. After reading the following passages, few will hesitate to concede that it was known to the father of natural history.

Aristotle (*Hist. Nat.*, iv. 1), after well describing the different *μαλάκια* (naked cephalopods), says, 'There are also two Polypi in shells; one is called by some *Nautilus*, and by others *Nauticus*. It is like the *Polypus*; but its shell resembles a hollow comb or pecten, and is not attached. This Polypus ordinarily feeds near the shore; sometimes it is thrown by the waves on the dry land, and the shell falling from it, it is caught, and there dies. These are small, and in form like the *Bolitæna*' (cephalopods probably, of the form of which *Eledone moschata* is the type). 'And the other,' continues Aristotle, 'is in a shell, like a snail; and this does not go out of its shell, but remains in it like a snail, and sometimes stretches forth its arms (or cirri, *περράνας*) externally.'

The first of these Polypi is evidently the *Nautilus* or *Pompilus* of Pliny and other ancient writers, the *Argonauta* of Linnæus and the moderns, which is treated of in this work under the title PAPER NAUTILUS.

The second, to which the term *Pompilius* is now exclusively applied, is, as evidently, the *Nautilus* of Lamarck, to which genus alone this article will be confined.

Belon figured the shell of the animal, now termed *Nautilus Pompilius* (and we believe that his figure is the first that appeared) under the name of *Nautilus alter seu secundus*; but it seems clear that he was unacquainted with

the soft parts. *Rondeletius*, apparently confounding Aristotle's two genera of Polypi, seems to refer the animal of the first to the shell of the second; and dwells on the impossibility of so delicate and feeble an animal dragging about so heavy a shell.

Gesner relates that 'Jo. Fauconerus,' a celebrated physician of England, formerly gave him the picture of a *Nautilus*, with a written description (by letter). This description Gesner gives; and it is not improbable that the soft parts there described may have been those of *Nautilus Pompilius* (it is clear that the shell was); but the account is so obscure and brief that there is room for doubt, though the term *velum* is used, which would hardly be applicable to the palmated arms or *vela* of the other kind.

We now return to the period which followed the publication of Rumphius's figure; and for many years no further information was obtained, though special directions were given by the French and other nations to collectors to be assiduous in procuring the soft parts. These directions were given in vain, and all was conjecture. Fragments even of molluscous animals were caught at and published as probable parts of this much desired animal; and MM. Quoy and Gaimard published their 'Description d'un Fragment de Mollusque inconnu, présumé être celui du Nautilo flambe' (*Nautilus Pompilius*, Linn.), with figures, in the 'Annales des Sciences Naturelles' (vol. 20). The materials are not sufficient to come to any safe conclusion as to the animal, of which the fragment was a part; but it may now be confidently denied that it is any portion of the soft parts of *Nautilus Pompilius*. The parenchyma of the fragment indeed is said to have been identical with that of *Pirola* and *Carinaria*. This fragment is preserved at Paris in the Jardin du Roi.

The recovery of this interesting animal was reserved for a British voyager; and its structure has been demonstrated and illustrated by Professor Owen in a most masterly manner, leaving nothing to be wished, excepting that some fortunate collector may speedily capture a male specimen, and put it into his skilful hands.

Mr. George Bennett, F.L.S., a member of the Royal College of Surgeons, thus describes the capture of this interesting animal in his 'Wanderings in New South Wales,' &c.:—'It was on the 24th of August, 1829 (calm and fine weather, thermometer at noon 79°), in the evening, when the ship *Sophia* was lying at anchor in Marakini Bay, on the south-west side of the island of Erromanga, one of the New Hebrides group, Southern Pacific Ocean, that something was seen floating on the surface of the water at some distance from the ship; to many it appeared like a small dead tortoise-shell cat, which would have been such an unusual object to be seen in this part of the world, that the boat which was alongside the ship at the time was sent for the purpose of ascertaining the nature of the floating object. On approaching near it was observed to be the shell-fish commonly known by the name of the Pearly Nautilus (*Nautilus Pompilius*); it was captured and brought on board, but the shell was shattered, from having been struck with the boat-hook in capturing it, as the animal was sinking when the boat approached, and had it not been so damaged it would have escaped. I extracted the fish in a perfect state, which was firmly attached to each side of the upper cavity of the shell. On being brought on board, I observed it retract the tentacula still closer than before, and this was the only sensation of vitality it gave after being caught; I preserved the soft parts immediately in spirits, after making a rude pen-and-ink sketch of its form. On breaking the lower part of the shell, the chambers or cavities were found filled with water. The hood has been stated by Dr. Shaw (*Lectures*, vol. ii., p. 166) as being of a pale reddish purple colour, with deeper spots and variegations; the colour however, as it appeared in this recent specimen, was of a dark reddish-brown, in fact, resembling the colour produced by the *Koka* on the stained cloth of the Tongatabu natives, intermingled with white. We had fine weather; light winds and calms a day or two previous to this animal being caught.' After noticing the incorrectness of Shaw's figure (which, as we have above noticed, was copied from those given by Denys de Montfort), and the greater general accuracy of that of Rumphius, Mr. White informs us that this species is called *Kika*, *Lapia*, and *Krang Modang* by the natives of Amboyna; and *Bia papada*, *Bia tojin*, by the Malays. He then adverts to another instance of the capture of this animal, by an officer of H.M.S. *Ariadne*, on a

reef at the island of Pemba near Zanzibar, on the east coast of Africa, in 1824. The animal was not floating upon the water, but was in a hole on the reef, and the officer did not recollect which part of the shell was uppermost. The mantle, like a thin membrane, covered the shell, and was drawn in as soon as it was touched, when the shell was displayed. 'I and others,' said this officer to Mr. Bennett, 'when it was first seen, did not notice it, regarding the animal, as the membrane enveloped the shell, merely as a piece of blubber; but having touched it by accident, the membranous covering was withdrawn, and we soon secured our beautiful prize. The fish was a large mass attached to the shell, which we soon extracted and threw away, as we only wanted to collect shells.' The same officer compared the mantle to what he had subsequently seen covering the shells of the *Harps* [ΕΝΤΟΜΟΣΤΟΜΑΤΑ, vol. ix., p. 455] and *Couries*. [CΥΠΡΑΙΔÆ.] Mr. Bennett states that a section of the shell captured by him was afterwards made on board, but none of the appearances, nor whether air or water was contained within, could be recollected. A mate of a whaler, who had been shipwrecked upon the Feejee Islands in the South Pacific, and had resided among that group for nearly three years, told Mr. Bennett that he had seen the shell of the *Pearly Nautilus*, containing the living animal, floating on the water near one of the islands. He had only seen two living, although the empty shells were very numerous among the islands. The first he saw when in a canoe with some other shipwrecked Europeans; it was then floating on the surface of the water with the mouth of the shell uppermost. It was enveloped in the mantle, which extended some distance upwards, and over the whole of the shell; and it had such an appearance as caused one of the men to say, 'There is a large piece of blubber upon the water.' On approaching it the animal, retracting the mantle, displayed the beautiful striped shell, and sank before they could capture it. (G. Bennett, *Wanderings*, vol. ii.)

The specimen captured by Mr. Bennett is preserved in the museum of the Royal College of Surgeons in London, and has produced the admirable 'Memoir on the Pearly Nautilus (*Nautilus Pompilius*, Linn.), with illustrations of its external form and internal structure,' published by direction of the council of the college, a summary of which we shall endeavour to lay before our readers.

The external form, of which an elaborate description is given, for which we must refer our readers to the 'Memoir' itself, will be collected from the following cuts, which are reduced from Professor Owen's figures.

Nautilus Pompilius (female) in the prone position, with its natural relation to the shell shown by a section of that part in outline. (Reduced from Owen.)

The same, with the animal as well as a part of the shell in outline, explanatory of the parts, on a larger scale. (Reduced from Owen.)

aa, the mantle; *b*, its dorsal fold, applied to the involute convexity of the shell; *c*, its free anterior margin; *d*, the orifice for the passage of the funnel; *e*, the convexity produced by the ovarian gland; *ff*, the horny girdle for the adhesion of the mantle to the shell; *g*, the horny lamina covering the extremity of the left shell muscle; *h*, a portion of the shell, which was left adhering to this muscle; *i*, the membranous tube or siphon, which traverses the testaceous tubes in the camerated portion of the shell; *k*, the funnel; *l*, the left lateral process of the funnel; *m*, the left crus or pillar of the funnel; *n*, the hood, or ligamento-muscular disk that surmounts the head; *oo*, the exterior digitations on the left side; *o'*, the larger one, with a papillose surface like that of the hood; *pp*, the digitated tentacles, protruded from their sheaths; *q*, the groove which separates the hood from the papillose digitation; *rr*, the ophthalmic receptacles; *s*, the eye; *t*, its peduncle; *u*, the inferior ridge or rudimentary eyelid; *v*, the ridge running from this to *w*, the pupil; *x* & *x*, the portions of the chambers; *yyy*, the septal tubes, which give passage to the membranous siphon; *z*, the chamber of occupation. (Owen.)

Professor Owen thus concludes the elaborate description to which our limits have compelled us to refer our readers: — 'From what has been already said, it will be seen how considerable are the external differences between the *Pearly Nautilus* and the higher *Cephalopods*; nevertheless its general plan of organization renders its claim to rank with them indisputable; and as its locomotive apparatus is confined to the head, the received denomination of the class remains undisturbed by its admission. The inferior or ventral pair of labial processes I consider as analogous to the superadded pedunculated arms of the Cuttle-fish and Calamary, which also come off more internally than the shorter arms, and are approximated or united at their bases on the ventral aspect of the mouth. The other pair in *Nautilus* appear to result from a higher degree of organization of the part analogous to the external lip in the preceding genera. The curtailed digitations are however but feeble representatives of the elongated and cotyigerous arms of the Pulp or Cuttle-fish; and the retractile tentacles, pedicellate eyes, and flattened disk, which, according to the testimony of Rumphius, is applied to the ground in the progressive motions of the animal, attest an obvious tendency towards the *Gasteropoda*. And while tracing these examples of affinity with the different and heretofore widely spread groups of *Mollusca*, between which this remarkable form, I apprehend, is osculant, there may also be perceived in the whole of this singular but at the same time regular and symmetrical arrangement of the palpigerous organs about the mouth, an analogical relation to the higher *Annulosa*.'

Before Mr. Owen enters upon the *Muscular System*, which is described carefully and in detail, he notices what he aptly terms the internal skeleton or frame-work from which its principal masses take their origin. Like that of the *Dibranchiate Cephalopods*, this skeleton, according to Mr. Owen, is cartilaginous, yields readily to the knife, and in texture and semitransparency closely resembles the cartilage which constitutes the skeleton of the Skate. In *Sepia*, he observes, this cartilaginous part completely encircles the œsophagus, and on the dorsal aspect of that tube is dilated into a large cavity, which contains the brain; but in *Nautilus* the circle is incomplete behind, and the brain is protected only by its membranous sheath.

Digestive System.—The jaws are two, endowed with a

vertical motion, and in form resembling a parrot's bill reversed, the upper mandible being encased in the lower when they are closed. Posteriorly they are adapted to a muscular basis, to which they owe their motions. 'Thus far,' continues Mr. Owen, 'they resemble the mandibles of the *Dibranchiate Cephalopods*; but they are not composed entirely of horny matter, nor are they uniformly of a brown or black colour, their extremities being of a dense calcareous nature, and of a bluish-white colour; they are also less pointed at the end, and the oval margins of the lower mandible are notched and dentated.' They are larger in proportion than in the Cuttle-fish. Mr. Owen proceeds to state that the calcareous extremities of both mandibles are of a hardness apparently adequate to break through the most dense crustaceous coverings, or even shells of a moderate thickness. The extremity of the upper mandible is sharp-pointed, and solid to the extent of five lines from the extremity; but in the lower one the calcareous matter is deposited on both sides of a thin layer of the black horny substance, and thus a combination of tough with dense matter is obtained, which much diminishes the liability to fracture. This mandible is also more hooked than the upper one, but is more obtuse at the end. 'It seems,' observes Mr. Owen, 'from its dentated margin, evidently intended to break through hard substances, whilst the sharp edges of the beak of the Cuttle-fish better adapt it for cutting and lacerating the soft bodies of fish.' In the particulars here stated the mandibles of *Nautilus* differ, as Mr. Owen remarks, from those of every other known species of recent *Cephalopods*. The circular lip which surrounds the jaws is much deeper than in the Cuttle-fish, and the jaws are provided with four retractor muscles, and one for protrusion. The tongue is large, and supported by an oblong horny substance. The fleshy substance is produced anteriorly, and forms three caruncles, which are very soft in texture, and beset by numerous papillæ, having all the characters of a perfect organ of taste. The anterior extremity of the horny substance is embraced by a pair of retractor muscles, which arise from the posterior margin of the lower mandible, and four delicate retractor or depressor muscles are inserted into the anterior or terminal caruncle. Behind the caruncles the dorsum of the tongue is encased with a thin layer of horny matter, from which arise four longitudinal rows of slender recurved prickles between one and two lines in length, the same in number as the labial tentacles, viz. 12. There is an analogous structure in the *Cephalopoda* and in many of the *Gasteropoda*. 'The necessity of such a structure,' says Mr. Owen, 'becomes very apparent in the *Pearly Nautilus*, if, as Rumphius has asserted, it creeps with the shell uppermost; since in that case the tongue, having its position reversed, would be opposed instead of being assisted by gravitation while regulating the movements of the food in the mouth. And it is worthy of remark that in the Flamingo, which turns the upper mandible to the ground while taking its food, the tongue is similarly armed with regularly developed recurved spines, calculated, as in the *Pearly Nautilus*, to rake the alimentary morsels towards the fauces.' [FLEMING, vol. x., p. 293.] Behind the horny parts the tongue again becomes soft and papillose, but the papillæ are larger and coarser. The only traces of a salivary system detected were in two broad fleshy processes projecting forwards from the sides of the fauces: they were papillose, and perforated in the middle of their inner surfaces by a small aperture which led into a glandular cavity between the folds of the membrane, and from these cavities an opaque whitish substance could be expressed. In the *Dibranchiate Cephalopods* these glands are remarkably developed. The alimentary canal, which was filled with the fragments of crustaceans, was everywhere connected to the parietes of the abdomen by numerous filaments; the only trace of a mesentery existed between the last two portions of the intestine, which were connected together by the ramifications of an artery and vein. Among the crustaceous fragments, portions of branchiæ, claws, and palpi were distinctly recognised, so as to leave no doubt that the greater part of them had belonged to a *Brachyurous Decapod* of a hirsute character, and not a swimmer. The crop, which was capacious and pyriform, was tensely filled with these fragments, and Mr. Owen remarks that the capability of propelling such rude and angular particles through a narrow canal into the gizzard without rupturing the tunics of the preparatory cavity is not one of the least extraordinary examples of the powers of living matter. The gizzard very much resembles

that of a fowl, as it does in *Octopus*. A globular cavity communicates with the intestine at a little distance from the pylorus, and its reception of the biliary secretion renders it in some measure analogous to a gall-bladder; but Mr. Owen thinks that its chief use is probably to pour into the commencement of the intestinal canal a fluid necessary for digestion; so that, like the laminated and spiral cœcum of the higher *Cephalopods*, and the pyloric appendages of fish, it is essentially a simple form of pancreas. The interior of the alimentary canal, which was filled with smaller fragments of crustaceous shell, presented a few longitudinal rugæ and slight transverse puckering. The liver is bulky, and extends on each side of the crop from the œsophagus to the gizzard. There was no trace of structure analogous to the ink-bag of the *Dibranchiate Cephalopods*.

Nautilus Pompilius, in the prone position, with the labial processes and tentacles, the mandibles, and the digestive organs displayed. (Reduced from Professor Owen's figure.)

a a, the hood, or upper part of the oval sheath, longitudinally divided; *b b*, the posterior lobes or angles of the hood; *c c*, the posterior concavity of the hood; *d d*, the ridge in the same; *e e*, the cut surfaces of the above parts; *f f*, the internal surface of the oval sheath; *g g*, the external labial processes; *h h*, the external labial tentacles; *i i*, the internal labial processes; *k k*, the internal labial tentacles; *l*, the olfactory lamina; *m m*, the circular fringed lip, longitudinally divided; *n*, the superior mandible; *o*, the inferior mandible; *p*, the muscular basis on which the mandibles are fixed; *q q*, the superior pair of muscles which retract the jaws; *r r*, the semicircular muscle which protrudes the jaws, divided longitudinally; *s*, the œsophagus; *t*, the crop; *u*, the narrow canal leading to *v*, the gizzard; *w*, the intestine; *w'*, the terminal fold of intestine drawn out of its situation; *x*, the anus; *y*, the laminated pancreatic bag; *z*, the liver; 15, a branch of the anterior aorta, which ramifies in the membrane connecting the two portions of the terminal fold of the intestine; 19, the continuation of the posterior aorta along the dorsal aspect of the crop; 20, its bifurcation at the œsophagus, to form a vascular circle corresponding to the nervous circle round that tube; 21 and 22, arteries of the crop, gizzard, &c. (Owen.)

In the museum of the Royal College of Surgeons (*Physiological Series*, No. 499, A.) is a preparation exhibiting the crop, gizzard, and laminated pancreatic pouch. (See the *Catalogue*, vol. i.)

Circulating and Respiratory System.—Our limits will not permit us to go into the details of this system in the Pearly *Nautilus*, interesting as it is. The respiratory organs are elongated and pyramidal, and have the same laminated structure and symmetrical disposition as in the cuttle-fish; but they are four in number, being disposed two on either side, and each pair arising by a common peduncle from the inner surface of the mantle. 'From this difference in the number of branchiæ, in addition to the other peculiarities in the structure of *Nautilus*,' says Mr. Owen, 'the existence of at least two orders of the class *Cephalopoda* is, I imagine, demonstrated; and the denominations of these orders

might conveniently be taken from the modifications of the respiratory system. Assuming therefore that it is common to the class to possess branchiæ of a laminated structure, symmetrically disposed, and concealed beneath the mantle, those genera which possess two such branchiæ will form an order under the term *Dibranchiata*, and the Pearly *Nautilus* and other cephalopods with shells of an analogous formation, a second order, under the term *Tetabranchiata*. It is in this sense that the expression 'Dibranchiate cephalopods' has been made use of in this memoir; and to this group most of the characters of the class, as given by the immortal Cuvier in his '*Règne Animal*,' exclusively appertain.'

The preparation, No. 900, B. (*Physiological Series*) in the museum of the College of Surgeons, exhibits the circulation and respiratory organs of the species now under consideration. The branchial vessels are continued from a series at the lower part of the vena cava. They are four in number, corresponding to the four branchiæ, and have each three clusters of glandular follicles appended to them, representing the branchial auricles. The blood, after circulating through the branchiæ, is returned by four branchial veins, which open into the four corners of a transversely oblong ventricle. This has been laid open on the opposite side of the preparation to show the columnæ carneæ within. The blood is conveyed to the system in two arteries, one inferior and large, commencing by a muscular bulb, the other superior and small, which is seen partially injected with quicksilver. A branch of this artery winds over the ventricle, and is continued downwards into the membranous siphon, and a white bristle is passed through it along the pericardium, and through one of the apertures, by which the pericardium communicates with the branchial chamber. It is thus that the fluid contained in the siphon has an outlet, and on the supposition that the chambers of the shell contain gas, the sinking and rising of the *Nautilus* may be regulated by the varying proportions of gas and liquid in the chambered part of the shell. (*Cat.*)

We must refer the student for further and ample information to Mr. Owen's '*Memoir*,' and the fifth and sixth plates illustrating it.

Nervous System and Organs of Sense.—This part of the system in the Pearly *Nautilus* is in many respects inferior to that of the *Dibranchiate Cephalopods*, though it is analogous to it. 'The part,' says Mr. Owen, 'which corresponds to the brain of the cuttle-fish, is neither enlarged nor lobulated, nor contained in a cartilaginous receptacle; but is a simple rounded chord or commissure placed transversely above the œsophagus, and connected at its extremities to the great ganglions. These are six in number; are disposed symmetrically about the œsophagus, and, together with the central commissure, are loosely enveloped in a tough membrane, or *dura mater*.' The double œsophageal collar is not peculiar to *Nautilus*, but is also found in other Mollusks, *Aplysia* for example; though in these latter cases the subœsophageal ganglions being more remote, the connecting filaments running to the common centre above are longer. The details of the nervous system are most clearly explained in Mr. Owen's *Memoir*, and beautifully displayed in the 7th plate. In the museum of the College of Surgeons the preparation (No. 1306, A, *Physiological Series*) exhibits the head and anterior or muscular part of the body of this species laid open longitudinally along the dorsal aspect, and the sides divaricated to show this part of the system. The brain, or supracœsophageal mass, will be seen to consist of a transverse chord-like ganglion, from the ends of which three nervous trunks are continued on each side. The anterior pair pass downwards and forwards by the sides of the œsophagus to unite below it, forming a ganglion on either side; these supply the digital processes and tentacles, and give off nerves to the organ of smell and the funnel. The middle and superior trunks dilate into the optic ganglions; the retina, which terminates that of the left side is shown. The posterior chords surround the œsophagus in a manner analogous to the anterior pair, forming also two ganglionic swellings, from which the nerves of the great shell-muscles and those of the viscera are given off; the latter nerves are of small size, and are continued down by the side of the great perforated vein, and are analogous in their distribution to the sympathetic nerves and *par vagum*. (*Cat.*, vol. iii., part 1.)

Sight.—The eye of the *Nautilus*, as might be expected from the comparative inferiority of the brain, is less com

plex than in the Dibranchiate Cephalopods. 'Indeed,' says Mr. Owen, 'it appears to be reduced to the simplest condition that the organ of vision can assume without departing altogether from the type which prevails throughout the higher classes. For although the light is admitted by a single orifice into a globular cavity or *camera obscura*, yet the parts which regulate the admission and modify the direction of the impinging rays are entirely deficient.' The eyes are not situated in orbits, but are attached severally by a pedicle to the side of the head, immediately below the posterior lobes of the head. This attachment to a muscular pedicle gives great mobility to the organ, and enables the animal easily to bring it to bear on objects in a variety of directions. Mr. Owen found that the contents of the globe had escaped by the pupil; but he comes to the conclusion, on satisfactory grounds, that if it had ever contained a crystalline lens, it must have been very small.

Hearing.—Mr. Owen was unable to detect a distinct organ for this sense; but he is inclined to the opinion that there does exist in the Nautilus a distinct organ of passive smell, formed after the type of that organ in the inferior *Vertebrata*, and especially in fish.

Taste.—The structure of the tongue and the nerves with which it is supplied indicate a considerable development of this faculty; greater, Mr. Owen seems to think, than the analogous part in many of the *Vertebrata*.

Touch.—Mr. Owen observes that the papillæ upon that part of the head which is termed the hood, if they could be proved to be endowed with nerves, would be peculiar to it among invertebrate animals; but he adds that the great difficulty experienced in tracing the nerves in the substance of the sheath renders their existence as nervous papillæ matter of conjecture only. The numerous tentacles however, soft in their texture, annulated on their surface, and well supplied with nerves, must give the animal an ample enjoyment of the sense of touch.

Generative System.—Aristotle was well aware of the distinctions of sex in the *Malákia*; and Mr. Owen remarks that the propriety with which that great zoologist classed this animal, although it was covered with a shell to which it adhered like a snail, is fully borne out by the dissection of the female, upon which he operated. The organs consist of an ovary, an oviduct, and, as in the Pectinibranchiate Gasteropods, of an accessory glandular apparatus, and are delineated in the eighth plate of Mr. Owen's Memoir. No. 2651, A. in the *Physiological Series* of the Museum of the College of Surgeons, exhibits these organs. The single ovary is lodged in an appropriate peritoneal sac in the posterior part of the abdominal cavity. It is an oblong, compressed body, convex towards the lateral aspect, and on the opposite side having two surfaces sloping away from a middle longitudinal elevation. Its cavity is occupied by numerous ovisacs of different sizes, the largest of which appear to have recently discharged their contents. They present an elongated oval figure, and are attached by one extremity to the ovarian capsule, while the other floats freely in the ovarian cavity, and exhibits the rent by which the ovum has escaped. The ovisacs are smooth on their external surface, but present internally very numerous and minute wavy folds. They are principally attached along the line of the exterior elevated ridge, at which part the nutrient vessels penetrate the ovary. The oviduct is single, wide, and short; it is a continuation of the membranous external covering of the ovarium, the thick glandular and fibrous tunic of which presents, at the anterior extremity of the ovarium, a distinct perforation with plicated borders, which projects into the membranous commencement of the oviduct. At a short distance from this part a laminated glandular structure begins to be developed in the tunics of the oviducts, and increases in thickness to the external outlet of the canal. The eggs doubtless receive an outer covering from this gland, and a still more exterior nidamental coat, with probably also a connecting thread from the large laminated gland, which is here placed over the oviduct. This organ is situated, like the nidamental laminae in the whelk, in the branchial chamber; it is adherent to the mantle, and gives rise to the two round convexities observable in the entire animal, in the ventral aspect of the body behind the infundibulum. It is a transversely oblong, trilobed mass, composed of numerous close-set pectinated laminae, which are about a quarter of an inch in depth, and are disposed in three groups, forming the lobes of the gland; the laminae of the larger group extend transversely across the

P. C., No. 991.

middle line of the body, and have their free margins unprotected by a membrane; but the two smaller symmetrical groups have these margins covered by a thin membrane, which is reflected over them from the anterior margin of the glandular body; this is analogous to the detached laminated glands observable in the succeeding preparations. (*Cat.*, vol. iv.)

Habits.—Rumphius says of the Nautilus, 'When he floats on the water, he puts out his head and all his barbs (tentacles), and spreads them upon the water, with the poop (of the shell) above water; but at the bottom he creeps in the reverse position, with his boat above him, and with his head and barbs upon the ground, making a tolerably quick progress. He keeps himself chiefly upon the ground, creeping sometimes also into the nets of the fishermen; but after a storm, as the weather becomes calm, they are seen in troops floating on the water, being driven up by the agitation of the waves: whence one may infer that they congregate in troops at the bottom. The sailing however is not of long continuance; for having taken in all their tentacles, they upset their boat, and so return to the bottom.' (*Rariteit-Kamer.*)

Mr. Owen, who quotes this passage, observes that the extent to which the Pearly Nautilus is covered by its shell, and its close attachment to it, indicated the affinity to the Gasteropods in too strong a manner to escape the penetration of Aristotle, who, as we have seen, directly compares it in this respect to a snail; 'and the general resemblance,' says Mr. Owen in continuation, 'must have been sufficiently striking when, with his house above him and in the supine position, he makes his way along the sand with a moderate degree of rapidity.'

We here give representations of the external appearance of the shells of two species.

Shell of Nautilus Pompilius.

Shell of Nautilus scrobiculatus, or Umbilicated Nautilus.

The genus Nautilus is thus characterised by Mr. Owen
Body oblong, rounded posteriorly, terminated by a slender
VOL. XVI.—Q

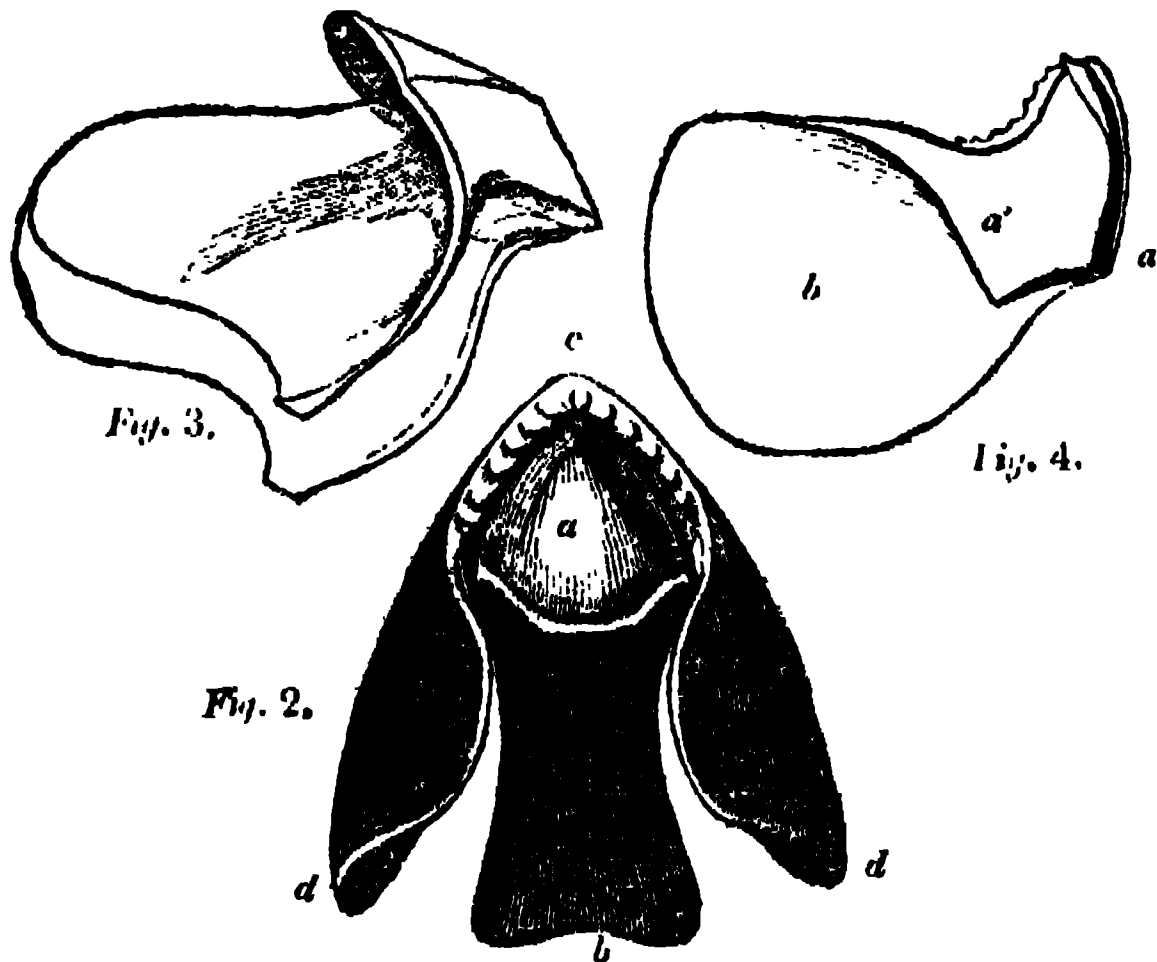

membranaceous tube. *Head* above with an ambulatory disk. *Arms* on each side, nineteen. *Tentaculiferous labial appendages* four, disposed around the mouth. *Tentacles* (ninety-two!) of three kinds, viz.: *Ophthalmic*, lamellose, on each side two; *Brachial*, annulose, on each side twenty; *Labial*, annulose, on each side twenty-four. The whole body laid up in the last chamber of a large multilocular shell, and affixed by two lateral muscles. [TETRABRANCHIATA.]

Geographical Distribution of the Genus.—The seas of warm climates, especially those of Asia and Africa, and their islands, Amboyna, Zanzibar, and New Guinea; and the Pacific and Australian Oceans.

FOSSIL NAUTILI.

The *Rhyncholites*, formerly considered to be the beaks of birds, are now, upon unquestionable evidence, proved to be the jaws of fossil Nautili and Ammonites. Blumenbach recognised these *Rhyncholites* as being rather the mandibles of Cephalopods, differing from all recent genera then discovered; and M. d'Orbigny, who found some large ones in the same beds with the shell of a *Nautilus Gigas*, suspected that those *Rhyncholites* appertained to that species.

We here give figures of the mandibles or beaks of the *Nautilus Pompilius*, the structure of which is above noticed, and some of these *Rhyncholites*.

2, Mandibles of *Nautilus Pompilius*. a, calcareous extremity of upper mandible; b, extended internal horny laminae of the same; c, notched calcareous extremity of lower mandible; d, d, external horny laminae of the same. 3, Upper mandible, showing the form of the calcareous extremity, and the proportions of the external and internal horny laminae. 4, One-half of the lower mandible, showing the different proportions of the two horny laminae, and the extension of the horny substance at a, upon which the calcareous matter is deposited; a', the internal horny lamina; b, the external horny lamina. Nat. size. (Owen.)

Rhyncholites, upper, side, and internal views.

1, Side view (muschelkalk of Luneville). 2, Upper view (same locality). 3, Upper view (lias of Lyme Regis). 4, Calcareous point of an under mandible, internal view, from Luneville. (Buckland.)

The oolite (Stonesfield), and the lias of Lyme Regis and Bath, will serve as examples of the British strata wherein these beak-stones occur.

Fossil Nautili occur both in the tertiary and subjacent strata. M. Deshayes (Tables) records four fossil species (tertiary). Dr. Mantell notices *Nautilus imperialis*, from the arenaceous limestone or sandstone of Bognor; *N. elegans*, from the chalk (Lewes); the last-named species and *N. expansus*, from the chalk marl; *N. inaequalis*, from the gault or Folkstone marl (Folkstone); and a nameless species, from the Shanklin sand (lower green-sand). Professor Phillips (Yorkshire) records the following:—*N. lineatus* (inferior oolite); *N. astacoides* (lias); *N. hexagonus* (Kelloways rock); *N. annularis* (lias); and others in the Speeton clay and Brandsby slate. Mr. Lonsdale (*Oolitic District of Bath*) enumerates *N. lineatus* (lias); and *N. obesus* (inferior oolite). Dr. Fitton (*Strata below the*

Chalk) records *Nautili elegans, inaequalis, plicatus, radiatus, simplex, undulatus*, and an uncertain species, the first-named species from the upper and the rest from the lower green-sand. Mr. Murchison (*Silurian System*) describes and figures one species, *N. undosus*, from the Caradoc sandstone.

Dr. Buckland, who, in his 'Bridgewater Treatise,' gives a note describing the *Modus operandi* of the *Nautilus Pompilius* in swimming and sinking, thus concludes his observations upon the affinities of the chambered shells of *Cephalopods*.

It results from the view we have taken of the zoological affinities between living and extinct species of chambered shells, that they are all connected by one plan of organization, each forming a link in the common chain which unites existing species with those that prevailed among the earliest conditions of life upon our globe; and all attesting the identity of the design that has effected so many similar ends through such a variety of instruments, the principle of whose construction is, in every species, fundamentally the same.

Throughout the various living and extinct genera of chambered shells, the use of the air-chambers and siphon, to adjust the specific gravity of the animals in rising and sinking, appears to have been identical. The addition of a new transverse plate within the conical shell added a new air-chamber, larger than the preceding one, to counter-balance the increase of weight that attended the growth of the shell and body of these animals.

These beautiful arrangements are, and ever have been, subservient to a common object, viz. the construction of *hydraulic instruments* of essential importance in the economy of creatures destined to move sometimes at the bottom and at other times upon or near the surface of the sea. The delicate adjustments whereby the same principle is extended through so many grades and modifications of a single type, show the uniform and constant agency of some controlling intelligence: and in searching for the origin of so much method and regularity amidst variety, the mind can only rest, when it has passed back, through the subordinate series of second causes, to that great first cause, which is found in the will and power of a common Creator.*

NAVAL ARCHITECTURE. [SHIP.]

NAVAN. [MEATH.]

NAVARETE, JUAN HERNANDEZ, was born at Logroño in Castile. He is commonly known by the name of *El Mudo*, from having been rendered deaf and dumb by an illness in the third year of his age. This misfortune probably led to the choice of a profession, in which he made such rapid progress in the school of Fr. Vicente, at Madrid, that he was soon able to visit Italy, and especially to study at Venice the works of Titian. After his return to Madrid in 1568, he was appointed painter to the king, for whom he painted his finest works, which are preserved in the Escorial. Among them are a small picture of the Baptism of our Saviour, the celebrated 'Presepio,'* in which the principal light proceeds from the infant, the 'St. Hippolytus, in search by night of the body of St. Lawrence,' and a Holy Family, generally considered as his masterpiece, in which the singularity of the accessories† attracted as much notice as the beauties of the composition. His works at Valencia, Salamanca, and Estrella are scarcely inferior to the preceding, and all are distinguished by a brilliancy of colouring which justly gained him the appellation of 'El Ticioano Español.'

He died in 1577, aged fifty-three years.

NAVARETE DOMINGO FERNANDEZ, a learned Spanish Dominican of the seventeenth century, was sent in 1647 as missionary to the Philippine Islands, from whence he afterwards proceeded to China, where he remained many years, as head of the missions of his order, studying at the same time the language and the history of the country. He was at last put in prison by the Chinese authorities, but succeeded in escaping to Macao, from whence he returned to Europe in 1673. He gave to the pope an account of the missions in China, in which he exposed the latitudinarianism of the Jesuits in accommodating themselves to

* Presepio, a stable; a term applied by the Spaniards to that in which our Saviour was born.

† A cat, a dog, and a partridge. They were perhaps the cause of his being obliged to bind himself in a contract with King Philip not to introduce cats, &c., again in such subjects: 'Y en las dichas pinturas non pongo, gato, ni perro, ni otra figura que sea deshonesta.'

several of the superstitions of the natives, in order to increase the number of their pretended converts. This practice had already been denounced by Morales, another Dominican, and condemned by a papal decree of the 12th of September, 1645, of which Morales was the bearer to China. The Jesuits however, having obtained from Rome several modifications of this decree, persisted in their practices, which Navarrete himself appears to have winked at while in China.

On his return in 1673, Navarrete went to Rome, where he was well received by the pope. In 1678 he was appointed archbishop of Santo Domingo in the West Indies, where he died in the following year.

Navarrete wrote a work in Spanish, which has become very scarce, on the history and the moral and political condition of China, the first volume of which was published at Madrid in 1676; but the second volume, which contained an account of the disputes between the Jesuits and the Dominicans in China, is said to have been suppressed by the Inquisition. This work is entitled 'Tratados historicos, politicos, ethicos, y religiosos de la Monarchia de China,' fol., Madrid, 1676. It contains many curious particulars. At the end of the first volume are several decisions and decrees of the popes concerning the regulation of the Chinese missions.

NAVARINO, called *Neocastro* by the Greeks, a small town and fortress of Morea, built on the south coast of the bay of the same name, about five miles north of Modon, and about three miles measured across the bay from old Navarino, which is a ruined town with an old fort of the middle ages, built on a steep hill on the northern coast of the bay, near the site of ancient Pylos, which, according to Pausanias, was situated on the promontory Coryphasium. But there was another Pylos in Eleia, and a third one in Tryphylia, and all three claimed the honour of being the Pylos of Nestor. The Messenian Pylos was deserted by its inhabitants in the second Messenian war. It seems however to have revived afterwards, and Pausanias (*Messen.*, 36) speaks of it as an inhabited place, and mentions a temple, a monument of Nestor, and other ancient buildings existing in his time, of which no traces now remain. (*Leake's Morea.*) The island of Sphacteria, or Sphagia, lies across the entrance of the bay, and adds to its security, rendering it one of the best harbours in the Levant. Sphacteria is known in ancient history for the defeat and capture of the Lacedæmonians by the Athenians, in the seventh year of the Peloponnesian war. (*Thucyd.*, iv. 39.) [CLEON.] In modern times the bay of Navarino has become memorable for the naval battle which took place on the 20th October, 1827, between the French, English, and Russian combined fleet on one side, and the Turco-Egyptian fleet which was anchored in the bay on the other. The English had three ships of the line and four frigates, the French three ships of the line and two frigates, and the Russians four ships of the line and four frigates. The Ottomans had three ships of the line and twenty-five frigates, besides smaller vessels. Admiral Codrington had the command of the combined fleet, and his object was to oblige Ibrahim Pasha to evacuate the Morea. After some desultory negotiations and some evasions on the part of Ibrahim, Admiral Codrington resolved to attack Ibrahim's fleet. After a warm resistance, the Turco-Egyptians were completely defeated, with the loss of three ships of the line, four frigates, and about forty or fifty smaller vessels. The rest surrendered, and a convention followed by which Ibrahim evacuated the Morea, and the Greek prisoners whom he had sent to Egypt were restored to their country. The Egyptian ships which had not been destroyed were returned to the Pasha of Egypt. The battle of Navarino decided the independence of Greece.

The justice of the attack made by the combined fleets on the Turco-Egyptians at Navarino has been questioned on the ground of international rights, supposing those rights to be applicable to a semi-barbarous power as the Turks then were, which had frequently and unscrupulously violated them. The policy of the attack has also been questioned in reference to the national or individual interests of England and France. But one thing may be safely asserted in favour of the battle of Navarino: it fully attained the object for which it was fought—the emancipation of Greece. Unlike many other battles which have proved a useless waste of human lives, that of Navarino established the independence of a country and put an end to a murderous warfare. In this respect it may be compared to the battles of Trafalgar

and Waterloo in our own times, as the former may be said to have put an end the maritime contest of France against England, and the second effectually terminated the Continental war. Before the battle of Navarino, the Greeks were obviously unable to drive the Ottomans and Egyptians out of their country, whilst at the same time they were determined not to submit; the contest had lasted seven years, and it could never have been terminated except by the extermination or transportation of the Greek population, measures which had begun to be carried into effect on a large scale by Ibrahim in the Morea. But the extermination of a whole people and the slavery and sale of the women and children are things which will not be tolerated in Europe at the present day.

NAVARRA (Navarre), a kingdom or province of Spain, lying between 41° 58' and 43° 17' N. lat., and between 43 and 2° 27' W. long. It is bounded on the north by France, on the east by Aragon, on the south by the province of Soria in New Castile, and on the west by the provinces of Guipuzcoa and Alava in Biscay. In shape it is an irregular quadrilateral, about 80 miles in extreme length from north to south, and 64 in its greatest breadth from east to west. Its area is nearly 2500 square miles, and its population now 271,000; by the census of 1788 it was estimated at 288,000, of whom 3550 were priests, monks, and nuns, 9910 servants, and 13,054 nobles.

Three-fourths of the surface of Navarre are mountainous; the remaining fourth consists of a few large valleys and some small fertile plains. The grand chain of the Pyrenees, which forms the northern frontier, sends off numerous other chains, which gradually decrease in height as they approach the south. The loftiest mountain, Altobiscar, attains the height of 5380 feet above the sea. Adi is 5218 feet high, and Alcorrunz, Arza, and La Runa are all considerably above 3000 feet. That part of the province which borders on France is very rugged, barren, and thinly peopled, excepting however the valleys of Baztan, Santistevan de Lerin, and las Cinco Villas de Navarra (Lesaca Vera, Sunbilla, Echalar y Aranzaz), a rich and delicious country. The southern part is much more level and fertile, and better inhabited.

The principal river is the Ebro, which, for nearly 40 miles, forms the southern boundary of the province; its tributaries are the Borunda, Ega, Arga, Aragon, Irati, Salazar, and Esca, all flowing from the north; and the Queilas and Alhania from the south. The extreme north of the province is watered by the Bidasoa, which rises in the Pyrenees, and empties itself into the Bay of Biscay at Fuenterrabia. Besides these rivers Navarre is watered by innumerable small streams, many of which, being formed wholly of melted snow, are dried up by the summer heats. The climate of the northern districts is exceedingly cold in winter, and rarely subject to excessive heat in summer; in the south it is far more genial, and highly delightful and salubrious. The soil in the low grounds is very rich, and susceptible of a higher degree of cultivation than it has received: there is also much fine pasture-land. The principal valleys are, Baztan in the north, containing fourteen villages and 7500 inhabitants, very fertile in fruit and maize, and abounding in cattle; that of Roncesvalles, renowned in history for the defeat of Charlemagne and his twelve peers, in 778; and those of Lescou, Roncal, Baigorri, Salazar, and Aezcoa.

Navarre, from its mountainous character, is by nature almost isolated from the countries around it. In the northern frontier there are ten passes; the five principal are those of Vera, Maya, Roncesvalles, Ochagavia, and Isava. On the sides of Biscay and Aragon the approaches are more difficult of access; and on the side of Castile the deep and rapid Ebro forms a barrier passable only by the three bridges of Logroño, Lodosa, and Tudela. The roads which traverse the province are excellent.

Of the geology of Navarre little is known. The mountains are mostly of transition and secondary rocks; jasper and marbles are also found. There are many mines of iron and one of copper; one also of rock-salt near Valtierra, yielding annually about 298,000 lbs., and several hot springs.

Forests of pines (*pinus sylvestris*) cover the slopes of the Pyrenees, and much wood is cut and sent down by the mountain streams to the Ebro, by which it is floated onward to Aragon and Cataluña. The other principal forest trees are the oak, evergreen and deciduous, the olive, the chestnut, the beech, and box. The forests are not extensive, yet

Navarre yields more valuable timber than any other province of Spain. Heaths, ferns, and broom, with many aromatic plants, grow on the mountains. Of grain Navarre yields annually 3,452,800 bushels, of which about 2,053,550 are of wheat, 303,850 of maize, 673,200 of barley, 308,000 of oats, 70,850 of rye, and the remainder of spelt-wheat. Of vegetables (including chesnuts) the annual quantity is about 197,600 bushels, of which the principal part are broad and kidney beans. The annual produce of hemp is 600,000 lbs., of flax 200,000 lbs., of olive-oil about 130,000 gallons, and of wines, which are excellent, and of various descriptions, about 10,500,000 gallons. After a rich vintage people are invited by the public crier to take the old wine away from particular vaults gratis, in order to make room for the new. The old wine is even wasted sometimes, and allowed to run down the streets. A small quantity of cyder is also produced in the Baztan and Cinco Villas.

According to Miñano, there are in Navarre about 38,000 head of horned cattle, 630,000 sheep, 70,000 goats, 32,000 pigs, and 26,000 mules. The annual produce of wool amounts to 1,412,000 lbs. The mountains abound in game and the rivers in fish. The average value of all the natural productions of Navarre, animal, vegetable, and mineral, Miñano estimates at nearly 1,500,000*l.* The wild animals are wolves, foxes, and wild boars in the Larraun Mountain.

The manufactures of Navarre are inconsiderable. There are 634 factories of coarse linen, 319 of woollen cloth, 67 of leather, 12 of soap, 30 of iron, and of brandy the quantity annually distilled averages 2,000,000 gallons. Besides these are some potteries, a royal shot and shell foundry, and some manufactories of Spanish liquorice. At the commencement of the present century the average value of manufactures was 142,600*l.* per annum.

The greater part of the produce, natural and manufactured, is consumed in the province, but about 30,800 English bushels of grain, a little oil, half the wine, the greater portion of the wool, and two-thirds of the iron annually remain unconsumed, and are exported, which however fall very far short in amount of the cottons and silks, cutlery, tobacco, sugar, spices, and other luxuries imported, principally from France.

Navarre is divided into five districts, or *merindades*, as they are called, viz. that of Pamplona in the north, of Tudela in the south, Sangüesa in the east, Estella in the west, and Olite in the centre. Each *merindad* has a capital town of the same name. The kingdom contains 9 cities, 145 towns, 675 villages, with a total of 38,289 houses. It has two bishoprics, those of Pamplona and Tudela; 753 parishes, 70 convents and hermitages, 1 university, 4 colleges, and 12 hospitals.

The metropolis is Pamplona, situated on an eminence on the left bank of the river Arga, in the midst of a small, fertile, circular plain, called La Cuenca, enclosed by lofty mountains. It was antiently the court of the kings of Navarre, is still the residence of the viceroy of the province, the seat of administration, and see of a bishop, suffragan of Burgos. It is divided into twenty wards, and contains a cathedral (a neat Gothic edifice of great antiquity, disfigured by a modern façade), 4 parish churches, 7 convents of monks and 2 of nuns (suppressed in 1835, because under the authority of the queen), a royal and an episcopal palace, a senate-house, a town-hall, a mint, a public granary, a university, an hospice, a foundling hospital, a theatre, 41 inns, 1632 private houses, and a population of 15,000. The city, including the citadel, measures 960 yards from north to south, and 1633 from east to west. It is ill built, but contains a few handsome houses; the streets are narrow, but well paved, and kept thoroughly clean by means of sewers. There are 3 large and 3 small squares, in the largest of which bull-fights are occasionally held, 6 public fountains, and an aqueduct, by which the city is supplied with water from the mountain of Subiza, twelve miles distant. Pamplona is well fortified; the citadel is a regular pentagon, of 1000 feet each side: it was built by Philip II. There is a beautiful promenade, called Taconera, within the walls, and three others without. The manufactures of Pamplona are very trifling, namely, two tanneries, two factories of wax, one of woollen cloth, and one of guitar-strings, besides a paper-mill and six corn-mills on the Arga. Its commerce is confined to the importation of woollen and silken goods, principally from England and France; but some cloth is imported from Castile, serges and silk from Aragon, and a little Indian silk from Cataluña.

Pamplona is called Pompelon by Strabo (161. *Casaub.*), who adds, 'as if it might be Pompeiopolis,' that is, the city of Pompey. The people are called Pompelouenses by Pliny (iii. 3). The name of the city was corrupted by the Arabs, who took it in the beginning of the eighth century, into Bamblona. In 778 it was destroyed by the French, but afterwards rebuilt. In 907 it was besieged by the Moors, and in 1138 by the Castilians, but on both occasions it maintained a successful resistance. In 1277 it was again taken by the French. In 1512 it was blockaded and taken by the duke of Alba, general of Ferdinand the Catholic. In 1808 it was seized by the French, who had been allowed to enter as friends; in 1812 blockaded by Mina; and in 1813 it capitulated to the allies under the duke of Wellington, after the battle of Vitoria.

The city next in importance is Tudela, situated on the right bank of the Ebro, which is here crossed by a very fine bridge of seventeen arches and 1200 feet in length. It has a cathedral, 10 convents (lately suppressed), 2 hospitals, and a population of 8150. The streets are narrow and crooked, but well cleansed; the houses are lofty, and all contain fountains. About two miles east of Tudela is the commencement of the canal of Aragon, which, when finished, will connect Navarre with the Mediterranean.

The other cities are—Estella, a town lately fortified by the Carlists, with 4600 inhabitants, recently the stronghold of Don Carlos; Olite, with 5000 inhabitants, celebrated for its salubrious climate, and at one time the residence of the kings of Navarre; Corella, with 4000; Tafalla, with 2800; and Sangüesa, with 2500 inhabitants.

The political constitution and laws of Navarre are still the same which it enjoyed when an independent monarchy, and differ altogether from those of the rest of Spain. It is governed by a viceroy, who presides at the royal council, the supreme tribunal for civil and criminal causes. The legislative body is composed of the three estates of the kingdom: the clergy, who attend by right of their station; the nobility, by right of birth; and the deputies, who are elected by the people. Navarre enjoys also peculiar fiscal privileges.

The inhabitants of Navarre are tall, well made, muscular, very hardy and brave, independent in spirit, strongly attached to their government and religion, and jealous of their privileges. The guerrilla bands under Mina proved most formidable opponents to the French in the War of Independence. The Navarrese are also grave and reserved, but witty and shrewd, obstinate and quarrelsome, and yet industrious and honest.

Castilian is the general language of the province, but the Basque, or a mixture of these two languages with French, is spoken in some districts.

The earliest inhabitants of Navarre were called Vascones by the Romans. In A.D. 470 they were subdued by the Goths. Early in the eighth century Navarre was conquered by the Arabs; but the Christian inhabitants who had fled to the recesses of the Pyrenees, resolving to expel the invaders, chose a noble knight, Garci Ximenez, for their chieftain or king; and thus was founded the monarchy of Navarre. His family became extinct in the middle of the ninth century, and the Navarrese then elected Iñigo Sanchez, count of Bigorre, in the hands of whose descendants the sceptre of Navarre remained for five centuries. In 1512 Ferdinand the Catholic obtained possession of that part of the antient kingdom of Navarre which forms the present province, and annexed it to the Spanish dominions, leaving unconquered the portion on the northern side of the Pyrenees, which was afterwards united by Henri IV. to the crown of France, and is now known as the department of the Lower Pyrenees. On the invasion of Spain by Bonaparte, Navarre eminently distinguished itself by its obstinate resistance: and it has recently attracted the eyes of all Europe as being, with Biscay, the principal theatre of the civil contest between Don Carlos and Isabel II. of Spain.

NAVICELLA. [NERITIDÆ.]

NAVIGATION. [COMPASS; LONGITUDE AND LATITUDE, METHODS OF FINDING; MERCATOR'S PROJECTION; SAILING.]

NAVIGATION LAWS. [SHIP AND SHIPPING.]

NAVIGATOR'S ISLANDS, a group of islands, situated in the Pacific, between 10° and 15° S. lat. and 185° and 195° E. long., consists of nine islands, of which the largest, called Pola, or Chatam, is the most western. It is twice as large as Otaheiti, and not inferior in fertility and beauty. From east to west it measures about 45 miles. Eastward of Pola are Ojalava and Mouna, which are hardly inferior in size. The other six islands are small. They all appear to be volcanic; all the rocks of the beach, upon which the sea breaks with such force as to throw the water more than fifty feet high, are only pieces of lava, rounded basalts, or coral, by which the islands are wholly surrounded. In the coral reefs are narrow passages for boats. Along the beach are level tracts, but at some distance the country rises into hills and mountains. The islands are clothed even to the very summits of the hills with trees loaded with fruit, and are very populous. They abound in pigs, dogs, fowls, birds, and fish, and the lower parts are covered with extensive plantations of guavas, bananas, and other fruits. The sugar-cane grows spontaneously on the banks of the rivers. The inhabitants belong to the Malay race, and speak a language which is a dialect of that used in the Friendly Islands. They are averse to the visits of Europeans, and much inclined to quarrel with them. (*La Perouse's Voyage round the World.*)

NAVY. Before we describe the present constitution and force of the British navy, we shall give a short sketch of the rise and progress of that vast machine, to which England is so much indebted for the power and prosperity which she enjoys, commencing with the origin of naval enterprise among our barbarian ancestors.

All nations inhabiting the shores of the sea or navigable rivers possessed from the earliest period vessels of a rude construction. But these were so inadequate to withstand the winds and waves in our northern seas, that it was not until the reign of the emperor Probus, A.D. 276-82, that the veil of terror hanging over the ocean and distant voyages was removed. That emperor, in pursuance of his plan of colonising the border lands, which were exhausted by war, with people from the crowded countries of the barbarians, had carried a party of Franks into Pontus, with a view of defending that country against the Alani. Love of home induced some of these people to attempt their return; they seized ships on the Euxine, and plundered the coasts of Greece, Asia, and Sicily, either to supply their wants or for revenge: passing the Pillars of Hercules, they veered to the right, and completed their voyage by disembarking at the mouth of the Rhine. From this voyage we may date the origin of nautical enterprise. The Saxons took advantage of the rich harvest thus opened to all who would attack the Roman provinces by sea, and ravaged the coasts to such an extent as to oblige the Romans to establish a fleet in the English Channel to repel them. After the Saxons had been long in possession of England, they lost their naval arts, and in their turn became a prey to the constant attacks of the Sea-kings, Vikings, and other pirates. We have no record of the size or number of the vessels which sustained so many conflicts with the Danes in the ninth century. Alfred the Great was the founder of the English navy. He first perceived the necessity of a fleet to protect the coasts from the swarms of pirates in the northern seas. A slight advantage gained by some ships of his over the Danes, in 876, induced him to build long ships and galleys, which, as his countrymen were not competent to manage them, he manned with such piratical foreigners as he could engage. After he had driven out the Danes, he applied his talents to improve his ships, and built vessels higher, longer, and swifter than before, some rowing thirty pairs of oars, others more. Ethelred made a law that whoever was lord of 310 hydes of land should furnish and build one vessel for the service of the country.

William the Conqueror established the Cinque Ports, and gave them certain privileges on condition of their furnishing 52 ships for 15 days, in case of emergency. King John claimed for England the sovereignty of the seas, and declared that all ships belonging to foreign nations, which should refuse to strike to the British flag, should be deemed fair and lawful prize. In the year 1293, an English sailor having been killed in a French port, war ensued, which it

was agreed to settle by a naval action, which was fought in the middle of the Channel, and the English, being victorious, carried off above 250 sail. In 1340, when King Edward III. with 240 ships was on his voyage to Flanders, he fell in with and completely defeated, off Sluys, the French fleet of 400 sail, manned with 40,000 men. The same monarch blockaded Brest with 730 sail, containing 15,000 men. Many of the ships composing these fleets were Genoese and Venetian mercenaries, but they must have been very small, and the numbers of ships and men are probably exaggerated. Henry V. had something of a navy, for we find among the records in the Tower, a grant under his hand of annuities to 'the maistres of certaine of our owne grete shippes, carrakes, barges, and ballyngers.' Henry VII., who succeeded in 1485, seems to have been the first king who thought of providing a naval force which might be at all times ready for the service of the state. He built the Great Harry, properly speaking the first ship of the royal navy; she cost 15,000*l.*, and was accidentally burnt in 1553. Henry VIII. perfected the designs of his father. He constituted the Admiralty and Navy Office, established the Trinity House, and the dockyards of Deptford, Woolwich, and Portsmouth; appointed regular salaries for the admirals, captains, and sailors; and made the sea service a distinct profession: he also made laws for the planting and preservation of timber. In 1512, when a fleet was fitted out against France, under Sir Edward Howard, lord-high-admiral, the following allowances were made:—

For his own diet, maintenance, wages, and rewards, per diem	s.	d.
Each captain for ditto, ditto	10	0
Every soldier, mariner, and gunner, for his wages per lunar month	5	0
And for his victuals	5	0

The ships of this period were high, unwieldy, and narrow; their guns were close to the water, and they had lofty poops and prows, like Chinese junks, insomuch that Sir Walter Raleigh informs us 'that the Mary Rose, a goodly ship of the largest size, by a little sway of the ship in casting about, her ports being within 16 inches of the water, was overset and sunk.' This took place at Spithead in the presence of the king, and most of her officers and crew were drowned. The Henri Grace de Dieu, the largest ship built in this reign, is said to have measured above 1000 tons. At the death of Henry VIII., the tonnage of the navy was 12,000 tons. Elizabeth increased the navy greatly. The fleet which met the Spanish Armada numbered 176 ships, manned by 14,996 men; but these were not all 'shippes royal,' for she encouraged the merchants to build large ships, which on occasion were converted into ships of war, and rated at 50 to 100 tons more than they measured. She raised the wages of seamen to 10 shillings per month. Signals were first used in this reign as a means of communication between ships. In 1603 the navy had 42 ships, measuring 17,000 tons. In the reign of James I. lived the first able and scientific naval architect, Phineas Pett, and the king had the good sense to encourage him. Pett introduced a better system of building, and relieved the ships of much of their top hamper. Before the civil wars broke out, Charles I. built the Sovereign of the Seas, of 100 guns, and measuring 1637 tons. In this reign the navy was first divided into rates and classes. Cromwell found the navy much reduced, but his energy restored it, and he left 154 sail, measuring 57,643 tons, of which one-third were two-deckers. Cromwell first laid before parliament estimates for the support of the navy, and obtained 400,000*l.* per annum for that purpose. The navy flourished under Charles II., with the duke of York at its head, assisted by Samuel Pepys, as secretary, until 1673, when the duke's inability to take the test oath caused his retirement, and the king's pecuniary difficulties leading him to neglect the navy, it fell into decay. The duke of York was recalled to his post in 1684, and at his accession in the following year there were 179 vessels, measuring 103,558 tons. James II., on coming to the throne, took active measures for the restoration of the navy; he suspended the Navy Board, and appointed a new commission, with which he joined Sir Anthony Deane, the best naval architect of the time, who essentially improved the ships of the line by copying from a French model. Four hundred thousand pounds per annum were set apart for naval purposes, and so diligent were the commissioners that at the Revolution the fleet was in excellent condition, with sea stores complete for eight months for each ship. The force was

154 vessels, carrying 6930 guns, and 42,000 men, whereof nine were first-rates.

King William immediately on being placed on the throne went to war with France, whose navy was then very powerful; in 1681 it consisted of 179 vessels of all sorts, carrying 7080 guns, besides 30 galleys. An act was passed in his second year, for building 30 ships, to carry 60, 70, and 80 guns respectively. The dockyard at Hamoaze, out of which has since grown the considerable town of Devonport, which now returns two members to parliament, was then established. Queen Anne found at her accession the navy to consist of 272 vessels, measuring 159,020 tons, but this estimate includes hulks, boys, and other vessels not carrying guns. In 1704 one of the greatest and most destructive storms ever known took place. It began in the middle of November, and did not attain its greatest height till the 27th. The Eddystone lighthouse was destroyed, no less than 10 men-of-war were totally lost, and many more were driven on shore and damaged. All measures adding to the strength and efficiency of the navy were exceedingly popular during this reign. We find at the death of Anne in 1714, that the number of ships was less, but the tonnage increased, being ships 198, guns 10,600, tons 156,640. The parliamentary vote of that year was 245,700*l.* and 10,000 seamen and marines. During the first four years of George I., large sums were voted for the extraordinary repairs which were required after the long war. A new establishment of guns also was ordered in this reign. The navy remained stationary till 1739, when hostilities commenced against Spain, and the navy was augmented, particularly in the smaller classes, and the dimensions of several classes were enlarged. War broke out with France in 1744, at which period there were 128 sail of the line. At this time all prizes taken by H.M.'s ships were declared to be the property of the captors. In 1747 a naval uniform was first established. The navy increased vastly during this war, in which 35 sail of the line were taken or destroyed by the English. George III. at his accession found the navy to consist of,

Ships of the line 127 } measuring 321,104 tons.
50 guns and under 198 }

The vote for the year 1760 was 432,629*l.*, and 70,000 seamen and marines. In the short war of 1762, 20 sail of the line were added to the navy, and at the end of the American revolutionary war it was composed as follows:—

Sail of the line 171 } about 500,000 tons.
Under 203 }

The navy was kept in a high state of preparation, and when, on the 1st of February, 1793, the French republic declared war against England, this country was not unprepared. A period now commences in which the gigantic efforts made by England, and the protection necessary for a mercantile marine, which almost monopolised the commerce of the world, raised the British navy to such a height as to enable it single handed to maintain the sovereignty of the seas against all other navies combined. Sir Charles Middleton, afterwards Lord Barham, had, when comptroller of the navy in 1783, established the regulation that a great proportion of stores, sails, &c. should be laid by for each ship in ordinary; so that in a few weeks after the declaration of war there were 54 sail of the line and 146 smaller vessels at sea. The vote for the service of the navy was 5,525,331*l.*, 85,000 seamen and marines. The navy of France had never been so powerful: it amounted to above 200 vessels, of which 82 were of the line and 71 in addition were immediately ordered to be built. The English had about 115 sail of the line fit for service, but the majority of the French ships were larger and finer, and carried heavier guns on their lower or principal battery. The following abstract will show the losses on both sides up to the peace of Amiens, exclusive of the casual losses.

	Captured.	Destroyed.
British ships of the line	5	..
Smaller vessels	37	9
Total	42	9
French ships of the line	32	11
Dutch do.	18	0
Spanish do.	6	5
Danish do.	2	0
Total	58	16

	Captured.	Destroyed.
French smaller vessels	266	44
Dutch do.	62	6
Spanish do.	57	10
Total	443	76

This estimate does not include 807 privateers, chiefly French, taken and destroyed. Of the above, 50 sail of the line and 94 under that size were added to the British navy.

During the peace of Amiens preparations for war were actively continued on both sides, and the declaration on the part of England was made in the month of May, 1803, at which time the navy was of the following force, as compared with 1793:—

	Ships of line.	Under.	Tonn.
1793	153	411	402,555
1803	189	781	650,976

Notwithstanding the apparent increase, there were not so many line-of-battle ships fit for sea at the latter as at the former period by about ten. The French force in serviceable line-of-battle ships in March, 1803, was 66, the British 111. During this war there were employed from 100,000 to 120,000 seamen and marines till 1810, when the number was increased to 145,000. There were about 100 sail of the line, 150 frigates, and above 200 sloops, besides small armed vessels, amounting in the whole to about 500 sail of pendants constantly employed. The following abstract shows the losses on each side during the war:—

	Captured.	De.royed.
British—Ships of line	0	0
Under	83	7
	83	7
Enemies'—Ships of line	55	14
Under	79	23
	134	37

of which 33 sail of the line and 68 under were added to the British navy.

In George III.'s reign the dockyard of Pembroke was established.

The parliamentary vote for the service of the navy, 1839-40, was as follows:—

Officers	3,400	For the effective service	£3,492,132
Petty do.	3,998	For the non-effective do.	1,488,221
Seamen	12,846	Other departments, viz.,	
		convicts and transport	
	20,244	of troops	217,158
Marines	9,000		
	29,244	Total charge	£5,197,511

The following tables will show the force of the British navy at three distinct periods, viz.: the breaking out of the French revolutionary war; a few years subsequent to the peace; and the present time: also the disposition of the British naval force at the present time, as well as the naval force of other countries possessing a navy.

Prince Regent in a memorial. The present establishment of rates and classes was fixed by order in council, February, 1817:—

Class I.—Rated ships:

First-rate, comprising all three-decked ships.

Second. One of Her Majesty's yachts, and all two-decked ships whose war-complements consist of 700 men and upwards.

Third. Her Majesty's other yachts, and all ships whose complements are from 600 to 700.

Fourth. Ships whose complements are from 400 to 600.

Fifth. Ships whose complements are from 250 to 400.

Sixth. Ships under 250.

Class II. Sloops and bomb vessels.

All such vessels as are commanded by a commander.

Class III. All other smaller vessels, such as are commanded by lieutenants, or other inferior officers.

Table showing the armament of a ship of each class, and the weight of metal.

Holland has 104 gun-boats; Denmark, 67; Sweden, 337.

Until the Restoration there does not appear to have been any precise division into classes; nor have we any account of the armament of ships; at that time certain ships were ordered to be built to carry the following:—

Description of Guns.	1st Rate. 780 men.	2nd Rate. 680 men.	3rd Rate. 470 men.
Cannon = 42 pounders	26
Demicannon = 32 pounders	26	26
Culverins = 18 pounders	28	26	..
Demi do. = 12 pounders	26
Sakers = 6 pounders	28	26	..
Forecastle	4	..	4
Quarter-deck	12	10	10
3-pounders	2	2	4
Total number of guns	100	90	70

There was however no uniformity preserved; and in 1745 a committee was appointed, which recommended certain changes in the rating and armament, which however were not adhered to any more than the former systems. At the peace the Board of Admiralty represented this to the

Great improvements have taken place in the size and form of the British ships, as well as in the arrangement of the materials composing them, especially during the present century. As France and Spain enlarged their ships, the English were obliged to do the same; while from many of their ships added to the English navy we greatly improved our models. The following view of the increase of the size of first-rates will demonstrate this point:—

Year.	Tonnage of First-Rates.
1677	1500 to 1600
1720	1800
1745	2000
1795	2350, the Ville de Paris.
1808	2616, Caledonia.
1839	3100, Victoria, and 3 others building.

There is now a frigate of greater tonnage than the first-rate of 1745, viz. the Vernon, of 2080 tons, and 50 guns.

We cannot do more than glance at the improvements in naval architecture. Sir Robert Seppings, late surveyor of the navy, introduced the circular bow and stern, the system of diagonal timbering or bracing, whereby the strength and durability of our ships are so immensely increased; the method of scarfing short pieces, by which the delay and difficulty often attendant on the procuring of crooked timber are avoided; the making frigate-timber applicable to the building of line-of battle ships, by the use of a circular coak, or dowel, instead of chocks, thereby effecting a saving of about 1000% in the building of a 74-gun ship, and the use of iron knees, by which he effected an immense saving of timber and space.

Sir William Symonds, now surveyor of the navy, has effected a still further economy of space by removing the chocks behind the iron knees, and using metal diagonal braces instead of wood. In latter years the various naval architects, Sir R. Seppings, Captains Hayes and Symonds, R.N., and Professor Inman, have been permitted to try their respective systems in various experimental squadrons, composed of vessels built under their directions; and although many opinions are held as to the merits of each, there can be but one with regard to the general advantage arising to the science of naval architecture, so long neglected. A school for shipwright apprentices was established at Portsmouth, which, after producing more officers than could be provided for, was broken up. Our ships, those at least built of oak—for we have not yet worn out a ship built of teak—do not seem to be as durable as in former times. The Royal William, of 100 guns, which bore the flag of Sir Richard Bickerton at Spithead in 1813, and was shortly after broken up, was built in the year 1719. The Sovereign of the Seas, built in 1637, was repaired in 1684, when all the ancient timber was so hard that it was difficult to work it. It was the practice in the north of England, and in Staffordshire especially, to bark timber standing, and to let it remain in that state for a time to season. The Sovereign of the Seas was built of such timber. The Achilles, 60, was built by contract in 1757, of timber barked in the spring and felled in the next winter: she was docked in 1770, and found exceedingly sound, and was sold 1784, because she was too small for the line-of-battle. The Hawke sloop was built in 1793. Half of this vessel was built of timber barked in 1787, and felled in 1790; the other half of timber felled in the usual manner from the same soil and neighbourhood. In 1803 she was so decayed that she was taken to pieces; both sides appear to have been equally decayed.

The government of the navy is vested in the lord-high-admiral, which office has been in commission since the Revolution, with the exception of two short periods, 1707-8 and 1827-8, when it was held respectively by Prince George of Denmark and his late majesty when duke of Clarence. At present the Board consists of a First Lord, who is a member of the cabinet, and five junior lords. By their orders all ships are built, sold, or broken up; commissioned, employed, and paid off. All appointments and promotions are made or approved by them; all honours, pensions, and gratuities are granted on their recommendation. All orders for the payment of naval monies are made by them; they prepare the navy estimates, and lay them before parliament. The civil departments of the admiralty are directed by the surveyor of the navy, accountant-general, storekeeper-general, comptroller of victualling, and physician-general.

The navy is composed of two bodies of men—seamen and marines.

There are commissioned, warrant, and petty officers.

The commissioned officers are flag-officers, captains, commanders, and lieutenants.

Flag-officers are divided into the following classes, and rank and command in the order here following:—

Admirals of the fleet.

Admirals of the red, white, blue squadrons.

Vice-admirals of the red, white, blue squadrons.

Rear-admirals of the red, white, blue squadrons.

There are superannuated and retired rear-admirals, who enjoy the rank and pay, but do not rise.

The admiral of the fleet, when in command, bears the union flag at the main-top-gallant-mast. The other flag-officers bear a square flag of the colour of their squadron at the main, fore, or mizen top-gallant-mast, according to their rank.

The flag-officer holding the chief command of a fleet or squadron employed within certain geographical limits, termed a station, is called a commander-in-chief. He is responsible for the efficiency and conduct of the fleet under his orders; he disposes of the vessels composing it in such manner as will be most advantageous for the service; but without some especial necessity he is never to send one beyond the limits of his station. All vacancies in ships under his orders which are caused by death or dismissal from the service by the sentence of a court-martial, are in his gift.

A temporary rank is given to captains called commodore; they are of two classes; the first class having the pay and allowance of a rear-admiral, with a captain under him; they bear a broad pendant, but must strike it in the presence of a senior captain. Captains and commanders are appointed to command her majesty's ships, except when the latter are appointed to flag-ships and ships of the line, under a regulation of his late majesty when lord-high-admiral; in which case they must have served three years in command of a sloop or as first-lieutenant of a rated ship.

When a captain or commander is ordered to commission a ship, he does so by hoisting a long pendant, having a St. George's cross on a white field next the mast, and a fly of the colour of the Admiral's flag under whose orders he is placed. No vessels, except such as belong to her majesty, or are hired for her service, and commanded by a naval officer, are entitled to wear this pendant. The ship being commissioned, a hulk, or receiving ship, is allotted for the use of the crew while sitting for sea; a party of marines, commanded in rated ships by a commissioned officer, is sent on board; seamen are entered as they volunteer, on being reported fit for the service after examination by the surgeon; stores are demanded as required, and the sea-stores, provisions, and water stowed away. When ready for sea, the ordnance and powder are received on board; the crew are paid two months' wages in advance, and the ship only waits the sailing orders from the admiralty to proceed to her destination. The duty of the captain as regards the books and accounts is regulated by act of parliament; but the interior arrangements and discipline depend mainly on himself, in which he has for his guidance the act 22 Geo. II., called the Articles of War, and the General Printed Instructions issued by the Admiralty. All muster and pay books, &c. are signed by the captain, commander, or senior lieutenant, master, and purser, or other officer in whose charge the stores in question may be placed. A commander must have been employed on actual service and full pay for one complete year to become eligible for promotion to the rank of captain.

The senior lieutenant is nominated by the captain, and has under his direction the whole management and superintendence of the internal arrangements of the ship; indeed on the qualifications of this officer must in a great measure depend the state of discipline and efficiency. The other lieutenants take the watch by turns, during which time they have charge and command of the ship; they are never to quit the deck without being relieved. The watches are periods of four hours, except that from four to eight p.m., which is divided into two, called the dog-watches. No mate is eligible for the rank of lieutenant until he has served six complete years in the navy, has completed his nineteenth year, and passed in seamanship and navigation.

A lieutenant must have served two complete years at sea to qualify him for promotion to the rank of commander. The warrant and petty officers take rank and command in the order in which they stand in the table of pay, with the exceptions here following:—

Masters,	} Rank with, but subordinate to Lieutenants.	Mates,
Secretaries,		Second Masters,
Physicians,		Assistant Surgeons,
Chaplains,		Gunners,
Surgeons,		Boatswains,
Pursers,		Carpenters,

of whom, masters, mates, second-masters, gunners, boatswains, carpenters, and take military command.

The master has charge and stowage of the holds; a general charge of stores and storerooms, over the gunner, boatswain, and carpenter; and navigates the ship under the directions of the captain. Secretaries are appointed by the flag-officer whom they serve.

Chaplains must be in priest's orders of the Church of England.

The purser has charge of the provisions, and the issuing of them, also of the slop clothing, soap, and tobacco; he enters into a penal bond with sureties for the honest discharge of his duties.

Mates are midshipmen who, having passed the examination qualifying them for the rank of lieutenant, receive a warrant from the captain; their rank and command cease on their discharge or the ship being paid off.

Gunners, boatswains, and carpenters must have served a complete year as petty officers before they can be promoted. The gunner has charge of all ordnance stores; the boatswain, of all the sails, rope, and rigging; the carpenter, of all stores in his department, and is also to see the ports secure and water-tight, and to sound the well daily, and have the pumps in order for service.

In the event of the command of a ship devolving on petty officers, they are to take rank and command as they stand in the table of pay, except the following, who are not to take command:—

Schoolmasters, Masters-at-arms,
Clerks, Ship's corporals.

Midshipmen are rated by the captain, being fourteen years of age, and having served two years as volunteer of the first-class, or three in any other capacity; they are appointed by the captain, subject to the approval of the Admiralty, only one fresh entry into the service being allowed in each ship. They have no specific duties.

Schoolmasters must pass an examination to qualify them for that situation.

Cooks, Ropemaker,
Masters-at-arms, Caulkers,
Sailmakers, Coopers,

are appointed by warrant from the Admiralty or commander-in-chief.

The crew of a ship consists of petty officers, able seamen, ordinary seamen, landsmen, boys, and marines. In time of peace the whole crew are entered voluntarily; during war, the very superior rate of wages which the merchants are compelled to give, renders the press inevitable. The following persons are exempt from it, and no seaman can be impressed except by an officer having a press-warrant:—

Masters of merchant vessels;
Mates of those above 50 tons;

Boatswains and carpenters of vessels of 100 tons and upwards;

Men belonging to craft of all kinds employed in the navy, victualling, ordnance, excise, customs, and post-office;

Watermen belonging to the insurance offices in London and Westminster;

All men above 55 or under 18 years of age;

Apprentices not having used the sea before the date of their indentures, and not more than three years from the said date;

Landsmen not having served at sea full two years;

Harpooners, line-managers, steerers, and all seamen and mariners who have entered the Greenland and southern whale-fisheries.

The best seamen are rated petty officers by the captain; they are of two classes, distinguished by a crown and anchor for the first class, and an anchor for the second, worked in white cloth upon the left arm; they have an increase of pay, and are not amenable to corporal punishment while holding that rank.

There is a supply of boys to the navy from the asylum at Greenwich and from the Marine Society, but many more are brought into the navy by volunteering. Every ship, according to her rate or class, bears a certain number of marines, as part of her complement. [MARINE.]

For the due maintenance of that discipline without which the navy would be powerless, the captain or commander of every ship or vessel is authorised to inflict corporal punishment on any seaman, marine, or boy, by warrant under his hand. Courts-martial are ordered by the Admiralty and commanders-in-chief.

P. C., No. 992.

The following abstract shows the daily allowance of provisions to every person in the fleet:—

Fresh meat, 1 lb. Soft bread, 1½ lb.
Vegetables, ¼ lb. Beer, 1 gallon.

When the above are not issued, the following:—

Salt beef, ½ lb. } alternately { Salt pork, ½ lb.
and } and
Flour, ½ lb. } Peaso, ½ pint.

Biscuit, 1 lb.
Spirits, ½ pint, or wine, 1 pint; and, whether on fresh or salt provisions,

Cocoa, 1 oz. Vinegar, ½ pint } weekly.
Tea, ¼ oz. Oatmeal, ½ pint }
Sugar, 1½ oz.

A portion of the flour may be exchanged for a proportion of suet and raisins; and after 14 days on salt provisions, lemon-juice is allowed in addition.

The following tables will show the full-pay of every officer and seaman in each class of her Majesty's ships, and the half-pay of all officers entitled to the same:—

	Full-Pay.	Half Pay.
	£. s. d.	£. s. d.

Pursers	957	644	560
Chaplains	62	64	29

There are 19 naval instructors and schoolmasters appointed under regulations issued May 1st, 1837, who receive 6l. 14s. per lunar month, and 30l. per annum bounty, and 5l. a-year from each young gentleman who shall receive instruction from him. An additional rating of first-class petty-officers is also allowed, called 'seamen's schoolmaster'

There are at present 56 retired rear-admirals and 8 retired captains; 100 retired commanders under order in council of 30th January, 1816, and 181 under order in council November 1st, 1830. There are 7 naval Knights of Windsor, 9 superannuated masters, 11 physicians, 81 retired surgeons, 40 retired chaplains, and, in the above table, there are 138 surgeons and 27 masters unfit for active service: of the lieutenants, probably not many more than 1000 are fit for active service.

The following table shows the number of officers for active service at three periods since the peace:—

" 4th class	0 14 6	"	

The carpenter and each of his crew are allowed seven shillings per month additional for tools.

Where no surgeon is borne, the assistant-surgeon receives an increase of pay of 1s. 6d. per diem.

Having shown the emoluments of those who are fit for active employment in her Majesty's naval service, we will now turn to the rewards and pensions for services rendered and wounds or other injuries received; and in the first place we must name that noble establishment and asylum for worn-out seamen, Greenwich Hospital. The idea of establishing an hospital for infirm and disabled seamen originated with Mary, consort of William III., and Sir Christopher Wren was employed to build an additional wing to Greenwich Palace. The king granted 2000l. a-year towards it, large subscriptions were added by noble and wealthy persons, estates were willed to it by individuals, all mariners were made to subscribe 6d. per month, forfeited and unclaimed prize-money and various grants were given. The forfeited estates of the earl of Derwentwater, the net rental of which is now between 30,000l. and 40,000l. a-year, were given. The revenue of the hospital is about 150,000l. a-year. The establishment consists of a governor, lieutenant-governor (both flag-officers), four captains, and eight lieutenants, residing in the hospital. There are about 2710 in-pensioners, and 120 matrons and nurses, all of whom must be seamen's widows.

The following is the scale of pensions for officers and seamen wounded and worn-out in the service:—

	Per Annum.		Per Annum.
	£. s.		£. s.
For an admiral, from	300 0	to	700 0
" captain (wounds),	250 0	Loss of limb	300 0
" commander "	150 0	"	200 0
" lieutenant "	91 5	"	91 5

Marine officers, as in the army.

Every mate, second master, assistant-surgeon, midshipman, master's assistant, naval instructor, clerk, and volunteer of the first and second class, from 1s. to 2s. 6d. a day, according to the nature and degree of the injury.

Boatswains, gunners, carpenters, and engineers, when unfit for further service, shall receive a superannuation allowance of 3l. a year for each year they served in a ship in commission, and 1l. a year each year in ordinary, and a further sum of from 1l. to 15l. a-year may be added by the Admiralty. They retain besides any pension for servitude as a petty-officer to which they may be entitled, and for wounds from 15l. to 50l. a year in addition to all other pensions.

Every other petty officer, seaman, marine, and boy, shall receive for wounds from 6d. to 2s. a day; and every able seaman for twenty-one years' servitude, reckoning from the age of twenty, from 10d. to 1s. 2d. a day; if discharged from infirmity after fourteen years' service, from 6d. to 9d. a day; and under fourteen years' service, if discharged from disability contracted in the service, from 3d. to 6d. a day, or a gratuity in lieu, of 1l. to 1s. If a man become totally blind, he shall have 3d. a day added to any of the above. Ordinary seamen receive three-fourths, land-men two-thirds, boys half the able seaman's pension. Marines, as able seamen.

The following petty and non-commissioned officers shall receive, in addition to the above, the following allowances:—

Superior Petty.	Yrs. of Service.	Inferior Petty.		
		£	s.	d.
	0	15	2	1 0 7 7 1

	22	1	0 1/2	29 11 0 6 1/2
	22	16	3	30 11 8 1 1/2

Persons discharged with disgrace, or by sentence of a court-martial, are not entitled to a pension. On a ship being paid-off, the captain may recommend any petty-officer or seaman, non-commissioned officer or marine, for the medal and gratuity for invariable good conduct; 15l. for first-class petty-officers and serjeants, if they have served as such ten years, 7l. to second-class petty-officers and serjeants who have served as such seven years, and 5l. to able seamen and marines.

The widows of officers who are left in distressed circumstances receive pensions on the following scale, under the regulations and at the discretion of the Board of Admiralty.

	Per Annum.
Flag-officer	120/.
Retired rear-admiral	100
Captain, three years' standing	90
" under three years,	80
Commander	70
Superannuated commander	60
The widow of a Physician	60
Lieutenant	50
Master	40
Chaplain	40
Surgeon	40
Purser	40
Assistant-surgeon	36

The amount paid in pensions to officers for wounds and good service, to widows of officers, widows and relatives of officers slain, and the out-pensioners of Greenwich Hospital, is 521,572*l*.

Abstract of Pensions paid to the Navy.

	£.
Good-service pensions	4,350
Commissioned and warrant officers	81,619
Widows and relatives of officers slain	11,786
Widows of naval officers	172,381
Widows of marine do.	10,356
Compassionate fund	11,000
Out-pensions of Greenwich Hospital	227,000
	521,572

There are two schools at Greenwich, called the Upper and Lower Schools.

The Upper School comprises two classes:

1st. One hundred sons of commissioned and warrant-officers of the Royal Navy and marines.

2nd. Three hundred sons of officers of the above or inferior rank, of private seamen and marines who have served or are serving her Majesty, and of officers and seamen of the merchant service.

They are admitted from eleven to twelve years of age, under certain regulations, and are subject to the same discipline, diet, education, clothing, and destination. The term of education is three years, at the expiration of which, or sooner if the course of education be completed, they are sent to sea in the queen's or merchant service, or otherwise disposed of, as may be determined on.

The Lower School consists of 400 boys and 200 girls, the children of warrant and petty officers, seamen and non-commissioned officers and privates of marines, who have served or are serving, or have lost their lives in the service of her Majesty. They are admitted from nine to twelve years of age, and quit at fourteen, the boys being sent to sea, and the girls put to trades and household service; any unprovided for at fourteen are sent to their parents. Any boy may be removed from this to the Upper School on obtaining a presentation, if not more than twelve years old, and possessing character and abilities.

We have seen that in 1744 all prizes were declared to be the property of the captors; the following is the scale of the distribution of prize-money by order in council, February 3, 1836:—the flag-officer or officers have one-sixteenth part of the proceeds; the captain or captains one-eighth part of the remainder, or, where there is no flag-officer, one-eighth part of the whole; the remainder shall be distributed in shares, according to the following scale:—

First class. The sea-lieutenants, captains of marines, master and physician of the fleet, and masters, ten shares each.

Second class. Lieutenants of marines, secretaries, chaplains, surgeons, pursers, mates, second-masters, gunners, boatswains, carpenters, and first engineers, six shares each.

Third class. Assistant-surgeons, midshipmen, masters'-assistants, schoolmasters, junior engineers, clerks, masters-at-arms, admirals' and captains' coxswains, quartermasters, gunners' and boatswains' mates, captains of the fore-castle and hold, coxswain of the launch, sailmakers, ropemakers, carpenters' mates, caulkers, armourers, captains of the fore and main top, pilots and serjeants of marines, three shares each.

Fourth class. Volunteers of first class, ships' cooks and corporals, captains of the mast and afterguard, yeomen of signals and coxswain of the pinnace, sailmakers' mates, coopers', caulkers', and armourers' mates, and corporal of marines, two shares each.

Fifth class. Gunner's crew, seamen-gunners, carpenters', sailmakers', and coopers' crews, able and ordinary seamen, yeomen of store-room, stokers, privates and sifers of marines of seven years' service, one share each.

Sixth class. All other ratings, boys of the first class, and marines under seven years' service, two-thirds of a share each.

Seventh class. Volunteers of 2nd class and boys of 2nd class, one-third of a share each.

When captains and commanders share together, the captain to have double the commander. Lieutenants in command share as captains when not in company with a captain or commander. Clerks in charge, as pursers if no purser be present.

When any of her Majesty's ships carries bullion or jewels on freight, the captain or commander is allowed a per centage, regulated by the queen in council, as compensation for the risk and charge, one-fourth part of which is given to Greenwich Hospital, one-fourth part to the commander-in-chief if he shares the responsibility, and the other half to the captain.

Officers settling in the Australian colonies are allowed a remission of the purchase-money, in amount from 100*l*. to 300*l*., according to their rank and length of service.

NAXIA. [MAIADÆ, vol. xiv., p. 298.] Dr. Leach appears to have been the first who established the genus.

NAXOS, NAXIA, one of the larger Cyclades, between 36° 45' and 37° 15' N. lat. and 25° 20' and 25° 35' E. long., lies east of Paros, from which it is separated by a channel six miles wide. It is situated in the middle of the Archipelago, about half way between the coast of Greece and that of Asia Minor. It was antiently called Strongyle (round) on account of its shape, and also Dia, in honour of Jupiter, and Dionysias, from the worship of Dionysus, who, according to the mythi, was brought up on this island. Its first inhabitants were said to have been Thracians. The name of Naxos has been stated by some to have been derived (Stephanus of Byzantium: Νάξος) from that of the leader of a Carian colony which settled on the island. According to Herodotus the Greek inhabitants of Naxos were Ionians from Athens (viii. 46). The island was taken by the Athenians in the time of Pisistratus. The Persians made a fruitless attempt to take the island, under the conduct of Aristagoras, but it afterwards was captured and ravaged by them under Datis and Artaphernes (B.C. 490). After the defeat of Xerxes at Salamis (B.C. 480), the Naxians threw off the Persian yoke and recovered their independence. After the battle of Mycale, Naxos became one of the confederate states, at the head of which was Athens; and it was the first of those states that fell under political subjection to Athens.

In modern times, Naxos, after the conquest of Constantinople by the Latins, became the seat of a dukedom founded by the Venetians, which embraced most of the other Cyclades. [ARCHIPELAGO, GRECIAN.] It was taken possession of by the Turks in the sixteenth century, and it now forms part of the new kingdom of Greece.

Naxos is the most fertile of the Cyclades, and its wine is much esteemed; it produces corn, oil, cotton, silk, most kinds of fruit, and abounds with game. The plains and valleys are well supplied with springs, and all travellers describe Naxos as a very pleasant country. The chief town, called Naxia, is on the western coast of the island, and near it is the harbour, called Porto Saline, on account of the sea-salt which is collected there. The castle of Naxia, on the hill above the town, was built by the Venetians, and was the residence of the dukes. According to Thovenot, the plant which produces the ladanum grows here, and in his time the substance was collected from the beards of the goats which fed on the plant, in the manner mentioned by Herodotus (iii. 112). There are about forty villages and many country-houses scattered about the island, the population of which is reckoned at 10,000. There is a Greek and a Latin bishop; with convents of both churches. The northern part of the island contains some mountains, from which came a kind of marble called by the Greeks ophites on account of its being spotted like a serpent's skin, and which was much valued. Emery is also found there, which is considered of the best kind, and

constitutes an article of export. According to the description of Thevenot, what he calls the palace of Bacchus, that is the temple of Bacchus, must have been in tolerably good preservation in his time: but the Turks and others were then constantly employing the materials for various purposes. Tournefort, who travelled forty years later, describes the gate of the temple as the only part left standing, and gives a sketch of it; it was of white marble, of elegant though simple workmanship, 18 feet high and 11 wide; it stood on a detached rock near the coast of the harbour. There was an antient city of Sicily called Naxos, north of Catane and near the site of Taormina, which was founded by some Chalcidians from Eubœa. (Strabo, p. 267.)

Coin of Naxos.

British Museum. Actual Size. Silver.

NAZARENES. It appears from many parts of the New Testament, that the majority of the Jewish converts to Christianity continued to observe the precepts and ceremonies of the Mosaic law. The destruction of Jerusalem by Titus was the cause of many of the Jewish Christians laying aside their peculiar customs; and from this time those Christians who continued to preserve the Mosaic law appear to have received the name of Nazarenes and Ebionites. The two sects, though frequently confounded, differed in many essential particulars; the latter held many erroneous opinions on some of the leading doctrines of the Christian faith, while the former only differed from the orthodox in maintaining that Jewish Christians were bound to observe the Mosaic law as well as the precepts and commandments of the Christian religion. The early fathers do not appear to have regarded the Nazarenes as heretics. This may be the reason why we find no mention of them till the fourth century, when they are named, for the first time, by Epiphanius. On the gospel of the Nazarenes, see *GOSPEL*.

(Burton's *Lectures on the Ecclesiastical History of the Second and Third Centuries*, p. 89, 90; Mosheim's *Ecclesiastical History*, vol. i., p. 191, 192, ed. of 1826; Lardner's *Works*, vol. vi., p. 383-387; vol. x., p. 104, ed. of 1831; and the article *EBIONITES* in this work.)

NAZARETH. [SYRIA.]

NEAGH, LOUGH, a lake in the province of Ulster, in Ireland. Its form approaches to that of a parallelogram, having its length from north to south, from the village of Toome to the place where the Blackwater river enters the lake, about 18 miles; and its breadth from east to west, about 11 or 12 miles. It is bounded on the north and east sides by the county of Antrim; on the south-east, for a very short distance, by that of Down; on the south side by that of Armagh; and on the west side by that of Tyrone. The area occupied by Lough Neagh is estimated at more than 98,000 English acres, or 154 square miles; and its circumference, following the windings of the shore, at about 80 miles. The surface of the lake is 48 feet above the level of the sea at low-water, and its greatest depth is about 102 feet. It is the largest lake in the British Islands.

The border of Lough Neagh forms by its windings several small bays; such as Antrim bay, which forms the north-eastern angle, Sandy bay and Bartin's bay, on the east side, and Washing bay, in the south-western angle. The points of land projecting into it are Ardmore and Lignabey points on the east side, Mulloch point on the west side, and Rauskinn point in Washing bay. There are several islands, but they are very small; on Ram Island, one of them, there is an antient round tower. Lough Neagh receives a number of streams: the Blackwater enters it at the south-western angle, in Washing bay; the Upper Bann, which is incorporated with the line of the Newry canal, on the south side; the Six-mile-water at the north-eastern angle, near Antrim; the river Main on the north side; and the river Moyowla or Moyola in the north-western angle. The only outlet is the Lower Bann, which quits the lake at the north-western angle, near where the Moyowla enters it, and, passing through Lough Beg, enters the ocean below Coleraine.

The shores of Lough Neagh are low and flat, and in some parts marshy and liable to be frequently flooded; they are altogether deficient in picturesque beauty. The water of the lake possesses in several parts a petrifying quality, which it is supposed to derive from the adjacent shore. The petrified wood is manufactured into approved hones, and the pebbles found in the white sand of the shores, chiefly chalcedony, are polished and employed for seals and necklaces. The char, the pullan, or fresh-water herring, the dollaghern (a species of trout), and other fish, are taken in its waters; and the swan, the heron, the bittern, the teal, and the widgeon frequent the shores.

Lough Neagh is navigated by small vessels, and communicates by one canal with Lisburn, Belfast, and by another with Newry. A steam-boat is employed on it in towing vessels across.

NEAL, DANIEL, an English dissenting divine and writer of considerable eminence, was born in London on the 14th of December, 1678. His early education was received at Merchant Taylors' school. In 1697 he entered the academy of the Rev. Thomas Rowe; and after having continued there about three years, went to prosecute his studies at Utrecht and Leyden. On returning to England he became assistant to Dr. Singleton, the pastor of an independent congregation in Aldersgate Street; and at the death of the latter in 1706, was chosen his successor. Notwithstanding his official duties, in discharging which he was eminently faithful, he found leisure for literary labours. In 1720 he published a 'History of New England,' and subsequently edited a 'Narrative of the Method of Inoculating for Small-pox,' practised in the same state. His printed discourses also are numerous. But his chief work is the 'History of the Puritans,' which is written with great minuteness and accuracy. It was originally published in 4 vols. 8vo., the first of which appeared in 1732, and the second, third, and fourth in 1733, 1736, and 1738 respectively. It has since passed through many editions. The first volume was reviewed by Dr. Maddox, bishop of St. Asaph, and the remaining volumes by Dr. Zachary Grey. To the former Neal himself replied; and an answer was given to the latter by Dr. Toulmin, in an edition of Neal's History, published in 1797. Neal died in Bath, in April, 1743, highly esteemed as an author and a divine. (*Neal's Life*, by Toulmin.)

NEANDER, CHRISTOPHER FREDERIC, deservedly esteemed as the author of some of the best specimens of devotional poetry in the German language, was equally estimable as a man. He was born at Ekau in Courland, December 26, 1724, and lost his father when about eight years old, but was so fortunate as to possess in his surviving parent not only a tender guardian, but a model for those virtues by which he afterwards distinguished himself. Having completed his studies at the university of Halle, he first became tutor in a private family, and in 1750 was appointed pastor of a small congregation in a retired part of the country, to whom and to the duties of his office he became so attached, that when a professorship at Halle was pressingly offered him, he refused to accept it, preferring to remain in obscurity, where he felt that he could be eminently useful. If he afterwards consented to quit his former living for the more lucrative one of Gränzhof, it was with no other interested motive than that of being thereby enabled to support a widowed sister and her five children. By this change too the sphere of his usefulness was greatly enlarged, for he became greatly followed as a preacher. In 1775 he was made dean of the diocese of Doblen; and in 1784 superintendent of church matters in the duchies of Courland and Semgallen; but he still continued to reside among his congregation at Gränzhof. He died July 21, 1802, regretted by all who knew him either as a man or as a writer. In the latter character his fame rests chiefly upon his 'Geistliche Lieder,' a collection of devotional songs, which may justly be regarded as models of that apparently easy, yet in reality exceedingly difficult species of composition. At once animated, simple, dignified, and breathing heartfelt piety, they are equally free from affected sublimity and bombast on the one hand, and from puerility or unbecoming familiarity on the other. They are the genuine effusions of devotional feeling regulated by cultivated taste.

NEAP or NEEP TIDES. [TIDES.]

NEAPOLIS. [NAPLES.]

NEARCHUS, the son of Androtimus, was a Cretan by birth, but an inhabitant of Amphipolis on the Strymon.

He accompanied Alexander in his invasion of Asia, and was appointed by him to conduct to the Persian Gulf the fleet which had been built on the Hydaspes. The narrative of this voyage, the earliest of which any account is given, was written by Nearchus himself; and though the original journal has been lost, Arrian appears to have given us, in his 'Indien,' everything of importance which it contained. Strabo and Pliny have also preserved some account of this voyage, but their narratives are full of mistakes and inconsistencies, and cannot be compared with the full and accurate account of Arrian.

Dodwell and some other modern critics have considered the journal of Nearchus, as preserved by Arrian, to be spurious; but its authenticity has been fully established by Gosselin (*Géographie des Grecs*, p. 25), Sainte Croix (*Examen Critique*, p. 250), and especially by Vincent (*Commerce and Navigation of the Antients in the Indian Ocean*, vol. i., p. 68-77).

The course of the fleet from the Hydaspes to the mouth of the Indus is described under ALEXANDER (p. 300, 301), who explored in person the mouths of the Indus, and sailed into the great Indian Ocean.

The fleet under Nearchus took its departure from a station south of Pattala, about nine miles from the mouth of the Indus, in the beginning of October, n.c. 328. After getting clear of the mouths of the Indus, the first place which they reached in the Indian Ocean was Krokela, which Arrian describes as a sandy island. This place appears to correspond to the modern Curachee, or Crotchet Bay, in which there is a sandy island, dry at low-water. At Krokela, Arrian places the commencement of the territory of the Arabii, an Indian nation, and its termination at the river Arabis.

After remaining one day at Krokela, the fleet proceeded to the west, keeping a promontory (*ὄρος*) named Eirus (*C. Monze*) on the right, and a low island, almost level with the sea, on their left, which ran so near the coast as to leave only a narrow channel between both. Having cleared this passage and doubled the cape, they came to a bay, or harbour, protected from the ocean by an island called Bibacta (*Churnā*, or *Chilney*). This harbour Nearchus called by the name of Alexander, and here he determined to remain till the season should be more favourable for his progress. It has been already remarked that he left the mouths of the Indus at the beginning of October; and as the north-east monsoon does not commence till November, and only becomes settled in December, a delay of some time was almost unavoidable. Having remained at this place for twenty-four days, he continued his voyage, though the monsoon had not yet completely changed; but he proceeded very slowly for some days. The fleet anchored successively at Domæ, Saranga, Sakala, and Morontobara, or Morontobarbara, the position of which places cannot be determined, and afterwards arrived at the mouth of the river Arabis (*Sommeunny*), which separates the country of the Arabii from that of the Oritæ. From the Arabis they proceeded twelve miles and a half to Pagala, and from Pagala nineteen miles to Kabana, an open and desert shore: between Pagala and Kabana they lost two galleys and a transport. From Kabana they proceeded twelve miles to Kokala, where Nearchus disembarked his men and formed a camp on the shore. Here Leonnatus, who had been left in the country of the Oritæ by Alexander with a particular charge to attend to the preservation of the fleet, joined them, and supplied them with provisions.

After remaining some days at Kokala, they proceeded thirty-one miles to the river Tomerus. This was the longest distance they had sailed yet in a day; and their progress corresponds to the change of the monsoon, which would become more fixed about this time. They remained six days at the Tomerus, where they found barbarians, shaggy on the body as well as on the head, and with nails sharp and long like the paws of wild beasts. Thence they proceeded nearly nineteen miles to Malana (*Ras Malin*), where Arrian fixes the boundary of the Oritæ and the commencement of Gadrosia. The whole of the coast from Malana to Cape Jask, a distance of 450 miles in a right line, was inhabited by the Ichthyophagi (fish-eaters), who lived almost entirely on fish. Their bread was dried fish, pounded and made into loaves or cakes; and even the few cattle which they had fed upon dried fish. Arrian's description of the coast and the people is confirmed by modern travellers, one of whom, quoted by Vincent, informs us that 'they have few

ports, little corn or cattle; their country is a low plain and desert; their chief support is fish, of which they take some of a prodigious size: these they salt, partly for their use, and partly for exportation; they eat their fish dry, and give dried fish likewise to their horses and cattle.'

From Malana the fleet proceeded thirty-seven miles to Bagisara; and on the following day they sailed round a rock or promontory, which extended a considerable way into the sea (probably *Cape Arubah*), and proceeded successively to Kolta and Kalama (*Kalyba*), where they found the dates green. Opposite to Kalama was an island called Karnine, which appears to be the same as the modern Ashtola, or Sungadeep Island. From Kalama they proceeded twelve miles to Karbis; and thence, after doubling a high rocky promontory, which projected nine miles into the sea, and which is probably the modern Cape Passeenoe, they reached a safe harbour, called Mosarna, which must be looked for a little to the west of this cape.

At Mosarna Nearchus found a pilot, who undertook to conduct the fleet to the Persian Gulf, and from this time they sailed on each day a much greater distance. From Mosarna they proceeded in succession to Balomus, Barna, Dendrobosa (perhaps the Dendrobilla of Ptolemy), and Kophas, the position of which places is uncertain, with the exception of Kophas, which is perhaps the same as the modern Koppah. From Kophas the fleet sailed round Cape Gwadel, and proceeded fifty miles to Kyiza, where they did not land, as the coast was rocky and barren. On the following day they surprised a small town, probably situated on Gutter Bay, and obtained some corn, which they were greatly in want of. They afterwards anchored at a cape in the neighbourhood called Bageia; and thence proceeded about eighty-seven miles in two days to Kanasis, a town in ruins, probably situated on Choubar Bay. From Kanasis Nearchus sailed twenty-four hours without intermission to a desert coast, where he was obliged to anchor at some distance from the shore, as the distress of the people was now risen to such a height, that if he had suffered them to land, he had reason to suspect that they would not have returned on board. From this place they proceeded, in great want of provisions, to Kanate (*Tunka*), Troi, and Dagasira, and at length reached Badis, a place on the western side of Cape Jask, which separated the country of the Ichthyophagi and Karmania. At Badis they found corn, vines, and fruit-trees of every kind except the olive, a town inhabited, and the inhabitants ready to relieve their wants.

From Badis they proceeded fifty miles, and came to an anchor on an open coast, opposite Cape Maketa (*Ras Musendon*), from which point Nearchus considered that the Persian gulf commenced. From Badis they proceeded forty-four miles, to Neoptana (near *Karrom*), in the Persian gulf. From Neoptana they sailed on the following day six miles to the river Anamis (*Ibrahim*), at the mouth of which was a town called Harmozeia, the name of which is still preserved in the celebrated island of Ormuz, in the neighbourhood. Near this place Nearchus landed his men, and ordered the ships to be drawn on shore; and learning that Alexander was only distant a journey of five days, he went with a few attendants to his camp, and was received by the king with marks of the greatest honour and respect. At first Alexander would hardly believe that the fleet had arrived in the Persian gulf in safety; and when he was assured by Nearchus of the fact, he is reported to have said, 'By the Grecian Zeus and the Libyan Ammon, I swear to you that I am more happy in receiving this intelligence than at being the conqueror of all Asia; for I should have considered the loss of my fleet, and the failure of this expedition, as a counterbalance to all the glory I have acquired.' So anxious was Alexander to establish a commercial intercourse between India and the western provinces of his vast empire.

After remaining a few days with Alexander, Nearchus returned to the fleet, and set sail again about the beginning of the following year (n.c. 325). During the third day's sail three of the ships grounded during a storm on a shoal off the western coast of the island of Oaracta (*Kishma*); but they got off when the storm ceased, and joined the fleet on the following day. The remainder of the fleet escaped the danger by sailing to the south-westward, and anchored at the islands called at present the Great and Little Tomb. On the following morning they sailed again to the mainland, leaving on their left the island Pulora (*Pulior*), and after a

saile of two or three days arrived at Katæa (*Kaish, Guase, or Kenn*), a low desert island, opposite to which, according to Nearchus, is the boundary of Persis and Karmania on the coast.

From Katæa they proceeded along the coast of Persis, anchoring successively at Ila, opposite the island of Kai-kandros (*Inderabia*); at Ochus, under a high mountain; at Apostani (*Shewar?*), where they found many ships at anchor; at a bay, probably the same as the modern Nabend, on the borders of which were many villages with palm and other fruit-trees; at Gogana (*Congoon*), situated at the mouth of a mountain-stream called Areon; and at the river Sitacus, west of the modern *Ras Khann*, where Nearchus remained twenty-one days in order to repair and refit several of his ships, during which time he received a large supply of corn from Alexander. About the 1st of February they sailed from the Sitacus to Hieratis (*Khora*), a place well inhabited, and thence to Mesambria, and anchored at the mouth of a river called Padargos. Arrian describes the whole of this country as a peninsula, which corresponds most correctly with Aboushehr, generally called Bushire. Thence they proceeded to Taoke, near the mouth of the river Granis (*Khisht*), on which there was said to be a palace of the Persian kings, about 200 stadia up the country. Strabo (xv., p. 728. *Casaub.*) also mentions a Persian palace near the sea, called Oke, which apparently is a shortened form of Tu-oke. From Taoke they proceeded in succession to Rhogonis (*Bunder Reight*), to Brizana, a winter torrent, and to the river Arosis, called Oroatis by Strabo, Pliny, and Ptolemy (*Tab.*), which, according to Arrian, divided Persis from Susiana.

At the Arosis they took in a supply of water for five days, as the pilots told them that no harbour could be gained without considerable danger, in consequence of the number of shoals which extended from the land far out into the sea. The whole of the navigation along the coast of Susiana was attended with great difficulty and danger; but the fleet eventually passed through the shoals in safety, and sailed up the river Pasitigris (*Karoon*), when Nearchus joined Alexander and his army, who were on their march from Persepolis to Susa. Vincent supposes that the expedition was concluded on the 24th of February, B.C. 325.

After the death of Alexander, we find that Nearchus was governor of Lycia and Pamphylia (Justin, xiii. 4), and that he attached himself to the fortunes of Antigonus, whom he accompanied in several of his expeditions. The time and manner of his death are unknown.

A very complete and interesting examination of the voyage of Nearchus is given by Vincent in the first volume of *The Commerce and Navigation of the Antients in the Indian Ocean*, from which the preceding account has been chiefly taken, compared with the maps of Beloochistan, and of ancient and modern Persia, published by the Society for the Diffusion of Useful Knowledge.

The Greek text of Arrian, with some useful notes and a map, is contained in Schmieder's edition. [ARRIAN.]

NEATH. [GLAMORGANSHIRE.]

NEBRUS, one of the family of the Asclepiadæ, and the most eminent physician of his day, lived in the island of Cos, about 580 years B.C. The Amphictyons, having consulted the oracle of Delphi, in consequence of the plague breaking out among their army while besieging the town of Crissa in Phocis, were directed to fetch from Cos 'the young of a stag, together with gold.' This was interpreted to mean Nebrus* and his son Chrysus, who accordingly joined the camp of the Amphictyons, where the former helped to reduce the town by poisoning the water; and the latter was the first person who mounted the wall at the time of the general assault. (*Thessali Oratio ad Athen., apud Hippocratis Opera.*) For the Crissæan war see Strabo, ix., p. 418; and Pausan, *Phoc.*, 37, who attributes the poisoning of the water to Solon.

NEBULÆ. [STARS AND NEBULÆ.]

NECESSITY, in metaphysics, according to the common definition, is that quality of a thing by which it cannot but be, or whereby it cannot be otherwise. When, in a proposition which affirms any thing to be true, there is a fixed invariable connection between the subject and the predicate, then that thing is understood to be necessary. Necessity is opposed to chance, accident, contingency, and to whatever involves the idea of uncertainty and of possible varia-

tion. It is usually distinguished into logical, physical, and moral necessity. Logical necessity consists in the circumstance that the conception of something being different from what it is, implies a contradiction or absurdity. In this sense, it is necessary that two and two should be four, that converging lines, if produced far enough, should meet: thus also the eternal existence of being generally is necessary, as are innumerable other truths. Physical necessity has its origin in the established order and laws of the material universe. The necessity, in this case, differs from that formerly specified, in that it is only conditional, is a necessity of consequence. Everything that takes place in the natural world happens by virtue of certain laws: these laws are known by experience to operate regularly and uniformly; and the results of their operation are hence, with reference to them, said to be necessary. When we ascribe anything to chance, we merely state our ignorance of the law or laws to which its existence is to be referred. Physical necessity is founded on the relation of cause and effect. By tracing back this connection, we arrive at the knowledge of a great first cause, that is God, who is the only Being existing independently and by an absolute necessity. His infinity and other attributes are necessary; and it is evident that the purposes and acts of such a Being must also be necessary, being determined by that necessity by which he is what he is. He must always resolve and act with the most perfect wisdom, justice, and goodness. To affirm the contrary would be to affirm that he is different from what he is. Moral necessity has reference to the volitions and actions of rational agents, and is intended to express the connection between these volitions and actions, and certain moral causes, as inclinations, desires, or motives generally. Whether there be any connection which, strictly speaking, may be termed necessary, between such motives, and the resolutions of the human will, and the consequent actions, or whether, independent of them, the will has a self-determining power, is an inquiry which has largely engaged the attention of both philosophers and theologians. It is one of great interest, and which has an important bearing, on whatever relates to man as the subject of a moral government. [WILL.]

The doctrine of a universal necessity, or fatalism, was maintained by many of the ancient philosophers; and formed the characteristic tenet of the Stoical school. According to it, necessity was to be considered as an inevitable and all comprehending principle, to which gods as well as men were subject. Everything was conceived to exist in a necessary series of causes and effects—the whole constitution of nature—the modes and circumstances of all things without exception—being irresistibly and unchangeably determined. Hence the language of Seneca, the elegant expounder of the opinions of this sect, in his treatise 'On Providence':—'The same necessity binds both gods and men—Divine as well as human affairs proceed onward in an irresistible stream—one cause depends upon another—effects are produced in an endless series—nothing is the offspring of chance.' Democritus held opinions closely resembling the Stoical doctrine of fate; as also Heraclitus, the founder of the sect that went by his name. In modern times, the doctrine of necessity, especially in regard to the human will, has been defended by Hobbes, Leibnitz, Priestley, Hume, Kames, Hartley, and many others.

NECKAR, river. [RHINE.]

NECKER, JAMES, son of a professor of law at Geneva, was born in 1734. He was sent to Paris in his youth, and was employed in the house of Thelusson, the great banker, who, after a time, in consequence of his abilities and the services which he had rendered to the house, took him into partnership. In the course of twelve or thirteen years, Necker realised a very large fortune by various successful speculations, and retired from business at forty years of age. He now began to aspire to official situations, and wrote several works on financial affairs, which made him favourably known. He wrote concerning the French East India company, and also upon the corn-laws, 'Sur la Législation des Grains.' His 'Eloge de Colbert' obtained a prize from the French Academy. He afterwards wrote a memoir upon the French finances, suggesting the means of making up the deficiency in the revenue, and forwarded it to the minister Maurepas, the president of the council of finances. The president, being delighted with it, obtained for the author, from Louis XVI., after some hesitation on account of Necker being an alien and a Protestant, the appointment of

* νεβρός, in Greek, signifies 'a stag,' and χρυσός, 'gold.'

director of the treasury, in 1776. This was a new office, and was created for the purpose of giving assistance to that of comptroller-general, which was filled by the counsellor of state Taboureau de Réaux, a mild and unassuming man, who, feeling his inferiority to Necker, resigned his place in the following year. Necker was appointed director-general of finances, in June, 1777, but without a seat in the council. That was a critical period; the finances had been long in a state of great embarrassment, and the impending war with England on account of the American colonies required a great increase of expenditure. Necker, being averse to imposing new taxes, endeavoured to make up the deficiency by economy and loans. [LOUIS XVI.] In 1781 he published his 'Compte Rendu,' which disclosed for the first time the state of the revenue and expenditure of France, and made him numerous enemies. In order to counteract their intrigues, Necker asked for a seat in the council as a mark of the king's confidence, but this being refused on the score of his religion, he tendered his resignation, which was accepted, in May, 1781. He withdrew to Switzerland, where he purchased an estate at Copet, on the banks of the Lemane Lake, and here he wrote his work, 'Sur l'Administration des Finances,' 1784. 'Both Necker and his predecessor Turgot,' says a contemporary writer, 'worked for the public good, and both made war against abuses. But Turgot had the disinterestedness of a philosopher and a philanthropist who entirely forgot himself for the good of the state and of mankind. Necker was disinterested, but only in money matters, for he was tormented by the ambition of fame and popularity. Turgot had faith in his principles; Necker confided in himself. Turgot had fixed ideas on legislation, and he wished to give a durable government to France; Necker combated only partial abuses, and appeared to have no settled notions of the science of government. . . . Turgot wished to give to the French a political and moral education; he wished to form public opinion; Necker believed that public opinion in France was very enlightened, and he bowed himself before it. The former spoke to the people as a legislator, the other as a courtier of the people.' In his retreat however, after his second resignation, he altered his tone. 'Public opinion,' he says, in the preface to his work 'De l'Administration de M. Necker, par lui-même,' 1791, appears to me no longer as it did once. The respect which I felt for it has been weakened since I have seen that opinion influenced by the arts of the wicked, since I have seen it waver and tremble before men whom it ought to have rightly estimated and marked with its scorn and reprobation.' 'Necker's first resignation however was much to be regretted; it was a loss to France at a critical moment, and it was a great fault on his part, for he might have maintained himself in office; but his unconquerable self-love prevented him. He fancied that they could not do without him, and that he would be soon recalled, and thus become all-powerful. He was mistaken; and when at last he returned to office, the situation of the state was greatly changed, and circumstances had become such as to require talents very superior to his.' (Droz, *Histoire du Règne du Louis XVI.*, b. 11, 1839.)

In 1787 Necker returned to Paris, where he wrote against Calonne, who had just been dismissed from his office of comptroller-general of the finances, and he was, in consequence, banished from the capital, but was soon after recalled. In the following year (August, 1788), on the resignation of Brienne, and at the suggestion of that minister, Louis XVI. appointed Necker director-general of finances, as the only man capable of restoring order in the administration. The king had already promised the convocation of the states-general, and Necker urged him to keep his promise. But he failed as a statesman, in not arranging beforehand a plan for the sittings of those states, so as to prevent the collision that took place on their first meeting. In fact Necker was a financier, but no general statesman; he was a philosopher and a man of letters, but not a jurist or a legislator, and he was thus considered by a man well qualified to judge of these matters. [MIRABEAU.] His second ministry was short. Unable to check or direct the popular storm, and not enjoying the confidence of the court, Necker, unwilling to become a watchword of the agitators, offered privately to Louis XVI. to quit his place and the kingdom, if he thought his absence would tend to calm the public effervescence. On the 11th of July, 1789, the king wrote him a confidential note, requesting him to set off quickly and privately. Necker obeyed, and set off for Switzerland

that very night. But this step, instead of preventing, only precipitated the Revolution. After the taking of the Bastille, the National Assembly demanded the recall of Necker, and Louis complied. Necker was received in triumph, but his popularity was short-lived. He did not go far enough to please the movement-men. In December of the following year, 1790, he gave in his resignation to the National Assembly, which received it with cool indifference. He spent the remainder of his life in Switzerland, in retirement and study, and wrote several political tracts. He had written, several years before, a work, 'De l'Importance des Opinions Religieuses.' He died in April, 1804. His daughter has become celebrated as Madame de Staël. [STAËL.]

NECRO'SIS (from νεκρός, 'dead') is the term applied particularly to mortification or death of bone. Its general causes and the mode of reparation are the same as those of mortification generally. [MORTIFICATION; INFLAMMATION; BONE.]

NECTARINE. [PEACH.]

NECTARINI'ADÆ. [SUN-BIRDS.]

NECTO'PODA. [NUCLEOBRANCHIATA.]

NECTUR'US, M. Rafinesque's name for a genus of *Desmotelemata*, placed by Cuvier between the *Axolotls* [AXOLOTL] and the *Proteii* of Laurenti. This form is the *Menobranchus* of Harlan and the *Phanerobranchus* of Fitzinger.

Generic Character.—Four toes on each foot. A row of teeth on their intermaxillaries, and another, parallel but more extended, on their maxillaries.

Necturus lateralis (*Triton lateralis* of Say; *Menobranchus lateralis* of Harlan; and *Phanerobranchus* of Fitzinger) is the species best known, and will serve for an example of the genus. It is olive, with blackish spots above, and a blackish stripe running from the muzzle just above the eye and reaching to the branchiæ, where it becomes continuous with the blackish belly, which is variegated with olive spots. The size is considerable; some say as much as two or three feet in length.

Geographical Distribution.—The great North American lakes.

Necturus lateralis.

NEDJED, or NEDJD. [ARABIA.]

NEEDLE MANUFACTURE. This branch of industry is supposed to have originated in Spain, from the circumstance of the name *Spanish needles* being originally used in England, although the art was brought here from Germany. Needles were first made in England about the year 1565, by Elias Crowso or Krause, a German, who settled in London. This manufacture can never become one of much importance to a nation, and it is not therefore surprising that we are without any historical details of its progress. The reputation long enjoyed by *Whitechapel* needles points out the particular locality in London where the manufacture was carried on. At this time, the largest number of needles are made at Hathersage in Derbyshire, in Warwickshire, in and near Birmingham, and also at Redditch in Worcestershire.

The manufacturing processes are as follows:—Soft steel wire of the required thickness is first cut into lengths of about five inches, and these lengths, being placed together in a bundle, are bound together by means of iron rings, five inches in diameter, placed at each end of the bundle. This bundle is then placed on a cast-iron table, and rolled to and fro upon it, under the pressure of a flat bar of iron, by which means the wires are made perfectly straight. About a dozen and a half or two dozens of these wires are then taken by the grinder, and together are pointed on a small dry grindstone. This process requires considerable dexterity for its proper accomplishment, as each wire must be so held by the grinder as to revolve in contact with the grindstone. It is this dry-grinding which makes the trade of a needle-grinder so injurious to health, through the inhaling of the small particles of steel which are thrown off during the operation. A preservative against this evil has been pro-

wided: this consists of a mask of magnetic wire-gauze, worn so as to protect the mouth, and the particles of metal, being attracted by this means, are prevented from passing into the lungs. It is but seldom however that the grinders can be induced to wear these masks.

When the pointing is finished, the wires are cut into the required lengths, and the holes or eyes are perforated. This operation is usually performed by females. The tools employed are, a small anvil fixed on the work-bench, a hammer, a finely-pointed and well-tempered steel punch, a pair of plyers, a file, and a block of lead. The woman first slightly flattens the unpointed end by a stroke of the hammer, then makes an indentation on one side by means of the punch and hammer; the needle is then taken from off the anvil, and, being placed with the indented side downwards on the block of lead, the perforation is completed by striking with the punch and hammer on the opposite side of the needle. Holding then the needle in the plyers, the head is somewhat bent, and with the file the *guttering* is performed, which is the forming of the channel that may be seen on each side where the perforation is made. The head is then smoothed by passing the file over it. Needles to which the name drilled-eyed is applied are perforated in the manner here described, but the additional process is used of smoothing the eye by means of a drill after it is perforated.

For making the eyes and gutters in large needles, machinery is employed. The wires used for making these needles are pointed at both ends, and the channels and eyes are formed in the middle, when the two needles thus made are cut asunder, and their heads smoothed with a file.

These operations being performed when the steel wires are in a soft state, they are more or less bent, and must be straightened, which is done by rolling them on one plate of metal under the weight of another. The needles are then placed, many thousands together, in a kind of crucible, and covered over with ashes, when they are put into a close furnace and exposed to a cherry-red heat. When this degree of heat has been attained, the crucible is withdrawn, and the needles are dropped into cold water, from which they are taken out and put upon an iron plate almost red hot, where they are turned about so as to cause the heat to apply equally to all, and as fast as the needles become of a blue colour, they are removed as being of a proper temper.

Such of the needles as now appear crooked are straitened on a small anvil by blows from a hammer.

The needles are next ranged in parallel rows upon a coarse cloth, which has been smeared with a mixture of oil, soft soap, and fine emery powder. In this cloth from 40,000 to 50,000 needles are rolled up, and several of these rolls are placed together in a machine like a mangle. The rolling to which they are here subjected is continued, by means of steam or water power, for two and sometimes three days, during which time the cloth wrappers, being worn out, require to be once or twice replaced by new ones. When taken out, after this rolling, the needles are perfectly bright.

They must now be sorted, by placing the heads of all in the same direction. This task, as well as that of separating broken and spoiled needles from such as are sound, is performed by children. Placing a finger-stall of cloth on the fore-finger of the right hand, the ends of about a dozen needles are pressed against it, when such as have their points next to the cloth stick into it, and are withdrawn with ease. The needles thus arranged are then placed, a quarter of a hundred together, in papers for sale.

It is not possible to form any satisfactory estimate of the number of needles made and used in this kingdom, neither do we know the quantity nor value of such as are exported, as they pass at the Custom-house, with a great variety of small objects, under the general name of haberdashery. Needles of English make are very generally esteemed for their superior quality.

(Babbage's *Economy of Machinery and Manufactures*; Lardner's *Cabinet Cyclopædia*, 'Manufactures in Metal.')

NEEFS, PETER, called 'the Old,' born at Antwerp in the year 1570, was a disciple of the elder Henry Steenwyck, whose manner he closely imitated. He painted views of churches and convents, especially interiors, preferring those in the Gothic style of architecture. He possessed a profound knowledge of perspective, and represented his subjects, with all their rich ornaments, and every member of the architecture, with strict truth, and yet without betraying the appearance of anxious labour. Every object is

P. C., No. 993.

marked with minute precision, and finished with an exquisite touch and a light pencil. His bright clear pictures, in which he avoided the darkish brown colouring sometimes observable in the works of his master Steenwyck, are the most esteemed. Being an indifferent designer of figures, he often got F. Francks, Van Thulden, Velvet Brenghel, or Teniers, to paint the figures; those of the two last greatly enhance the value of the pictures of Neefs.

He died in 1651, at the age of eighty-one. His son, Peter Martin (called 'the Young') painted in the same style, and chose the same subjects as his father, but was by no means equal to him.

NEER, ARNOLD VANDER, born at Amsterdam in 1619, is well known to connoisseurs and artists both by the peculiarity of his style and by the handling and transparency of his landscapes. His subjects are chiefly views of villages with fishermen's huts on the low banks of rivers and canals. His pencilling is remarkably neat, his touch free and clear, and his imitation of nature faithful. His reputation is founded on his moonlight scenes, in which he has never been excelled, and perhaps never equalled. The lustre of his skies about the moon, and the reflection of the beams on the water, whether calm or slightly rippled, are inimitable. His genuine pictures are highly prized all over Europe. In some instances they are rather too black, probably from the effects of time. He died in 1683, aged sixty-four.

NEER, EGLON HENDRICK VANDER, son of the preceding, was born at Amsterdam in 1643. He studied first under his father, and afterwards under Jacob Vanloo. He was well versed in all the branches of the art. In history, his composition is skilful and his drawing correct; his portraits, both large and small, are spirited and well coloured; and his conversations have all the excellencies of Terburg. He lived first at Paris, then at Orange, and lastly at the court of the elector palatine at Düsseldorf, where he died in 1703.

NE EXEAT REGNO, the name of a writ which issues out of Chancery on the application of a party complainant, to prevent his debtor from leaving the realm. The writ is directed to the sheriff of the county in which the debtor is; and after reciting that 'it is represented to the king in his Chancery on the part of the complainant against the debtor, the defendant, that he the said defendant is greatly indebted to the said complainant, and designs quickly to go into parts beyond the seas (as by oath made on that behalf appears), which tends to the great prejudice and damage of the said complainant,' commands him to 'cause the said debtor to give sufficient bail or security, in the sum of £, that he will not go, or attempt to go, into parts beyond the seas, without leave of the said court;' and in case the said debtor shall refuse to give such bail or security, the sheriff is to commit him to prison until he shall do it of his own accord, &c.

The question which always arises on application to the Court of Chancery for this writ, is nothing more than this: whether the plaintiff has made out a case which is conformable to the terms of the writ, as interpreted by the decisions of the court.

The writ cannot be applied for unless in a suit, that is, unless a bill is already filed; but a plaintiff may apply for it in any stage of a suit, whether the writ is prayed for by the bill or not. The plaintiff cannot have the writ if he is out of the jurisdiction. There must be a debt in equity actually due at the time when the writ is applied for; and the writ will not be granted for a demand on which a party can be held to bail at law. The application for the writ must be accompanied with an affidavit swearing positively to the debt, except where the bill is for an account, in which case it is sufficient if the plaintiff swear that he believes there is a balance in his favour; or except where there is other decisive evidence of the debt, such as may appear from the master's report absolutely confirmed, or from admissions in the answer. The affidavit must also show that the defendant is going abroad, or it must show facts which prove that conclusion, and that the debt will be in danger if he quit the realm. The writ may be moved for ex parte, and it issues until answer and further order. A defendant may apply to discharge the writ on putting in his answer.

It is unnecessary to enter into further particulars here.

This writ is founded on the real or supposed prerogative of the king to restrain his subjects from departing from the realm. The 'Natura Brevium' contains two forms of

writs, one of which has for its object to restrain a clergyman from going abroad without the king's licence, and commands the sheriff to take security from him or commit him to prison; the other has for its object to prevent a layman from going abroad without the king's licence; but it requires no security from the party, and differs in several other respects from the other writ. These writs are both entitled *De Securitate Invenienda*, &c., and seem to be in substance, though not in name, writs of *Ne Exeat Regno*. From the former of the two the present writ of *Ne Exeat* seems to be derived.

It is said that the object of the writ, as applied to clergymen, was to prevent them from having frequent intercourse with the Papal see. Whether the prerogative on which these writs were founded was a usurpation on the part of the crown or not, is a matter which has been somewhat discussed. The opinion that such a power as that which is exercised by this writ 'appears to have been unknown to the ancient common law, which, in the freedom of its spirit, allowed every man to depart the realm at his own pleasure' (Beames), is a vague surmise, expressed in language equally vague. This writ, which was originally designed solely for political purposes, has now been applied, as already explained, to the object of restraining a debtor from evading his creditor's demand by quitting the realm; this application has been sanctioned by long usage, the commencement of which is now unknown.

(*A Brief View of the Writ Ne Exeat Regno*, by Beames.)

NEGAPATAM, a town and port on the Coromandel coast, in $10^{\circ} 45' N.$ lat. and $79^{\circ} 55' E.$ long. The Portuguese had formerly a settlement here, which was taken from them in 1660 by the Dutch, who added materially to its defences, and made it their principal station in that quarter. They established a mint for coining gold money, and carried on an extensive trade from the port. The fort fell into the hands of the English, after an obstinate resistance, in 1781, and since then the European inhabitants have deserted the place. Many of the houses fell quickly into ruins, and others were pulled down, such of the materials as were of value being carried away to Madras. The native town is likewise much decayed, and the population is greatly diminished. The trade at present is quite inconsiderable, being almost wholly confined, as far as Europeans are concerned, to the procuring of refreshments for ships that touch at the port for that purpose.

NEGATIVE AND IMPOSSIBLE QUANTITIES. If the plan of this work had permitted detailed treatises on different branches of science, the subject before us would have fallen under the head of **ALGEBRA**, and would have been fully treated in the description of the difference between algebra and arithmetic. As it is, the present article and that on **OPERATION** will embrace the consideration of those peculiar abstractions the attainment of which distinguishes the *science* of algebra from the *art* which was cultivated by the Italians of the sixteenth century.

In the oldest treatises on algebra which exist there is mention of a modification of quantity unknown in arithmetic, called *negative* quantity, as distinguished from *positive*. In the **VIGA GANITA** we find this distinction and the rules for its use precisely as in modern treatises: one of the commentators says that negation is contrariety; and the 'Liliwati' contains the geometrical interpretation of a negative line, namely, a line measured in the direction contrary to that of a positive line. The commentator says that Patna is fifteen yojanas east, and Allahabad eight yojanas west, of a place called Varanasi; 'the interval or difference is twenty-three yojanas, and is not obtained but by addition of the numbers. Therefore, if the *difference* between two *contrary* quantities be required, their *sum* must be taken.' Surely it will be said that algebra began in a strange confusion of ideas; but yet the fault is rather in expression than in conception. An art was in existence presenting undoubted means of discovering truth, commencing with a generalization of which the use was obvious, but not the meaning. In Diophantus we find the common rule announced as a definition (without even a previous notice of the distinction of quantities) in terms as broad as the following: 'Ἀεὶψὸς ἐπὶ λείψιν πολλαπλασιασθεῖσα ποῦν ὑπαρξεν,' &c.; literally, 'Defect upon defect repeated, makes existence.' In Mohammed Ben Musa [MUSA] the rules are announced in the same way, though the separate existence of positive and negative quantities does not seem to be assumed: it must be remembered that this work

was written for popular use. The European promoters of algebra, with the exception only of Vieta, adopted the use of two species of quantities, positive and negative, with the explanation above noticed. Vieta not only avoided the negative quantity, but, as far as he could, dispensed with subtractive terms and subtraction itself. He discards the double nature of quantities in the words 'Plus autem vel minus non constituunt genera diversa.'

It is not our intention to follow the earlier algebraists through their different uses of negative quantities. These creations of algebra retained their existence, in the face of the obvious deficiency of rational explanation which characterised every attempt at their theory. Newton and Euler distinctly admit the existence of the quantity less than nothing: the latter asserts that a man who has no property and is in debt 50 crowns, would only have nothing if any one else made him richer by a gift of 50 crowns, and therefore begins with 50 crowns less than nothing. Elementary treatises for the most part try to append an explanation of negative quantities to an algebra which is nothing more than arithmetic, instead of introducing those new abstractions which are the basis of the separate science: so that algebra, instead of being systematically learnt, is collected by slow and often dubious steps from arithmetical examples, in which the rules of operation of the former science are employed, preceded by the principles of the latter. Few therefore acquire a real perception of the meaning of the subject, except those who study mathematics to great extent. It is matter of notoriety that difficulties attend the beginner in algebra of a nature totally different from those which are found in geometry; so that while a person who has read a few books of Euclid may be imagined capable of writing an intelligent commentary on what he knows, another who has mastered a common elementary treatise on algebra is conscious only of a great increase of working power, with a glimmering of principles which owe their reception more to the never-failing accuracy of their results than to native evidence or logical deduction from easily admitted truths.

It is but recently that such a view has been given of algebra as will at once explain both the distinction of positive and negative quantities, and the difficulty attending the square roots of negative quantities, usually called *impossible* quantities. We shall endeavour to ascend to this view of algebra, on the supposition that the student has read what beginners usually read, and is well acquainted with the common operations. We must however premise that, as in all other cases where the first principles of a science have been matter of dispute, it by no means follows that one view of the subject is the most easy to every mind. Something must depend on the intellectual constitution of the individual; and if this be most probably true in geometry, the remark applies with still greater force to algebra.

The first abstraction which meets us in arithmetic follows the transition from actual magnitudes (concrete numbers, so called) to their numerical representations. We then find general properties of numbers, in which we learn to consider number independently of a specific concrete unit. Thus we see in $7+5-3=7-3+5$ a relation equally true, whatever may be the nature or magnitude of the unit. When we drop the concrete number and rise to the abstract, we gain something more by the transition than immediately appears; and this the student should particularly note, because some of the succeeding difficulties which attend the passage into algebra are very similar in character, though preceded by a stranger and harder process. The operation of multiplication takes a power and a property which it had not before: thus if we denote concrete number by Roman numerals, and if we speak of yards, it is clear that $5 \times VII = XXXV$, or seven yards taken five times is thirty-five yards. But we may not therefore say that $VII \times 5 = XXXV$, for $VII \times 5$, the number 5 multiplied by 7 yards [MULTIPLICATION], is an incongruous and unmeaning set of words, and it would be equally improper to say that it is and that it is not thirty-five yards. In abstract numbers no such caution is necessary; 7×5 and 5×7 are both the same. If men had never considered *number* independently of magnitude measured or repeated by it, the arithmetician would have confounded $VII \times 5$ and $5 \times VII$, because he would soon have found that no false results would have sprung therefrom; while $VII \times 5$ would have been a sort of impossible quantity, useful in practice and difficult in theory.

We are now on the ground of abstract arithmetic, and on

examining the four fundamental operations, we see no difficulty in either addition, multiplication, or division. As soon as we have mastered the subject of fractions, and have clearly admitted the introduction of a part of a repetition [MULTIPLICATION], we say as follows: let a and b be any two numbers or fractions, and $a+b$, ab , and $a:b$ must be real numbers or fractions, assignable by demonstrated operations as soon as a and b are assigned. But there is still a restriction upon the possibility of subtraction; $a-b$ has no imaginable existence, unless a be greater than b ; when $a=b$, the magnitude of $a-b$ vanishes entirely, and when a is less than b , the direction to perform $a-b$ is just the same as asking for a part which shall be greater than the whole of which it is a part. If we confined ourselves to particular arithmetic, in which all numbers used have specific values, it would most likely be thought of no use to carry the subject further, and in one point of view correctly; that is, it would be of little moment to deduce methods by which an individual so careless as to write down and operate upon such a symbol as $3-4$ might be enabled to arrive at a subsequent correction of the mistake which a glance at the symbol should show him he has made. But when we use general symbols of number, we are liable to mistakes of two kinds, both dependent upon our liability to invert the order of terms of which the less should be subtracted from the greater.

First, we may mistake the nature of the quantity which results: thus if it be part of the conditions of a problem that I pay $\text{£}a$ and receive $\text{£}b$, and if the application of the conditions requires that I should state how much I gain or lose, the answer should be either a loss of $\text{£}(a-b)$ or a gain of $\text{£}(b-a)$, according as a or b is the greater. We have then the choice between adopting one of these with the chance of being entirely wrong, or of working the problem in two distinct ways. And if it should happen that the conditions of the problem present this alternative in six distinct instances (and sometimes it happens oftener), there would be no less than 64 cases of solution, all, arithmetically speaking, essentially different in the mode of obtaining the answer, whether the answers obtained be the same or different.

Secondly, we may make an error of the same kind in the details of operation. For instance, suppose we have $a+b-c$, which it is convenient to exhibit in the form of a altered by one single addition or subtraction. If we assume an addition, and write $a+(b-c)$, we may be in error; for if b be less than c , the proper alteration is $a-(c-b)$.

It is evident that both species of mistakes are precisely of the same kind. Let us call them, for distinction, errors of interpretation and errors of operation, and let us show first that an error of interpretation will produce the error of operation and no other. If, in the first problem, we suppose $a-b$ to be lost where $b-a$ is really gained, and if the problem, for instance, require the result of the preceding to be annexed to a loss x , we shall suppose there is altogether a loss of $x+(a-b)$, whereas it should be a loss of only $x-(b-a)$. Secondly, the error of operation will produce the error of interpretation, whenever any interpretation is made; for when we look at $x+(a-b)$ as a loss, we shall evidently suppose it to be more of a loss than x , or that $a-b$ is lost besides; whereas, had we looked at $x-(b-a)$, we should have inferred that there is a less loss than x , or if x were lost, $b-a$ was gained. Now the first step of the young algebraist, before he attempts any transition from universal arithmetic to algebra, must be to examine by many instances the effect of both classes of errors upon the subsequent proceedings and results. We shall here only state the truths at which he will finally arrive, with an example of each. The beginner cannot, as the proficient may do, see a sufficient reason for these results in the common rules of algebraical operation; and we should doubt that anything but a large number of examples would serve to give him the necessary insight into the conclusions.

1. The mistake of operation, how often soever repeated, and how complicated soever the deductions which may be drawn from it, produces no result in any way different from that of the correct process; that is, its result can be reduced to the result of the correct process by the use of no more than those rules which apply in the rational process.

Thus if $x+a-b$, wrongly taken to be $x+(a-b)$, b being greater than a , be multiplied by $x+p-q$, wrongly taken as $x+(p-q)$, q being greater than p , we find as the (supposed) product

$x^2+(a-b+p-q)x+(a-b)(p-q)$,
to which the application of the common rules gives
 $x^2+ax-bx+px-qx+ap-bp-aq+bq$,
precisely the same as the product of $x+a-b$ and $x+p-q$.
The reason of this is as follows:—In all the rational cases of the four operations, a term in the construction of which two signs are used has $+$ before it, if those two signs be alike, and $-$ if they be unlike, as in

$$a+b-(c-d), \text{ or } a+b-(0+c-d) \\ = a+b-c+d \\ (a-b)(c-d) \text{ or } (0+a-b)(0+c-d) \\ = 0+ac-ad-bc+bd.$$

If then a term were subjected to the signs $++$, it would make no difference if the same term were subjected to the signs $+-$, for the effect of $--$ is the use of $+$. If then we take $x+a-b$ wrongly as $x-(b-a)$, we see that when we come to add this, say to c , we have

$$c+\{x-(b-a)\}$$

in which a , before it is disengaged, must come under the signs $+-$, or, if the phrase be less objectionable, under the application of the rules to those signs, successively. But the correct process would give

$$c+\{x+(a-b)\}$$

in which a falls under the application of the rules to $++$; and such application to $++$ gives the same result as that to $+-$, necessarily and demonstrably, though in one of the two applications there is the symbol of absurdity. In the same way the other cases may be proved, whence it follows that however many of these simple operations may be performed, no result can arise except either that of the correct operation or one which may be brought to it by the operations on signs, already described.

We must here pause to remind the reader that errors, however palpable and admitted, are not necessarily productive of error. True reasoning, on true principles, must lead to truth; but if for true we write false, and for truth falsehood, we have no longer any right to say *must*, but only *most probably will*. If then we can show of a particular class of errors that, used in a certain way, the results agree with those of true reasoning on true principles, we may demand the use of those errors as demonstrated means of finding truth. The mind of man would never stop at such a point; but, for all that, we have the conclusion, as a logical consequence of the rules of arithmetic, that the mistake of the impossible subtraction introduced in operations, and not having previously vitiated the interpretation by which the fundamental objects of operation (equations) were deduced from the conditions of the problem, will produce no falsehood in the result.

2. Let us now examine the consequences of the error of interpretation. The effect of this is, that we write $a-b$ instead of $b-a$, but at the same time we suppose the quantity of which we are thinking to be of a diametrically opposite character to that which it ought to have. But also at the same time we add this symbol where we should subtract it, and *vice versa*; so that where we should take $a-b$, and add, giving $c+(a-b)$, we make one mistake in taking $b-a$, and another in subtracting, giving $c-(b-a)$. When mere rules come to be applied, we find the same result from both, namely, $c+a-b$ and $c-b+a$. We might then so manage as to elude the actual presentation of the negative quantity, as in the following problem:—Two persons are now aged 50 and 40; at what date is (was, or will be, as the case may be) the first twice as old as the second? Let us suppose that we reach the date by going a years forward and afterwards b years back from the epoch to which we then come: here is a supposition which is perfectly competent to yield any result, before or after the present epoch, by properly assuming a and b . But we must now choose a supposition; let it be that the ratio in question exists at some future time, that is, a is greater than b . In $a-b$ years then the thing happens; consequently,

$$50+(a-b)=2(40+(a-b)) \dots (1) \\ 50+a-b=80+2a-2b \dots (2) \\ 80+2a-2b-50-a+b=0 \\ 30+a-b=0 \\ b=a+30.$$

Or any number of years forward and 30 more years back is all the answer the conditions of the problem will give, or the event took place 30 years ago. But the correctness of this reasoning is only a semblance, for the result contradicts the supposition on which it was obtained, namely, that a is

greater than b . To increase 50 by the excess of a over 30 more than a is beyond the power of the arithmetician. If then it be taken that a is less than b , or that the event happened $b-a$ years ago, we have

$$50 - (b-a) = 2(40 - (b-a)) \dots (3)$$

$$50 - b + a = 80 - 2b + 2a \dots (4)$$

and (4) is the same as (2); so that we arrive at the same result as before, and find our conclusion to justify the supposition on which it was made. The steps (1) and (3) differ to the same effect as if an error of operation had been made on (4) or (2) in retracing the steps.

In the preceding, by the use of two symbols, a and b , we have enabled ourselves to obtain a correct and intelligible answer, even by the incorrect process, since we end with the determination of $b-a (=30)$, even where we reasoned on $a-b$. If however we had represented our unknown quantity by a single symbol, x , our first process would have stood as follows:—

$$50 + x = 2(40 + x) = 80 + 2x$$

$$x = 50 - 80$$

And the answer is obviously impossible. Our second process is,

$$50 - x = 2(40 - x) = 80 - 2x$$

$$x = 80 - 50 = 30.$$

From such instances as the preceding it may be collected that an error of interpretation, which causes us to write $a-b$ instead of $b-a$, will, in finding the value of $a-b$, cause an impossible subtraction to appear; and *vice versa*, that the appearance of an impossible subtraction in the result can arise from nothing but a primitive error of interpretation in fixing the nature of that result. This point must be well ascertained by every beginner from repeated instances.

Such a result as $3-8$ may be written $3-3-5$, or $0-5$; so that the error of attempting to subtract 8 from 3 is reducible to that of attempting to subtract 5 from nothing. At our present point we can say that the occurrence of $0-5$ shows us that the result which we supposed ourselves about to obtain was diametrically wrong in quality in our previous supposition: thus in the preceding problem we found $50-80$, or $0-30$, and the real answer is 30 in its magnitude, but instead of being, as we supposed, 30 years after the present time, it is 30 years before it.

Having arrived at this point, the earlier algebraists at once received such symbols as $0-5$ and $0-30$, which they wrote -5 and -30 , into the list of algebraical objects of reasoning, calling them *negative* quantities, and treating them as diametrically opposite in meaning to 5 and 30, which should for comparison be written $0+5$ and $0+30$. These they called *positive* quantities. And, because, in all possible subtractions the remainder is less than the minuend ($a-b$ is less than a) they called $0-5$ less than nothing. The fault committed by elementary writers, in beginning algebraical works by an exhibition of these definitions without the least warning of the manner in which arithmetical terms had been extended, converted the whole science into a mystery.

If we extend the notion of quantity so as to give different names to those of diametrically opposite kinds, we may call one set of quantities direct, and the others inverse. Thus property and debt, distance north and distance south, time before and time after, ascent and descent, loss and gain, progression and retrogression, &c. &c., are of different kinds; either of any one pair may be called direct, but the other is then inverse. And in circumstances which require the addition of the direct quantity, the subtraction of the inverse is equally required: thus whatever an increase in A's property will augment, a diminution of it will diminish; whatever distance on a line progression on that line will increase, retrogression will diminish. If then we have $a+b$ where we imagine both quantities were what we took them to be; but if it should turn out that b is of the contrary kind, we know that we should have had $a-b$. If we put $+b$ for the quantity we thought we were using, and $-b$ for its opposite, the ordinary rule of signs will be sufficient to make the conversions which the correction of the mistake requires. Thus if, attending only to the rule that like signs produce $+$ and unlike signs $-$, we treat

$$a + (+b) \text{ and } a + (-b)$$

we find

$$a + b \text{ and } a - b;$$

or, in this instance, the affixing of $+$ or $-$ to a quantity

according as our initial supposition is correct or incorrect, leaves us with our result if we were correct, and makes the necessary alteration if we were incorrect. The application of the same reasoning leads to the same conclusion in all the cases of addition and subtraction. Observe also that if any one, disputing the propriety of making the signs $+$ and $-$ take a new meaning, should prefer, say, to denote direct quantity by the prefix of ¶, and inverse quantity by that of §, the rule he would arrive at by induction is that like signs produce $+$ for operation, and ¶ for interpretation, while unlike signs produce $-$ for operation and § for interpretation; where by like signs he would find he must mean $+$ and ¶, or $+$ and ¶, $-$ and $-$, or $-$ and §, and all others unlike. His final rule then would be, use ¶ as if it were $+$, and § as if it were $-$, so that he would ultimately differ from the algebraist by the continual use of two new signs without any new uses or practical meanings.

In the operations of multiplication and division the rule of signs is thus shown:—It is said that two negative quantities multiplied together produce a positive quantity, which means that a mistake of direct for inverse, or *vice versa*, made in both the terms of a product, produces no mistake in the product, when the latter is formed by the usual rules. Thus, if a , which should be $x-y$, has been taken to be $y-x$, and if b , which should be $v-w$, has been taken to be $w-v$, the algebraical product

$$(w-v)(y-x) \text{ or } wy - wx - vy + vx$$

at which we arrive in the mistaken process, is precisely the same as

$$(x-w)(x-y) \text{ or } vx - vy - wx + wy$$

at which we should have arrived in the correct process.

The first step then from arithmetic to algebra is made by the following definitions:—

1. Quantities are distinguished into positive and negative, which are to be considered as of diametrically opposite kinds; and common arithmetical quantities (abstract numbers without signs) are to be considered as positive. 2. The rules of arithmetical algebra are to be applied to the extended algebra, and in all cases in which the latter presents a case unknown to the former, the rule of signs already known in the former must be applied. The purely verbal question of the terms *less than nothing*, &c., will be considered under the word NOTHING.

The preceding extension gives an extended meaning to all the terms of operation; thus addition is no longer the simple arithmetical process, but a compound operation, first reducing a multiplicity of signs to one alone, and then following the direction of that sign; and the same of subtraction. Thus $a - (-b)$ is $a + b$. It may be asked then how we are to trace our steps through any problem so as to form its equation out of symbols which seem to have various meanings; for it might appear as if the $+$ of algebra were either the $+$ or $-$ of arithmetic, as the case may be. The answer is very simple: since the extended algebra is no more than arithmetic in its actual operations, however the meaning of those operations may be extended, we may be sure that if we assign a particular case of a problem, and treat it entirely as in arithmetic, we are, though with one case only in view, performing upon limited symbols (limited because we think at the time only of a limited meaning) the same steps which we should have to follow if we could, by one act of the mind, grasp the symbols in their utmost generality.

Our limits will not allow us to pursue this subject to the extent which might be necessary for an unpractised user of symbols, and we therefore pass on to the yet higher view of the question, in which the introduction is made to a purely symbolical algebra. If we examine any symbolical identity (the sign of identity being $=$) for example, so simple a one as

$$a + b = b + a$$

we see of course that its truth is a consequence of the definition of $+$ and of the conceptions which are inseparable in our minds from the addition of quantity to quantity. The truth of the identity, then, follows from the meaning of the symbols, but the converse is not true; the meaning of the symbols does not follow from the truth of the identity. That is, let it be granted that $a + b = b + a$, and it does not follow that $+$ means addition, for consistently with the preceding it might mean multiplication, or it might mean the formation of a rectangle by erecting a line equal to the second

symbol upon a line equal to the first. In fact, the identity before us merely expresses that + is a symbol of an operation so connected with two subjects of operation that the latter may be interchanged without any alteration of the result. And the same may be said of any other fundamental symbol of identity; it may preserve its truth under many different meanings.

Next, when we perform operations of algebra with that mechanical expertness which practice teaches, we do not look back to the meaning of our operations at each step, but proceed upon a few rules of operation, of the meaning of which we must become conscious the moment we have to stop and contrive the mode of proceeding, dropping that consciousness as soon as we are again in the routine of operation. If we collect the symbols of algebra, we shall find them all in the following list. 1. The numerical symbols of arithmetic. 2. Letters denoting magnitudes. 3. The signs of addition, subtraction, multiplication, and division, the latter with their usual abbreviations of $a \times b$ into

ab , and $a \div b$ into $\frac{a}{b}$. 4. The exponent, as in a^b , b being any algebraical magnitude. 5. The symbols of logarithms, sines, cosines, &c., which may be considered but as abbreviations of series composed of terms made up of and connected by the preceding symbols. The list of fundamental operations is not very large: such as

$$+ (+ a) = + a, \quad ab + ac = a (b + c), \quad \frac{ma}{mb} = \frac{a}{b}, \quad \&c.;$$

so that it would be perfectly possible to imagine a person who had forgotten the meaning of the symbols able to perform the mere operations by reference to a few primary rules.

This being the case, suppose these few rules of reference collected together; we can then conceive a person operating by means of these rules, without thinking of their meaning. As it is of importance that a clear idea should be formed of this separation of symbolic from arithmetical reasoning, we shall propose the following illustration. A person who has thoroughly studied the algebra of positive and negative quantities, is attacked by a severe illness, on recovering from which he finds all memory of connection between his conceptions and the symbols which represented them totally gone, while his expertness in performing the mere transformations with which algebra abounds remains undiminished. When he sees $(a + b)^2$ he perfectly remembers that its substitute was $a^2 + 2ab + b^2$, but what $a, b, +$, &c. stood for, or might have been supposed to stand for, he has wholly forgotten.

He is now a purely symbolical algebraist. Suppose that he endeavours to recover the meaning of his symbols by close examination of their relations. He remembers, for example, that $a + b$ had such a meaning as made it identical with $b + a$, and he tries all meanings which will fulfil this condition, and attempts to give conformable meanings to other symbols, in the hope of picking out a set of definitions which shall be consistent with each other, and of which the relations which live in his memory shall be logical consequences. He succeeds in his attempt, and thus gives meaning to his transformations, and converts his symbolical algebra into a deduction from some fundamental notions of magnitude which he has slowly recovered. Perhaps the reader will say, he must then have discovered or remembered that a, b, c , &c. stand for numbers, that + and - mean addition and subtraction, &c. &c. By no means; the tenor of this article will require us to show another set of meanings on which he may have happened to alight, not only as consistent with each other as the arithmetical meanings, but more consistent; and in the article OPERATION we shall have to show still further the pliability of the algebraical system, by pointing out that the number of different interpretations under which its symbolical relations will represent truths, is absolutely unlimited. The basis of the algebra which our supposed recoverer of meanings might construct, is geometry, as arithmetic was that of the one which we imagine him to have forgotten: and its definitions are as follows. A plane is chosen and a point in it, and a line of a definite length, which may be called the *unit-line*, is drawn at pleasure from the point, in any direction in the plane. All letters denote lines drawn from the origin, either in the direction of the unit-line, or at any angle, angles being always measured in one given direction of revolution. An equation, $a = b$, means that the line

a actually coincides with b , or is of the same length, and drawn in the same direction. The sign $a + b$ means the diagonal of the parallelogram whose sides are a and b : this becomes the sum when a and b are in the same direction. The sign $a - b$ means the remaining side of a parallelogram in which a is a diagonal and b one side. Again, ab means a fourth proportional to the unit-line, a , and b , directed so as to make an angle with the unit-line equal to the sum of the angles made by a and b with the unit-line; and $\frac{a}{b}$ is

a fourth proportional to b , the unit-line, and a , placed so as to make an angle with the unit-line equal to the excess of the angle of a over the angle of b , in the usual direction of measurement (if the angle of a be the greater), or to the excess of the second over the first, in the *contrary* direction (if the second be the greater). All the other definitions follow as in common algebra; thus aa is abbreviated into a^2 , and \sqrt{a} means such a line that $\sqrt{a} \cdot \sqrt{a} = a$. The numbers of arithmetic stand for lines measured on the unit line.

Grant such a change of definitions, and every formula which expressed a truth in the old algebra, expresses another and a very different truth in the new one. We shall now point out how to show (by construction) the truth of the old formula

$$(a + b)(a - b) = aa - bb,$$

supposing the terms to have their new meanings.

OU is the length and direction of the unit-line, and OA and OB those of the lines a and b . Hence OC is what is called $a + b$, and OD is $a - b$, since it is the other side of a parallelogram which has a for diagonal and b for one side. Again, take OE, a fourth proportional to OU, OA, and OA, with the angle UOE double of UOA, and we have what is called aa . Similarly OF is bb ; whence OG is $aa - bb$, the other side of a parallelogram which has aa for diagonal and bb for one side. And it will be found on measurement that OG is also a fourth proportional to OU, OC, and OD, inclined at an angle which is the sum of the angles UOC and UOD: whence it is $(a + b)(a - b)$.

To show the truth of symbolical algebra, when the terms have the above-described meanings, would require a small treatise: we shall presently give references to works on the subject. We shall now recapitulate the conclusions at which we have arrived.

1. The conclusions of algebra may be made logical consequences of a few simple relations, without reference to the meaning of the symbols used: all algebra is true when these relations are true, so that all algebra is true under any meaning of the symbols which will allow of the truth of these relations.

2. It is not true that there is only one set of meanings under which the fundamental relations of algebra are truths, for three sets have been already alluded to in this article, namely, the common and limited arithmetical meanings, the extensions under which the difficulties of the negative sign disappear, and the geometrical meanings last described.

3. The order of discovery is as follows:—We first ask what sort of magnitude is to be reasoned upon; next, what are the obvious relations existing between such magnitudes; lastly, what is a convenient mode of representing the magnitudes in question; all that follows is an application of the logic common to all branches of reasoning. But when we wish to give the idea of symbolical algebra, we invert the order of the preceding questions; and we ask, firstly, what

symbols shall be used (without any reference to meaning); next, what shall be the laws under which such symbols are to be operated upon; the deduction of all subsequent consequences is again an application of common logic. Lastly, we explain the meanings which must be attached to the symbols, in order that they may have prototypes of which the assigned laws of operation are true.

We have two remarks to make before proceeding to the consideration of what are called, in common algebra, impossible quantities.

First, we have talked hitherto of change of meaning in symbols, as if we really passed from one to another and a totally different and even contrary meaning, keeping the same symbol to express both. The word *change* is too general; it is that particular change called *extension* which is employed, at least throughout this article. The meaning of a term is said to be changed by *extension*, or extended, when the new meaning contains all the old, and more; or when all cases which fall under the old meaning fall under the new one also. Thus in the preceding geometrical definition, the new meaning of $a + b$ (the diagonal whose sides are a and b) contains the old one (or simple addition); for if the two sides of a parallelogram be made to coincide, one diagonal becomes the sum of these sides. If then we call the last-mentioned set of definitions the new algebra, it may be made to appear that the old algebra is all that part of the new which treats of lines making no angle with one another. We shall presently see further illustration of it.

Secondly, we have noted the two extreme cases, in one of which we begin with the meanings of all symbols fixed, and in the other of which we have no specific meanings attached to any symbol, but wait for the time when it may be convenient to investigate sufficient meaning for all. But between these two comes the possible case of having found it advisable to affix meanings to some symbols of operation, leaving others only defined by the symbolic relations which dictate the manner of operating, and not further defined in meaning. Thus from the enumeration above given of the definitions of a geometrical algebra, it will be clear that a^{10} means the eleventh geometrical proportional to the unit and a , inclined to the unit-line at 10 times the angle of a . But it would be impossible from that enumeration to decide at once on all the cases of a^b , for instance, where $b = \sqrt{-1}$. In such a case, namely, where the meaning of a symbol is left undetermined, we must wait until we can investigate the question whether such meaning is possible to be given, consistently with the meanings attached to the previous symbols. This process is called *INTERPRETATION*, and in the article cited will be found an instance which occurs in common algebra. If such meaning cannot be given, then the symbol is properly *impossible*; if it can be given in more ways than one, it is usually called *ambiguous*.

We now drop what we have gathered on symbolical algebra, and take up the science at the point at which such extensions were made as abolished the difficulty of the simple negative quantity. It is then obvious that a^2 , or $+a^2$, is both $+a \times +a$ and $-a \times -a$, so that every positive number has two square roots of equal numerical value, one positive and the other negative. But it immediately follows that a negative quantity has no square root, at least none within the range of quantity, as defined, for the squares of positive and of negative quantities are equally positive. Consequently such a symbol as $\sqrt{-1}$ is (with reference to this algebra) impossible, just as $7-10$ is impossible in simple arithmetic. This observation is as old as algebra: the 'Viga Ganita' says, 'there is no square root of a negative quantity, for it is not a square.'

The impossible quantity however, like the negative one, was admitted among the objects of algebra. Bombelli showed that the case in which the root of a cubic equation is a complicated function of impossible quantities, is precisely that in which all the roots are real and possible: Wallis and others attempted the explanation of impossible roots, but with no success; they continued to be used as algebraical symbols, and a large number of verified cases led to the following result. Whenever an algebraical operation, beginning with a symbolical truth, leads to a result in which no impossible quantities appear, that result will be not the less numerically true because the reasoning contained rules of operation on quantity applied to symbols which represent no quantities. This law stood upon the same sort

of evidence as a physical law of nature; it was constantly found to prevail. It had also analogy in its favour, for precisely the same law had been observed as to negative quantities, though the explanation of the latter was obtained too soon to need the aid of induction in their case.

We will suppose ourselves using these impossible (or imaginary) quantities, not with a view to establish results, but to examine the consequences of applying to them precisely the rules which have been shown to apply to quantities. The following is perhaps the shortest synthetical mode of treating the subject.

If, by rules, we multiply together $\cos x + k \sin x$, and $\cos y + k \sin y$, k being merely an abbreviation of $\sqrt{-1}$, so that $k^2 = -1$, $k^3 = -\sqrt{-1}$, $k^4 = 1$, &c., we find as the result,

$$\cos(x+y) + k \sin(x+y)$$

if then $\phi x = \cos x + k \sin x$, we have

$$\phi(x+y) = \phi x \times \phi y;$$

from which relation, as shown at length in BINOMIAL THEOREM, it follows that

$$\cos x + k \sin x = K^x$$

where K is a constant independent of x . From this it follows that

$$\cos nx + k \sin nx = (\cos x + k \sin x)^n$$

which is called *De Moivre's Theorem*. It is true for all values of n . Let $nx = \theta$, which gives

$$\cos \theta + k \sin \theta = \left(\cos \frac{\theta}{n} + k \sin \frac{\theta}{n} \right)^n$$

where $\theta : n = x$. The second side may take the form

$$(\cos x)^n (1 + k \tan x)^n \text{ or } (1 - 2 \sin^2 \frac{1}{2}x)^n (1 + k \tan x)^n.$$

Let $\sin \frac{1}{2}x : \frac{1}{2}x = p$, and $\tan x : x = q$, then it is known that both p and q have the limit unity when x is diminished without limit. The preceding is the product of $(1 - \frac{1}{2}p^2 x^2)^n$ and $(1 + kqx)^n$: let these formulæ be developed by the binomial theorem, and they become (writing $\theta : n$ for x)

$$1 - \frac{1}{2}p^2 \frac{\theta^2}{n^2} + (\frac{1}{2}p^2)^2 \frac{\theta^4}{n^4} \frac{n-1}{2} - \dots$$

$$1 + kq\theta + k^2 q^2 \theta^2 \frac{n-1}{2n} + k^3 q^3 \theta^3 \frac{n-1}{2n} \cdot \frac{n-2}{3n} + \dots$$

If we now suppose n to increase without limit, x diminishing without limit so that nx remains $= \theta$, p and q approaching without limit to unity, we have unity as the limit of the first series, and

$$1 + k\theta + \frac{k^2 \theta^2}{2} + \frac{k^3 \theta^3}{2 \cdot 3} + \dots \text{ or } \epsilon^{k\theta}$$

as that of the second, ϵ being the base of Napier's logarithms. [LOGARITHMS.] Consequently

$$\cos \theta + k \sin \theta = \epsilon^{k\theta}, \quad \cos \theta - k \sin \theta = \epsilon^{-k\theta}$$

the second of which is obtained from the first (which is true for all values of θ) by writing $-\theta$ instead of θ . From these, by addition and subtraction, the well-known exponential expressions for the sine and cosine are deduced, namely,

$$\cos \theta = \frac{\epsilon^{k\theta} + \epsilon^{-k\theta}}{2}, \quad \sin \theta = \frac{\epsilon^{k\theta} - \epsilon^{-k\theta}}{2k}$$

expressions which, however widely used, never fail to give true results, in all cases in which they give results containing only even powers of k , or real algebraical quantities.

We shall give a glance at some of the symbolical consequences of the preceding, previously to entering upon their rational explanation.

1. The representation of impossible quantities. It might be supposed that such a symbol as k or $\sqrt{-1}$ would lead to a number of other symbols, just as -1 led to $\sqrt{-1}$. Such however is not the case, and it can be easily shown that any algebraical expression, however complicated, which is a function of $\sqrt{-1}$, can be reduced to the form $A + B\sqrt{-1}$, where A and B are possible quantities. For instance (k being $\sqrt{-1}$)

$$(a + bk)^{m + n\sqrt{-1}} = \epsilon^A \cos B + k \epsilon^A \sin B$$

where A and B are determined as follows. Let

$$r = \sqrt{a^2 + b^2}, \quad \tan \theta = \frac{b}{a}$$

$$A = m \log r - n\theta, \quad B = n \log r + m\theta.$$

If we take a simple quantity, $y = a + bk$, then if $\tan \theta = b : a$, $r = \sqrt{b^2 + a^2}$, we have

$$y = r (\cos \theta + k \sin \theta) = r e^{k\theta}$$

2. The extension of the theory of logarithms. The whole revolution, or four right angles, being 2π [ANGLE], we have $\cos 2m\pi = 1$, $\sin 2m\pi = 0$, where m is any whole number, positive or negative. Consequently

$$e^{2m\pi k} = \cos 2m\pi + k \sin 2m\pi = 1$$

for all such values of m . If then x be the common algebraical logarithm of y , positive or negative, we have

$$y = e^x, y \times 1 = e^x \times e^{2m\pi k} \text{ or } y = e^{x+2m\pi k}$$

so that according to the definition of a logarithm, the moment we admit impossible quantities, and in what sense soever we explain them, from that moment and in that sense we must say that x being the usual or real logarithm of y , it has an infinite number of other logarithms contained in the formula $x + 2m\pi k$. In the same manner, using $(2m+1)\pi$ where m is a whole number (+ or -) we find that $-y$, which, when we talk of real quantities, has no logarithm, has now an infinite number, included in the form $x + (2m+1)\pi k$.

3. The complete extraction of the roots of any quantity. We know that 1 has two square roots, three cube roots, and four fourth roots, since we can find them by common algebra. Now since unity can be represented in an infinite number of different ways, in the formula $e^{2m\pi k}$, and since the n th root of this formula is

$$e^{\frac{2m\pi k}{n}} \text{ or } \cos \frac{2m\pi}{n} + k \sin \frac{2m\pi}{n}$$

we might at first suppose that there is an infinite number of these roots, made by giving different whole values to m . On examining them however it is found that they occur in parcels, each containing n distinct roots, and each parcel being a repetition of the preceding one. [Root.]

4. The complete conversion of trigonometry into a branch of algebra. We see that we have given symbolic expressions for the sine and cosine of any angle, which would, were such a thing necessary, enable us to dispense with separate symbols for these functions.

5. Ready means of calculation, by means of the trigonometrical tables, in cases where ordinary means fail. For instance, in what is called the IRREDUCIBLE CASE of cubic equations, Cardan's formula gives the root in the form

$$\sqrt[3]{(a+b\sqrt{-1})} + \sqrt[3]{(a-b\sqrt{-1})}$$

If we assume $a = r \cos \theta$, $b = r \sin \theta$, or $r = \sqrt{b^2 + a^2}$, $\tan \theta = \frac{b}{a}$, the preceding becomes (making $k = \sqrt{-1}$)

$$\sqrt[3]{r \{ \cos \theta + k \sin \theta \}} + \sqrt[3]{r \{ \cos \theta - k \sin \theta \}}$$

$$\text{or } \sqrt[3]{r \{ \cos \frac{1}{3}\theta + k \sin \frac{1}{3}\theta \}} + \sqrt[3]{r \{ \cos \frac{1}{3}\theta - k \sin \frac{1}{3}\theta \}}$$

which is $2 \sqrt[3]{r} \cos \frac{1}{3}\theta$; and since the original suppositions will not be altered by writing $\theta + 2\pi$ and $\theta + 4\pi$ instead of θ , the results of these latter suppositions are equally values of the expression under calculation: so that its three values are

$$2\sqrt[3]{r} \cos \frac{\theta}{3}, \quad 2\sqrt[3]{r} \cos \frac{\theta+2\pi}{3}, \quad 2\sqrt[3]{r} \cos \frac{\theta+4\pi}{3}$$

These three are distinct: but $\theta + 6\pi$ (which might equally be written for θ) would give

$$2\sqrt[3]{r} \cos \frac{\theta+6\pi}{3} \text{ or } 2\sqrt[3]{r} \cos \frac{\theta}{3}$$

a repetition of the first. This amounts to the discovery made by BOMBELLI.

We now come to the explanation of these quantities. Since we have used no rules except those which apply to real positive and negative quantities, it follows that if we had merely laid down the symbolical foundations of algebra, without reference to the meaning of symbols, the symbol $\sqrt{-1}$ and formulae in which it occurs would have been logical consequences of the relations permitted at the outset, as much as those in which no such sign occurs. It is only when we come to attach meaning to signs, that we can say whether any result is real or not: and a result which is

real under the extended meanings may be incongruous and self-contradictory under the limited meanings. Such was the case with the negative quantity, which is no less impossible than its square, considered with reference to strict arithmetical definitions. The preceding results, then, are rationally true, whenever such a signification is given to the symbols as will, first, satisfy the fundamental relations, secondly, give rational meaning to $\sqrt{-1}$. Ordinary algebraical definitions only fulfil the first of those conditions.

We shall now turn to the fundamental definitions of what we have called the geometrical algebra: this name is given because it is only in geometry that a subject matter has yet been found, our conceptions of which are wide enough to give meaning to all the symbols which result from the primitive rules. In most of the objects of calculation we can only conceive two states, which we call *diametrically* opposite; and this geometrical word enters here, precisely because in geometry there are other states of opposition, of a weaker character, so that when we wish to express the most decided opposition, we turn to that sort of magnitude in which a less degree can be conceived. Thus we have no word drawn from the relation of loss and gain to express complete opposition; nor could we have, since there is nothing less complete with which to compare it: between absolute loss and absolute gain there are no gradations. Thus property, debt, or neither, before, after, or now, may be compared with ascent, descent, or neither; but though we can, for instance, imagine time after to be represented by a line drawn north, and time before by another drawn southward, our power of comparison ends here; it would be impossible to give necessary or even obviously convenient meaning to a line drawn east. But in geometry there are an infinite number of directions, no one of which is north or south, all being intermediate. Again, a gradual passage from one state to its opposite can generally only be attained by a passage through the intermediate state in which magnitude vanishes: for instance, a gradual loss of property followed by a gradual increase of debt requires that at one moment there should be neither property nor debt. But in geometry, a line can attain the direct opposite of its first position without changing its magnitude, by revolution round one of its extremities. These preliminary observations will prevent its being matter of surprise if geometry should be found to admit a wider use of symbols, consistently with rational interpretation, than arithmetic or the algebra derived from it.

We have explained the meaning of $a + b$, $a - b$, ab , and $a : b$, from which it follows that we know how to construct aa , aaa , &c., which we may abbreviate into a^2 , a^3 , &c. And we are here in the position just now pointed out, namely, that some of the ordinary symbols of algebra have received meaning, whereas others are yet without it; for instance, a^{-n} , $a^{\frac{1}{n}}$, $a\sqrt{-1}$, &c. And since our object is to detect meanings which shall make the symbolic relations of algebra true, we must always interpret exponents so that their meanings may make the following relations exist:

$$a^m \cdot a^n = a^{m+n}, \quad (a^m)^n = a^{mn}$$

We shall now proceed with the interpretation of symbols.

1. The symbol $-a$ must stand for a line of length equal, and direction opposite, to that of $+a$; for $0 - a$ means the other side of a parallelogram of which the diagonal disappears, one side being a .

2. a^{-n} must represent 1 : a^n , and a^0 must always represent the unit line; for a^0 must be such that $a^m a^0 = a^{m+0} = a^m$; that is, a fourth proportional to 1, a^0 , and a^m , is a^m ; whence a^0 must be 1 as to length. In direction $a^m a^0$ is the same as that of a^m ; whence the sum of the angles of a^m and a^0 is that of a^m , or the angle of a^0 is nothing. Again, a^{-n} must be so explained that $a^n a^{-n}$, and a^{n-n} or a^0 , may be the same; whence $a^n a^{-n} = 1$.

3. $a^{m/n}$ must be so explained that $(a^{m/n})^n = a^m$; whence it means the first of $n - 1$ mean proportionals between 1 and a^m , inclined at an angle which is the n th part of the angle of a^m .

But it is necessary to notice that any angle θ is, considered as pointing out a direction, the same thing as $2\pi + \theta$, or $\theta - 2\pi$, or $\theta \pm 2m\pi$, m being a whole number. That is to

say, a line which sets out from the unit line may be conceived to have attained the position denoted by an angle θ , either by moving simply through θ , or by afterwards making any number of complete revolutions in either direction. So long as we multiply angles by a whole number, this makes no ambiguity; for instance, if a have the angle θ , or $\theta + 2\pi$, &c., a^4 has the angle 4θ , $4\theta + 8\pi$, &c., all of which indicate the same direction. But if we wish to find $a^{1/4}$ or to take the first of three mean proportionals between 1 and a , inclined at the fourth part of the angle of a , then the fourth parts of the angles

$$\dots \theta - 8\pi, \theta - 6\pi, \theta - 4\pi, \theta - 2\pi, \theta, \theta + 2\pi, \theta + 4\pi, \theta + 6\pi, \theta + 8\pi, \dots$$

are severally

$$\frac{\theta}{4} - 2\pi, \frac{\theta}{4} - \frac{3\pi}{2}, \frac{\theta}{4} - \pi, \frac{\theta}{4} - \frac{\pi}{2}, \frac{\theta}{4}, \frac{\theta}{4} + \frac{\pi}{2}, \frac{\theta}{4} + \pi, \frac{\theta}{4} + \frac{3\pi}{2}, \frac{\theta}{4} + 2\pi, \dots$$

giving a succession of directions, each of which differs from the preceding, not by four right angles, but by one right angle. There are then four distinct meanings of this symbol $a^{1/4}$.

5. The symbol $\sqrt{-1}$ stands for a line equal in length to the unit line, and inclined to it at a right angle; for 1 and -1 make two right angles with each other, whence $(-1)^{1/2}$ is the mean proportional between 1 and 1 (or 1 itself) inclined at half that angle, or at a right angle. Similarly $-\sqrt{-1}$ is in the opposite direction, and makes three right angles with the unit line. Also $a\sqrt{-1}$ is a line in length equal to a , but making an angle with the unit line larger by a right angle than the angle of a .

6. Any line may now receive a simple representation; for the line a , inclined at the angle θ to the unit line, is the diagonal of a rectangle, of which the side in the direction of the unit line is $a \cos \theta$, and that perpendicular to the unit line is in length $a \sin \theta$, so that its symbolical representation is $\sqrt{-1} \cdot a \sin \theta$. Hence the line a , inclined at the angle θ , is

$$a(\cos \theta + \sqrt{-1} \cdot \sin \theta).$$

Hence we see the meaning of the symbol $a \cdot \epsilon^{\theta\sqrt{-1}}$; for since the definitions satisfy all the fundamental relations of algebra, the theorem

$$\epsilon^{\theta\sqrt{-1}} = \cos \theta + \sqrt{-1} \sin \theta,$$

which is a necessary consequence of these relations, requires us so to define the first side as to establish its identity of meaning with the second. Consequently, $\epsilon^{k\theta}$, k being $\sqrt{-1}$, must represent a line equal in length to the unit line, inclined at an angle θ .

To enter further into the details of this extension of algebra would require too great a length: we shall now proceed to some remarks upon it.

If any one should object that it is founded on geometry, we answer that it is not so much founded on geometry as applied to it. The symbolical algebra, which we draw in the first instance from arithmetical suggestions, and afterwards cut loose, so to speak, from that science, founding it upon purely symbolical definitions, is applied to geometry, because in the latter science, and in the latter only, do we find notions of magnitude, the different affections of which are sufficient to supply rational meaning to all its symbols. Let any one produce other ideas of magnitude, of loss and gain for instance, as varied in their different affections, and the general truths of symbolical algebra will find a new application.

The subject-matter of the preceding algebra is geometry of only two dimensions; whereas it might be supposed that the application would never be complete until it embraced geometry of three dimensions. No such extension has however yet been made; though it is not unreasonable to suppose that it may be made at some future time.

But perhaps it may be said that this new algebra, being based upon its own definitions, however logically its conclusions may follow from those definitions, can afford no aid to the common algebra in explaining those quantities which are as impossible in the latter as they are possible in the former. What does it profit us, troubled as we are with symbols which upon our own definitions we cannot rationally explain, to know that those same arbitrary marks, being made to have other meanings, would not present the same

difficulties? It may almost seem as if we should relieve ourselves from the trouble of investigating the error of a process which ends in $2 + 2 = 5$, by remembering that those who should mean by 5 what we mean by 4 would not see any necessity for revising the operations. The difficulty thus broadly stated must be felt more or less by every one before he can entirely make up his mind, if not to the reception, at least to the proposed application of symbolical algebra. The answer is as follows:—

In the common operations of algebra we do not set particular value upon any symbols or meanings, except in so far as they answer our purpose. If that purpose be the discipline of the mind, there is no point at which a greater enlargement of its power takes place than must happen when it begins to comprehend that any set of definitions may be such as to require restriction upon operations; so that the alternative is, the enlargement of the definitions to an extent which will allow of every result of operation being rationally explained. If it be one of the errors to which our bounded faculties are liable, that we may invent the processes and mechanism of a genus upon the definitions incidental to the consideration of a species, or anything of that kind, we have made a discovery, when we find our error, which is well worth the trouble, even leaving out of consideration the expansion of views which is obtained by the investigation of the correction. But if the purpose be the investigation of a formula for practical use, whether in physics or any other branch of application, nothing can be more indifferent than the manner in which our result is obtained, provided only we are sure of its truth.

When we reason upon the principles of the old algebra, we are sufficiently sure of the truth of our results, partly by actual verification, partly by those imperfect views of the nature of symbolical algebra which preceded the new science. But it was not always possible to arrive at the highest degree of mathematical assurance, for even in cases where a result could be obtained free from impossible quantities, the intermediate steps could not always be fully comprehended; and their verification, if required, was sometimes (though not often) imperfect: and in every case, it must be remembered, no result was fit for actual application until the impossible quantities had disappeared.

Let us say that we are now considering such a case, namely, one in which quantities impossible in ordinary algebra have been used in the process, though they disappear in the result. The consequence is that if the extended definitions were employed, the answer represents a line drawn in the direction of the unit line if positive, or in the contrary direction if negative; and the same of the symbols of which the answer is a function. But for lines measured in that unit line the extended definitions coincide with the ordinary ones, as has been noticed. So that, as far as the result is concerned, we are sure of the same answer (when there is an answer that we call possible), whether we employ one or the other set of definitions; with the advantage of being able, in employing the new definitions, to put a rational interpretation upon every step of the process.

But has the new algebra no impossible quantities peculiar to itself? We cannot tell, for all time to come, what the answer to this question shall be; at present we can reply that though there are symbols which would indicate previous misconception if they appeared in a result, yet there are none which do not admit of interpretation. For instance, we see that angles in our definitions may be positive or negative (measured on one side or the other of the unit line), but we have no angle which $\sqrt{-1}$ can represent. If then, in the most extended algebra, the answer to the question, 'At what angle must a line assumed $=h$ be inclined to satisfy such and such conditions?' were, 'The angle must be $a + b\sqrt{-1}$,' we should at first say that the question was impossible. But if we examine further, we see that a line h applied at an angle $a + b\sqrt{-1}$ is represented by

$$h \cdot (a + b\sqrt{-1})\sqrt{-1} \text{ which is } h \epsilon^{-b} \epsilon^a \sqrt{-1}$$

when treated by symbolical rules. We should conclude then that we have made some error by which h was determined in a manner which cannot satisfy the conditions, but that a line equal in length to $h \epsilon^{-b}$, inclined at an angle a , will satisfy them. This last answer must at least be examined, before it is asserted that the question is impossible. The following formulæ, if they occur, may be interpreted by

the identical expressions given in the second sides ($k = \sqrt{-1}$)

$$\cos(a + bk) = \cos a \frac{\epsilon^b + \epsilon^{-b}}{2} - \sin a \frac{\epsilon^b - \epsilon^{-b}}{2} \cdot k$$

$$\sin(a + bk) = \sin a \frac{\epsilon^b + \epsilon^{-b}}{2} + \cos a \frac{\epsilon^b - \epsilon^{-b}}{2} \cdot k$$

The whole of the ambiguous cases of algebra depend upon this, that any quantity x can also be represented by $x \cdot \epsilon^{ak}$, where a represents any whole number of revolutions. As long as only multiples of a occur, different appearances of form present themselves, not indicating real alteration either of length or direction; but when submultiples of a occur, an alteration of direction takes place, unless such submultiple be also an exact number of revolutions.

The logarithmic theory of the most extended algebra merits a particular notice. It is remarkable that the first hint of it was given by a purely symbolical investigation, conducted entirely with reference to the common algebraical definitions. Some years ago Mr. Graves* asserted that the logarithms of unity, in the most general sense of the term, should be contained in the formula

$$\frac{2\pi m \sqrt{-1}}{1 + 2\pi n \sqrt{-1}}, \text{ instead of } 2\pi m \sqrt{-1};$$

m and n being any whole numbers.

If we define a logarithm by the symbolical relation $a \log x = x$, where a is an arbitrary base, and if, for well-known reasons of a purely numerical character, we assume ϵ to be the length of the base, we may ask what is the logarithm of a unit inclined at the angle θ , the base being ϵ inclined at an angle ϕ . The answer must be such a value of x as will satisfy

$$(\epsilon \cdot \epsilon^{\phi k})^x = \epsilon^{\theta k}, \text{ or } x = \frac{\theta \cdot k}{1 + \phi k}$$

in which if, as we may do, we increase or diminish either ϕ or θ by a whole number of revolutions, we find, as in other cases, that a line which has attained a certain position by one number of revolutions, distinguishes itself, always in form, and sometimes in results, from the same line in the same position, attained by another number of revolutions. If our unit be in the unit line after m revolutions, and the base be also in the unit line after n revolutions, the logarithm of such a unit to such a base is what was given as the logarithm of unity by Mr. Graves. Nor is the preceding process impossible: for it shows a set of real operations by which ϵ , inclined at an angle ϕ , might be converted into a unit inclined at an angle θ . If we ask whether the fundamental properties of logarithms remain true, we shall find that the logarithm of a unit added to the logarithm of a unit differently inclined, and with a differently inclined base, is still the logarithm of a unit, in which both the angles have received another alteration. If the logarithms of two units inclined at angles θ and θ' , to bases inclined at ϕ and ϕ' , be added together, the result is the logarithm of a unit inclined at an angle

$$\theta + \theta' - \frac{\theta \theta (\phi' - \phi)^2}{\theta (1 + \phi'^2) + \theta' (1 + \phi^2)}$$

to a base inclined at the angle

$$\frac{\phi \theta (1 + \phi'^2) + \phi' \theta' (1 + \phi^2)}{\theta (1 + \phi'^2) + \theta' (1 + \phi^2)}$$

But these conclusions do not hold when the logarithm of a is added to that of b , a and b not being units, and the bases being differently inclined: nor is it necessary here to state the extensions which the above formulæ must receive in such a case.

The following list contains all the recent works of which we can collect the titles, in which general algebra, or the difficulties which preceded its introduction, are considered to any extent:—Woodhouse, 'Phil. Trans.,' 1802; Woodhouse, 'Principles of Analytical Calculation,' 1803; Bué, 'Phil. Trans.,' 1806; Argand, 'Essai sur la Manière de représenter les Quantités Imaginaires,' Paris, 1806; various papers in the 'Annales de Mathématiques,' for 1813, &c.; Gompertz, 'On the Principles and Application of

Imaginary Quantities,' 1817 and 1818; Warren, 'On the Geometrical Representation of the Square Roots of Negative Quantities,' Cambridge, 1828 (the first systematic elementary work based on extended definitions); Peacock, 'Treatise on Algebra,' Cambridge, 1830 (the first work on symbolical algebra); Davies Gilbert, 'Phil. Trans.,' 1831, 'On the Nature of Negative and Impossible Quantities'; Peacock, 'Report on certain branches of Analysis, in the Report of the Third Meeting of the British Association,' London, 1834. (This work contains the modern history of the extensions, and an account of several of those above cited.) See also a Review of Professor Peacock's 'Algebra,' in the ninth volume of the 'Journal of Education'; and De Morgan's 'Trigonometry,' 1837. On the method of determining the signs of geometrical magnitudes, see the 'Differential Calculus,' in 'Library of Useful Knowledge,' chapter xiv.

We cannot omit to mention a paper by Sir William Hamilton, recently published in the 'Transactions of the Royal Irish Academy.' The author treats algebra as the science of time, not of magnitude; and as far as the explanation of positive and negative quantities are concerned, it is not difficult to follow him. The symbol $\sqrt{-1}$ however is of a harder character. M. Cauchy and others had previously considered it as merely a symbolical contrivance to express the coexistence of two equations; thus

$$a + b \sqrt{-1} = c + d \sqrt{-1}$$

is a well-known method of implying $a = c$ and $b = d$, both in one equation. The manner in which Sir William Hamilton has connected this symbol with his system would justify us in saying that, if his science of time were re-translated into a science of magnitude, his explanation of impossible quantities would fall back into the one just alluded to; and it is difficult to describe it more fully without entering further into the matter than we have room for. We are inclined to think that this explanation of algebra with reference to time may finally be admitted as one method of supplying the foundations of the purely symbolical science; but we must confess ourselves not yet sufficiently clear upon the manner in which the symbol $\sqrt{-1}$ is connected with its definition, to hazard a positive opinion.

NEGRO. [MAN.]

NEGROPONT. [EUBŒA.]

NEGUNDO, a genus of trees, separated from Acer because of its pinnated leaves and diceious apetalous flowers. Two species are known, one of which is a handsome hardy tree, inhabiting the United States of North America, and now common in the gardens of this country; the other is a native of Mexico, and at present but little known: it may be a mere variety of the other.

NEHEMIAH. [EZRA.]

NEISSE is a principality in Silesia, the larger portion of which, containing 480 square miles, with 110,000 inhabitants, belongs to Prussia; the remainder, which contains 320 square miles, with 56,000 inhabitants, belongs to Austria. The Prussian portion is very fertile, but the Austrian part is mountainous. Till 1820 the whole principality belonged to the bishop of Breslau, who now possesses only the Austrian portion, with the title of a duchy; the Prussian portion is converted into a royal principality, including the circles of Grottkau, and Neisse; in the government of Oppeln.

NEISSE, the capital, in 51° 25' N. lat. and 17° 20' E. long., is situated in the Prussian portion, at the conflux of the rivers Neisse and Biele, in a marshy and unhealthy spot, 574 feet above the level of the sea. It is said to have been built in the year 966, but was not fortified till 1594, since which time it has undergone several sieges, and its works have been gradually strengthened and extended, so that it is now one of the most important fortresses in the Prussian dominions. In 1743 Frederick II. laid the first stone of Fort Preussen, on an eminence, at the foot of which is the newly-built and strongly fortified suburb Friedrichstadt, which extends to the Neisse. The fortress is surrounded by broad and deep moats, and the surrounding country can be laid under water in case of a siege. Neisse is a clean well-built town. The public buildings are, a splendid episcopal palace, six Roman Catholic churches, a Protestant church, a Catholic gymnasium, a town-hall, and a synagogue. There are numerous schools and charitable institutions. The gymnasium has very fine collections of various kinds; but the library of 10,000 volumes was destroyed in the siege in 1807. As the capital of the principality and the

* Now professor of jurisprudence in University College, London; in a paper published in the 'Phil. Trans.' for 1829. This extension, however simply it may follow from the extended definitions, excited some discussion and opposition when advanced in connection with the ordinary principles of algebra.

circle, the town is the seat of the courts of justice and different public offices; and the inhabitants, who are about 11,000, gain their subsistence by breweries and manufactures of linen, woollen, ribands, and stockings, and a great trade in yarn. There are likewise a royal manufactory of arms and a powder-mill. In the environs there are quarries of excellent freestone, of which considerable quantities are exported.

NELEDINSKY-MELETZKY, YURIL, the most eminent song-writer Russia has yet produced, was born in 1751, and served in the campaigns against the Turks, from the year 1770 to 1774, and, after the peace between the two countries, accompanied the Russian mission to Constantinople. Subsequently an office in the civil department was bestowed upon him by the emperor Paul, and in 1797-8 he accompanied that sovereign in his journey to Kazan and White Russia. This last mark of the imperial favour was followed by others of a more substantial nature, for an estate with several hundred peasants was shortly after allotted to him as the reward of his services, besides the order of St. Anne, to which that of St. Alexander Nevsky was added in 1809.

Though, considered singly, his songs and ballads may appear merely elegant poetical trifles, and indicate no very high literary effort or ambition, they prove him to have possessed a decided talent for that species of composition, and the power of infusing into it a gracefulness and charm for which the language afforded no previous models. To great simplicity they unite great tenderness and warmth of feeling. He died in 1829, at the age of 78.

NELLA MALA MOUNTAINS. [HINDUSTAN, vol. xii., p. 208.]

NELLYGREEN MOUNTAINS. [HINDUSTAN, vol. xii., p. 210.]

NELLORE, a district of the Carnatic province, lying between the 14th and 16th degrees of north latitude. It is bounded on the north by Guntore, on the east by the Bay of Bengal, on the south by the northern division of Arcot, and on the west by Cuddapah. The district is well watered by many streams, which rise in the Eastern Ghauts and fall into the Bay of Bengal. It is also traversed from west to east by the Pennar. The principal towns of the district are Nellore, Ongole, and Sarapilly.

The Ryotwary system prevails almost universally in Nellore, the cultivator paying the rent of the land directly into the hands of the government collector. The gross revenue received in 1817 amounted to 68,853*l.* As regards the numbers of the population, very different statements are given. According to returns made to the government of Madras in 1822, the total population was 439,467; while the number of inhabitants according to a statement laid before parliament in 1833 was 432,540 males and 406,927 females, together 839,467. There is evidently a great mistake in one of these statements; and it is probable, as the difference amounts to the number of 400,000 exactly, that the error has resulted from the accidental substitution of one figure for another in the returns of 1822; the larger number, being given with more circumstantiality, has the greater appearance of exactness.

Some copper-mines have been found in the district, but not under circumstances that admit of their being profitably worked. A considerable quantity of salt is made for account of the government on the coast near the town of Nellore.

The town of **NELLORE** is situated on the south bank of the Pennar river, in 14° 29' N. lat. and 80° 3' E. long. The town is surrounded by a mud wall, with some towers of stone at intervals. It is a populous place, and a considerable amount of business is carried on by the inhabitants: the principal street, which is three-quarters of a mile long, is composed of well-furnished shops, but there are no handsome buildings in the town. There is a ferry across the Pennar, which is here, three-quarters of a mile wide.

Ongole, in 15° 31' N. lat. and 80° 8' E. long., is irregularly built, and contains very few buildings better than mere huts made of earth and thatched. It has a fort, in which a small English garrison is constantly stationed. **Sarapilly** is a place of no importance, in 14° 18' N. lat. and 80° 2' E. long.

NELOCIRA. [ISOPONA, vol. xiii., p. 53.]

NELSON, ROBERT, born 1656, died 1714, author of various works in practical divinity, which have long been held in very high estimation by serious and pious persons.

He is also remarkable for having been a bountiful contributor, both during his life and at his death, to institutions for the education of the poor and the diffusion of Christian knowledge.

He was the grandson of Lewis Roberts, a merchant of London, who is believed to be the person of that name who wrote 'The Merchant's Map of Commerce,' printed in 1638, and whose descendants, the Roberts, Nelson, and Hangers, were very extensively engaged in the trade to the Levant. How far he was himself connected with commerce does not appear; but he was of Trinity College, Cambridge, and while a young man elected a Fellow of the Royal Society. He was intimate with Halley, with whom he travelled in France and Italy.

It was while at Rome that he met with the lady who became his wife in 1682, Lady Theophila Lucy, widow of a baronet and daughter of the earl of Berkeley. This lady was a Roman Catholic, having been led to enter that church by the celebrated Bossuet.

This circumstance was a great grief to Mr. Nelson, whose mind was much occupied with the consideration of both the practical and controversial points in divinity, and whose chief friends were eminent divines in the English Church, particularly Bull, Hickes, Lloyd, and Tillotson: the last especially was his intimate friend.

At the Revolution he scrupled to take the oaths to King William, and remained a non-juror till the year 1709, when he returned to the Church of England as then established.

He died at Kensington, and was buried in the cemetery of St. George's, Queen-square.

The following are his principal works:—'Practice of True Devotion, in relation to the End as well as to the Means of Religion;' 'Companion for the Festivals and Fasts of the Church of England;' 'Great Duty of frequenting the Christian Sacrifice;' 'An Account of the Life and Writings of William Kettlewell.' He also published the English works of Bishop Bull, who had been his tutor, with an account of his life and writings.

The long inscription on Mr. Nelson's monument, written by Bishop Sinalridge, may be read in the 'Literary Anecdotes of the Eighteenth Century,' by John Nichols, vol. iv., p. 190, where is a fuller account of the subject of this article.

NELSON, HORATIO, son of Edmund Nelson, rector of Burnham Thorpe, and Catherine his wife, was born at his father's residence in Norfolk, on the 29th September, 1759. His mother died in 1767, leaving eight children, for whom an early provision was desirable, on account of the slender income of their father. Nelson had neither a strong frame nor a hardy constitution, yet his weakness did not disincline him to leave home: he embraced willingly the opportunity of going to sea, which was offered through the position in the navy which was held by his uncle, Captain Suckling, who had been appointed to the *Raisonable*, 64, in which Nelson was entered as midshipman. The *Raisonable* was soon afterwards paid off, and service in a guard-ship, to which his relation was appointed, being objectionable for a boy, he entered the merchant service, and sought active employment in an outward-bound West Indiaman. Mr. Southey says, 'He returned a good practical seaman, but with a hatred of the king's service, and a saying then common among sailors, "aft the most honour, forward the better man." To remove this hatred, his uncle received him on board his guard-ship in the Thames, and though this service was less enterprising than might have been desired, it was advantageous to Nelson in two respects; it enabled him to overcome his prejudice against the navy, and to acquire skill in pilotage, which he afterwards turned to good account. By his uncle's influence he obtained a rating on board the *Carcass*, Capt. Lutwidge, in the North Polar expedition under Capt. Phipps: on his return he was placed on board the *Seahorse*, and went to the East Indies in her, from whence he was invalided. Recovering his health on the passage home, he was appointed acting-lieutenant to the *Worcester*, and subsequently lieutenant of the *Lowestoffe* and the *Bristol*; commander of the *Badger*, brig, in Dec., 1778; and post-captain to the *Hinchinbroke*, June, 11, 1779. He distinguished himself in the siege of Fort San Juan, Nicaragua, and took the island of St. Bartolomeo. Pestilence reduced his crew from 200 to 10 men, and Nelson, crippled by disease, was obliged to return home. The Bath waters having restored him, he was appointed to the *Albemarle*,

in which he cruised during the winter of 1781-2 in the North Sea, whence he was ordered by Lord Sandwich to Quebec. On this station he remained until peace was concluded, when he went for a short time to St. Omer. He was appointed to the *Boreas*, 28, and sent to the Leeward Islands, in March, 1784. The Americans were then trading with the British colonies on the footing of British subjects, but as they had become foreigners by their separation from Great Britain, and as such were not allowed to trade with those islands, Nelson determined to put a stop to these proceedings, and induced Sir R. Hughes to issue orders to enforce the navigation act, which orders however were subsequently recalled. Nelson then found he must either disobey his orders or the acts of parliament; he determined on the former, and seized four American vessels with freight at Nevis, carrying island colours. The whole colony rose against him, but the ships were ultimately condemned in the admiralty court. He married at Nevis, 4th March, 1787, the widow of Dr. Nisbet, a physician, and daughter of Mr. Herbert, President of that island, who had one son, named Josiah. He returned to England in June, 1787, and lived in retirement till the eve of the French revolutionary war, when he applied for employment. On the 30th of January, 1793, he was appointed to the *Agamemnon*, of 64 guns, and took with him Josiah Nisbet as midshipman. The fleet, under Lord Hood's orders, reached the south of France at a time when it would willingly have become a separate republic under the protection of England. Nelson was sent with despatches to the court of Naples, where he became acquainted with Sir William and Lady Hamilton. He afterwards joined Commodore Linzee at Tunis, to expostulate with the dey on the impolicy of supporting France. On the passage, he fell in with three French frigates, a corvette, and brig; a running fight of three hours ensued, when a change of wind enabled the enemy to get out of reach of the *Agamemnon's* guns, which ship had received so much damage in her sails and rigging, that she was unable to renew the action, and the enemy left her unmolested. Subsequently Nelson was detached with a small squadron to co-operate with Paoli in Corsica. The French having withdrawn from St. Fiorenzo to Bastia, Lord Hood, with Nelson as his senior captain, determined to reduce that place with a naval force, General Dundas having refused to co-operate. The garrison capitulated to Lord Hood, May 19, 1794. At the siege of Calvi, whither the *Agamemnon* was sent to co-operate with Sir Charles Stuart, Nelson lost an eye, from a shot striking the ground near him and driving the sand into it. Here the dog-days and an epidemic thinned his crew, whose health was previously impaired with hard service. Admiral Hotham had now succeeded Lord Hood in the Mediterranean command, and in the partial action with the French fleet which took place soon after, the *Agamemnon* engaged the *Ca Ira*; the action was renewed on the following day, when the *Agamemnon* again engaged the same ship, which was taken, together with the *Censeur*. Nelson was desirous of continuing the action with the rest of the fleet, but the admiral was satisfied with this slight success. The next service on which he was employed was the blockade of Genoa, in co-operation with the Austrian army, in order to drive the French out of that state. He had a squadron of frigates under his orders, and narrowly escaped capture by the French fleet within sight of the English fleet, which was becalmed in St. Fiorenzo Bay. Another partial action succeeded, in which the French ship *L'Alcide*, 74, was taken, but burnt by the explosion of some combustibles then in use among the French. Only 200 of her crew were saved. The Austrians, being beaten, gave the French possession of the Genoese coast, and Nelson sailed for Leghorn to refit. Sir John Jervis took command of the Mediterranean fleet in 1795, and Nelson resumed his station in the Gulf of Genoa. He next superintended the evacuation of Bastia, and having effected this, proceeded in the *Minerva*, Captain George Cockburn, to perform the same service at Porto Ferrajo. On the passage they fell in with two Spanish frigates, took one, and compelled the other to haul off, when a squadron, of which these frigates formed a part, hove in sight, and the prize was retaken. From Porto Ferrajo, Nelson took convoy to Gibraltar, fell in with the Spanish fleet at the mouth of the Straits, and joined Sir J. Jervis with the intelligence. He hoisted his broad pendant as commodore on board the *Captain*, 74 guns, Captain R. W. Miller, and was eminently distinguished in the general action of February 14, 1797, with the Spanish fleet, in

which the Captain, after engaging, with the *Culloden*, three first-rates and three others, being at length crippled, fell alongside the *San Nicolas*, of 80 guns, and carried her by boarding. Nelson himself on this occasion boarded through the cabin windows. The *San Josef*, of 112 guns, was lying on the other side, and he led the boarders from the *San Nicolas* to her, with the cry of 'Westminster Abbey or victory!' Their efforts were crowned with success, and on the quarter-deck of this Spanish first-rate Nelson received the swords of the rear-admiral and his officers.

Before the news of the action reached England, Nelson had been promoted to the rank of rear-admiral; the order of the Bath was now bestowed on him, and the freedom of Norwich was voted to him, to which city he gave the sword of the Spanish rear-admiral. He now hoisted his flag in the *Theseus*, and commanded the in-shore squadron employed in the blockade of Cadiz. On the 3rd July, 1797, Lord St. Vincent bombarded that town. In withdrawing the bomb-vessel out of gun-shot, the Spanish gun-boats and launches endeavoured to capture her, but were successfully met by a similar force under Nelson, in which the Spanish commander attempted to carry his boat, and both distinguished themselves personally in a hand to hand fight. His next service was an unsuccessful attack on the town and fort of Santa Cruz, Teneriffe, with three sail of the line, one fifty-gun ship, and three frigates: the British gained a footing on the mole, but were repulsed. In the act of stepping out of his boat, Nelson received a shot through his right elbow. He was with difficulty carried on board his ship, where the arm was immediately amputated. The loss of the English amounted to 1 captain, 6 lieutenants, 37 seamen and marines killed; the admiral, 2 captains, 1 lieutenant, 101 seamen and marines were wounded; 97 were drowned in the *Fox* cutter, which was sunk; and 5 were missing. Notwithstanding the failure of this enterprise, fresh honours awaited him. He was rewarded with a pension of 1000*l.*, on which occasion he was obliged to present a memorial, which exhibited a singular catalogue of services. He stated that he had been in four actions with hostile fleets, in three with boats employed in cutting out, and at the taking of three towns; employed at Bastia and Calvi; had assisted in capturing seven sail of the line, six frigates, four corvettes, and eleven privateers, taken fifty merchant vessels, and been in action 120 times; lost his right eye and arm, and received other severe wounds. He also received a pension of 1000*l.* a year, and the freedom of the cities of London and Bristol. Early in 1798, Sir Horatio hoisted his flag in the *Vanguard*, 74, and joined Lord St. Vincent at Gibraltar, by whom he was detached on the 9th May, to watch the port of Toulon, where the expedition for Egypt was then fitting. The *Vanguard* was dismasted in a heavy gale of wind off Toulon, on the 20th, and, during the thick weather that followed, the French fleet escaped. Having refitted his ship, and being reinforced by eleven sail of the line, he went in pursuit of the French fleet, with the following ships:—*Culloden*, *Goliath*, *Minotaur*, *Defence*, *Bellerophon*, *Majestic*, *Zealous*, *Swiftsure*, *Alexander*, *Orion*, *Theseus*, *Audacious*, and *Leander*, all of 74 guns.

Nelson heard of the enemy's armament at Malta, and shaped his course to Candia, but getting no tidings there, he returned to Sicily. Having obtained supplies at Syracuse, he sailed for the Motea on the 25th July, obtained intelligence at Coron which caused him to shape his course for Alexandria, where he arrived August 1, 1798, and found the French fleet lying in the bay of Aboukir. The haziness had prevented the two fleets from perceiving each other, although they actually crossed in the night of the 22nd June. The French had reached Alexandria on the 1st July, and Brueys, unable to enter the long-neglected port, moored his fleet, consisting of one first-rate, three second-rates, nine seventy-fours, and four frigates, in Aboukir bay. On perceiving the enemy's position, Nelson adopted the plan projected by Lord Hood in Gourjoan Road, but which he had there found impracticable, of stationing his ships one on the outer bow, and another on the outer quarter of each of theirs. The action commenced at 6h. 20m. p.m., August 12th, and at noon of the 13th, of the French fleet one ship had blown up, eight had surrendered, two escaped, and two were aground, of which one yielded, and the other was burnt by her crew. The loss sustained by the English was 218 killed, and 678 wounded; that of the French is variously stated, but it probably amounted to 2000 killed, wounded, and missing. Brueys,

after being thrice wounded, was blown up in his ship *L'Orient*, part of whose mainmast was made into a coffin by order of Captain Hallowell, and by him presented to Nelson. Nelson received a severe wound in his forehead from a piece of langridge-shot. The *Culloden* grounded at the commencement of the action, and was unable to take part in it. On this occasion Nelson was created Baron Nelson of the Nile, and pensions of 3000*l.* per annum were settled on him and his two next heirs male. The thanks of the parliament and gold medals were voted to him and all the captains engaged. From this time Nelson remained chiefly employed on the Neapolitan coasts, during which period he sanctioned that which must ever remain a blot on his character, and which tarnished the honour of the British flag—the murder of Prince Carraccioli. Capua and Gaëta now surrendered to the naval force under Nelson's orders. In February, 1800, Nelson sailed for Malta, and captured the French ship of the line *Généreux*, which escaped from Aboukir, and also a frigate. On Lord Keith's return from England, Nelson came home, leaving Captain Trowbridge in command of the squadron blockading Malta, which island capitulated in September, 1800. Within three months after his return, he separated from Lady Nelson, in consequence of his infatuated attachment to Lady Hamilton. He sailed, March 12, 1801, as second in command to Sir Hyde Parker, to the Baltic, with a fleet of eighteen sail of the line, frigates, bombs, fire-ships, &c., amounting in all to fifty-three sail, having on board the 49th regiment, two companies of rifles, and a detachment of artillery. The fleet arrived in the Sound, and after some time lost in negotiation by Mr. Vansittart, anchored between the island of Huen and Copenhagen. Lord Nelson having offered his services in the attack on the Danish fleet, he was detached with twelve ships of the line and smaller craft, making thirty-six sail, 1st April, 1801, and anchored at dark off Draco Point, two miles from the Danish line. The formidable force opposed to the British consisted of eighteen vessels, mounting 628 guns, chiefly 36 and 34 pounders, manned by 4849 men, moored in a line a mile in length, flanked by two batteries, called *Trekroner*, of thirty 24-pounders and thirty-eight 36-pounders, with furnaces, commanded by block-ships. The action commenced at nine A.M. and lasted five hours, when a truce was agreed upon by the crown-prince sending the Danish adjutant-general to the commander-in-chief to settle the terms, in reply to Lord Nelson's celebrated note: 'Vice-Admiral Lord Nelson has been commanded to spare Denmark when she no longer resists. The line of defence which covered her shores has struck to the British flag; but if the firing is continued on the part of Denmark, he must set on fire all the prizes he has taken, without having the power of saving the men who have so nobly defended them. The brave Danes are the brothers, and should never be the enemies of the English.' The British killed and mortally wounded were 350; and the wounded 850. The Danish loss was estimated at between 1600 and 1800 men killed and wounded; of the eighteen floating batteries, thirteen were taken or destroyed.

Amicable relations having been restored between England and the northern powers, Lord Nelson returned in command of the squadron to England (Sir Hyde Parker having been recalled), when the thanks of parliament were voted to him for Copenhagen. To allay the public alarm excited by Bonaparte's proposed invasion, Nelson took the command of the shores, reconnoitred Boulogne in the *Medusa* frigate, attacked the flotilla in the mouth of the harbour, and withdrew with a loss of 172 men, having gained no advantage. From this time he lived in retirement in Surrey, till he was called on to assume the Mediterranean command. He hoisted his flag in the *Victory*, on war breaking out in 1803. His chief employment was watching the French in Toulon. On the 17th January, 1805, the French fleet put to sea under vice-admiral Villeneuve, but was driven back by heavy gales. Villeneuve sailed again on the 29th of March, received a reinforcement at Cadiz, and made for Martinique, with seventeen sail of the line, seven frigates, and four sloops. On the 15th May, Lord Nelson sailed for the West Indies in pursuit of Villeneuve with ten ships of the line and three frigates, and arrived at Barbadoes on the 4th of June, on which day Admiral Villeneuve sailed from Martinique, and having effected nothing except the recapture of the *Diamond* Rock, and made prizes of a convoy of fifteen sail of West Indiamen, returned to Europe, and arrived off Cape Finisterre, July 9. Lord Nelson quitted Antigua, June 18th,

and made Cape St. Vincent, July 17th, having been absent sixty-six days. Thus frustrated in his plans, he judged best to reinforce the Channel squadron, lest the enemy should bear down on Brest.

With this view he joined Admiral Cornwallis off Ushant, and leaving his fleet there, he went home, and struck his flag. He hoisted it again in the *Victory* on the 15th of September, 1805, and arrived off Cadiz on the 29th (his birth-day), to take command of the Mediterranean fleet. The force under him consisted of twenty-seven sail of the line, and four frigates, which he withdrew from the vicinity of Cadiz to a station sixteen or eighteen leagues to the westward, in the hope of inducing the enemy to put to sea. On October 21st, at day-break, the combined French and Spanish fleets, consisting of thirty-three sail of the line and seven frigates, were seen a-head twelve miles to leeward. At 11h. 40m., while bearing down in two lines on the enemy, whose position was in the form of a crescent, concave towards the British, Lord Nelson hoisted the celebrated telegraphic signal, 'England expects every man to do his duty.' At ten minutes past noon Collingwood, in the *Royal Sovereign*, commenced the action on the part of the British. At one P.M. the *Victory* passed under the stern of the *Bucanar*. In the heat of the action, about 1h. 25m., while in the act of turning in his walk on the quarter-deck, Lord Nelson received his death-wound by a musket-ball fired from the *Redoubtable*, which entered his left shoulder, and lodged in the spine. He expired in three hours and a half. The total British loss was 450 killed, 1250 wounded. Seventeen French and Spanish ships were captured, and one burnt. Admiral Dumanoir escaped to the southward with four sail, which were shortly after taken by Sir R. Strachan. Admiral Gravina, with the remaining eleven ships, got into Cadiz.

On the 9th of January, 1806, the body of Nelson was buried at St. Paul's. His brother William was created an earl, with a grant of 6000*l.* per annum; 10,000*l.* were voted to each of his sisters, and 100,000*l.* for the purchase of an estate.

Sir James Mackintosh says, 'Nelson seems to have been born with a quick good sense, an affectionate heart, and a high spirit; he was susceptible of enthusiasm either of the tender or the proud feelings, and easily melted or inflamed; to say that he was fearless seems unnecessary; he was not merely averse to falsehood or artifice, but he was in the highest degree simple and frank. These qualities formed no small part of his genius; they secured to him attachment and confidence, and revealed to him the feelings of other men, that great secret in the art of command, which reason alone can never disclose. His understanding was concentrated on his profession, and as danger always excites when it does not disturb, by stimulating his mind in the moment of action, it roused his genius to the highest exertions. A passion for glory, indignant contempt of money, the sincerity of his character, and energy of his sayings, distinguish him from other modern heroes; while the murder of Carraccioli and his breach of faith to the two garrisons in the Bay of Naples are too atrocious to pass without notice. He believed the prisoners or their ringleaders deserved death, and thought that the existence of the government required a terrible example; by this error in judgment, by the drunkenness of guilty passions, and the maddening power of political fanaticism, he was driven into these deplorable acts.'

'The death of Nelson,' says Southey, 'was felt in England as a public calamity; yet he cannot be said to have fallen prematurely whose work was done, nor ought he to be lamented who died so full of honours and at the height of human fame.'

(James's *Naval History*; Southey's *Life of Nelson*; Sir J. Mackintosh.)

NELUMBIA'CEÆ, a natural order of exogenous plants, by some writers associated with *Nymphæaceæ*, or *Water-lilies*, which they resemble in appearance and manner of life, inhabiting the fresh waters of the temperate parts of the world, and producing large polypetalous flowers with numerous stamens. But these orders differ in such important circumstances that they can hardly be regarded as plants of very close alliance, much less as members of the same order; for *Nelumbiaceæ* have no albumen, and their system of female organs is broken up into its original elements, while in *Nymphæaceæ* there is an abundance of albumen, and the female system is completely consolidated.

Nelumbiaceæ are readily known by their carpels being distinct, one-seeded, and buried in the cavities of a large

truncated fleshy receptacle, which eventually forms a broad hard bed, filled with holes, in each of which there is a single ripe nut. Notwithstanding their large flowers, these plants must be regarded as among the lowest forms of the exogenous type. The best known species is *Nelumbium speciosum*, a magnificent water-plant floating in the rivers and ditches of all the warmer parts of Asia, and also found in the Nile: its nuts are supposed to have been the sacred bean of Pythagoras; its flesh stems are used as food by the poorer inhabitants of China.

Nelumbium speciosum.

1, the ripe receptacle of *Nelumbium speciosum*; 2, a seed; 3, the same, with the two cotyledons so separated as to show the large plumbeous which they enclose.

NEMATO'PODA. [CIRRIPEDA.]

NEMATU'RA. [TROCHOIDEA.]

NE'MEAN GAMES, one of the four great national festivals of the Greeks, derived their name from Nemea, a village in the north-eastern part of Argolis, on the borders of the Corinthian territory. They were celebrated under the presidency of the Corinthians, Argives, and inhabitants of Cleonæ (*Schol. on Pindar*); but in later times they appear to have been entirely under the management of the Argives. (*Liv.*, xxxiv. 41.) They are said to have been celebrated every third year; and sometimes, as we learn from Pausanias, in the winter (ii. 15, § 2; vi. 16, § 4).

The Nemean games are said to have been first established by the Epigoni, in memory of Opheltes (*Schol. on Pind.*; *Apollod.*, iii. 6, 4; *Paus.*, x. 25, § 2), and to have been afterwards revived by Hercules in honour of Zeus, in consequence of his victory over the Nemean lion.

The crowns bestowed on victors were made of parsley. [OLYMPIC GAMES.]

NEMERTE'SIA. [SERTULARIA.]

NEMESI'ANUS, MARCUS AURELIUS OLYMPIUS, a Latin poet, said to have been a native of Carthage, lived under the reigns of Carus and his sons Carinus and Numerianus. Nothing more is known of the particulars of his life. He wrote a poem on hunting, 'De Venatione,' which he dedicated to Carinus and Numerianus, and which has come down to us unfinished. He also wrote four eclogues, which have considerable poetical merit, and have been repeatedly published, together with the eclogues of his contemporary Calpurnius. Mairault has made a French

translation of Nemesianus's eclogues, with copious notes, 8vo., 1744. The writings of Nemesianus have been inserted in the collection 'Poetæ Rei Venaticæ,' with notes, by G. Kempher, Leyden, 1741.

NE'MESIS (*Néμεις*), a female Greek divinity, who appears to have been regarded as the personification of the righteous anger of the gods. She is represented as inflexibly severe to the proud and insolent. (*Paus.*, i. 33, § 2.) According to Hesiod, she was the daughter of Night. (*Theog.*, 223; compare *Paus.*, vii. 5, § 1.) There was a celebrated temple sacred to her at Rhamnus, one of the demi of Attica, about sixty stadia distant from Marathon. In this temple there was a statue of the goddess, made from a block of Parian marble, which the Persians had brought thither to erect as a trophy of their expected victory at Marathon. Pausanias says that this statue was the work of Phidias (i. 33, § 2, 3); but Pliny ascribes it to Agoracritus; and adds that it was preferred by M. Varro to all other statues which existed. (*Hist. Nat.*, xxxvi. 4, § 3.) A fragment, supposed by some to be the head of this statue, was found in the temple of Rhamnus, and was presented to the British Museum in 1820. (*Elgin and Phigaleian Marbles*, i. p. 120; ii. p. 123.) The inhabitants of Rhamnus considered Nemesis to be the daughter of Oceanus. (*Paus.*, vii. 5, § 1.)

The practice of representing the statues of Nemesis with wings was first introduced after the time of Alexander the Great by the inhabitants of Smyrna, who worshipped several goddesses under this name. (*Paus.*, vii. 5, 1; ix. 35, 2.)

According to a myth preserved by Pausanias, Nemesis was the mother of Helen by Zeus; and Leda, the reputed mother of Helen, was only her nurse (i. 33, § 7); but this myth seems to have been invented in later times to represent the divine vengeance which was inflicted on the Greeks and Trojans through the instrumentality of Helen.

There was a statue of Nemesis in the capitol at Rome; though we learn from Pliny that this goddess had no name in Latin. (*Hist. Nat.*, xxviii. 5; xi. 103.)

NEME'SIUS, bishop of Emesa in Syria, and one of the ablest of the ancient Christian philosophers. Of his life very few particulars are known; and even the time when he lived is uncertain, though this is generally supposed to have been during the reign of Theodosius the Great, towards the end of the fourth century. He has been accused of holding some of Origen's erroneous opinions, but has been defended by Bishop Fell (*Annot.*, p. 20, ed. Oxon. 1671), who however confesses, with regard to the pre-existence of souls, that he 'differed from the commonly received opinion of the church.' But it is as a philosopher and physiologist that Nemesius is best known, and his work 'De Naturâ Hominis' is one of the most accurate treatises of antiquity. Some persons (among whom we may mention Bishop Fell, in edit. Oxon.; Fabricius, 'Biblioth. Gr.;' and Brucker, 'Hist. Philos.') have even supposed that he was acquainted with the circulation of the blood; but in the opinion of Freind (*Hist. of Physic*), Haller (*Biblioth. Anat.*), and Sprengel (*Hist. de la Médecine*), he has no right whatever to be considered as the author of this discovery. Still the passage which has given rise to the discussion is certainly remarkable: 'The motion of the pulse,' says he, 'takes its rise from the heart, and chiefly from the left ventricle of it: the artery is with great vehemence dilated and contracted, by a sort of constant harmony and order. While it is dilated, it draws with force the thinner part of the blood from the next veins, the exhalation or vapour of which blood is made the aliment for the vital spirit. But while it is contracted, it exhales whatever fumes it has through the whole body and by secret passages, as the heart throws out whatever is fuliginous through the mouth and nose by expiration' (cap. 24, p. 242, ed. Matth.). There is another passage equally curious respecting the bile, which is constituted, he says, 'not only for itself, but also for other purposes; for it helps digestion, and contributes to the expulsion of the excrements, and therefore it is in a manner one of the nourishing powers; besides, as a vital faculty, it imparts a sort of heat to the body. For these reasons therefore it seems to be made for itself: but because it purges the blood, it seems to be made partly for the sake of the blood' (cap. 28, p. 260, ed. Matth.). From this passage Nemesius has been supposed to have known all that Sylvius afterwards discovered with respect to the functions of the bile; but his claim in this case is no better than in the former, and indeed Haller and Sprengel both say that his physiology is not at all more perfect than that of Galen.

But even if we cannot allow Nemesius all the credit that has been claimed for him, still from his general knowledge of anatomy and physiology (which is quite equal to that of the professional men of his time), his acuteness in exposing the errors of the Stoics and the Manichees, the purity and elegance of his style compared with that of his contemporaries, and the genuine piety which shows itself throughout his work, he has always ranked very high in the list of ancient Christian philosophers. The following opinions in his book are recorded by Sprengel (*Hist. de la Méd.*) as worthy of notice: 1, He calls the substance of the lungs ἀφρόδης σαρκίς, 'frothy flesh' (cap. 28, p. 256); 2, He distinguishes the nerves from tendons, and says that the former possess the power of sensation, which the latter do not (cap. 27, p. 254); 3, he says that the semen is prepared in the brain, that it descends by certain vessels (which he calls 'two veins and two arteries') situated behind the ears, which he says is the reason why 'when those veins that are near the ears and those near the carotid arteries (καρωτίδας, or, as some read, παρωτίδας, 'the parotid glands') are wounded, the animal becomes barren; that it is distributed throughout the whole body, and is deposited at last in the testicles (c. 25, p. 244); 4, he explains the sensus, like Aristotle, by an intelligent spirit, which is propagated from the organ of sensation to those of the senses (c. 6, p. 176); 5, he places the sensations in the anterior ventricles of the brain, the intellect in the middle, and the memory in the posterior (c. 13, p. 204); 6, he says that the elements composing the human body are in a manner mutually opposed to each other, and that the assistance of certain intermediate substances is necessary, in order to effect their union (c. 5, pp. 151-156); and 7; that food and medicines only differ inasmuch as the former is similar to the elementary particles of our body, while the latter are opposed to them (c. 1, p. 49). The treatise *περὶ φύσεως ἀνθρώπου*, 'De Naturâ Hominis,' was first edited by Valla in Latin, Lugd. 1538, ap. Seb. Gryphium; the first Greek edition was by Ellebodus, Antwerp, 1565, 8vo., ap. Christ. Plantin; the next was by Dr. (afterwards bishop) Foll, Oxon., 1671, 8vo.; the last and most complete is by Matthæi, Halm Magd., 1802, 8vo. There is an English translation by George Wither, Lond., 1636, 12mo., and a German one, by Osterhammer, Salzburg, 1819, 8vo.

NEMORHÆDUS, Colonel Hamilton Smith's name for the Goral antelopes. [ANTELOPE, vol. ii., p. 89.]

NEMOSIA, a genus of birds established by Vieillot, and placed by Mr. Swainson in the subfamily *Tanagrinae* in his family *Fringillidae*. [TANAGRINÆ.]

NE'MOURS. [SEINE ET MARNE.]

NE'MOURS, DUKES OF, a title derived from a town of France in the department of Seine et Marne. It was borne first by a branch of the Armagnac family, the last of whom, Louis d'Armagnac, duke of Némours, held a command in the army of Louis XII., in Italy, against the Spaniards under Gonzalo of Cordova, and was killed at the battle of Cerignola in Apulia, in April, 1503. With him ended the line of Armagnac, which was descended from Caribert, son of Clotarius II., who died A.D. 630. The duchy of Némours was then bestowed by Louis XII. upon Gaston de Foix, son of Mary, the sister of the king. Gaston fell, at twenty-three years of age, in the battle of Ravenna, against the Spaniards and Italians, in 1512. The duchy of Némours was afterwards given by Francis I. to his uncle Philip of Savoy, in 1528, in whose line it continued till 1659; when Henry of Savoy, duke of Némours, died, the last male descendant of Philip. His widow Mary of Orléans, daughter of the duke of Longueville, survived him many years. She inherited in 1694, from her brother the Abbé de Longueville, the county of Neuchâtel, in Switzerland, and died in 1702; with her ended the line of Orléans Longueville. [NEUCHÂTEL.] The title of duke of Némours is now borne by the second son of the present king of the French, Louis Philippe.

NEN, River. [NORTHAMPTONSHIRE.]

NE'NNIUS, or **NINNIUS**, a monk of Bangor, in Wales, who lived in the first part of the ninth century, according to several passages of his own work, if those passages are genuine. *Vossius (De Historicis Latinis)* says that he lived in the early part of the seventh century, but he assigns no authority for this assertion. Nennius states himself to have been a Briton, and not a Saxon, and a disciple of the holy bishop Elbodus, or Elvedug. He wrote a history of Britain, styled 'Eulogium Britannicæ,'

which, he says at the beginning, he compiled from all he could find; 'from the Roman annals and the chronicles of the Fathers, as well as from the writings of the Scots and the Angli, and from the traditions of our ancestors.' The history begins with a fabulous genealogy of Brutus, grandson of Æneas, who reigned in Britain. The author afterwards relates the arrival of the Picts in North Britain, and of the Scots in Ireland; and after a brief and confused narrative of the Roman conquest and empire in Britain, he comes to the only part of the work which is deserving of some attention, namely, the Saxon invasion and gradual subjugation of the country. It appears that Nennius's MS. was sadly mutilated and interpolated by an ignorant transcriber, who signs himself 'Samusi,' and 'a disciple of Beularius Presbyter,' and who acknowledges that he left out what he thought useless in Nennius's work, and added what he gathered from other writers concerning the towns and wonders of Britain. See end of chap. 64 of *Nenni Banchoriensis Eulogium Britannicæ*, edited by C. Bertram, and published together with 'Gildas' and 'Richard the Monk of Westminster,' 8vo., Copenhagen, 1757.

NEOLOGY. [RATIONALISM.]

NEOMERIS, a group of articulated Corallines thus named by Lamouroux. [PSEUDOZOARIA.]

NEOMORPHA, a new genus of birds, established by Mr. Gould on two species from New Zealand; but the specimens wanted the feet and the greater part of the wings.

Generic Character.—Bill longer than the head, compressed at the sides, arched, horny, solid, sharp at the apex, with a denticle. Nostrils open, placed in the basal furrow; carina mandibulæ superioris in pontem tendente. Tongue hard, slender, bristly at the apex; angles of the mouth with pendent fleshy caruncles. Wings —. Feet —. Tail as long as the body. Total length of the largest species 17½ inches. (*Zool. Proc.*, 1836, where it is announced as one of the birds from which drawings had been taken for Mr. Gould's great work on the Birds of Australia.) We cannot find the genus either in the 1st or 2nd part, and suppose that the figure is advisedly kept back, in the hope that Mr. Gould may obtain further information as to the wings and feet, before his return from New Zealand and Australia.

NE'OPHRON. [VULTURIDÆ.]

NEOPHYTES (from a Greek word which means 'newly planted') is the appellation given to the converts to Christianity who have just received baptism. In the early church the Neophytes, after that solemn ceremony, wore white garments for eight days. They were also subject to a strict discipline or probation for a much longer period. The Jews, Mussulmans, or Pagans, who are converted to Christianity, are called Neophytes by the Catholic missionaries, and there are houses at Rome and other places for their reception and instruction.

NEOTRAGUS, Colonel Hamilton Smith's name for the Pygmy Antelopes, the *Guevi (Antilope pygmaea)*, for instance. [ANTELOPE, vol. ii., p. 82.]

NEOTS, ST. [HUNTINGDONSHIRE.]

NEOTTIA is a name given to a brown, leafless, scaly plant, found in woods in this country, growing parasitically on the roots of other species. It belongs to the natural order Orchidaceæ, and flowers in May and June. The only species is the *Nidus Avis*, or bird's nest, so called from the appearance of the entangled fleshy fibres of the root. Some modern botanists strangely enough apply the name of Neottia (itself meaning literally a nest) to plants having no entanglement of the roots that can justify the appellation, and more generally called *Spiranthes*: by those writers the true bird's nest is called *Listera nidus avis*, a perversion of nomenclature for which there is no necessity, and which no necessity could justify. This genus gives its name to a division in the Orchidaceous order, called after it *Neottieæ*, composed of terrestrial species, especially characterised by the anther being placed at the back of the stigma, not vertically upon the end of the column, and by the pollen being pulverulent.

NEPAUL, or **NEPAL**, a country in Asia, situated almost entirely within the range of the Himalaya Mountains, between 26° and 31° N. lat. and 80° and 88° E. long. It extends in length from west to east 450 miles, and from north to south, on an average, 100 miles; its surface is about 45,000 square miles, or about 5000 miles less than that of England. On the north it borders on Tibet, on the west on the English province of Kumaon, on the south on the plains of the Ganges, and on the east on Sikkim and Bootan.

Surface, Soil, Climate, and Productions.—The Himalaya Mountains are the natural boundary between the elevated table-lands of Central Asia and the extensive lowlands on the banks of the Ganges. The highest part of these mountains is contiguous to the table-lands: towards the plain of the Ganges they slope down with an exceedingly broken surface. The high masses of the range occupy the surface of Nepal along its northern boundary, and a great portion of this lofty mountain region is always covered with snow. Among the elevated peaks are the highest mountains on the globe. The Dhawalagiri, or White Mountain, attains in its highest summit, called Ghosa Cotee, an elevation of 28,000 feet above the sea-level. It lies between $28^{\circ} 30'$ and 29° N. lat., and between $82^{\circ} 30'$ and 83° E. long., and is separated by a narrow valley from Mount Swetagar, or White Tower, which rises to 25,261 feet. Farther east, between 85° and 86° E. long. and 28° and $28^{\circ} 30'$ N. lat., extends the Dhayabung range, in which the Gosaingthan peak rises to 23,044 feet. The Salpurange is between 86° and 87° E. long., on both sides of 28° N. lat.; two of its summits attain more than 24,000 feet. Farther east are the snow-capped summits of the Mirgu range, which have not yet been measured. In the mountains extending west of Dhawalagiri to the Tri Sula Mountains in Kumaon, the number of snowy peaks is likewise great, and extensive tracts of country between them are covered with snow all the year round, as their surface rises above the line of perpetual congelation. These enormous mountain masses are furrowed by a comparatively small number of very narrow valleys, a circumstance which may be attributed to the small quantity of snow which is annually dissolved. Rain is said to fall on the mountains only in winter, and even then not frequently; and the periodical rains, produced by the south-west monsoon, do not rise to the elevation of the great snow-masses: probably they do not ascend much more than 8000 feet of perpendicular height. Yet during their prevalence the heated vapours which rise from the rain-drenched surface of Bengal and Bahar dissolve a portion of the snow, and the rivers swell to a certain extent, but far less so than in countries where the mountains rise with a more gradual ascent. The narrow valleys are cultivated in their lower parts, where they sink down to about 6000 feet, but the upper parts are only inhabited during four months of the year by herdsmen, who find pasture for their cattle and sheep on the lower declivities of the mountains. They have also a small number of chowry-tailed cattle or jacks. In these regions the Tibet musk (*Moschus moschiferus*, Linn.) is frequent, and also a species of wild sheep, and a kind of wild dog. The antelope Hodgsonii occurs north of the Mirgu range. The few forests contain, in addition to pine-trees and birch, two new species of juniper, which grow to the height of large trees; the boards cut from them are sent to Tibet and China.

The steep descent of this high mountain region lies about 30 miles south of the northern boundary-line of Nepal, and south of the steep descent extends the elevated region which constitutes the most fertile and best cultivated portion of Nepal. It varies between 30 and 40 miles in width, and its southern boundary is formed by a range of mountains of moderate height, running at the distance of 16 or 20 miles from the level plains on the Ganges. This range, which, at least in a great part of its extent, is called the Lama Dangra Mountains, may attain in general an elevation of 6000 or 7000 feet above the sea. The surface of the country between the Lama Dangra Mountains and the Himalaya is between 4000 and 5000 feet above the sea, except in some valleys, where it appears to sink considerably below that level. The surface is very uneven and broken, numerous hills and ridges of hills rising to 3000 or 4000 feet above their base, and occupying by far the greatest portion of it. In the northern districts these ridges run mostly north and south, and are connected with the Himalaya; but in the southern they generally extend east and west, parallel to the Lama Dangra range. The valleys which lie between these ridges are long, but generally not more than one or two miles wide: in a few places they expand into plains of moderate extent. Agriculture however is not limited to them; it extends on the declivities of the hills nearly to their summits, when they are not too steep. This country is subject to the periodical rains of the monsoon, which last longer here than in Bengal; and to this circumstance Sir Francis Hamilton ascribes the fact that some fruits, as peaches and grapes, do not ripen, whilst oranges come to the greatest perfection.

Pine-apples are only grown in some less elevated valleys, and are of excellent quality. In winter the more elevated summits of the hills are covered with snow, and frost is usually experienced. We know only the mean temperature of the spring. At Khatmandu it is 64° and at Chitlong 56° of Fahrenheit. The principal object of cultivation is rice, to which grain nearly one-half of the cultivated lands are appropriated, as the unevenness of the ground allows irrigation generally. Besides rice, the inhabitants raise maize, cotton, several kinds of legumes, wheat, barley, sugar-bane, and two species of madder. The pastures are indifferent, and hence the number of cattle and buffaloes is small. The small horses, the *Tunguns*, are noted for their hardihood and activity, but they are not natives, but introduced from Tibet, and it is said that they degenerate on the south of the Himalaya Mountains. Sheep are very plentiful; in winter they find pasture on the hills of this country, and in summer they pass to the declivities of the Himalaya Mountains. They are of a large size, give much milk, and have a fine wool. This region also contains several metals in abundance, especially iron, lead, copper, and zinc; the first three are worked rather extensively. Gold is found in the sand of some rivers. The mountainous districts which are not cultivated are covered with large trees, many of which are yet unknown to botanists; but oak, fir, walnut, chestnut, prickly paltus, birch, and others also are frequently found among them. Some of the trees which are yet unknown furnish excellent wood for furniture.

The Lama Dangra range does not extend to the plains on the Ganges, but is divided from them by a hilly tract about 15 miles wide. The hills rise to a considerable height near the range, but subside as they approach the low plain, until they entirely disappear. Some of the valleys between these hills are wide and well cultivated, producing the common grains and plants of Bahar; but most of them are narrow, and these, as well as the hills, are covered with almost uninterrupted forests, consisting principally of oaks, of the *Shorea robusta*, and of different kinds of laurels, bamboos, &c. On the higher hills are pines and different species of mimosas; from the juice of the latter great quantities of catechu are made, which goes to Patna and Benares. These woods contain numerous parrots, which are trained and sent to Bengal. The climate of this region is very hot. Hamilton found that the thermometer rose to 74° at the end of March.

Nepaul contains a small portion of the Gangetic plain, which is contiguous to the hilly country. It is a portion of the Tarai, or swamp, but of a much better description than that which lies south of Bootan, and belongs to Bengal. The Nepalese Tarai is not a continuous forest, but the greater part of it is covered with a long coarse grass, which at certain seasons is destroyed by setting fire to it, and the herds of cattle pasture on the new grass which immediately springs up. The forests cover a considerable part of the plain, though in several places they have been destroyed, and the ground cultivated. The soil produces good tobacco and cotton. As it is watered by a great number of small rivers, which rise in the hilly tract or in the Lama Dangra range, and the soil is very fertile, it would sustain a great population, but for its unhealthiness. From the beginning of April to the month of September, the inhabitants are exposed to continual diseases, but still the climate is more healthy than that of the Tarai of Bengal, and the country is more populous. The forests contain numerous wild animals. Tigers are rare, but the elephant and the rhinoceros are common; also bears, deer, jackals, foxes, and hares.

Rivers.—Most of the rivers which drain the mountain-region of the Himalaya do not originate on the highest portion of that range, but beyond it, on the table-land of Tibet. This is particularly the case with the two principal rivers which drain Nepal, the Gunduc and the Coosy. The Gunduc is formed by two branches, which rise 150 miles from one another. The western branch, properly called Gunduc or Salagrani, originates, as it is supposed, not far from the banks of the Sampoo (Brahmapootra), the great river of Tibet. It flows southwards, and after entering Nepal, runs through the narrow valley which separates the Dhawalagiri from Mount Swetagar. It soon leaves the high mountains and enters a tolerably wide valley. At Kerigat it becomes navigable, and continues to be so until it breaks through the Lama Dangra range, where its course is interrupted by some rapids. Soon afterwards it enters the plain of Bahar. The eastern branch, which is called Bori Gun-

due in its upper course, likewise rises on the table-land of Tibet, and in its south-western course surrounds a portion of the Dhayabung range. Afterwards it runs southwards, and is called Trisul Ganga; it then runs west-south-west, and joins the Gunduc before it breaks through the Lama Dangra range. It does not appear that this branch is navigable. The Coosy is also formed by two branches. The western and principal branch rises within the Himalaya Mountains, in the valley which separates the Dhayabung range from the Salpoo Mountains, and runs first southward and then westward under the name of Bhotiya Coosy. Where it turns to the south-east at Dumja, it becomes navigable, and is called San Coosy. It runs about 100 miles to the east and south-east, until it breaks through the Lama Dangra range, where it has some falls which interrupt navigation. The eastern branch of the Coosy is called Arun: it rises within the Himalaya Mountains, but flows first northwards and enters the table-land of Tibet, on which a considerable part of its course is said to lie, until it turns by degrees southwards and enters Nepal, where it continues to flow in the same direction to its junction with the San Coosy. Its current is too rapid for navigation.

Towns.—Nepal contains several considerable towns, which owe their origin or prosperity to the circumstance of this country being the principal thoroughfare by which the table-land of Tibet and the plains of the Ganges exchange their productions or supply their wants. Other towns owe their origin to the fertility of the country which surrounds them. This is particularly the case with those which are found in the plain called Great Nepal. This plain, which is surrounded by mountains rising from 3500 to 4000 feet above it, is only about twenty miles long and sixteen miles wide, and yet it contains three large towns, Khatmandu, Lalita Patan, and Bhatgong, and several smaller towns. Khatmandu, the present capital of Nepal, contains 4000 houses, and, as it is said, a population of 48,000 or 50,000. The great number of temples and steeples, built in the style of Tibet, gives to the city a considerable degree of magnificence. The palace of the Ghorcali princes is an extensive but irregular building. Lalita Patan is said to be still larger, and to contain 24,000 houses. Bhatgong, the third royal residence, is stated to contain 12,000 houses, and to exceed the other two in the magnificence and size of its buildings. It is the school of learning, and its temples contain large libraries in Sanscrit and other languages relating to the Buddhist literature. The plain on which these three towns are built is nearly 4800 feet above the sea-level. Kirkpatrick assigns to it a population of half a million, which Hamilton thinks an exaggeration, but he admits that it is cultivated with great care and is very populous.

Noyacote, north-west of Khatmandu, on a high hill, near the banks of the Trisul Ganga, is a considerable place, being situated on the most frequented mountain-road which leads to Tibet along an affluent of the Trisul Ganga, and over the mountain-pass of Kheru. In 1792 the Chinese army invaded Nepal by this road. Baglung Chaur, in the valley of the Gunduc Proper, or Salagrani, is a large place of trade, being situated on another much frequented road to Tibet. In the western districts of Nepal is Cheenachin, the capital of Jemlab, or Yumila, built in a plain, which is stated to be not inferior in extent to that of Khatmandu, and equally well cultivated and populous; but its elevation above the sea-level is greater, and the sugarcane does not succeed: rice, maize, and wheat are raised in abundance. The town is very large, but not regularly built. It has a great trade in horses, salt, musk, and chowry-tails.

In the eastern district of Nepal, in the wide and well-cultivated valley of the river San Coosy, are several considerable towns, among which the best-known is Calesi. In the valley of the Arun the principal trading place is Tuming Tar, which has 6000 inhabitants; it is situated in a plain six miles wide and nearly eighteen miles long. Hatiya, farther north, has also a considerable commerce with Tibet.

Inhabitants.—Several tribes inhabit the alpine valleys of Nepal. According to the opinion of Sir Francis Hamilton, the structure of their body shows that they belong to the Mongol race, though some of them, on account of their intermixture with Hindus, rather resemble the Malays, who seem to form a link between the Chinese and Hindus. The best-known of these tribes are the Newars, or Newari,

who inhabit the plain of Khatmandu. They have attached themselves to one of the sects of Buddhism, but have introduced the division of castes, and their priests do not depend on the lamas of Tibet. The Newars are mostly cultivators of the soil, and exercise many arts and trades. They make coarse cotton-cloth, and work very well in iron, copper, and brass, and are particularly ingenious in carpentry. This tribe, as well as some others, still speak their own language, which is quite different from those of their neighbours. The higher region of the Himalaya Mountains is occupied by the Bhot, the same nation which inhabits Tibet. Their language seems to be diffused over the greater part of the table-land of Central Asia, and they have a rich literature, which hitherto is little known in Europe. They are Buddhists, and chiefly occupied with their herds and with commerce. The majority of the population south of the high mountain are either Hindus, or a mixed race, the offspring of the Hindus, and native tribes. They are called Parbatiya, because they speak the Parbatiya Basha, a dialect of the Prakrit. This language continually becomes more and more prevalent, and in some districts it has already destroyed the languages of the native tribes. It is spoken by the reigning family and their tribe, the Ghorkas. The Parbatiya adhere to Brahmanism, are employed by the Ghorkas in administration, and occupy themselves with the culture of the ground and commerce.

Commerce.—The trade with Tibet is mostly in the hands of the Bhot, who transport their goods on the backs of sheep or men over the mountain passes. They bring from Tibet to Nepal sheep, musk, skins of the musk-deer, showry-tails, quicksilver, borax, sal ammoniac, Chinese silk stuffs, paper, drugs, gold, and silver; and they carry back rice, wheat, oil, iron, copper, cotton-cloth, catechu, juniper-boards (which are used in fine cabinet-work), pepper, spices, indigo, tobacco, otter-skins, sugar, and some smaller articles.

Nepal exports to British India elephants' teeth, timber, hides, ginger, catechu, turmeric, wax, honey, oranges, long pepper, ghee, bastard cinnamon, large cardamoms, and some smaller articles. It exports from the British dominions in Bengal cottons and muslins, silks of various sorts, raw silk, gold and silver, laces, carpets, English cutlery, saffron, spices, sandal-wood, quicksilver, cotton, tin, zinc, lead, soap, camphor, tobacco, pepper, and coral.

History.—In former times this country seems to have been divided among a great number of princes, each of whom was an independent sovereign of a valley, district, or tribe. In the middle of the last century the chief of one of these tribes, the Ghorkas, Goorcas, or Ghorcalis, began to extend his dominions by conquest, and he and his successors were so successful, that in less than half a century they subjected all the countries situated within the mountains between Bootan on the east to the river Sutlej on the west, and they carried more than once their arms to Teshoo Lumloo, in Tibet. In 1792 their depredations on that side were stopped by the Chinese, who entered Nepal with an army of 70,000 men, and, after several victories, advanced as far as Noyacote. After that time they turned their ambitious views towards the plains of the Ganges, and came to a war with the English in 1814. Though the British arms in the beginning were only partially successful, the Ghorkas, by the peace concluded in 1816, were obliged to cede to the British all the countries situated between the Sutlej and the Kali rivers, and to evacuate the territories of the Sikim Raja. Since that time they have been quiet.

(Kirkpatrick's *Account of Nepal*; Sir Francis Hamilton's *Account of the Kingdom of Nepal*; Hodgson's 'Notices on the Languages, Literature, and Religion of the Baudhas in Nepal and Bhot,' in *Asiatic Researches*, vol. xvi.)

NEPENTHA (GEL) are exogenous plants inhabiting the damp and warmer parts of Asia, and having, in the place of leaves, large hollow bodies, furnished with a lid, and containing water, secreted from a peculiar glandular apparatus with which they are lined. These bodies, or pitchers, as they are called, appear at the end of a leafy tendril-like expansion of the bark, and are considered to be a hollow state of the apex of the petiole of a leaf, while the lid that closes them is regarded as the blade. Their flowers are dioecious, green or brown, apetalous, arranged in cylindrical racemes, and are succeeded by a capsular fruit filled with fine fusiform seeds, which look like very small sawdust. They are considered to be closely akin to Aristolochiaceæ, and with them have been recently referred by the writer of this to a

new class in the vegetable kingdom called Homogens. [PTYCHOGENS.]

Nepenthes distillatoria.

1, a male flower; 2, a female flower; 3, a vertical section of the ripe capsule; 4, a vertical section of a seed very much magnified; 5, the seeds.

NEPER. [NAPIRR.]

NEPHELINE. *Somme.* This mineral occurs in attached hexagonal prisms. Primary form a rhomboid. Indications of cleavage parallel to the planes of the prism. Fracture conchoidal, shining. Hardness, scratches glass. Colour white; streak the same. Lustre vitreous. Transparent, translucent. Specific gravity 2.360.

When a transparent fragment is put into cold nitric acid it becomes cloudy, and afterwards gelatinizes. Before the blow-pipe the edges are rounded; with borax it slowly melts into a colourless transparent glass.

Occurs on Monte Somma, Vesuvius; and in the lava of Capo di Bore near Rome.

Analysis by Arfwedson, from Vesuvius:—Silica, 44.11; Alumina, 33.73; Soda, 20.46.

NEPHRITE. *Jade; Axe Stone.* Occurs in masses. Structure compact. Fracture coarse, splintery. Hardness 7.0. Very tough. Colour dark-green and green of other shades. Translucent on the edges. Specific gravity 2.9 to 3. Before the blow-pipe, whitens but does not fuse, but with borax forms a transparent glass.

Analysis by Küstner:—Silica, 59.50; Alumina, 10.00; Magnesia, 31.00; Oxide of iron, 5.50; Oxide of chromium, 0.05; Water, 2.75.

NEPHRITIS. [KIDNEYS, DISEASES OF.]

NEPHROPS. [HOMARUS, vol. xii., p. 274.]

NEPOS, CORNELIUS, a native of Hestilia (now Ostiglia) on the Po, was a Roman writer and a friend of Cicero, who speaks of Nepos in several of his Letters (*Epist. ad Attic.*, xvi. 5 and 14). Macrobius (*Saturn.*, xi. 1) quotes the second book of Cicero's Epistles to Cornelius Nepos, which have not come down to us. Lactantius mentions Nepos's Letters to Cicero, and Aulus Gellius (xv. 28) speaks of Nepos's 'Life of Cicero.' Catullus dedicated his poems to him. Nepos however was most intimate with Pomponius Atticus, whom he survived a few years, and whose life he wrote. He also wrote a short notice of Cato the Censor, in P. C. No. 995.

which he says that, at the particular request of T. Pomponius Atticus, he had written a more extended biography of Cato, which however has been lost. According to the old scholiasts, the lives of Atticus and Cato formed part of a larger work of Nepos, 'De Historicis Latinis.' In a passage in the Life of Dion, in the 'Vitæ Imperatorum,' attributed to Nepos, the author mentions a work which he had written 'on the Greek historians,' and the grammarian Charisius (*Instit. Grammat.*, lib. i.) quotes a sentence of the sixteenth book 'Illustrium Virorum' of Cornelius Nepos.

The work styled 'Vitæ Imperatorum,' which is put into most schoolboys' hands, not being mentioned by any ancient writer, was for a long time attributed to Æmilius Probus, who lived in the fourth century, and who in the MSS. appears as having presented a copy of the book to the emperor Theodosius I., and prefixed to it some verses in which he seems to claim the authorship. Accordingly the earlier editions of the 'Vitæ Imperatorum,' the first by Janson, 1471, that of 1506, and others, were entitled 'Probi Æmilii Excellentium Imperatorum Vitæ.' But afterwards the critics began to question the claims of Probus to the authorship of the work. The style and especially the sentiments of the lives certainly appear not suited to a writer of the age of Theodosius, such as the manifest disapprobation of a monarchical government, which is exhibited in many passages, among others in the lives of Timoleon (i. 3) and Dion (ix. 5). It is remarkable that the author in his preface addresses the work to Atticus; and yet at the end of the last life, that of Hannibal, when speaking of the uncertainty about the date of that great commander's death, he says that 'Atticus, in his "Annals," had left it written ('scriptum reliquit') that Hannibal died under the consulship of M. C. Marcellus and Q. F. Labæus,' speaking thus of Atticus as of a person dead. After the first editions of the 'Vitæ Imperatorum' were published, Petrus Cornerus found in an old MS. containing the letters of Cicero to Atticus, the life of Atticus and the short notice of Cato the Censor above mentioned. These two biographies were published together with the 'Vitæ Imperatorum,' and the whole under the name of Æmilius Probus, contrary to all evidence, as the author of those two biographies speaks of Atticus as a personal acquaintance. At last Lambini, in the commentary to his edition of the 'Imperatorum Vitæ,' 1568, asserted the claims of Nepos as author of the whole. But several solecisms and barbarisms which occur in the 'Vitæ' appearing to invalidate Lambini's supposition, as not being likely to occur in a writer of the Augustan age, Barth and some other critics have supposed that Probus abridged the original work of Nepos in the same manner as Justin has epitomised the history of Trogus Pompeius. Vossius however (*De Historicis Latinis*, i. 14), Funccius (*De Virili ætate linguæ Latinæ*, part 11, ch. 14, § 38), and others, maintain that there is nothing in the 'Vitæ Imperatorum' which could not have been written by the Cornelius Nepos of the Augustan age, and that neither Probus nor any writer of the Theodosian age could have written in so pure a Roman style. Tzschucke's Proemium to his edition of Nepos, Göttingen, 1804; Schoell, 'Abrégé de l'Histoire de la Littérature Romaine;' and Dunlop, 'History of Roman Literature,' may be consulted as to this controversy. It is worthy of remark that in some of the old MSS. of the 'Vitæ Imperatorum,' which furnished the text of the earlier editions, there is written at the end, 'Completum est opus Æmilii Probi, Cornelii Nepotis,' as if the copyist had been in doubt as to the real author. (Lambini, *Commentarius*.)

The 'Vitæ Imperatorum' are short biographies of twenty Greek commanders, and of two Carthaginian, Hamilcar Barca and Hannibal. From a passage at the end of the last it appears that the author intended to write also the lives of the great Roman commanders, 'that their exploits might be compared with those of the Greek, in order to judge which were the greatest.' These lives of the Roman commanders, if ever written, have not come down to us, but it seems that some of them at least were written, and, it would appear, by Nepos, as Plutarch quotes the authority of Nepos for facts concerning the lives of Marcellus and Lucullus. The 'Vitæ Imperatorum,' besides the faults in language which are pointed out by Tzschucke in his proemium and in the commentary which follows the text, contain many erroneous statements of facts, such as mistaking Miltiades, the son of Cypselus, for the great Miltiades, the son of Cimon, confounding the battle of Mycale with that of the Eurymedon, and others

which are noticed by Tzschucke and Schoell. The author however gives many details of private life and manners, which are curious, as in the life of Epaminondas. The sentiments expressed by the author of the 'Vitæ' are generous and virtuous, though often puerile and trifling. The sketch of the character of Alcibiades has been admired for its graphic touches; but the life of Pomponius Atticus is much better both for the matter and manner than any of the rest, and, although too panegyric, gives a lively description of his character. [ATTICUS.] It has been translated into English by Sir Matthew Hale, 1677, and by the Rev. E. Berwick, 1813.

The editions of the 'Vitæ Imperatorum' are numerous: those of Longolius, 1543; Lambinus, 1569; Bosius, 1657; Van Staveren, 1734, 1773; Tzschucke, 1804; Harles, 1806; Fischer, 1806; and lastly, Breme, 1827, are reckoned the best.

NEPOS, FLA'VIUS JU'LIUS, was the nephew of the patrician Marcellinus, who, in the confusion into which the affairs of the Western Empire had fallen after the death of Majorianus, A.D. 460, made himself independent sovereign of Dalmatia, was acknowledged as such by Leo I., emperor of the East, and was afterwards killed in Sicily in an expedition against the Vandals. Leo, having given his niece in marriage to Nepos, named him emperor of the West, A.D. 473, after the death of Olybrius. But a certain Glycerius, supported by the Burgundian and other barbarian auxiliaries who were then the real masters of Italy, had already been proclaimed emperor at Ravenna. Nepos sailed from Constantinople with some troops in 474, and landing at Ostia, surprised Glycerius in Rome, made him prisoner, and, having stripped him of the imperial garments, caused him to be ordained bishop of Salona in Dalmatia, which was considered as a kind of exile. Nepos made peace with Euric, king of the Visigoths, by ceding to him the provinces of Gaul which lay west of the Rhone. But soon after, A.D. 475, Orestes, a native of Pannonia, who had long served in the Roman armies, revolted against Nepos, and marched upon Ravenna, when the emperor, unable to oppose him, fled across the sea to Dalmatia, over which province he seems to have retained his authority, with the title of Augustus; whilst Orestes had his own infant son Romulus proclaimed emperor of the West. Nepos applied in vain to Zeno, emperor of the East, to assist him in recovering Italy. In the year 480 he was murdered at Salona by two officers of his court, upon which Odoacer, who then ruled over Italy, passed over into Dalmatia and conquered that province. Nepos is said to have been a good and amiable but weak man, and unfit for the times. Sidonius Apollinarius praises him for the excellent choice which he made of those whom he employed under him.

NEPTÆA, a genus of alcyoniform Zoophyta, established by Blainville.

NEPTU'NUS, or NEPTUMNUS, a Roman divinity, whose attributes are nearly the same as those of the Greek Poseidon (Ποσειδών). Poseidon was the son of Kronus and Rhea, and the brother of Jupiter and Juno, and appears to have been one of the antient divinities of Greece; although, according to Herodotus (ii. 50), he was not originally a Greek deity, but was imported from Libya. Poseidon was the god of the water in general, of the sea, the rivers, and the fountains; but he was more particularly regarded as the god of the sea, which he acquired as his share in the division of the dominions of his father Kronus. His wife was Amphitrite, and their son Triton.

Poseidon is said to have produced the horse in his contest with Athena (Minerva) for the right of naming the city of Athens; by which myth we are to understand, according to the interpretation of some writers, that the horse was imported into Greece by sea. But this explanation is far from satisfactory. It is difficult to give a reason for the connection of Neptune with the horse; but it is evident from several passages in the Greek writers that he was regarded as a kind of equestrian deity, as well as the god of the sea. (Aristoph., *Knights*, l. 449.) Poseidon had a magnificent palace beneath the sea at Ægæ (Il., xiii. 20). The animals offered to him in sacrifice were usually black bulls, rams, and boar pigs.

Poseidon was not originally a god of the Dorian race. He was principally worshiped by the Ionians, who were in most places a maritime people. In those Dorian cities however which had acquired a love for foreign commerce, we find that the worship of Poseidon prevailed extensively; as for instance, at Tænæum, whence it was carried to Tæn-

tum, at Cyrene, in Ægina, and more particularly on the Corinthian isthmus, and at Træzen, from which place the worship of this god was transmitted to Posidonia in Italy. (Müller's *Dorians*, vol. i., p. 417, 418, fr.)

The etymology of the names Poseidon and Neptunus is doubtful. Poseidon is written in Doric Greek, Potēdan (Ποτειδάν), of which we have another example in the name of Potidæa, written Poteidaia (Ποτειδαία) in the inscription, now in the British Museum, on those Athenians who fell before this city. The name, according to some writers, contains the same root, in the first syllable, as we find in πορός and ποταμός. Neptunus is derived by Cicero from *nando* (*Nat. Deor.*, ii. 26); and by Varro from *nuptu*, because this god covers (*obnubit*) the earth with the sea (*De Ling. Lat.*, iv. 10); but neither of these derivations has the least show of probability. We may compare the form of the word Nept-unus or -umnus, with Port-umnus, Vert-umnus, and the word al-umnus; but the meaning or origin of the root *Nept* or *Nep* seems uncertain. It may perhaps be connected with the same root as is contained in the Greek νεπ-τω.

The statues of Neptune resembled in many respects those of Jupiter; but the figure of the former was more angular, and there was less of repose and thoughtfulness in the countenance. The Greek sculptors gave a certain degree of roughness to the statues of Neptune, which appears to have been regarded as appropriate to the god of the ocean. His hair was usually somewhat in disorder, and the whole of his figure was represented as exceedingly powerful and muscular. Hence the 'chest of Poseidon' (στρίπρον Ποσειδάωνος, *Il.*, v. 479) is the poetic expression for this characteristic of the deity, which is illustrated by the noble fragment from the pediment of the Parthenon in the British Museum. (*British Museum*, 'Elgin Marbles,' vol. ii., p. 26.) His right hand held the trident; and he was usually surrounded by dolphins and other marine objects. (Müller's *Archäologie der Kunst*, p. 452.)

NERAC. [LOT ET GARONNE.]

NERBUDDA. [HINDUSTAN, vol. xii., p. 211.]

NEREIDS (Νηρηίδες), nymphs of the sea, were the daughters of Nereus and Doris. Nereus was the eldest son of Pontus and the Earth (Hesiod, *Theog.*, 233); and Doris was one of the daughters of Oceanus. The Nereids are said by most antient writers to have been fifty in number, but Propertius makes them a hundred (iii. 5, 33). The most celebrated of them were Amphitrite, the wife of Poseidon; Thetis, the mother of Achilles; Galatea, Doto, &c.

The worship of the Nereids was generally connected, as might be supposed, with that of Poseidon. Thus they were worshiped in Corinth, where Poseidon was held in especial honour, and in other parts of Greece. (Paus., ii. 1, § 7, 8; compare iii. 26, § 5; v. 19, § 2.) The Nereids were originally represented as beautiful nymphs [Νύμφης]; but they were afterwards described as beings with green hair, and with the lower part of their body like that of a fish. (Plin., *Hist. Nat.*, ix. 4.)

NE'REIS (Zoology), Cuvier's name for a genus of Dor-

Nereis (Sylla) phosphorensis.
a. the animal, $\frac{1}{2}$ inch long; b. head of the same, $\frac{1}{2}$ inch long. (Garner.)

sibranchiate Annelids, comprehending the genus *Lycoris* of Savigny. Tentacles equal in number are attached to the sides of the base of the head; a little more forward are two other biarticulated ones, and between them two simple ones: they have only one pair of jaws in their proboscis (trompe). The branches only form small laminae on which a net-work of vessels creeps: there are besides two tubercles to each of their feet, two bunches of filaments, a cirrus above, and one below.

Lamarck states that the antennae of the Nereids are in general short. The eyes, when distinct, he says, are four in number. The proboscis is large, open at its extremity, and often furnished with salient points or small tentacles. Lamarck divides them into six genera, viz.: *Lycoris*, *Nephtys*, *Glycera*, *Hesione*, *Phyllodon*, and *Syllis*, principally on the ground of the presence or absence of jaws and the modifications of the antennae. To these he adds *Spio*.

Geographical Distribution.—The Nereids are widely spread, and some of the species are found in most seas. Some are found on our own coasts.

NERI, FILIPPO DE', born in 1515, of a noble Florentine family, after studying in his native country, proceeded to Rome, where he fixed his residence. Naturally of warm feelings and benevolent disposition, he turned his whole attention to the relief of the poor, the instruction of children, and the reclaiming of vicious persons. In the pursuit of these objects he displayed a sincerity and a single-heartedness which exposed him to the sneers and the slanders of the worldly, the prudish, and the sticklers for outward decorum. The particulars of his life, some of which are very curious, have been fully narrated by his biographers Bacci and Gallonio. He founded an asylum for poor and sick strangers, and other houseless or helpless persons, in which they were sheltered until they were able to return to their home. Having taken holy orders, he associated with himself several pious friends, among whom was Baronius, afterwards a cardinal. They performed spiritual exercises together, and instructed the poor, and especially youths, in the streets, at the doors of the churches, and in the market-places. He attended the sick and the dying, visited the prisoners, and pleaded in the courts of justice for the oppressed. Neri was not gloomy or morose; his piety was not repulsive: he conversed freely with all kinds of people; and being a man of education and general information, he entered into the spirit of their respective pursuits, and joined in their harmless mirth, whilst he checked any excess or vicious tendency. He was the founder of the oratorios, or sacred musical entertainments, the object of which was to attract the youth and wean them from the public theatres and their temptations. At first the oratorios were hymns which were sung after the sermon, accompanied by music. Afterwards dramas were introduced, founded upon scriptural subjects, and some of them were written by distinguished writers, such as Zeno and Metastasio, and the parts were sung like those of an opera, with this difference, that there was no acting or stage, the singers being stationed in a gallery of the chapel. The chapel being called in Italian 'Oratorio,' that is, a place of prayers, gave its name to the performance; and the congregation or order constituted by Neri took the name of 'Fathers of the Oratory.' But Neri, more prudent in this than other founders of monastic orders, did not bind the members of his congregation by perpetual vows: he said that the spirit of charity should be the only common bond. The institution was approved of by Gregory XIII. in 1575, and it soon spread over Italy, France, and other countries. The congregation 'de l'Oratoire' has produced many distinguished men, Baronius and Massillon among others. Study, preaching, and the education of youth are the chief occupations of its members. Their handsome church at Rome, Santa Maria in Vallicella, has a good library, and the oratorios continue to be performed in a chapel devoted to the purpose. Neri, after resigning the generalship of his congregation to his disciple Baronius, died in 1595. He was canonised by Gregory XV. Some of his letters, and his 'Ricordi,' or advice to youth, have been published, as well as two sonnets out of many which he composed. He was an amiable, virtuous, and religious man, and his example had a great influence on the clergy of Rome.

NERI, POMPEO, was born at Florence in 1707. After studying in the university of Pisa, he was made professor of law in that institution. He was afterwards appointed by Francis of Lorraine, the new grand-duke of Tuscany, secre-

tary to his council. In 1749 Maria Theresa called him to Milan and made him president of the 'Giunta di Censimento,' or commission for the valuation of all the landed property in Lombardy. This undertaking was effected, and the tax was laid equally upon all landed property: the new 'Cadastro,' or register, was published in 1759. The communal administration was at the same time reorganised. This example was followed by several Italian and other governments. The empress also commissioned Neri to confer with the Sardinian minister for a concordat concerning the currency of both states. It was in consequence of this commission that Neri wrote and published his book on currency, 'Osservazioni sopra il Prezzo Legale delle Monete,' 1751. In 1758 Neri, being recalled to Florence, was named one of the counsellors of the regency during the minority of Leopold. He died at Florence in 1776. Besides the work above mentioned, he wrote other treatises on political economy, on taxation, on the municipal laws in Tuscany, and on the former contrasted with the actual condition of the nobility in that country. Neri ranks among the first Italian economists of the eighteenth century, with Carli, Verri, Genovesi, and others.

NERITA. [TROCHOIDEA.]

NERITIDÆ. [TROCHOIDEA.]

NERITINA. [TROCHOIDEA.]

NERITOPSIS. [TROCHOIDEA.]

NERO, CLAUDIUS CÆSAR, the sixth of the Roman emperors, was born at Antium in Latium, in the latter end of A.D. 37, nine months after the death of Tiberius (Suet., *Nero*, c. 6). He was the son of Domitius Ahenobarbus and Agrippina, the daughter of Germanicus, and was originally named Lucius Domitius. After the death of Domitius and of a second husband, Crispus Passienus, Agrippina married her uncle the emperor Claudius, who gave his daughter Octavia in marriage to her son Lucius, and subsequently adopted him with the formal sanction of a Lex Curiata. (Tacit., *Ann.*, xii. 26.)

The education of Nero was carefully attended to in his youth. He was placed under the care of the philosopher Seneca, and he appears to have applied himself with considerable perseverance to study. He is said to have made great progress in the Greek language; of which he exhibited a specimen in his sixteenth year by pleading in that tongue the rights or privileges of the Rhodians and of the inhabitants of Ilium. (Suet., *Nero*, c. 7; Tac., *Ann.*, xii. 58.)

On the death of Claudius, A.D. 54, Nero succeeded to the sovereign power. Agrippina, who had paved the way for the accession of her son by the murder of her husband, endeavoured to obtain the chief management of public affairs; and her vindictive and cruel temper would have hurried Nero, at the commencement of his reign, into acts of violence and bloodshed, if her influence had not been counteracted by Seneca and Burrus, to whom Nero had entrusted the government of the state. Through their counsels the first five years of Nero's reign were distinguished by justice and clemency. He discouraged public informers, refused the statues of gold and silver which were offered him by the senate and people, and used every art to ingratiate himself with the people. But his mother was enraged to find that her power over him became weaker every day, and that he constantly disregarded her advice and refused her requests. His neglect of his wife Octavia, and his criminal love of Acte, a woman of low birth, still further widened the breach between him and his mother. She frequently abused him with the most contemptuous language; reminded him that he owed his elevation to her, and threatened that she would inform the soldiers of the manner in which Claudius had met his end, and would call upon them to support the claims of Britannicus, the son of the late emperor. The threats of his mother only served to hasten the death of Britannicus [BRITANNICUS], whose murder forms the commencement of that long catalogue of crimes which afterwards disgraced the reign of Nero.

But while the management of public affairs appears from the testimony of most historians to have been wisely conducted by Burrus and Seneca, Nero indulged in private in the most shameless dissipation and profligacy. He was accustomed, in company with other young men of his own age, to sally into the streets of Rome during the night in order to rob and maltreat the passengers, and even to break into private houses and take away the property of the owners. But these extravagancies were comparatively harmless; his

love for Poppæa, whom he had seduced from Otho, led him into more serious crimes. Poppæa, who was ambitious of sharing the imperial throne, perceived that she could not hope to obtain her object while Agrippina was alive, and accordingly induced Nero to consent to the murder of his mother. The entreaties of Poppæa appear to have been supported by the advice of Burrus and Seneca; and the philosopher did not hesitate to palliate or justify the murder of a mother by her son. (Tac., *Ann.*, xiv. 11; Quint., *Inst. Orat.*, viii., c. 5.)

In the eighth year of his reign Nero lost his best counsellor Burrus, and Seneca had the wisdom to withdraw from the court, where his presence had become disliked, and where his enormous wealth was calculated to excite the envy even of the emperor. About the same time Nero divorced Octavia and married Poppæa, and soon after put to death the former on a false accusation of adultery and treason.

In the tenth year of his reign, A.D. 64, Rome was almost destroyed by fire. Of the fourteen districts into which the city was divided, four only remained entire. The fire originally began at that part of the Circus which was contiguous to the Palatine and Cælian hills, and raged with the greatest fury for six days and seven nights; and after it was thought to have been extinguished, it burst forth again and continued for two days longer. Nero appears to have acted on this occasion with the greatest liberality and kindness; the city was supplied with provisions at a very moderate price; and the imperial gardens were thrown open to the sufferers, and buildings were erected for their accommodation. But these acts of humanity and benevolence were insufficient to screen him from the popular suspicion. It was generally believed that he had set fire to the city himself, and some even reported that he had ascended the top of a high tower in order to witness the conflagration, where he amused himself with singing the destruction of Troy. From many circumstances it appears improbable that Nero was guilty of this crime. His guilt indeed is expressly asserted by Suetonius and Dion, but Tacitus admits that he was not able to determine the truth of the accusation. In order however to remove the suspicions of the people, Nero spread a report that the Christians were the authors of the fire, and numbers of them were seized and put to death. Their execution served as an amusement to the people. Some were covered with skins of wild beasts, and were torn to death by dogs, others were crucified, and several were smeared with pitch and other combustible materials, and burned in the imperial gardens in the night: 'Whence,' says the historian, 'pity arose for the guilty, though they deserved the severest punishments, since they were put to death not for the public good, but to gratify the cruelty of one man.' (Tac., *Ann.*, xv. 44.)

In the following year, A.D. 65, a powerful conspiracy was formed for the purpose of placing Piso upon the throne, but it was discovered by Nero, and the principal conspirators were put to death. Among others who suffered on this occasion were Lucan and Seneca; but the guilt of the latter is doubtful. In the same year Poppæa died, in consequence of a kick which she received from her husband, while she was in an advanced state of pregnancy.

During the latter part of his reign Nero was principally engaged in theatrical performances, and in contending for the prizes at the public games. He had previously appeared as an actor upon the Roman stage; and he now visited in succession the chief cities of Greece, and received no less than 1800 crowns for his victories in the public Grecian games. On his return to Italy he entered Naples and Rome as a conqueror, and was received with triumphal honours. But while he was engaged in these extravagancies, Vindex, who commanded the legions in Gaul, declared against his authority; and his example was speedily followed by Galba, who commanded in Spain. The Prætorian cohorts espoused the cause of Galba, and the senate pronounced sentence of death against Nero, who had fled from Rome as soon as he heard of the revolt of the Prætorian cohorts. Nero however anticipated the execution of the sentence by requesting one of his attendants to put him to death, after making an ineffectual attempt at suicide. He died, A.D. 68, in the thirty-second year of his age, and the fourteenth of his reign.

It is difficult to form a correct estimate of the character of this emperor. That he was a licentious voluptuary, and that he scrupled at committing no crimes in order to gratify his lust or strengthen his power, is sufficiently proved; but

that he was such a monster as Suetonius and Dion have described him, may reasonably admit of doubt. The possession of absolute power at so early an age tended to call forth all the worst passions of human nature, while the example and counsels of his mother Agrippina must have still further tended to deprave his mind. Though he put to death his adoptive brother, his wife, and his mother, his character appears to have been far from sanguinary; his general administration was wise and equitable, and he never equalled in his worst actions either the capricious cruelty of Caligula or the sullen ferocity of Domitian. Nero was a lover of the arts, and appears to have possessed more taste than many of the emperors, who only resembled him in their profuse expenditure. The Apollo Belvedere is supposed by Thiersch (*Epochen der bildenden Kunst unter den Griechen*, p. 312), and some other writers, to have been made for this emperor.

His government seems to have been far from unpopular. He was anxious to relieve the people from oppressive taxes, and to protect the provinces from the rapacity of the governors; and it may be mentioned as an instance of his popularity, that there were persons who for many years decked his tomb with spring and summer flowers, and that in consequence of a prevalent rumour that he had escaped from death, several impostors at various times assumed the name of Nero and gave no small trouble to the reigning emperors. (Tac., *Hist.*, i. 2; ii. 8; Suet., *Nero*, c. 57, and Casaubon's note.) During the reign of Nero, the Roman empire enjoyed in general a profound state of peace. In the East the Parthians were defeated by Corbulo; and in the West the Britons, who had risen in arms under Boadicea, were again reduced to subjection by Suetonius and Paulinus. [BOADICEA.]

NERVA, MARCUS COCCEIUS, the thirteenth Roman emperor, was born at Narnia, in Umbria, in A.D. 27, according to Eutropius (viii. 1), or in A.D. 32, according to Dion (lxviii. 4). His family originally came from Crete; but several of his ancestors rose to the highest dignities in the Roman state. His grandfather, Cocceius Nerva, who was consul, A.D. 22, and was a great favourite of the emperor Tiberius, was one of the most celebrated jurists of his age. We learn from Tacitus that he put an end to his own life (*Ann.*, vi. 28).

Nerva is first mentioned in history as a favourite of Nero, who bestowed upon him triumphal honours, A.D. 66, when he was prætor elect. The poetry of Nerva, which is mentioned with praise by Pliny and Martial, appears to have recommended him to the favour of Nero. Nerva was employed in offices of trust and honour during the reigns of

Vespasian and Titus, but he incurred the suspicion of Domitian, and was banished by him to Tarentum.

On the assassination of Domitian on the 18th of September, A.D. 96, Nerva succeeded to the sovereign power, chiefly through the influence of Petronius Secundus, commander of the Prætorian cohorts, and of Parthenius, the chamberlain of the palace. The mild and equitable administration of Nerva is acknowledged and praised by all ancient writers, and formed a striking contrast to the sanguinary rule of his predecessor. He discouraged all informers, recalled the exiles from banishment, relieved the people from some oppressive taxes, and granted toleration to the Christians. Many instances of his clemency and liberality are recorded by his contemporary the younger Pliny; he allowed no senator to be put to death during his reign, and practised the greatest economy in order to relieve the wants of the poorer citizens. But his impartial administration of justice met with little favour from the Prætorian cohorts, who had been allowed by Domitian to indulge in excesses of every kind. Enraged at the loss of their benefactor and favourite, they compelled Nerva to deliver into their hands Parthenius and their own commander Petronius, both of whom they put to death. The excesses of his own guards convinced Nerva that the government of the Roman empire required greater energy both of body and mind than he possessed; and he accordingly adopted Trajan as his successor, and associated him with himself in the government. Nerva died in the beginning of A.D. 98, after a reign of sixteen months and nine days. (Dion, lxxviii. 4.)

(Dion; Aurelius Victor; Eutropius; the younger Pliny.)

NERVE and NERVOUS SYSTEM. The nerves consist of fine tubular filaments of a white or greyish colour and of a peculiar substance, which are arranged nearly parallel to each other in sheaths of fibrous tissue, and which are more or less directly connected with the brain and spinal chord, from which as a centre they proceed in all directions to be distributed in the substance of nearly all the tissues of the body. The nervous filaments vary in diameter from $\frac{1}{1000}$ to about $\frac{1}{100}$ of an inch, and each filament extends unbroken from the brain or spinal chord to the part in which it is distributed; the size of the nerves, that is, of the bundles contained in a common sheath or neurilema, depends on the number of filaments enclosed in each. In their course the nerves give off and receive numerous branches; in many parts their ramifications and connections are so numerous as to form a coarse kind of network or plexus; but in all these divisions and reunions there is no branching or communication of the ultimate filaments; the only change is that the filaments pass out of one sheath into another, and the only end that appears to be had in view is the more convenient passage of certain filaments to particular parts. *Fig. 1* is a nerve, that is, a sheath containing a number of nervous filaments branching and receiving branches from another adjacent to it. *Fig. 2* is a portion of nerve in which the sheath has been removed and the fibres and smaller fasciculi of filaments separated from each other.

Of the mode of termination of the nerves in the tissues little is distinctly known. In the retina [EYE] the nervous fibrils terminate in the small pointed processes by which the internal surface of that nervous expansion is beset; and it is very probable that a similar mode of termination exists in other analogous recipients of special sensation, and in the papillæ of the skin and mucous membranes; but for the nerves of the other tissues, whether the filaments unite in loops or form networks, or whether they terminate abruptly or gradually merge into the substance of the tissue in which they are placed, is at present undecided, the minuteness and obscurity of the objects having hitherto presented in-

superable obstacles to certainty of microscopic observation.

Fig. 2.

Fig. 1.

On many parts the nerves bear ganglia—small rounded vascular masses of nervous matter, not arranged in fibres, but composed of globules scattered in a network of vessels. Nervous filaments enter into the ganglia on one side, and pass from them on the opposite, but they lose their filamentous character within them and appear to merge into the substance of the general mass.

The nerves are arranged in two systems, the cerebro-spinal, or nerves of animal life, and the ganglionic, or great sympathetic system, or nerves of organic life. The nerves of the first system are all immediately connected with the brain and spinal chord, and include all those which are the media of sensation and voluntary motion; the second system contains those nerves which are connected with the brain and spinal chord, or the nerves proceeding from them, only by very small filaments, which bear numerous ganglia in all parts of their course, and which are subservient to the actions of those parts which are engaged in the nutritive functions, and upon which the mind has in general no direct influence.

These two systems of nerves are developed together from almost the lowest animals. Nervous filaments have not yet been seen in the bodies of the polygastrica, nor in the periphera, nor in the polyp-bearing animals, though many of them are sensible to light and other impressions, and their motions indicate the agency of the same means as those which act in the higher animals. In those of the radiata in which distinct nerves are traceable, their distribution is circular, and hence the name of cyclo-neurose, often given to this class. A nervous circle is placed around the mouth, in a single or double cord, bearing minute ganglia, from which filaments radiate to the several divisions of the body, and especially to the tentacula and other moving or sensitive organs.

In the articulata, or diplo-neurose classes, the nervous system assumes the same lengthened form as the animals themselves possess. The same form of a nervous circle placed around the entrance to the digestive cavity is preserved, but the nerves proceeding from it are not all of equal length or similar in distribution as in the radiata, but

one much larger and more distinct than the rest is continued as a double cord, extended along the under surface of the body. The ganglion on the upper part of the nervous ring around the pharynx constitutes the first trace of a brain, from which in many genera nerves proceed to the antennæ, the eyes, &c. The cords or columns proceeding along the body are more or less approximated and often united to each other. Each is composed of two distinct tracts, on the lower of which there are ganglia over which the upper tracts pass without communicating with them; the lower ganglionic tract supplies the sensitive, the upper, not ganglionic, the motor nerves, a relation similar to that which exists in the vertebrata, if we allow for the generally inverted position of the organs in the articulata. Besides these tracts another is placed between the motor columns and the viscera, which has no connection with the ganglia, and whose nerves are principally distributed to the respiratory organs. The first trace of a distinct sympathetic system is found in a few nervous filaments passing off from the œsophageal ganglia and distributed around the dorsal artery and the adjacent viscera.

The size of the ganglia on the longitudinal cord of the articulata and of the nerves connecting them and given off from them is directly proportioned to the volume and complexity of the sensitive or motor organs adjacent to and supplied by each. Thus in those which exercise important motions and have their chief organs of sense about the head, the supra-œsophageal ganglion is very large, as in the rotifera and the complete insects; while in those in which the chief nervous influence is required for lateral limbs that ganglion is small, but the ganglia and cords along the whole or some particular part of the trunk are developed proportionally to the organs adjacent to them. In the higher genera of this class the nervous cords are contained in a cavity separate from that which encloses the other viscera, as they are also much more distinctly in all the vertebrata.

The most striking character in the nervous system of the preceding classes is the repetition of similar elements in the several similar parts of the animal. In both classes the animal is made up of a number of similar parts, which in the radiata are arranged round a common centre, and in the articulata are placed longitudinally. Each of these parts in both receives its nerves from a distinct ganglion, and therefore possesses to a certain extent an independent nervous system, and an independent life. In higher animals, in which particular portions of the body contain organs for special functions to be performed for the benefit of the whole, this repetition and equal distribution of central nervous organs no longer exists.

In the mollusca, or cyclo-gangliata, the nervous œsophageal ring is still present, and is often provided with numerous distinct ganglia, whose size bears a direct proportion to the organs of sensation placed near the mouth, and to the activity and complexity of the masticatory apparatus. The columns continued along the abdominal portion of the animal are usually, like itself, short; and except when active motions are performed by a foot or other locomotive organ, they bear but few and very small ganglia.

The nervous system of the mollusca is thus chiefly concentrated about the head, and its development is proportioned to that of the organs of sense and motion which are subservient to nutrition, while the nerves of the body are but little developed. In the articulata, on the other hand, in accordance with the greater proportionate development of their locomotive powers, the part of the nervous system belonging to the trunk becomes predominant. In the vertebrata, or spini-cerebrata, which possess both nutritive and locomotive powers more highly developed than either of the preceding classes, the types of both are united; the cerebral mass being a more highly developed form of the large supra-œsophageal ganglion of the higher mollusca, while the spinal chord, with the ganglia on its sensitive roots, corresponds with the long ganglionic cords of the articulata.

The most essential part of the nervous system of the vertebrata is the spinal chord, with its continuation in the cranium as far as the crura cerebri and cerebelli, and the ganglia formed upon them, which together constitute that which is termed the cerebro-spinal axis. This axis is always enclosed in an osseous sheath placed in the posterior part of the body, and it is never as in the invertebrata, traversed by the alimentary canal.

The sympathetic system of nerves distributed to the vis-

cera, which in its simplest form, in the annelida, is composed of a few filaments from the supra-œsophageal ganglion, which pass along the dorsal artery, preserves in all the classes the same separation from the sensitive and motor cords, and the same general distribution about the viscera. It increases in complexity in the same degree as the cerebro-spinal system, and acquires in the vertebrata an extensive and still increasing development. It forms in the highest of them numerous and complicated plexuses, with many and some large ganglia, which follow the course of the principal blood-vessels, and are distributed to all the organs of organic life; it still communicates but little with the cerebro-spinal axis, sending only small filaments, which mingle with the spinal and some of the cerebral nerves near their roots.

The part of the nervous system of the vertebrata which is subject to most alteration is the brain. The chief differences in its form depend on the degree in which the hemispheres of the cerebrum and cerebellum are developed. In fishes these are usually smaller than the ganglia on the origin of the optic nerves; but ascending in the scale, they become more and more predominant in size over the rest of the nervous centres, and appear to have a certain relation to the development of intelligence in the animal. In the highest animals and in man the lobes of the cerebrum and cerebellum are by far the largest of all the nervous organs; their surfaces are convoluted and furrowed, the quantity of the grey matter upon them augmented, and the complexity of their structure greatly increased. But as a special article is devoted to this subject [BRAIN], it need not be further considered here; for similar reasons we shall here treat of only the general phenomena and laws of the actions of the nerves as they are observed in man, and the cerebro-spinal system only in reference to the nerves of common sensation and motion; referring for the description of the special senses to the articles EYE, EAR, &c., and for the peculiar influence of the nervous system in the most important organs, to the articles devoted to them. [HEART; STOMACH, &c.]

The constant functions of the cerebro-spinal nerves are, to convey impressions, made on the points in which they are distributed, to the brain, where they are perceived as sensations, or to the spinal chord, where they are perceived without sensation; and to convey the influence of the will from the brain, or some involuntary influence from it or the spinal chord, to the muscles by which some motion is to be performed. The influences that thus pass to and from the brain are conveyed through distinct nervous filaments, though the filaments subservient to each are generally enclosed in the same sheath, and appear to form a single and simple nerve. The filaments which convey impressions to the nervous centres are called sensitive or centripetal; while those conveying impressions from the centres to the muscles are named motor or centrifugal filaments.

The spinal chord, in which all the nerves of the trunk have their apparent origin, is composed of two lateral halves, symmetrical in form and size, and united together by a part of their inner surfaces at the median line. The outer portion of the chord is composed of white nervous matter, the inner of grey, an arrangement the reverse of that of the brain, in which the cortical substance is grey, and the medullary or central white. Each lateral half of the spinal chord is again obscurely divided by superficial furrows into an anterior and a posterior column, and a smaller middle portion between them. All the nerves by which sensitive impressions pass, arise from the groove between the posterior and middle columns; and all those (with the exception of the spinal accessory nerve [BRAIN]) by which the excitants to muscular motion are conveyed, arise from the groove between the anterior and middle columns. They all arise by what are called roots, that is, by a number of fine nervous threads or narrow bands attached to the grooves and passing for a short distance into the substance of the cord, which, as they proceed outwards, converge and unite into a single cord or nerve. There is an important distinction however between them; the roots of the posterior or sensitive nerves have a ganglion at their union just where they are leaving the vertebral canal, while those of the anterior or motor nerves unite without any ganglion into a single cord, which passes over, but does not communicate with the ganglion on the posterior roots. Beyond this ganglion the anterior and posterior roots unite in a common sheath, in which their filaments, though they continue distinct, are indiscriminately mixed; and in this manner they proceed through the varied branchings of the sheath to nearly all

parts of the body, conveying the power of perceiving impressions to all, and the power of motion to the muscles and probably a few other tissues.

Nearly the same mode of origin and distribution, and the same distinctness of office, are found in the nerves that have their centre in the brain, in which those of the fifth pair [BRAIN] are almost exactly analogous to the spinal nerves. But in the other cerebral nerves there is less regularity of origin, the nerves of peculiar sensation having no muscular nerves corresponding to them, the seventh nerve, or portio dura, being exclusively motor, without any corresponding sensitive root, &c. Thus of the nerves proceeding from the brain, some are in all their course sensitive only; others are (except for the occasional connection of some of their branches with branches of the fifth) entirely motor; others (part of those of the fifth) mixed, that is, containing in a common sheath both sensitive and motor filaments, like all the nerves derived from the spinal chord.

The conveyance of those impressions which produce common sensation is the property exclusively of those nervous filaments which arise from the posterior columns of the spinal chord and their continuations in the brain. To possess this power, their connection with the brain, either directly or through the medium of the spinal chord (which, in this view, may be regarded merely as a collection of a vast number of the nervous filaments, which have their centre in the brain), must remain uninjured. Hence, when any sensitive nerve is cut through, all the parts to which its filaments are distributed beyond the place of division are rendered perfectly insensible. The nearer to the brain that the injury is inflicted, the more extensive is the destruction of sensibility. When the spinal chord is injured by fracture of the vertebra, or by disease, or any other means, all the parts whose nerves come out from the portion below that which is destroyed become insensible; they lose also all power of voluntary motion, but for the present we shall consider the sensitive filaments and their functions only. If the posterior roots of a nerve be divided, all the parts supplied by that nerve lose their sensibility; or if a nerve be divided in any part of its course, then all the parts supplied by branches given off between the point of division and the brain retain their sensibility, while those which are supplied by branches given off in the other part of the nerve more distant from the brain are rendered insensible. These facts prove that the influence of an impression upon the distal or peripheral extremity of a nervous filament can only be conveyed to the brain so as to produce sensation through a continuity of nervous tissue, and only through the very filaments that are impressed; and that there is no such communication of adjacent filaments, that if one is injured, another can convey the impression made on it, as in the circulation, by the anastomosis or communication of the blood-vessels, when one is obliterated, the blood which should traverse it passes through another. The same facts evidently explain also many of the phenomena of partial paralysis.

If that part of a divided nerve which is still connected with the brain be stimulated, the same sensation is perceived as if the stimulus were applied to all the parts in which the branches that the nerve gives off below the division are distributed. This is shown in the sensation which every one must have felt on striking the inside of the elbow (the *funny bone*, as it is commonly called); the tingling pain that the blow produces, and which appears to have its seat in the inner side of the fore-arm and hand, and in the little and ring fingers, is owing to the filaments of the ulnar nerve (which passes behind the elbow) being distributed to those parts, and to the sensation being always referred to the peripheral termination of the filament, in whatever part of its course it is irritated. It is of course impossible to experiment upon a single nervous filament, but the accuracy with which the imagined seat of sensation produced by irritating a bundle of filaments accords with their distribution leaves no doubt of the fact just mentioned. The nearer to the brain that the stimulus is applied, the more extended is the sensation; hence in disease of the spinal chord, pain is often felt in all the parts supplied with nerves coming off from the chord below the diseased portion, and the pain of dividing a nerve is felt over all the parts to which its branches are distributed. The same circumstance gives rise to the apparently strange ideas which those who have lost a limb entertain, that they still possess it, till by their sight or some other means they correct the erroneous im-

pressions of their sense of touch. For example, the constant cry of a patient who has just lost his leg, while the stump is being dressed, is that his attendants are squeezing his knee, or cutting his foot, or injuring some other part of the limb, which he cannot believe has been cut off. The reason is, that when those filaments of the nerves in the stump which are destined for the knee are touched, the knee seems to be touched; when those which are going to the foot are injured, the foot appears to suffer. So deceptive are these sensations, that even years after the loss of a limb, or for the rest of their lives, persons occasionally endeavour to perform some act with the stump which they were accustomed to do with the part they have lost. From the same circumstance of the sameness of sensation, whatever be the part of a nervous filament to which the stimulus is applied, arises the well-known feeling of the foot having fallen asleep, when the ischiatic nerve has been pressed upon, and the peculiar character of the pain in many cases of tic douloureux, in which the trunk of a nerve being diseased, the pain is referred to all the parts to which its filaments are distributed.

The laws deduced from these facts, and which are of great importance in the explanation of many diseases of the nervous system, are briefly these. The impressions producing sensation always pass from the circumference of the distribution of the nerves to the centre; they are always centripetal, and their centre, the seat of sensation, is the brain. They can pass only through the tissue of the nervous filaments to which they have been applied, and whose connection with the brain must therefore be unimpaired. The sensation is the same on whatever part of the nervous filament the impression is first made, and it is always referred to the peripheral end of the filament.

If the connection of the nerve with the brain be broken, the same impression may pass along its filaments to the part where its continuity is destroyed, but it will produce no sensation; though when the spinal chord remains, its passage may be indicated by the phenomena of *reflex motion*, which will be presently considered. It is chiefly through the medium of the nerves of common sensation that we become acquainted with all that the contact of other palpable bodies teaches, as their form, size, hardness, heat, &c. For the perception of these properties we must suppose a peculiar condition of nervous matter; for although the laws under which impressions are conducted through all the sensitive nerves to the brain are the same, yet the nerves of peculiar sensation, as the optic [EYE] and the auditory [EAR] are no more capable of perceiving the impressions of contact of non-vibrating bodies, than the nerves of the limbs, &c. are of perceiving light and sound. If the retina be touched in an operation on the eye (as in the experiments which M. Magendie has often made in operating for cataract), the sensation produced is that of a brilliant flash of light; if the auditory nerve be electrified, the sensation is that of a sudden loud noise: but in neither case is pain produced, unless the nerves of common sensation, with which parts of the eye and ear are supplied, be irritated at the same time.

Our ideas of the form and size as well as of the hardness of bodies are dependent in some degree on another sense, which is peculiarly connected with the muscles [MUSCLE], and is called muscular sensibility. By it we know what degree and extent of muscular force we exert at any given time. Thus if the hand grasps a ball, we estimate its size by the degree in which the fingers are extended to enclose its circumference, for the mere impression of its contact on the fingers would be the same whether the ball were large or small; we estimate its weight by the muscular exertion which we feel it necessary to make to prevent it from falling; and its hardness by the degree of exertion which is sufficient or insufficient to make an impression on its exterior. In like manner, if the body be larger than the hand can grasp, then (unless we can see it) we estimate its size by the distance through which the hand moves in passing over the whole surface, and its form by the differences of position in which, in thus passing over it, the hand is from time to time placed. It is only the smaller differences in the form of the surfaces of bodies, their smoothness and roughness, and other similar characters, that are estimated by the touch alone. Thus when a sensitive part (as the hand) is placed or moved with a certain force on the surface of a body, we know that it is smooth if all the hand receives the same sensation, or rough if the sensation of contact is perceived at points distant from each other. In like manner, from

the extent of surface touched we form our ideas of the sharpness or obtuseness of bodies.

Perceptions of temperature are also the peculiar attributes of the nerves of common sensation, but they do not admit of our forming very accurate ideas of the heat of bodies, because our sensations depend rather on the rapidity with which heat is abstracted from or added to our bodies, than on the quantity which we lose or receive. Hence we feel marble, which conducts heat rapidly, as if it were much colder than a slowly-conducting carpet of the same temperature; and when the difference of temperature between the hand or any other part of the body and that which it touches is very great, we lose all power of judging, and cannot directly tell whether it is in contact with (for example) ice or boiling water. Peculiar states of the circulation in and around the nerves give rise to very different sensations of heat, as in fever or in shivering, in which, though the skin feels as if it were burning or freezing, the actual temperature of the surface does not in either case differ more than five or six degrees from that which is natural to it.

The acuteness of the common sensibility of parts probably depends, *cæteris paribus*, in the healthy state, on the closeness with which they are beset with the terminations of sensitive nervous filaments. E. H. Weber (*Annot. Anatom. et Phys.*) has suggested a mode of estimating the degrees of sensibility of different parts of the surface of the body by touching two adjacent points of it at the same instant, and observing at what distance from each other the two contacts can be discerned as two distinct impressions. This may be effected by putting small pieces of cork on the points of a pair of compasses, and pressing both at the same instant on the part to be examined; the angles which the legs of the compass form will thus measure the distances at which the two impressions are distinguished or are confounded into one. By this method of examination it is found that the tip of the tongue is the most sensible of all the surface of the body, being able to distinguish two impressions when the distance between the points on which they are applied is not more than $\frac{1}{10}$ of an inch, a result which might have been anticipated, from the accuracy with which the tongue perceives and estimates the characters of the smallest portions of foreign matter in the mouth, and from the great share which the sense of touch takes in what we confound in the general idea of taste. The balls of the fingers can distinguish double impressions from $\frac{1}{8}$ to $\frac{1}{4}$ of an inch apart; the palm at about half an inch, and other parts of the skin at various greater distances. Applied to the skin at the back of the neck, of the upper arm, the thigh, and some other parts, such double impressions are confounded into one when the points touched are upwards of two inches asunder.

Numerous circumstances have the power of modifying or increasing the sensibility of parts, giving rise to varieties of agreeable and painful sensations. Most parts moreover have certain sensations peculiar to themselves; thus no other tissue than the skin is ever the seat of the sensations of tickling, or itching, or burning heat, &c.; the muscles alone feel fatigue; the pain of disease in different tissues is as varied as any other of its phenomena. Certain parts also are insensible to any but particular impressions; the tendons and other similar tissues may be cut or burnt, or in any way injured without exciting any sensation, unless they are pulled or twisted, or subjected to any other of those mechanical influences which it is their office in the animal economy to resist. Other parts again, as most of the internal organs, the bones and cartilages, are insensible during health, but in disease excite severe and peculiar pain. For all these differences however no explanation is yet known. It is known that certain nerves (the motor) never, under any circumstances, convey sensible impressions; that others (the nerves of the sympathetic system) are, if ever, only occasionally conductors of sensations; that others (the nerves of the peculiar senses) convey only the impressions of those agents for the reception of which certain organs are peculiarly adapted; and that others have the constant office of conveying impressions of contact, heat, &c.; but upon what differences of structure or arrangement these varieties of function depend no reasonable opinion can at present be formed.

Many of the phenomena illustrative of the mode of conduction of the nervous influence in the sensitive nerves are repeated in the motor filaments, with this difference, that while in the sensitive nerves impressions always proceed

from the circumference to the centre, or from the termination of the nervous filament in any tissue, to its termination in the brain or spinal cord; in the motor nerves the impressions always pass in the opposite direction, that is, from the centre to the circumference, or from the brain or spinal chord to the muscle or other contractile tissue. When the motor filaments of a nerve are irritated in any part of its course, no pain is felt, but the muscles to which it is distributed contract; when a similar nerve is cut through (or otherwise prevented from conveying the nervous influence), all the muscles to which the filaments that pass off from it, beyond the injured portion, are distributed, lose the power of being acted upon by the will, and very soon of being excited by any stimulus, while those from between the injured part and the brain retain their power. If the end of that portion of a divided motor nerve which is still connected with the nervous centre be irritated, no perceptible effect follows; if the end of the other portion, which is now separated from the brain, be irritated, the muscles to which its filaments proceed will for a time continue to contract. The same observations on the necessity of a continuity of nervous substance, on the absence of any communication between adjacent filaments, by which one might assume the office of another, and on the sameness of effect, whatever part of a nervous filament is irritated, may be made of the motor as of the sensitive filaments. As in by far the greater number of nerves, sensitive and motor filaments are contained within the same sheath, the phenomena, which have been described separately, will, in the case of injury or other affection of such nerves, be combined. Thus when the nerve of any limb is irritated, sudden pain is felt and coincident convulsions ensue; when a similar nerve is divided, the limb becomes both senseless and motionless; if the upper part of the divided nerve (that still connected with the brain) be irritated, pain is felt, but no motion is excited; if the lower part be irritated, convulsions of the limb take place, but no pain is felt.

Of the nature of the influence which, passing along the nerves, excites motion, and of the manner in which it is set in motion, nothing whatever is known. Through some nerves it can be transmitted at will, and the muscles supplied with these are therefore called voluntary; through others the will has no influence in sending the excitant to motion, and the involuntary muscles to which they pass are entirely removed from any connection with the mind, except in the excitement of violent passion or grief, or other exalted mental affection. Whatever stimulus is applied to the motor nerves, the same effect is produced; whether it be the stimulus of the will, or of any mechanical, chemical, or electrical application, the same muscular contraction, varying only in degree, is produced. The mind alone has the power of determining the strength and extent of muscular contraction, and this it effects by an operation which it scarcely appreciates; for even one who knows accurately the position and the mode of action of each muscle cannot, except in certain cases, order the act of a single muscle, but to produce a certain kind or strength of motion, is obliged to exert coincidentally all the muscles that can minister to that motion. Thus there are two muscles, at least, that bend the fore-arm, and no person can make one of them act while the other remains inactive; the will can only determine certain effects, but it cannot determine the muscles by which they shall be accomplished.

In all the phenomena hitherto considered, the mind takes a part; but in some circumstances an impression passes along a sensitive nerve to the nervous centre, and although no sensation may have been produced, an influence is in return conveyed back from the centre through a motor nerve, and motion is produced, either in the muscles adjacent to the part first impressed, or in those of some other part of the body. The phenomena of this class are those of what is called the *reflex function*; a term which is derived from the idea that the impression, passing centripetally, is reflected from the centre as soon as it arrives there, and made to pass from it centrifugally.

For the occurrence of these reflex actions, it is essential that the nerves acted upon should retain their connection with the spinal chord or with the brain. The spinal chord is sufficient for some of these actions, and the power is therefore often spoken of as if it belonged exclusively to it; but it is evidently possessed by the whole cerebro-spinal axis. Thus, if the hind-leg of a reptile or any other animal be separated from the body, and the skin of any part of it

be irritated, no motion of its muscles will ensue; but if the leg be allowed to retain its connection with that part of the spinal chord from which its nerves come out, the same irritation of the skin will produce convulsive contractions of the muscles. In the first case the impression on the skin, if it passed along the sensitive nervous filaments at all, was lost at their out extremity; in the second, it passed through them to the spinal chord, and thence either it or some other influence returned immediately through the motor nerves to the muscles.

On this property of reflecting the impressions received from sensitive to motor nerves, many of the muscular motions which were formerly regarded as instinctive or sympathetic, and many others of the most important phenomena, depend. Thus when light falls on the retina, the impression received by the brain is instantly reflected through the third nerve, and the iris, without any effort of the will, contracts; and if the light be very strong and sudden, the eyelids involuntarily wince, as they do before any expected injury. In like manner a stimulus applied to the nose excites involuntary sneezing; food, or any other substance in the fauces or pharynx, excites the involuntary act of swallowing, and still more an irritation of the larynx is reflected from the medulla oblongata, and excites in all the respiratory muscles involuntary coughing. In all these cases sensation coexists with the reflection of the impression through the motor nerves; but sensation is by no means essential to the phenomena; on the contrary, in the most marked examples the centripetal impression is not perceived by the brain. Thus the sphincter muscles are constantly maintained in a state of contraction under the influence which passes unfelt from the spinal chord; and all the motions occurring in decapitated animals (in which the reflex actions are more remarkable than under any other circumstances) must probably be regarded as unaccompanied by sensation, since exactly similar phenomena occur in persons suffering from some forms of paralysis, and who can never feel the impression on the skin upon which the involuntary motions instantly follow. In the case of reflection from the optic nerve to the nerves of the iris, and in most of those in which the sensitive nerves pass directly to the brain, sensation is produced with the reflex action; but in all the cases where the centripetal nerves pass to the spinal chord, the reflex actions take place as well, or even more certainly, after the removal of the brain. The spinal chord is essential for a reflex action in the nerves that pass out from it; the brain for a similar action in its own nerves: in the first case sensation is not involved, in the second it generally is.

Mr. Grainger ('Observations on the Spinal Chord') believes that the impressions which produce reflex actions, and those which pass to and from the brain in sensation and voluntary motion, are not conveyed by the same sets of nervous fibres. He considers that there meet in the spinal chord four sets of nervous filaments: one passing only to the exterior white matter, and then ascending to the brain, to which they convey sensations; a second, corresponding to these, which pass from the brain along the exterior white matter of the chord, and thence to the muscles, for the conveyance of the influence of the will to them. These two sets are the same as the commonly described sensitive and motor filaments; the others are analogous to these, but are supposed to be subservient only to the reflex actions; they pass to and from the chord with the others, but instead of being continued up with them to the brain along the exterior of the chord, penetrate into its substance, and lose themselves in its central grey matter—the recipient and reflector of the impressions which they convey. The observations of the course of the filaments of the nerves, where they pass into the spinal chord, upon which this very ingenious view is founded, have not yet been sufficiently confirmed to establish its truth beyond doubt; but it still affords the most intelligible explanation of the manner in which impressions, passing apparently through the same filaments, in some cases produce sensation, and in others none; and in which, for certain purposes, organs supplied with nerves from the cerebro-spinal axis are yet usually removed from the influence of the brain.

It deserves particular remark, that in the cases in which the impression is conveyed only to the spinal chord, as in beheaded animals, the motions that result from the reflected influence, evince design. Thus, when a bird's or any other lower animal's (as a frog's) head is cut off, the body endeavours to escape, and evinces method in its attempts; if a

limb is touched, it is drawn away from the contact; if a part of the body is irritated, the foot will sometimes be raised in an endeavour to remove the source of irritation. These actions are similar to those of monsters born without brains, many of which have been known to cry, to take milk, and perform other apparently voluntary acts. Are we from these facts, indicating design in the actions of brainless animals, to believe that the spinal chord is capable of any exercise of will? Such an idea is very opposed to opinions which are deemed well founded, but is still far from groundless; the motions are scarcely otherwise explicable.

Of the nature of the agent which, passing along the nervous filaments, produces sensation or excites motion, nothing satisfactory is at present known. The imperceptible velocity of its passage naturally suggested the idea of an electric current, and except by the supposition of the motion, or the vibration of the particles of some such subtle material as electricity or the other imponderable agents are conceived to be, its velocity is scarcely to be accounted for. Some idea may be formed of its rapidity of passage along the nerves to and from the brain, by a rough calculation which the writer lately made, that when a person plays rapidly on the piano, upwards of 1000 distinct movements are performed within the minute; each of which has its time, place, and strength exactly ordered. At the same time that the mind imparts this number of impressions to the muscles, it is receiving not less than 2000 impressions by each of three distinct senses, the eye, the ear, and the touch, and perceives the most minute variations with each. From the similarity of this velocity of the nervous agent, to that of the passage of electricity, and from a few apparent analogies, some have imagined the nervous agent or fluid to be identical with the electric; but the grounds for such an opinion are at present few and uncertain, while many evident facts militate strongly against it, as the equal conducting power of all the moist tissues as well as the nervous; the improbability that electric fluid should be isolated in the filaments, the inconstancy of the results of experiments in which a current of electricity is used to replace a removed portion of a nerve, &c.

The nervous agent is prepared in the brain and spinal chord, and probably in all parts where there is ganglionic or grey nervous matter, and from them distributed to the nerves. Thus, if the trunk of a mixed nerve be divided, that part which is separated from the nervous centre soon loses that which may be called its stock of excitability, while that which remains attached to the centres retains its excitability as if no injury had been inflicted. For the maintenance of the excitability on which the reflex actions depend, the spinal chord alone seems to be necessary; for it is not more rapidly expended after the removal of the brain than when the brain is present. For the maintenance of the excitability for other actions the brain is essential.

Each impression made on the sensitive nerves, and each excitant to motion, may be considered to cause a certain consumption of the nervous influence, which it is the office of the nervous centres to replace; and a healthy condition of the nervous system may reasonably be conceived to depend on a due proportion between the waste and the supply. When the former has been excessive, weakness or fatigue of the senses, or of the power of muscular motion, is produced, which a period of sleep or rest from excitement is necessary to replace. The necessity of such rest is indicated to us by the fatigue at the close of each day, and cannot long be safely resisted; for after the loss of the night's rest, the excitant necessary to produce a certain effect is found to become greater in a rapidly increasing ratio through every hour of the succeeding day. During rest, the brain may be considered as producing the excitability by which the nerves may act during the period of exertion; and hence exertion is not less necessary for health than rest; and many disorders show that excitability may, for want of being wasted by exertion, accumulate. Hence much of that which passes under the popular name of nervousness—a condition in which a given excitant produces a greater effect than is natural or healthy; and this (although the use of terms usually applied to material things may give too definite an idea of it) we may reasonably believe to result from an accumulation of nervous influence, as fatigue, or the need of a greater excitement to produce a certain effect, results from its waste. The influence of exercise of

the nerves follows the same rule as that of exercise of the muscles or any other tissue; by it, within certain limits, the power of perceiving impressions and of exciting motion is progressively increased; the excitability of each organ or of the whole system being, within those limits, capable of adaptation to the need of the individual; hence the power by practice of attaining to perfection of touch, or of hearing, or sight, or any other sense. Impressions are distinctly felt by the practised sense which are completely imperceptible to that which has been only casually employed. In like manner, when the organ of one sense is destroyed, and thus one outlet for excitability is closed, the rest acquire increased acuteness; hence the accuracy of the hearing and touch in the blind, of the sight in the deaf, &c.

The system of the great sympathetic nerve is that whose branches are distributed to all the organs of organic life, the heart, lungs, digestive canal and glands, &c., chiefly following the course of the blood-vessels, bearing numerous and large ganglia in all parts of their course, and communicating with the brain and spinal chord or their nerves only by few and small filaments. The parts to which the branches of the sympathetic nerve are distributed have but vague if any sensibility, unless under peculiar circumstances of disease; and the motions which some of them possess are usually quite independent of the mind. Numerous experiments of irritating the ganglia of the sympathetic to see whether it produces pain, have had unsatisfactory results; nor would any results of apparent insensibility be conclusive, because the ganglia might, like part of the brain, be insensible to injury, though fully capable of perceiving the impressions transmitted to them through their nerves. But the pain of the diseases of internal organs is amply sufficient to prove their sensibility, though it does not determine whether the impression of pain is conveyed through filaments of the sympathetic system or through those few of the cerebro-spinal system which are mingled with the former in the common sheath. In the same manner, in extraordinary cases, the brain and spinal chord have an evident influence on the motions of the organs supplied by the sympathetic nerve, as in the effects of strong passion and other mental affections on the circulation, the digestive functions, &c. The impressions conveyed from the viscera to the brain and spinal chord may also be reflected either to the voluntary muscles, as in the convulsions of children with disordered digestion, or to the involuntary muscles, as in the increased rapidity of pulse, the sickness, &c. which occur in various diseases.

In the natural state however, the organs chiefly supplied by the sympathetic nerves are entirely independent of the cerebro-spinal system, and will maintain their actions for a time even after their removal from the body. Thus the peristaltic motion of the intestines, the contractions and dilatations of the heart of some animals, and some other similar actions, will continue for a considerable time after they are separated from the body, or after all the nerves passing to them have been divided. Many other facts prove also that the internal organs are much less dependent on the influence of the sympathetic nerve than the external animal organs are on that of their cerebro-spinal nerves: severe irritation of the sympathetic nerves, such as, if applied to the cerebro-spinal motor nerves, would excite sudden and violent convulsions of their muscles, gives rise to but weak and slow contractions of the viscera; and these follow at perceptible intervals after the application of the stimulus, so that it is often difficult to say whether the irritation have exerted any influence at all.

The office of the numerous ganglia placed in the course of the sympathetic nerves is perhaps the most obscure point in the whole range of physiology. Some have regarded them as so many brains, by which impressions are received through the branches of which each ganglion is the centre, and from which excitements to motion are sent out; others have believed that they exercise a power of isolating the organs they supply from the influence of the mind or of obstructing the constant passage of impressions to and from the brain; and many other functions have been supposed to be performed by them: but for each and all the evidence is altogether unsatisfactory.

The sympathetic nerve or system of nerves has received its name from the idea that it is of ultimate importance in the phenomena of what is called sympathy, in which one part of the body is affected in consequence of some pecu-

liar condition of another. A great number of the phenomena which were formerly regarded as the effects of sympathy are now more clearly explained by the reflecting action of the cerebro-spinal axis; many others depend on some generally operating influence, as a peculiar condition of the blood, &c.; and in those that remain it is questionable whether the sympathetic system of nerves exercises any peculiar power. The universality of its distribution among the viscera is the only ground on which it can be believed to possess this property of exciting impressions or actions in one, in consequence of being itself excited by the condition of another.

It exerts a more evident influence in the various secretions of the glands and other surfaces which it supplies. In some instances the excitant to secretion is conveyed primarily from the brain, either directly, as in the flowing of tears in grief, &c., or by a reflex action, as in the tears that flow when the mucous membrane of the nose is irritated, or as in the flow of saliva in a strong irritation of the membrane of the mouth, in the sweating of fear or of great agony, &c. In the more constant secretions the influence of the sympathetic nerves is in some degree assumed; but there are sufficient facts to prove that their injury is very soon followed by a suppression or modification of the secretion in the organ to which the injured nerves are destined. The cerebro-spinal nerves also exercise an influence on the secretion and nutrition of the parts which they supply; but its amount is indistinct, in consequence of the interruption of other circumstances favourable to those processes, by the same injury which cuts off the secretory power of the nerves, as the loss of exercise of the muscles, &c.

The best general account of the physiology of the nerves is in Müller's 'Physiologie,' translated by Dr. Baly; for all that relates to the distinct functions of the roots of the nerves, the several works of Sir Charles Bell (by whom this most important discovery was first made) may be consulted, and with them the physiological treatises of Mr. Mayo and M. Magendie. On the reflex actions, the best works are, Prochaska's 'Physiologie,' in which it is first distinctly announced, though long before alluded to by Glisson (*Tract. de Ventriculo et Intestino*), and the works of Dr. Marshall Hall, by whom the subject has been most fully illustrated and raised to its just importance, and of Mr. Grainger and Dr. Volkmann. The electrical theory of the nervous fluid is most extensively illustrated in the writings of Dr. Wilson Philip. The best account in English of the comparative anatomy of the nervous system will be found in Dr. Grant's 'Outlines of Comparative Anatomy.'

NE/SEA. Lamouroux gives this name to some of the articulated Corallines.

NESS, LOCH, is a lake in Scotland, situated between 57° 10' and 57° 27' N. lat. and between 4° 20' and 4° 40' W. long. It is 22 miles long: its breadth varies from a mile and a quarter to three-quarters of a mile. It extends south-south-west and north-north-east over a considerable portion of Glenmore, through which the Caledonian Canal passes. The depth of the water is from 106 to 129 fathoms in the middle parts; but near the ends of the lake it decreases to 85, 75, and much less. At the north-east end the depth is reduced to 7 and 9 fathoms. This lake is never covered with ice. At its south-western extremity it receives the waters of the small river Oich, which issues from Loch Oich, which lies farther south. From its north-eastern extremity issues the river Ness, which, after a course of six miles, discharges its waters into Moray Frith. Loch Ness is enclosed on both sides by lofty, rugged, steep, and barren mountains, which attain an average height of 1000 feet. The highest mountain-masses are on the western shore and near the middle of the lake, where they rise in the huge summit of the Mealfourvouny. This mountain is stated to be 2730 feet high, but it is probably higher, if the fact be true that not far from its summit there is a small lake which is always frozen. On the north and south of this enormous mass of rocks two pastoral glens open upon the lake, Glen Urquhart and Glen Morison, and the rivers which drain them bring a large quantity of water to the lake. The mountains south and north of these two glens are much less elevated: this is also the case with the rocks which skirt the eastern shores of the lake. These rocks are cut by deep gullies and frightful precipices, and the rivers Farrisg and Teachloin rush violently into the lake through two narrow fissures. These rivers drain Strath Erick, a pastoral valley, which is more than 400 feet above the level

of the sea, and extends parallel to the lake for about fifteen miles. It is a beautiful tract of country, and its charms are increased by the cataracts of Foyers or Fycers, which the river Feachloin forms in breaking through the line of elevated rocks which divide the strath from the lake. It rivals in beauty the waterfalls of the Clyde and of the Tumel.

NESTOR (Ornithology). [PSITTACIDÆ.]

NESTORIANS, the name of an important and early sect of Christians, which is derived from Nestorius, a Syrian by birth, who became patriarch of Constantinople in 428, under the reign of Theodosius II. He showed himself very zealous against the Arians and other sectarians; but after some time a priest of Antioch, named Anastasius, who had followed Nestorius to Constantinople, began to preach that there were two persons in Jesus Christ, and that the Word, or divinity, had not become man, but had descended upon the man Jesus, born of the Virgin Mary, and that the two natures became morally united as it were, but not hypostatically joined into one person; and that when Jesus died it was the human person and not the divinity that suffered. This doctrine, being not only not discountenanced, but supported by Nestorius, was the origin of the Nestorian schism. Nestorius refused to allow to the Virgin Mary the title of Theotokos, or mother of God, but allowed her that of Christotokos, or mother of Christ. Nestorius met with numerous opponents, among others Eusebius of Dorylæum; and the controversy occasioned great disturbances in Constantinople. Cyril, bishop of Alexandria in Egypt, with his characteristic violence, anathematised Nestorius, who in his turn anathematised Cyril, whom he accused of degrading the divine nature and making it subject to the infirmities of the human nature. [CYRIL OF ALEXANDRIA.] The emperor Theodosius convoked a general council at Ephesus to decide upon the question, A.D. 431. The council, which was attended by 210 bishops, condemned the doctrine of Nestorius, who refused to appear before the council, as many Eastern bishops, and John of Antioch among the rest, had not yet arrived. Upon this the council deposed Nestorius. Soon after John of Antioch and his friends came, and condemned Cyril as being guilty of the Apollinarian heresy. The emperor, being appealed to by both parties, after some hesitation, sent for Nestorius and Cyril, but it appears that he was displeased with what he considered pride and obstinacy in Nestorius, and confined him to a monastery. But as his name was still a rallying word for faction, Theodosius banished him to the deserts of Thebais in Egypt, where he died. His partisans however spread over the East, and have continued to this day to form a separate church, which is rather numerous, especially in Mesopotamia, where their patriarch resides at Diarbekr.

The Nestorians at one time spread into Persia, and from thence to the coast of Coromandel, where the Portuguese found a community of them at St. Thomé, but they persecuted them and obliged them to turn Roman Catholics.

(*Histoire du Nestorianisme*, by Father Doucin, a Jesuit, 1698; and a *Dissertation on the Syrian Nestorians*, in the 4th volume of the *Bibliotheca Orientalis* of J. S. Assemani.)

Eutyches, in his zeal to oppose the Nestorians, fell into the opposite extreme of saying that there was only one nature in Christ, namely, the divine nature, by which the human nature had become absorbed. [EUTYCHIANS.]

NETHERLANDS, THE. This kingdom as now constituted consists of the territory of the ancient republic of the Seven United Provinces and of some portions of the province of Limburg, but not including the grand-duchy of Luxemburg, which the king of the Netherlands possesses, with the title of grand-duke, as a part of the German Confederation. The kingdom of the Netherlands is situated between 50° 41' and 53° 34' N. lat. and 3° 30' and 7° 10' E. long. It is bounded on the east by Germany, on the north and west by the German Ocean or North Sea, and on the south by Belgium. The frontier line which divides it from Belgium is described in the article *Belgium*, as fixed by the treaty of 15th November, 1831, which has now been accepted and ratified by both parties. The area of the kingdom is about 11,000 square miles; the population, on the 1st of January, 1839, was 2,583,271.

KINGDOM IS NOW DIVIDED INTO TEN PROVINCES:—

	Area. Sq. miles.	Population.
North Brabant . . .	1,942	366,160
Guelderland . . .	2,000	336,401
North Holland . . .	930	423,873
South Holland . . .	1,170	509,661
Zealand	640	145,542
Utrecht	525	140,574
Friesland	1,027	227,415
Overyssel	1,240	191,062
Groningen	770	172,437
Drentho	920	70,146
Total	11,164	2,583,271

That part of Limburg (with 147,527 inhabitants) which is restored to the kingdom of the Netherlands is annexed in perpetuity to that crown, but is constituted as *the duchy of Limburg*, and is to form a part of the German confederation, in lieu of that part of Luxemburg which the German diet consents to cede to Belgium; but Muestricht and Venloo remain an integral part of the kingdom of the Netherlands.

Face of the Country; Soil; Climate.—The Netherlands are part of the great plain of Northern Europe, and are not separated from Germany on the north-east by any natural boundaries. The provinces about the mouths of the Schelde and the Rhine, and the country to the north of them, Zealand, North and South Holland, Friesland, Groningen, Drentho, and Overyssel, are indeed most appropriately called the Netherlands, that is, the Lowlands. They form one unbroken flat without a hill or rock, without forests or running waters, they lie in part even below the level of the sea, against the inroads of which they are protected partly by immense dikes, and partly by sandhills or *dunes* from 80 to 180 feet high, which have been cast up by the ocean, and, running parallel with the coast, protect it against the element to which they owe their origin. Nothing can be more dreary than this ocean of sand; it is a perfect image of aridity and barrenness; some broom scarcely green, some stunted shrubs growing at intervals in the hollows, where they are protected from the wind, alone interrupt this dreary solitude. From the Helder to the mouth of the Maas, a distance of 75 miles, these gloomy though protecting deserts everywhere extend between the cultivated country and the sea. The land thus rescued from the sea, consisting of moor and mud, is traversed by numberless canals, which are absolutely necessary to drain it and render it fit for cultivation. The labour is amply rewarded, for the land is extremely fertile and covered with the richest pastures. The lowest parts are called polders. When a marsh is to be drained, it is first enclosed with a rampart or dike to prevent any water from flowing into it. Windmills are then erected on the edge of the dike, each of which works a pump. As the mills raise the water, it is discharged into a canal, which conveys it to the sea or to some inland piece of water. But in general the operation cannot be performed at once; where the marshes are too deep below the surrounding country, two or three dikes and as many canals are made at different levels, rising by degrees to the upper canal, in which the whole terminates. The girdle of windmills, which announces at a distance the position of the polder, has the appearance of sentinels placed to guard the entrance. All the polders have an extremely rich slimy soil, which is generally used for pasturage, but in some places produces rich crops of corn. The eastern provinces nearest to Germany contain many meres and marshes, and especially the great series of turf moors which extend from the mouth of the Schelde eastward to the Maas, and there join the great morass called the Peel, on the east frontier of North Brabant, which is 10 leagues long and from 1 to 3 leagues broad.

This marshy country, which is so wholly artificial that it has justly been said 'the Dutch built Holland,' is one of the best cultivated, the most wealthy, and the most populous in Europe; and it would be difficult to find elsewhere, in so small a compass, such a number of large and well-built villages, towns, and cities. The atmosphere in these low tracts is for the most part damp, thick, and heavy; fogs and storms are very frequent; but both the heat and the cold are more moderate than in Northern Germany. The climate is unhealthy, especially for foreigners. The want of good spring water is very sensibly felt. The climate is more healthy in the eastern provinces, which are rather more

elevated, and contain some hills, which the inhabitants dignify with the name of mountains.

Bays, Rivers, Canals, and Lakes.—The whole coast, which is much broken and indented with considerable bays, large inlets of the sea, and the mouths of great rivers, would measure near 500 miles, or about 1 mile of coast for every 22 square miles. The German Ocean, or North Sea, which borders Belgium and the Netherlands from the frontier of France, a few miles east of Dunkirk, to the mouth of the Ems, has produced in the lapse of ages great physical revolutions in the maritime provinces. The most remarkable of these revolutions have been the retreat and encroachment of the sea, and the changes in the course of the Rhine. The whole country probably once belonged to the ocean, but the oldest accounts that we possess represent the land as more extensive than at present. The Yssel, it appears, ran into an inland lake called Flevo, from which a river pursued its course for fifty miles to the sea. That lake, with the adjacent continent, has been covered for many centuries by the Zuyder Zee, the only remains of the continent being the islands of Texel, Vlieland, Schelling, and Ameland, which lie in a curved line, convex towards the ocean, in front of and protecting the entrance of the Zuyder Zee. This inland sea, which is enclosed by the islands and the provinces of Holland, Utrecht, Guelderland, Overijssel, and Friesland, resembles a great lake: it is 80 miles long from north to south, and its breadth varies from 20 to 30 and 40 miles. On account of its great extent, the navigation is dangerous in stormy weather for small vessels, which however cross it from South Holland to Friesland rather than go all round the coast. The entrances between the islands being much obstructed by sand-banks, the trade of Amsterdam derives infinite benefits from that noble work the North Holland Canal. The Lauwer Zee, between Friesland and Groningen, and the Dollart, between Groningen and the German province of East Friesland, were formed by similar irruptions of the sea in the thirteenth century; and so late as the fifteenth century a great salt-water lake, called the Bies Bosch, was suddenly formed to the south-east of Dort, by the sea bursting through a dam and overwhelming 72 villages, with 100,000 inhabitants.

The principal river is the Rhine, which, coming from Germany, enters the Netherlands at Lobith, where it is 2300 feet broad; but in traversing this country it is divided into three arms, and before it reaches the sea even loses its venerable name. Soon after crossing the frontier it divides into two branches, the larger and left arm forming the Waal. The right or northern arm flows to Arnheim, where it again divides into two branches; one, called the Yssel, flows northwards to the Zuyder Zee; the other runs to Wijk, where it again divides into two streams, the larger, called the Leck, joining the Waal above Rotterdam, and the smaller, now reduced to an insignificant river, passing by Utrecht to Leyden and the sea. Till the beginning of this century, this branch was lost in the sand, the mouth being completely choked up; in 1804 works were commenced to re-open this mouth of the river near Katwyck, and the operation was happily completed in 1807. The other principal rivers are, the Maas, Maese, or Meuse, which comes from Belgium, and joins the Waal at the fort of St. Andries; and the Schelde, which, likewise coming from Belgium, enters Holland below Antwerp, and divides into two arms, the East and the West Schelde; the West Schelde falls into the ocean at Flushing, and the East Schelde between the Zealand islands of Schouwen and North Beveland. Of the canals the most important is the North or Helder Canal. [HOLLAND, *North.*] The greatest lake is that of Haarlem, which it has now been resolved to drain. [HAARLEM.]

Natural Productions.—The horses, which are a large strong breed, well adapted for draught and for heavy cavalry, are about 200,000 in number. The horned cattle are mostly remarkable for their size and beauty, and amount to about a million. Vast numbers of lean cattle from Denmark and Germany are fattened in the rich pastures of North Holland. There are about 700,000 sheep. The swine are of the German breed, and are most numerous in the provinces next to Germany. The only kind of game is hares, which are rare; wild rabbits however are very numerous among the sand-hills. Domestic poultry is plentiful. There are wild geese and ducks, snipes, woodcocks, and plovers. This is the paradise of storks, it being considered a great offence to kill one. Accordingly they build their nests

on the house-tops, and walk about unmolested and unconcerned. Fish is abundant on the coasts and in the rivers; the cod fishery on the Doggerbank and the Greenland whale fishery are very productive. But the herring fishery on the coast of the Shetland islands, formerly a chief source of the wealth of the Dutch, has greatly declined. In 1601 there were 1500 vessels employed in the herring fishery; in the years from 1795 to 1807 and 1808 there were only 30; but the number has since increased to nearly 200.

Sufficient corn for home consumption is not raised; hemp and flax are grown in great abundance.

There are no minerals, except a little bog-iron in Overijssel and Guelderland: there are brick-earth and potters' clay in most of the provinces. Fullers' earth (but mixed with too much sand) is got in pretty considerable quantities about Tilburg; and immense quantities of turf are dug in Holland and Friesland: some sea-salt, but in small quantities, is made on the coasts of Holland and Friesland.

Trade.—The history of the commerce of the Netherlands properly begins with Bruges in Flanders, in the fourteenth century. From Bruges the trade was for the most part transferred at the end of the fifteenth century to Antwerp, which became the greatest emporium in the world. But the ravages of the war with Spain and the capture of the city after the memorable siege in 1585 drove the wealthiest inhabitants to the northern provinces, especially to Amsterdam. The new republic of the 'Seven United Provinces,' founded on principles of civil and religious liberty, became a sure asylum for the oppressed, while religious dissensions and persecutions prevailed in many other parts of Europe. Poor as the country then was in natural resources, it was necessary to find for the rapidly increasing population employment beyond the seas. The republicans, who were at first driven by necessity to become bold corsairs against the Spanish squadrons, soon became excellent and intrepid seamen, and enterprising indefatigable merchants, who traversed every sea, for whom no source of gain was too remote, and to whom no obstacle was insurmountable. The commerce of Antwerp, Cadiz, and Lisbon fell into their hands, and thus, in the middle of the seventeenth century, the United Provinces became the first commercial state and the greatest maritime power in the world, and the trade of Amsterdam acquired an unparalleled degree of prosperity. The East India Company, founded in 1602, with a capital of only 6,500,000 florins, conquered kingdoms and islands in Asia. With 200 ships it traded with China and Japan; it alone furnished Europe with the costly productions of the Spice Islands; the gold, the pearls, and the diamonds of the East passed only through its hands. The prosperity of Amsterdam remained almost unimpaired till towards the latter end of the eighteenth century, when the French revolution in 1795 gave it the death-blow, and its rival, London, became the commercial capital of the world. Reduced to the condition of a vassal and afterwards of a province of France, and consequently engaged in a constant war with England, Holland lost its ships, its colonies, its commerce, and its public credit. After recovering its independence on the expulsion of the French in 1813, the commerce of Holland revived in a remarkable manner, but is still very far below its former magnitude. During the union of the northern and southern provinces, under the name of the kingdom of the Netherlands, both Holland and Belgium flourished. Holland indeed lost the colonies of Berbice, Demerara, and Essequibo, with the Cape of Good Hope and Ceylon. The very profitable contraband trade formerly carried on with Spanish America has also been destroyed, since those colonies declared themselves independent. The trade with India has undergone a great change, not only by the loss of the Cape and Ceylon, but by the fall of the East India Company and the throwing open of the East India trade to all the subjects of the Netherlands, excepting that to the Moluccas and to Japan. On the other hand the improved administration of Java has led to a vast increase of the productions of that fine colony, and new and profitable channels have been opened to Dutch commerce in Brazil, Cuba, and Haiti. The precarious state of affairs from the time of the revolt of the southern provinces in 1830 till the confirmation of their independence by the treaty of peace concluded in April last (1839), was certainly a great check to the progress of commerce; yet it continued to improve even during that period, and there is little doubt that it will again become very flourishing, and more so perhaps than during the union with Belgium.

The following official tables, for the year 1837, show:—
 I. The number of ships cleared inwards, to what countries they belonged, how many to each country, and their tonnage. II. At what ports in Holland they arrived, how many at each port, and how many under the flag of the Netherlands. III. From what countries they came; how many from each country, and how many under the Netherlands flag. IV. How many ships cleared outwards, and under what flags:—

IV. *Ships cleared Outwards.*—5784 ships, 776,300 tons with cargoes—3526 ships, 497,174 tons; the remainder in ballast. Dutch flag, 2720 ships, 327,481 tons. English, 1200 ships, 202,807 tons. North America, 65 ships, 20,598 tons. French, 94 ships, 14,462 tons. Norway, 463 ships, 100,589 tons. Denmark, 242 ships, 13,692 tons. Hanover, 492 ships, 26,230 tons.

Of which there were bound to Great Britain, 1692 ships, 83,769 tons; Russia, 239 ships; Denmark, 104 ships; Sweden and Norway, 1095 ships, 153,524 tons; Cape and East Indies, 135 ships, 72,032 tons.

The inland trade employs 5600 of the vessels called *trek-schuyts*, and 15,000 boats.

The exports consist, 1st, of colonial produce from the East and West Indies, coffee, sugar, spices, tea, silks, and other articles from China and Japan; and 2nd, chiefly of the productions of the country, among which they export to England annually 18 million pounds of butter and 27 million pounds of cheese; likewise flax, hemp, and corn, where the importation is permitted; tobacco, madder, flower-roots (especially hyacinths and tulips), cattle, and horses: 3rd, the produce of their fisheries, especially herrings, and of their distilleries and manufactories. The chief articles of importation are corn, salt, wine, timber in very large quantities, partly from Norway and partly from Germany, whence it is floated down the Rhine; stone, such as blocks of granite from Norway for the dikes, and free-stone for building; marble, and various manufactured goods; besides colonial produce of every kind from the possessions in Asia, Africa, and the West Indies. After the separation of the seven provinces from Spain, the Dutch, in the seventeenth century, held in their hands the greater portion of the carrying trade of Europe, and Holland was a general magazine of the productions of all countries; at that time a list of its exports and imports would have been an encyclopædia of merchandise; and though this cannot be now said, it is still true in a great degree.

Manufactures.—The principal manufactures are, linen of the very best quality; woollens, once the most celebrated in the world; silks, and leather. The sugar refineries have increased of late years in a very extraordinary degree. Tobacco-pipes are made in large quantities, both for home consumption and exportation. The distilleries of Geneva, or Hollands, of which there are 200 at Schiedam, have long been celebrated. It is remarkable that the distillers last year petitioned the government for a reduction of the excise-duty, on the ground that their exportation to the United States of North America has greatly diminished in consequence of the establishment of Temperance Societies in that country. Since the revolt of the Belgian provinces in 1830, great efforts have been made to establish manufactures, especially of cottons, in the northern provinces, which appear to have been very successful; so that in a few years the kingdom of the Netherlands, as now constituted, may probably be placed in the rank of manufacturing as well as commercial nations.

Religion.—The established religion is Calvinism, or, as it is called, the Reformed religion; but a general toleration has so long prevailed, that religious sects of almost every kind enjoy the free exercise of their own forms of worship. The exact proportions at this moment have not been published, but in 1837 it was estimated that there were—Calvinists, 1,700,000; Lutherans, 357,000; Mennonites, 120,000; Remonstrants, or Arminians, 40,000; Anabaptists, 2500; some other Christian sects, 15,000; Roman Catholics, 280,000; and Jews, 50,000. The proportions have probably not much altered since.

Education is very generally diffused throughout the kingdom. Besides the parish schools, under the protection of the government, private boarding-schools are as numerous as in England. No person is allowed to set up a school without a licence, which he cannot obtain without a previous examination by a special commission. There are four classes of licences, according to the branches of education to be taught; and no person is permitted to undertake a higher branch than that for which he has passed his examination. For the higher branches there are seminaries, called Royal Schools, where the ancient and modern languages, mathematics, rhetoric, and drawing are taught; of these there is one in every large town. The universities are those of Leyden, Utrecht, and Groningen, the first of which was formerly one of the most illustrious in Europe, and can boast a long and splendid list of learned men who have been educated within its walls. There are likewise schools for particular branches of education, such as military and naval schools.

The **Constitution** of the kingdom of the Netherlands is contained in the *Grond Wet*, or fundamental law of the kingdom of the Netherlands, promulgated by a royal ordinance of 24th August, 1815. This constitution resembles in many particulars that of Great Britain. The crown is hereditary in the male line, and, in default of male descendants, in the female line. The executive power is in the hands of the king, whose person is inviolable, his ministers being responsible. The legislative power is in the king and the states-general, consisting of two chambers: the members of the first chamber are appointed by the king for their life; the second chamber is elected by the provincial assemblies, and one-third of the members go out annually by rotation, but they may be re-elected. All new laws are proposed by the king to the second chamber. The sittings of the second chamber are open to the public; those of the first are not. Each province has its own provincial assembly, which has various important local duties, such as the superintendence of religious worship and charitable institutions, the care of the roads and bridges, and the election of the deputies to the second chamber. This constitution, having been made for the kingdom of the Netherlands as constituted in 1815, is to undergo various alterations and modifications, in consequence of the separation of the northern and southern provinces.

Finances.—This is a subject of extreme intricacy, rendered still more complex by the union with Belgium, and the precarious state of the country, which was neither at war nor at peace with Belgium, after the revolt of the latter in 1830, till the final separation of the two countries. The whole must be amply discussed in the present session of the states-general. We can here only state that the budget presented by the minister of finance on the 25th of October, 1839, proposes an expenditure for the year 1840 of 56,378,600 florins, of which 21½ millions are for the interest of the national debt, above 14 millions for the army, and 5½ millions for the navy. The ways and means are estimated at 56,386,298 florins. One of the items worth notice in the ways and means is the sum of 11,220,000 florins from the revenues of the colonies.

Army and Navy.—The amount and the organization of the army cannot at present be fully known. A very great reduction has already been made since the peace by disbanding the militia and volunteers. The navy consists of about eighty vessels, of which twelve are ships of the line. These are however of lower rates than in the British navy, there being only one 90-gun ship.

Colonies.—The Dutch still possess many important colonies: in Asia—Java, Amboyna, Banda, Ternate, Macassar, and settlements in Sumatra, Borneo, and Comorandel; in Africa, thirteen forts on the coast of Guinea; in the West Indies, the islands of Curacao, St. Eustatius, and part of St. Martin, and, on the continent of South America, Surinam, and a right to send stores and receive produce from Dem-

rara, Essequibo, and Berbice, formerly their colonies, but now in the possession of Great Britain.

History.—Julius Cæsar, in prosecuting his conquests in Northern Gaul, advanced as far as the Rhine. The inhabitants of the north bank of the Rhine were called Batavi, and considered as belonging to Germany. They were engaged in many wars, either with the Romans, or as their allies. We afterwards find them partly as trading, partly as sea-faring people, and as pirates, who were in the end subdued by the Romans. In the fifth century the Batavians, and in the sixth the Belgæ, were conquered by the Franks, but the Frieslanders not till the seventh century. At the peace of Verdun, in 843, Batavia and Friesland were incorporated with the newly created kingdom of Germany, of which Ludwig (*i.e.* Lewis), surnamed the German, was the first king, and were under governors, who afterwards made themselves independent. From the year 1000 to the end of the eleventh century, the country was divided into duchies, counties, and imperial cities. Utrecht became a bishopric, and extended its temporal power over Groningen and Overysse. Of all these princes the counts of Flanders were the most powerful, and their country having become subject, in 1383, to the still more powerful house of Burgundy, the latter made itself master of almost the whole of the Netherlands. Charles the Bold, the last duke of Burgundy, fell in a battle with the Swiss, and his only daughter and heiress Maria marrying Maximilian, son of Frederick III., duke of Austria, and emperor of Germany, the Netherlands came under the dominion of the house of Austria. Maximilian's grandson, Charles V., by the Pragmatic Sanction in 1548, united all the seventeen provinces for ever with Spain; they however retained the name of the circle of Burgundy, and were attached to the German empire. During the reign of Charles V., the Protestant religion began to spread in these provinces, though grievously oppressed, for the number of persons in the seventeen provinces put to death in his reign as heretics is estimated at several thousands. His son and successor Philip II. not only deviated from the policy of his father, who had respected the ancient liberties of the people, but introduced the Inquisition, and carried on religious persecution with a cruelty before unknown. The patience of the people was exhausted, and they rose in open rebellion, which the atrocities of the bloodthirsty Alba could not quell. The heads of the noblest of the nation, among whom were Egmont and Horn, fell indeed under the axe of the executioner. The prince of Orange, who escaped, long maintained an unequal combat, and though often defeated by Don John of Austria and Alexander duke of Parma, at length triumphed in the cause of liberty and the Protestant religion.

The struggle would certainly have been sooner and more easily ended, but for the jealousies between the several provinces and the nobles, and the unfortunate reciprocal distrust of the Protestants and the Roman Catholics. It is true that almost all the other provinces concluded with Holland and Zealand, the convention of Ghent, in 1576, and formed a still closer alliance in the following year, by the Union of Brussels. But the consummate abilities of the prince of Parma succeeded in bringing all the southern provinces under the authority of Spain. In 1579 the five provinces of Holland, Zealand, Utrecht, Guelderland, and Friesland concluded the celebrated Union of Utrecht, in which they declared themselves independent of Spain. They were joined in 1580 by Overysse. On the 26th July, 1581, they renounced their allegiance to Philip 'as a tyrant,' and being joined in 1594 by Groningen, formed the celebrated republic of the Seven United Provinces, which was afterwards generally called Holland, from that province, which exceeded the others in extent, population, wealth, and influence. Though Philip III. was obliged to conclude, in 1609, a thirteen years' truce, called the peace of Antwerp, and the independence of the provinces was recognised by all the European powers except Spain, it was not fully secured till the peace of Münster, at the close of the Thirty Years' War, in 1648. Towards the end of the seventeenth century, they were engaged in war with France and England, and at the beginning of the eighteenth century, in the war of the Spanish succession. Holland was weakened by these efforts, while republican jealousy of the attempts of the House of Orange to increase its authority sowed the seeds of party rage and civil war. In 1747 the House of Orange triumphed, and William IV. obtained the hereditary dignity of stadtholder in all the seven provinces. In 1795 the republicans again raised their heads, but the wife of the

stadtholder William V., who was sister to Frederic William II., king of Prussia, having been insulted by some violent patriots, applied to her brother, who sent a Prussian army of 25,000 men to avenge the indignity she had received, and secure the rights of her husband. The patriots resisted in vain; the rights of the House of Orange were confirmed and enlarged, and a close alliance concluded between the republic and Great Britain and Prussia. In 1794 the republican or Anti-Orange party, encouraged by the approach of the victorious armies of France, again rose. Pichegru easily conquered Holland, being favoured by the severe winter and by the popular party, and the stadtholder, with his family, was obliged to fly to England. The provinces were now organised under the title of the Batavian Republic. A necessary consequence of this change was war with England, which led to the capture of their fleets, the destruction of their trade, and the loss of their colonies, to all which evils were added the exorbitant demands of their French allies, who also changed several times the constitution of the republic. In 1806, it was formed by Napoleon into a kingdom, and given to his brother Louis, who studied the welfare of his subjects, but lost the friendship of his brother after the landing of the English, and unexpectedly resigned the crown in favour of his eldest son, a minor, on the 1st of July, 1810. Napoleon however refused to recognise his brother's arrangement, and incorporated the kingdom with the French empire, with which it remained united till November, 1813, when the people, encouraged by the disasters of the French, rose and expelled them from the country, and recalled the Orange family. The Prince landed from England on the 30th of November, 1813, and was welcomed with a delirium of joy which seemed to be marvellous in so cool and phlegmatic a people. The prince governed the country by the title of 'Sovereign Prince,' till 1815, when the seven northern and the ten southern provinces, after a separation of two hundred years, were again united, by the name of the Kingdom of the Netherlands, a grand and noble conception, destined to accomplish the object which England had so long attempted,—the union of all the provinces in one independent state, calculated to serve as a real barrier against France. This union continued for fifteen years, to the advantage of both countries, and especially of the Belgians, who however were not satisfied with the new state of things. In 1830, encouraged by the Revolution which had expelled Charles X. and his family from France, they revolted from their allegiance, and claimed to become an independent state distinct from Holland. This end they have at length attained, not however without the aid of France and England. The independence of Belgium is secured by the treaty concluded in April, 1839, which is guaranteed by Great Britain, France, Austria, Russia, and Prussia.

Literature, &c.—It is not a little remarkable, that of a people whose shores lie opposite our own, and whose national character likewise runs in many respects parallel with ours, who have been animated by a similar spirit of industry, commercial enterprise, and maritime ardour—even the language should be hardly at all known in this country, notwithstanding the study of it is calculated to throw so much light upon our own, which has not only the same common origin, but has immediately borrowed a great number of words and expressions from it. So far from meriting that contempt with which the insolence of ignorance has braided them, there are few nations which have contributed more towards the civilization of Europe, and to learning and science, than the people of the Netherlands. The country that has produced an Erasmus and a Grotius, a Swammerdam, a Leeuwenhoek, and a Boerhaave; that has done so much for the physical sciences, for medicine, jurisprudence, philology, classical and oriental literature; that can boast of such writers as a Vondel, and in our times a Bilderdijk; that has done so much for the cultivation of its language; that possesses so many literary societies and institutes, together with others for the encouragement of the fine arts,—ought not to be stigmatised as one inhabited by a dull plodding race of merchants. One circumstance, which, if it has served to diffuse over Europe the labours of its learned men, has also merged their celebrity in that of continental literature generally, has been the practice of employing Latin, a circumstance which has rendered an acquaintance with the Dutch language unnecessary for the purpose of profiting by their studies or their discoveries. Most probably too the universal celebrity of the Dutch

scholars throughout the learned world has in no small degree tended to divert attention from and excite a prejudice against the vernacular language and literature, as being rude and uncultivated, and unfitted for any nobler purpose than that of carrying on the intercourse of daily life. Yet so very far is this from being the case, that there is scarcely any modern tongue which either contains within itself more plastic elements or which has been more carefully wrought up and polished; nor have any people paid greater attention to purity of style and elegance of diction than the writers of Holland of late years. It cannot be said that the difficulty of acquiring it has deterred us from attempting to form any acquaintance with the literature of this country; because, of all foreign idioms, it is that which bears the strongest family resemblance to our own—so much so, that flippant and ignorant travellers have sometimes described it as a sort of bastard English, which is just as correct as it would be for a Hollander to call English a bastard jargon of Dutch. Those who have picked up a few commonplace phrases, and decide that the language in which Vondel wrote is a barbarous one, would be capable of pronouncing with equal effrontery that the language employed by Milton is altogether rude and unpolished, if they judged of it only as they could make out what was said to them by innkeepers and postillions. It certainly has its defects, but they are those of our own language, which sounds equally harsh to Southern ears, and is condemned as being clogged with consonants and abounding in monosyllables.* At the same time it possesses far greater homogeneousness, and, like the German, the power of combining out of its own elements and roots that class of words which we borrow immediately from the Latin and the Greek; for instance, *onnavolgbare*, 'inimitable,' *vereenigen*, 'to unite,' *veelomvullende*, 'comprehensive,' &c.; whereas we have only a very few of the kind, such as 'unchangeable,' wherein the Saxon root is employed. Hardly indeed is an Englishman a fair judge in such a case, because, while familiarity with them blinds him to the deficiencies and imperfections of his own language, his prejudices are shocked by one which is at once so similar and so unlike his native tongue. An Italian would be a more impartial umpire, inasmuch as he would have no particular prepossession in favour of either. We do not say that the literature of the Dutch language contains so much to reward the student as that of Germany, but it certainly contains a very great deal, and much too that is equally or even more worthy of finding translators in this country than many of the productions which have been imported from Germany into our own literary market; and by way of specifying at least something rather recent worthy of appearing in an English dress, we may mention the 'Plinius Secundus' and the 'Messala Corvinus' of Van Hall. There is indeed a current of sound and healthy feeling in the literature of Holland, which, but for our extravagant prejudices, would have recommended it to the sympathies of our countrymen. That devotional fervour and that regard for the hallowing influences of domestic life, together with nobleness and independence of spirit, which pervade so many of the higher poetical productions of that country, would at least, it might be imagined, secure them some attention among ourselves.

After indulging in the preceding remarks, it may perhaps be deemed somewhat inconsistent to say that we cannot attempt to give anything like a connected historical summary of the literature; yet though our limits prevent us from doing this, we have considered it important to correct popular prejudices against the subject itself, since by so doing, and pointing to it as one of considerable interest, we are likely to direct further inquiry more serviceably than by merely stating a few facts.

Although they now stand in somewhat the same degree of relationship to each other as the English and Scotch, the Dutch and Flemish languages were originally the same; the difference between them has been occasioned by that of the northern provinces having been cultivated and refined and employed in literature, while the other has continued almost stationary in its primitive rudeness. Even in the twelfth century the Dutch began to be used in public decrees and civil acts; nor was it long before writers arose

* As one instance at least that even in poetry an entire verse of monosyllables is not necessarily either rugged or poor, we may be allowed to quote a line of Darwin's, which is perhaps one of the most sonorous and energetic in our language—

'Cleaves the dark air, and asks no star but thee!'

who began to mould it into rhythm, if not always into poetry. Contemporary with our Roger Bacon, Jacob van Maerlant (1235-1300), who has been called the Father of the Poets of the Netherlands, may be said to have preceded Chaucer by an entire century, as the latter lived from 1328 to 1400. His most celebrated productions are his 'Rijmbibel' and 'Spiegel Historiaal' (or Historic Mirror). Neither was he the only writer in the language of that age; for Melis Stoke, Jan van Heln, Thomas van Ghessaert, Heijnic van Holland, and others of less note, belong to the same century. In the following one sprung up the literary societies known by the name of the 'Kamers der Rederijkers,' or 'Chambers of Rhetoric,' but which, so far from advancing poetry, rather corrupted the language itself; besides which, the party and civil dissensions that prevailed during the 14th and 15th centuries were exceedingly unfavourable to the progress of literature. It was in the last-mentioned period however that Holland distinguished itself by two most important inventions, that of oil-painting and that of printing. It is true that as regards printing rival claims to those of Haarlem in behalf of Laurence Koster have been made by both Mainz and Strasburg in favour of Guttenberg; but if even Koning's work on the subject has not completely established the former, neither are the arguments hitherto adduced to the contrary sufficient to completely invalidate them.

Of the services of Erasmus both to letters and to religious liberty, or of the share which Holland took in the Reformation, it is not our purpose to speak; neither can we bestow any notice on those writers of the 16th century who obtained celebrity by works of crudition or science. The period we now arrive at may be considered as not merely the dawn but the morning of Dutch literature; and one of the first who contributed towards purifying and refining the native tongue was Dirk Volkertsoon Koornhert, who was born at Amsterdam in 1522, and became private secretary to the States of Holland in 1572. Among other contemporary names of note appear those of Philip van Marnix, Peter Heijns, Spieghel, and Roemer-Visscher. The last-mentioned has been styled the Martial of Holland, but he is now chiefly indebted for celebrity to the fame of his daughters Anna and Maria, who, on account both of their learning and poetical talents, obtained the title of the 'Dutch Muses.' By the end of the century a new generation had begun to spring up, who not only greatly surpassed all their predecessors, but suddenly advanced both the language and literature in an extraordinary degree. The æra from the commencement of the seventeenth century to 1679, the time of Vondel's death, comprises some of the most illustrious names in the literary annals of Holland—those of Hooft, Cats, Decker, Kamphuyzen, Anso, and Antonides van der Goes. Referring to the respective articles in this 'Cyclopædia' for some biographical account of the three first-mentioned, we shall briefly sum up their literary merits. It is difficult to decide whether the prose or the poetical compositions of Hooft did most for the refinement of the language. His versification is particularly fluent and melodious, and, as far as his own talent is concerned, his poetry may deserve the preference; yet, by cultivating a prose style, he furnished a model which was then most wanted. Together with Vondel, he may be considered the chief founder of the Dutch tragic theatre. Of Cats it is difficult to comprise an adequate eulogium in a few words; yet, if ever there was a truly national and popular writer—one who has addressed himself to all the best feelings of his countrymen—one whose works are prized by all classes for whom he wrote—that writer is 'Father Cats.' The popularity which his works enjoy is as honourable to the character of his countrymen as to his own fame, for a vein of morality, benevolence, and strong religious principle runs through them all. If Decker's poems are not of the highest class on account of their subjects, they exhibit superior talent, and contributed very much to the improvement of the language. Kamphuyzen's productions display great poetical power, both in regard to the ideas and the expression, and his religious pieces breathe intense devotional ardour. Reinier Anso was greatly admired in his own time and praised for his talents by Vondel himself; and even now his poems may be perused with interest, especially his 'Pest tot Napels' (or Plague at Naples), the horrors of which are described by him with great power.

Before we come to speak of Vondel himself, there are several names which it would be unjust to pass by wholly

in silence, although they did comparatively little for the native literature of their country, their reputation being based chiefly upon their Latin productions. Huig de Groot, Dan. Heins, Kasper van Baerle, may seem strangely obscure names, but those of Grotius, Heinsius, and Barlaeus are certainly—the first two at least—of European celebrity. Constantine Huygens was not one of the least gifted or least remarkable writers of this period, since nearly all his productions are stamped by originality both of thought and expression. He was employed upon missions to various courts, and came over to this country on one to Charles II., and afterwards, although then greatly advanced in years, visited Italy, chiefly for the purpose of beholding Vauluse. Jan Vos, originally a glazier at Amsterdam, where he was born in 1620, was a man of some ability as a dramatic writer, but his taste was by no means equal to his talent, for his 'Aran en Titus' and his 'Medea' are filled with extravagances; yet his versification is masterly, and some of his comic pieces possess strong humour. The two daughters of Roemer-Visscher have already been named, but some few particulars relative to them may be acceptable. Anna, the elder of them, was highly esteemed both by Cats and by Grotius, the latter of whom translated into Latin her poem on his escape from prison. Maria, the younger, and by far the more gifted, was not only one of the most learned, but one of the most accomplished females of the age, nor was she less admirable for the excellence of her disposition. She enjoyed the friendship of Hooft, Vondel, Huygens, and other eminent literary men. Her poems have much merit, and a translation by her of Tasso's 'Jerusalem' was greatly extolled by her friends, but appears to have been never completed nor published.

Referring for fuller particulars to the article VONDEL, we can now merely take a glance at one of whom Holland has just cause to be proud, for never has poetic genius displayed itself more forcibly or with greater sublimity than it does in all his best productions. He was one of those superior spirits who give celebrity to their country and to their age; and if Camoens singly has sufficed for the literary glory of Portugal, Vondel alone would be sufficient to confer fame upon the land which, if it did not actually give him birth—for he was born at Cologne—was that which reared and cherished him. His tragedies are confessedly his master-pieces, not that they exhibit much of dramatic quality, of action, character, and passion, but rather on account of the lofty strains with which they abound, more especially in the chorusses, they being all moulded upon the ancient model, and some of them, such as his 'Lucifer,' 'Adam in Ballingschap,' 'Abraham,' 'Jephtha,' not at all adapted to the stage, on account of their subjects. They therefore may be characterised rather as dramatic oratorios without music than as dramas. Among his productions of this class his 'Lucifer' stands pre-eminent, and has given rise to comparison between the genius of Vondel and that of Milton; it may therefore be proper to observe that it preceded 'Paradise Lost' by fourteen years. As may be supposed from what has above been said, his odes and lyrical pieces abound in beauties; but he was scarcely inferior as a satirical poet, in which character however he displays far more of the spirit of Juvenal than of Horace. Defects avoided by far inferior writers may be detected in all his productions, but his merits are of first-rate order.

Jan Antonisz, or Antonides van der Goes, who belongs not only to Vondel's time, but also to his school, having been his friend and pupil, was gifted with great power of imagination, and his 'Ijstroom' is considered one of the best descriptive poems in the language. Of his two friends Dirk Buysero and Jan Pliymet, the former was rather the patron of literature than a writer by profession, but he wrote several dramatic pieces; the latter was director of the theatre at Amsterdam, and author of 'Ines de Castro' and some other tragedies.

Towards the close of the seventeenth century, French literature began to find imitators, and for a short time originality was checked. Vollenhove, another literary friend of Vondel's, author of the sacred poem entitled the 'Kruisstrijf' (or Triumph of the Cross) and of some miscellaneous poems (1685), was still living; as was likewise Lucas Rotgans, who had produced an epic poem, of which our own William III. was the subject, and two tragedies, which have been highly extolled by Van Effen. Elizabeth Hoffman, or, according to her marriage

name, Koolaert, may be included among the writers of this century, having been born in 1664. This lady would deserve notice were it only as one of the most learned women not only of her own but of almost any age or country. In her sixteenth year she made translations from Anacreon and Horace; and was so well skilled in Latin as to compose several poems in that language, while her ability in her own is proved by that entitled the 'Schowburg der Verwoesting,' in which she eloquently moralises on the transitoriness of all worldly grandeur, and of which the versification is no less smooth and flowing than the ideas and images are striking.

The first half of the eighteenth century was marked by the productions of Van Effen and those of Poot, Hoogvliet, Schim, Feitama, De Marre, Steenwijk, and Langendijk. Scarcely to any one is the prose literature of Holland more indebted than to Justus van Effen, who has, without any great exaggeration, been styled the Dutch Addison, not only as being a distinguished essay-writer, but on account of the terseness and elegance of his style. His 'Hollandsche Spectator' has deservedly taken its place as a classical work in the language, as a model both of style and correct taste. Hubert Corneliszoon Poot was another writer of much originality and talent, and obtained great popularity by his comic poetical tales, which, like those of Wieland, are chiefly founded upon mythological subjects. Arnold Hoogvliet, on the contrary, took a higher flight: he aspired to the sacred epic, and took for his subject the history of Abraham. Notwithstanding its defects, this poem displays genuine talent; the versification is masterly, and many of the descriptions and other passages both powerfully and finely touched. He had also previously distinguished himself by a clever translation of Ovid's 'Fasti.' Hendrik Schim was also a writer of religious poetry, viz. 'Bijbel-poesie,' 1723; 'Bijbel en Zededichten,' 1726; and 'Heerlijkheid van Christus,' 1731, &c. If not gifted with superior talent, Sybrand Feitama was a poet of most extraordinary patience and perseverance, for he spent upwards of thirty years upon his translation of Fénelon's 'Telemaque' into verse, and full twenty more on that of the 'Henriade.' In his own day his reputation was very considerable, nor was it wholly undeserved, for he certainly did much towards perfecting the mechanical part of poetry. He also produced two tragedies, 'Titus Vespasianus,' and 'Romulus,' besides translations of eleven others from the French, of which language he was a great admirer.

Jan de Marre, a seaman by profession, who, upon his return from a voyage to the East Indies in 1731, was appointed superintendent of the public buildings at Amsterdam, contributed to the Dutch stage one of its best and most popular tragedies, namely, 'Jacoba van Beijeren.' He also wrote a poem in six books entitled 'Batavia,' besides a variety of miscellaneous pieces. Peter Boddaert, a juriconsult, antiquary, and secretary to the admiralty, obtained repute as a writer of religious and moral poetry, and also adapted Crebillon's 'Thyestes' to the Dutch stage. Frans von Steenwijk, the pupil of Feitama, published in 1748 his religious heroic poem of 'Gideon,' the plan of which is greatly superior to the execution, if we except the style and versification. Almost about the same time, viz. 1752, another poem of the same class, on the subject of the patriarch Jacob, was produced by Frederick Duim, who also wrote several pieces of religious poetry. Peter Langendijk, originally a damask-weaver by trade, was one of the principal comic dramatic writers of this period; and that he possessed a natural genius for comedy can hardly be denied, when it is known that his 'Don Quixote,' which is still a stock-piece of the Dutch stage, was composed by him at the age of sixteen, though afterwards considerably improved. His 'Alexander the Great,' in which a countryman is served as Christopher Sly was, and made to believe, on waking, that he is the Macedonian hero, is highly comic, though defective from its want of interest in the plot. He also wrote several humorous poems and parodies—rather coarse in taste, among which may be mentioned 'Æneas in his Sunday Coat.' Dirk Smits, author of an excellent imitation of Pope's 'Eloisa to Abelard,' was, if not a forcible, a pleasing poet in his original compositions, which are chiefly of the lyric class. His friend Adrian van der Vliet wrote pastoral poetry.

Coming to those who, for convenience sake, may be considered as another generation, for some of them might with equal propriety have been introduced above, we have now to pass in review the writers who fall within the latter half

of the eighteenth century, reserving till afterwards such as have distinguished themselves chiefly in the present. The first names to be mentioned are those of William and Onno van Haren, two brothers of noble family, whose productions make an epoch in the poetical literature of their country, by their originality and spirit, which stamp them as of a quite different class from the school of Feitama. The 'Friso' of William van Haren is a romantic epopœia, founded upon old chronicles and legends of Friesland, and full of adventures, the scene of which commences in India. This poem has, with many defects, many striking beauties also, many interesting scenes and episodes, much graphic description, and further contains many noble sentiments and moral reflections. William van Haren also distinguished himself as a lyric poet; but considerable as his talents were, they were greatly surpassed by those of his brother. Onno Zweier van Haren filled, at various times, many high posts in the state, but his highest title to fame now rests upon his 'Geuzen' (first published in 1769, under the title of 'Het Vaderland'), which is not so much an epic as a cycle of national poems celebrating the leading events in the history of the Netherlands. Upon the whole, this production is the chef-d'œuvre of the Dutch literature in the eighteenth century. It has gone through many editions, one of which was edited with a volume of commentaries, by Bilderdijk, in 1825. Lucretia Wilhelmina van Merken, or Madame van Winter, the most distinguished female poet of the century, acquired great reputation by her 'David' and her 'Germanicus,' the latter of which is said by De Vries to be greatly superior to the other, while a contrary opinion is expressed by Van Kampen, who remarks that there is more of poetic power in the touches of Tacitus. Her husband Nicolaas Simon van Winter was also a poet of considerable ability, who published a collection of fables and other pieces, two tragedies, and 'De Jaargetyden' (1769), an imitation of Thomson's 'Seasons.'

Like Madame van Winter, Jan Nomsz attempted epic, choosing for his hero William I., but with inferior success: in his tragedies he displayed more talent. His 'Ledige Uuren' (Leisure Hours) establish Lucas Trip's claim to notice as a writer of religious and moral poetry; in which class of subjects his friend Johannes Eusebius Voet (who was by profession a physician) likewise distinguished himself.

If we could here speak of him as fully as he merits, Bellamy would detain us for some time, for he was not only a genuine poet, but he gave a fresher and more energetic tone to Dutch literature, and was almost the very first who ventured to shake off rhyme. Admiration of his genius is not lessened by knowing that until rescued from that situation by the liberality of other patrons, who took the charge of his education, he was originally apprenticed to a baker; or that what he actually did was only the promise of what he would have done, had he not been cut off when scarcely twenty-eight years old. Bellamy's is perhaps the only poetry which the Germans have transplanted from the literature of Holland into their own.

About the same time that his country lost the no less amiable than highly gifted Bellamy, it also lost, in the Baroness Cornelia Juliana De Lannoy, an accomplished woman, whose tragedies are extolled by De Vries as very superior to any similar productions by her contemporaries. Kastelyn, who was a man of considerable attainments in chemistry, distinguished himself also in poetry, especially by his didactic poem called 'Geloof aan de Voorzienigheid' (Trust in Providence), in which there is a tone of tender melancholy and resignation that recommends it to those who, like himself, have been schooled in affliction. Of Nieuwland [NIKUWLAND] we shall here only observe that he was scarcely inferior to Bellamy, while he resembled him in many of the circumstances of his life, its premature end not excepted. His poetical talents constitute but a small share of Van Alphen's claim to fame, for as a moralist, a philosopher, and a critic, he was no less distinguished. Admirable in themselves, his Cantatas have the further merit of being the first productions of the kind in the language, and are still unrivalled in it.

The two attached friends Elizabeth Bekker (Wolff) and Agatha Deken, both of whom died on the same day, may be considered as the first who introduced the modern novel into Holland, their productions of which class were eminently successful, and some of them were translated into German. Petronilla Moens was another female author in the same branch of literature, but she possessed less truth to nature. In the drama and likewise in history and biography, Simon

Stijl was a popular writer, more especially in the last-mentioned class of composition. Peter Leonard van de Kastelee, the pensionary of Haarlem, and Van Alphen's friend, showed considerable poetical talent, both by his original compositions, chiefly on religious and devotional subjects, and his translations from Klopstock and Wieland, besides his version of Ossian in hexameter verse. As a humorous and satiric writer, Arend Fokke stands without a rival in the language, and is styled by Van Kampen the Callot and Hogarth of Dutch literature, a distinction to which he is well entitled by his 'Boertige Reize' (Comic Journey through Europe), his 'Ironical Comic Dictionary,' &c.; while his 'Catechisms of the Arts and Sciences,' in 11 vols., show him to have been also a man of solid and extensive information.

Rhynvis Feith, Helmers, and Bilderdijk, are writers of whom any country might be proud. Both as a poet and as a critic, Feith is entitled to admiration. His 'Grave' (which first appeared in 1792, and has been translated into German), is a masterly production, with equal beauties and perhaps fewer defects than Young's 'Night Thoughts.' His 'Thirza,' 'Lady Jane Grey,' and 'Inez de Castro,' exhibit his powers as a tragic poet; while his 'Letters,' his 'Essay on Heroic Poetry,' &c. place him in a high rank as a prose writer. Helmers, a merchant by profession, affords a striking proof that the pursuits of commerce are not uncongenial to or incompatible with those of literature and taste, since, apart from their other merits, his poems breathe the most noble and generous sentiments, and are replete with striking ideas and imagery. Of Bilderdijk, one whose varied powers exhibited themselves with equal success upon the most opposite subjects, to attempt to speak here appears almost an injustice, since we have no space even to particularise any of his numerous productions, except it be to express regret that so fine a poem as his 'Ondergang der eersten Wereld' (the Destruction of the first World) should never have been continued beyond the fifth book. Kinker, who, though born in 1764, is, we believe, yet living, is another excellent poet, and has produced admirable translations of Schiller's 'Maid of Orleans' and 'Lady Jane Grey.' Loots, Loores, Tollens, Immerzeel, Van Hall, Da Costa, Van Lennep, all of them still or till very lately living, are writers who do honour to the literature of their country, which has recently lost in Van Kampen its historian, one to whose labours we are indebted for much of the information contained in this article, or rather which is here merely pointed at. To those who care for more than the necessarily imperfect outline of the subject here presented to them, we can recommend Van Kampen's 'Beknopte Geschiedenis der Letteren,' &c. as a most interesting guide in the study of the literature of the Netherlands; nor does he confine himself to the literature alone, but takes a view of all that his countrymen have achieved in every branch of science; and if territorial extent, and we may add population, can be taken as a standard in such matters, the Netherlands have certainly contributed infinitely more than their share towards the general civilization and enlightenment of Europe.

The table here appended, which might have been made much more complete, will be useful as a chronological map, wherein are supplied, as far as authority for them could be found, those dates which are not mentioned in this brief historical sketch. It is arranged according to the dates of the deaths.

	Born.	Died.
Brederode	1585	1618
Roemer-Visscher		1620
Kamphuyzen		1626
Groot, Huig de (Grotius)	1583	1645
Hooft, Pet. Corn.	1581	1647
Roemer-Visscher, Maria	1594	1649
Anna	1584	1651
Heinsse, Dan. (Heinsius)	1580	1655
Brune, Jan de	1585	1658
Cats, Jacob	1577	1660
Van der Veen		1660
Dekker, Jeronias	1610	1666
Anso, Reinier	1629	1669
Vondel, Joost van	1587	1679
Antonides van der Goes, Jan	1647	1684
Branda, Gerard	1626	1685
Bartholomaeus, Constantine	1596	1686
Brodthuis, Jan	1649	1707
Vollenbore, Jan	1631	1708

	Born.	Died.
Rotgans, Lucas	1645	1710
Poof, Hubert Corn.	1689	1733
Van Effen, Justus	1684	1735
Hoogvliet, Arnold	1687	1735
Schim, Hendrik	1695	1742
Smits, Dirk	1702	1752
Boddaert, Peter	1694	1760
Marre, Jan de	1696	1763
Feitama, Sybrand	1694	176*
Steenwijk, Frans		1772
Voet, J. Eusebius		1778
Van Haren, Willem	1710	
Onno	1713	1779
Nomsz, Jan		1779
Van der Vliet	1702	1780
De Lannoy, Jul. Cornelia	1738	1782
Trip, Lucas	1712	1783
Bellamy, Jacob	1758	1786
Kasteleyn	1750	1793
Nieuwland, Peter	1764	1794
Van Merken, Lucretia	1722	
Van Wiuter	1718	1795
Bakker, Huizinga	1718	1801
Van Alphen	1746	1803
Bekker, Eliz.	1738	1804
Deken, Agatha		1804
Stijl, Simon	1731	1804
Kastelee, Pet. Leon.		1811
Fokke, Arend	1755	1812
Feith, Rhynvis	1753	
Helmers, Jan Fred.	1764	1813
Moens, Petronilla	1753	
Bilderdijk, Will.	1756	1813
Van Kampen		1839
Loots, Cornelius	1764	
Kinker, Johan	1764	
Loosjes, Adrian	1762	
Tollens, Hendrik Corn.	1780	

NETSCHER, CASPAR, was born in 1619, at Heidelberg, from which place his family removed to Arnheim. In this city he was adopted by Dr. Tullekens, a rich physician, who placed him first under Koster, a painter of poultry and dead game, and afterwards under Gherard Terburg, at Deventer. He afterwards set out on his travels, intending to pass some time in Italy, but he got no farther than Bordeaux, where he married, and after the birth of his eldest son, in 1661, returned to Holland and settled at the Hague.

C. Netscher was one of the best painters of the Dutch school on a small scale. The necessity of providing for a numerous family obliged him to devote a considerable portion of his time to portrait-painting, in which he acquired great reputation, though he had talents for higher departments of the art. His most admired works are his Conversation pieces. His colouring is true to nature. He was a perfect master of chiaro-scuro; his touch is extremely delicate; above all, he is remarkable for his skill in representing linen, white satin, silks, and velvet, the draperies of which are cast in large and elegant folds. All the accessories, the furniture, ornaments, Turkey carpets, &c., are painted with inimitable truth and minuteness, but still they do not divert attention from the figures, with which they form a delightfully harmonious whole. King Charles II. invited him to London, but he declined that honour, preferring the enjoyment of an established reputation in his own country. He died in 1684, aged forty-three years.

Theodore Netscher, his eldest son, who was born in 1661, was his father's disciple. He went at an early age to Paris, where he remained twenty years, highly esteemed, and acquiring considerable wealth by possessing the happy art of taking an agreeable likeness. He was employed to paint a vast number of portraits of the principal persons about the court, especially the ladies.

In 1715 he came to London as paymaster of the Dutch forces, and was introduced to the court by Sir Matthew Decker. He remained in England six years, and acquired large sums of money by his painting. After his return to the Hague he lost a considerable sum through some deficiency in his accounts, and retired in disgust to Halst, where he died in 1732.

Constantine Netscher, the second son of Caspar, born in 1670, closely imitated the style of his father, many of whose portraits he copied in order to form his hand, but he did not

neglect the study of nature. He attained to a high degree of excellence, and was earnestly solicited by the duke of Portland, whose portrait he had taken, to go with him to England, but he was too infirm to undertake the voyage, being severely afflicted with the gravel, which at last carried him off, in 1722, at the age of fifty-two years.

NETTLE, a name applied to various plants. The true Nettles are various species of the genus *Urtica*, well known for their stinging properties, which are owing to the presence of an acrid poisonous secretion, that in some Indian species is so dangerous as to cause excruciating pain and even death. Dead-nettles are species of *Lamium*, monopetalous plants belonging to *Labiata*, and wholly inert. The Nettle-trees belong to the genus *Celtis*, also destitute of stinging properties, but having leaves resembling those of some kinds of *Urtica*.

Notwithstanding the acidity of the true Nettles, they are, when young, used for food, after being boiled, and form a favourite and wholesome ingredient in the spring-broth of the country-people in many parts of England, especially in Yorkshire. They also yield a tough fibre which may be used as a substitute for hemp; one of the species is indeed named *Urtica cannabina*, in consequence of its resemblance to *Cannabis*, or hemp, in the uses to which it is applied.

NEUBECK, VALERIUS WILHELM, born at Arnstadt in Thuringia, January 21, 1765, studied at Göttingen and Jena, at which latter university he took his degree as doctor of medicine, and practised first at Liegnitz, and afterwards at Steinau. His only professional production was his thesis 'De Natatione frigida, magno Sanitatis Præsidio;' it being as a poet that he acquired his literary reputation, chiefly however by his didactic poem entitled 'Die Gesundbrunnen' (or Mineral Springs), a production that has been greatly extolled by Schlegel as the very best that had then appeared in the language, enriched with admirable descriptions and imagery, and one in which the German hexameter verse is treated with the greatest ability. It was first published at Breslau, in 1795, and in 1798 a splendid folio edition of it appeared at Leipzig. Among his other productions is a translation of Dr. F. Sayer's 'Dramatic Sketches of the Antient Northern Mythology,' and several contributions, both in prose and poetry, to various literary journals.

NEUBURG, sometimes called **NEUENBURG**, is a well-built town in the Bavarian circle of the Upper Danube, agreeably situated on an eminence on the Danube, and opposite to an island which is connected with the town by a bridge. Among the public buildings are a large handsome palace, which contains the great hall, with a collection of antient armour; a college, formerly belonging to the Jesuits; a rich library, a collection of antiquities, a gymnasium, extensive barracks, the church of St. Peter, with a wonderful image of the Virgin, two other churches, an hospital, and an orphan asylum. Neuburg is the seat of a court of appeal, and of the courts of justice of the circle and the town. The inhabitants, who are 6000 in number, have considerable breweries and distilleries, a manufactory of earthenware, and a flourishing trade. In the neighbourhood are the royal country-seats of Grunau and Petzelheim, the royal stud at Rothenfeld, and, near the village of Unterhausen, the monument erected in honour of Latour d'Auvergne, 'the first grenadier of the French army,' who lost his life there, by the wound of a lance, on the 27th of June, 1800. Neuburg was formerly the residence of the palgrave, and the capital of the antient principality of Neuburg, called also the younger palatinate, which, in 1794, consisted of several detached portions, amounting together to 1050 square miles, with 96,586 inhabitants, chiefly Roman Catholics. It yielded a net revenue of 136,000 florins. At the beginning of the sixteenth century it was allotted to a separate line of palgraves, which was divided into the branches of Neuburg and Sulzbach. The elder line, that of Neuburg, succeeded in 1685 to the electorate of Bavaria, and became extinct in 1742, on which the younger branch of Sulzbach inherited both the principality of Neuburg and the electorate.

There are several other towns, of less importance, of the same name in different parts of Germany.

NEUFCHÂTEAU. [Vogues.]

NEUFCHÂTEL. [Suisse romande.]

NEUFCHÂTEL (generally written *Neuchâtel*, but called *Neuenburg* by the Germans), a canton of Switzerland, situated in the Jura mountains, which here form several

parallel narrow ridges running in the direction of north-east to south-west, and separated by elevated longitudinal valleys. The greatest length of the canton is about thirty-one miles, from the Verrières, on the frontiers of France, on the road from Pontarlier to Neuchâtel, to Le Pasquier at the north-east extremity of the Val de Ruz, on the road to the Val d'Imier, in the canton of Bern; its greatest breadth, from the lake to the river Doubs, on the French frontier, is about thirteen miles direct distance. Its area is reckoned at about 250 square miles. It is bounded on the west by the French department of Doubs, the river Doubs forming the boundary along one part of the line; on the south by the Canton de Vaud, on the east by the lake of Neuchâtel, and on the north by the canton of Bern. The canton is naturally divided into three regions: 1, the 'Vignobles,' being the banks of the lake, the level of which is 1400 feet above the sea, and the lower hills which rise immediately above, and are planted chiefly with vines; 2, the 'Vallon,' or the two fine valleys, Val de Travers and Val de Ruz, which run between two parallel ridges of the Jura, and rise from 2000 to 2400 feet above the sea; they produce corn, pulse, and fruits; 3, the 'Montagnes,' or highlands of the Jura, nearer to France, consisting of some naked and some wooded ridges, with high bleak valleys intervening, which are known by the names of La Chaux de Fond, Locle, Chaux du milieu, La Brevine, and La Sagne; they are nearly 3000 feet above the sea, and produce little else than grass, but have become the seat of manufacturing industry, especially watchmaking and jewellery. The highest summits in the canton of Neuchâtel rise to about 4000 feet above the sea, but their visible elevation, as seen from the neighbouring valleys, is not striking, the whole country being highland.

Nearly one half of the surface consists of pasture-land or artificial meadows; one-eighth is arable land, another eighth is forest, and about 5000 acres are planted with vines. The wines of Neuchâtel are the best in Switzerland; the red wine of Cortailod is equal to good Burgundy. Three-fifths of the wine are exported. The rearing of cattle and making of cheese constitute two other important branches of rural industry. According to recent returns there are about 16,000 head of large cattle, 7500 sheep, 7200 goats, and 2200 horses and mules. Honey is made in considerable quantity.

The population of the canton in 1837 amounted to 58,616, of whom 14,534 were natives of other parts of Switzerland, and 3214 strangers from other countries. Neuchâtel is one of the few countries where foreigners enjoy the same protection and security as the natives, are subject to the same laws without distinction of country or religion, and can form a settlement and purchase property; they do not however possess all the rights of citizens unless they become naturalized, which is easily effected. Of this population about 10,000 are employed in agriculture, 7000 are watchmakers, and between 3000 and 4000 are employed in cotton and linen manufactories. The women, especially in the Val de Travers, are employed in the manufacture of lace. The common trades, such as those of carpenters, masons, bakers, tailors, and shoemakers, are chiefly carried on by foreigners, as the natives prefer employing themselves in watchmaking and other ingenious industry. The religion of the people is the Protestant Calvinist, with the exception of about 2000 Catholics, who live chiefly in the district of Landeron. The language is French, which is spoken correctly by educated people, but the country-people speak various patois resembling those of their neighbours of Franche Comté and of the Canton de Vaud.

Neuchâtel, the capital, is built partly on the bank of the lake and partly on two hills divided by the river Seyon, which comes from the Val de Ruz. It contains 667 houses and 6300 inhabitants. On one of the two hills is the castle, which was built in the thirteenth century, and near it the cathedral, which dates from the tenth, and contains the tombs of the antient counts of Neuchâtel, and of Fare', who established the Reformation at Neuchâtel. In the lower town are the hôtel-de-ville, or town-house, which is very handsome, and the hospital for the burgesses, the orphan asylum, the hospital founded in 1810 by Pourtales the wealthy merchant, and a fine college, which was completed in 1835, and contains a public library and a cabinet of natural history. The lower town, generally speaking, is well built, and has a fine appearance when seen from the lake. Neuchâtel has several elementary schools, a savings'

bank, an insurance company, a bible society, and a missionary society. There is no other town of any importance in the canton, but there are many large villages, and the valleys of the Loche and La Chaux de Fond contain a great number of scattered habitations occupied by manufacturers.

Neufchâtel is a principality of which the king of Prussia, as representative of the house of Brandenburg, is the sovereign prince, but it has a representative assembly or legislative body consisting of eighty-five members, of whom seventy-five are returned by the electors of the various districts, and ten are named by the prince. They are appointed for six years. All the native or naturalized subjects of Neufchâtel who are twenty-two years of age, and not paupers or bankrupts, are electors. The candidates for the legislative body must be possessed of landed or house property of the value of 1000 francs. The laws are proposed by the executive, and also by the members of the legislature. The king or his representative gives or refuses his sanction to the bills which have passed the legislature. All the officers in the administration must be natives, except the governor, who is generally a Prussian officer of rank, and receives a salary of 10,000 francs annually. The civil list of the prince amounts to 70,000 francs.

The county of Neufchâtel was a fief of the old kingdom of Burgundy, and it had its line of counts until A.D. 1288, when it passed into the house of Châlons, from which it came into that of Longueville. Mary duchess of Nemours, the last of this house, dying in 1707, Frederic I., king of Prussia, claimed the succession as heir of the house of Châlons, and the assembly of the three estates of the county recognised his claim. Bonaparte obliged the king of Prussia to surrender Neufchâtel in 1806, and he gave it to General Berthier, but in 1814 the county returned to the allegiance of the house of Brandenburg, and it was at the same time received as a canton into the Swiss confederation, of which it had already been for a long time an ally.

The *Lake of Neufchâtel*, called also the *Lake of Yverdon*, is twenty-five miles in length from north-east to south-west, and about five miles in its greatest breadth; but it is much narrower in its southern part, being not quite two miles wide near the town of Yverdon, which is at its south-west extremity. Its greatest depth towards the middle is about 400 feet. Its feeders are, 1, the river Orbe from the south-west, which has its source in the Jura, and crosses a great part of the Canton de Vaud; 2, the Broie, which comes from the lake of Morat in the canton of Friburg; 3, the Reuse, which flows from the Val de Travers in the canton of Neufchâtel; and 4, the Seyon, which comes from the Val de Ruz, also in the same canton. The outlet of the lake of Neufchâtel is the Thiele at the north-east extremity, which carries its waters into the neighbouring lake of Biemme, from whence there is an outlet into the river Aar. [BIENNE.] The lake of Neufchâtel abounds with fish. A steam-boat of 20-horse power plies on this lake, and proceeds also by the Thiele into that of Biemme as far as the town of that name, and occasionally it also ascends by the Broie into the lake of Morat. The country lying between these three lakes is called Seeland, and is mostly low, and in seasons of great floods part of it is inundated, so as to form only one lake. This was the case in 1816. The basin of the lake of Neufchâtel belongs to the water-system of the Rhine, and is divided from that of the lake of Geneva by the ridge called Jorat, which runs from south-east to north-west, through the centre of the Canton de Vaud. The level of the lake of Neufchâtel is nearly 200 feet above that of the lake of Geneva. (Leroche, *Dictionnaire Géographique de la Suisse*.)

NEUHAUS (in Bohemian, *Gindrichu Hradec*) is a well-built town in the circle of Tabor, in Bohemia, 68 miles south-south-east of Prague. It is the chief place of a lordship belonging to Count Czerny, whose palace is a very magnificent edifice. It has one of the finest churches in Bohemia; a gymnasium, which formerly belonged to the Jesuits; a school; and extensive manufactories of woollens, linen, paper, and playing-cards. The population of the town and suburbs amounts to nearly 6000. A great part of the town was destroyed by fire in 1801. Fine topazes are found in the vicinity.

NEUHOFF, THEODOR VON, known at one time as King Theodor, a German adventurer, was born towards the end of the seventeenth century, of the noble family of the counts of La Mark in Westphalia. His father was an

officer in the French service, and he himself obtained a lieutenant's commission in the regiment of Alsace. He afterwards went to Spain, and gained the favour of Cardinal Alberoni, who gave him the rank of colonel in the Spanish service. In Spain he married a lady of honour of the queen, whom he deserted, and carried off her jewels. He then travelled through various countries under different names and titles, Sweden, Holland, Italy, and at last was put in prison for debt at Leghorn. On coming out of prison, he met with several Corsican leaders, among the rest with the canon Oriconi, who had known him at Genoa in 1732, and he proposed to undertake the cause of the Corsicans, who were then at war with the Genoese; he spoke of his high connections and his means of being useful in various ways. The Corsicans were then in the predicament of drowning men catching at straws. Oriconi believed or seemed to believe the adventurer, and promised to use his influence to have him named king of Corsica, on condition that he should first bring substantial assistance to his countrymen. Neuhoff upon this sailed for Tunis, where he succeeded in persuading the Bey to lend him arms and ammunition, promising him in return the exclusive trade of the island and a station there for his piratical vessels. The Bey entered into his views, and gave him ten pieces of cannon, four thousand muskets, with ammunition, shoes, corn, and about ten thousand gold sequins. It is a subject of astonishment how Theodor contrived to get so much from the Moorish chief, but the fact is authentic. He sailed from Tunis on board an English vessel with his cargo and a retinue of sixteen persons, including two French officers, and several Turks, and arrived on the 12th of March, 1736, in the roads of Alesia, on the eastern coast of Corsica. In the following April the general assembly of Corsicans elected Theodor for their king, and he swore to the draft of a constitution for the new kingdom which was then proclaimed. (Botta, *Storia d'Italia*, b. 42.) The rest of the story is briefly told under CORSICA. After many vicissitudes, Theodor died in London, in December, 1756, and was buried in St. Ann's churchyard, Westminster, where the epitaph on his tombstone records the singular events of his life.

NEUILLY. [SEINE.]

NEUKIRCH, BENJAMIN, a German poet of the seventeenth century, was born at Reinke, a village in Silesia, March 27, 1665. His earlier productions partake of the bad taste which stamps that period of German literature; yet although he greatly improved after his literary acquaintance with Canitz at Berlin, and was considered a reformer in poetry during his own day, he possessed few of the requisites that recommend a writer to posterity. Hence, though deserving a notice in literary history, it is chiefly on account of having contributed to bring a new mode of writing into vogue. His poetical translation of Fénelon's 'Telemachus' may be classed with the Russian one of Trediakovsky, a work of most unenviable celebrity in the language to which it belongs. His best productions are his satires and poetical epistles. He died at Anspach, August 15, 1729, in his fifty-sixth year.

NEUKIRCHEN is a town in the Saxon Voigtland, with a population of 1200 inhabitants, among whom there are 90 manufacturers of violins and violoncellos, 40 makers of wooden and 36 of brass wind-instruments, above 30 manufacturers of catgut-strings, and 45 makers of violin bows, besides many other persons also employed in making pegs, bridges, finger-boards, &c. They have made in one year (including the village of Adorf) 6220 bundles of violin and violoncello strings, 241 dozen of stringed instruments, 177 dozen of violin bows, 109 dozen of violoncello-bows, 316 clarionets, 46 oboes, 522 flutes, 46 bassoons, 96 octave flutes, 12 piccolo flutes, 13 basson-horns, 290 French horns, 172 trumpets, 17 pair of kettle-drums, and 214 post and bugle horns.

NEURALGIA, a word of modern origin (derived from *νεῦρον*, a 'nerve' and *ἀλγος*, 'pain'), first employed by Chaussier to designate a certain class of diseases of which the characteristic symptom is a most acute pain following the course of a nerve in one or more of its ramifications, subject to paroxysms and intermissions, in most cases unattended by either heat, redness, or swelling, and often without any apparent lesion at all.

Although from the nature and causes of the affection we have every reason to believe that neuralgia must have existed in all ages, still (historically speaking) it may be called

a modern disease, as the first distinct description of it that we possess is that published by André, a surgeon of Versailles, in 1756, in his 'Observ. Prat. sur les Maladies de l'Urèthre.' He however had only met with one species, viz., *Neuralgia Faciei*, which he called 'Tic Douloureux', a name which, in popular language, it still retains; but since his time the same disease (subject only to certain local modifications) has been observed in various other parts of the body, and it is probable that almost every organ is liable to be affected by it. Chaussier has enumerated nine species (of which the three first are merely varieties of the *Neuralgia Faciei*), viz.: 1, *Neuralgia Frontalis*, which is seated in the frontal division of the first or ophthalmic branch of the fifth pair of cerebral nerves. The pain begins at the supra-orbital foramen, and extends to the forehead, the upper eyelid, the eyebrow, the caruncula lachrymalis, the inner canthus of the eye, and sometimes to the whole of that side of the face. 2, *Neuralgia Suborbitalis*, which occupies the superior maxillary nerve, or second division of the fifth pair. The pain begins at the infra-orbital foramen, and extends to the cheek, the upper lip, the alæ nasi, the lower eyelid, and the teeth of the upper jaw. 3, *Neuralgia Maxillaris*, which is seated in the inferior maxillary nerve, or third division of the fifth pair. The pain commences at the mental foramen, and either extends to the chin and lip, or else to the teeth of the lower jaw, the tongue, and the temple. 4, *Neuralgia Ilio-Scrotalis*, which occupies the ilio-scrotal nerve, or external division of the musculo-cutaneous branches given off by the lumbar plexus, and derived from the first lumbar nerve. The pain commences at the crista ilii, follows the spermatic cord, and extends to the scrotum and the testicle. 5, *Neuralgia Femoro-Poplitealis*, which is seated in the great sciatic nerve. The pain begins over the sacrum, or about the great trochanter, follows the course of the nerve down the posterior part of the thigh to the popliteal space, and thence extends along the peroneal nerve, or external division of the great sciatic, to the outside of the foot. 6, *Neuralgia Femoro-Prætibialis*, which occupies the crural nerve, given off by the lumbar plexus, and derived from the second, third, and fourth lumbar nerves. The pain commences at the crural arch, extends along the anterior and internal part of the thigh, and sometimes follows the course of the internal saphenous nerve, one of the deep-seated branches of the crural, to the inner ankle and the dorsum of the foot. 7, *Neuralgia Plantaris*, which is seated in the external and internal plantar branches of the posterior tibial nerve, or internal division of the great sciatic. The pain begins at the heel, shoots across the sole of the foot, and extends sometimes up the calf of the leg towards the knee. 8, *Neuralgia Cubito-Digitalis*, which occupies the ulnar nerve, given off by the brachial plexus, and derived from the fifth, sixth, seventh, and eighth cervical nerves. The pain sometimes commences at the upper part of the arm, and follows the course of the nerve along the ulnar border of the fore-arm to its termination in the inside of the middle, the ring, and the little fingers; sometimes only part of the nerve is affected, and the pain is confined to the humerus, or commences at the elbow. 9, '*Névrologies Anomales: douleurs ordinairement chroniques, dont le siège varie à l'infini.*' Several of these have been particularly described, and constitute so many additional distinct species:—1, *Otalgia* (described by M. Itard), which is seated in the chorda tympani, a portion of the vidian nerve, or posterior branch of Meckel's ganglion; and which is characterised by an acute pain following the course of this nerve. 2, *Neuralgia Cervicalis* is of rare occurrence: M. Bosquillon has observed two cases after opening the external jugular vein, in consequence of wounding the superficial branches of the cervical plexus formed by the anterior branches of the second, third, and fourth cervical nerves; and M. Jolly has met with another after the application of leeches to the side of the neck. 3, *Neuralgia Intercostalis* (first described by Siebold, and afterwards by Corvisart) occupies either a portion or the whole of one of the intercostal nerves, generally

in the lower part of the thorax. 4, *Neuralgia Cervico-Brachialis* (first noticed by Professor Fulci of Catania) is seated in the internal cutaneous nerve, a branch furnished by the brachial plexus. The pain begins at the anterior and internal part of the shoulder, and descends along the inner side of the arm and fore-arm to the wrist. Sometimes it extends not only to all the branches of the internal cutaneous nerve, but also to those of the external, and then becomes confounded with the following species. 5, *Neuralgia Musculo-Cutanealis* was first described by M. Martinet, and occupies the external cutaneous (or musculo-cutaneous) nerve, another branch derived from the brachial plexus. The pain commences at the shoulder, descends along the anterior external surface of the arm and fore-arm as far as the wrist. 6, *Neuralgia Supra-Scapularis* was also first described by M. Martinet, and is seated in the suprascapular nerve, another branch given off from the brachial plexus. The pain begins at the inferior angle of the scapula, passes along its posterior surface, and sometimes descends along the radial border of the fore-arm to the thumb and fore-finger. 7, *Neuralgia Mammae*, first described by Dr. Good as consisting of 'sharp, lancinating pains, divaricating from a fixed point in the breast, and shooting equally down the course of the ribs and of the arm to the elbow; the breast retaining its natural size, complexion, and softness.' 8, and last, *Neuralgia of the facial nerve, or portio dura of the seventh pair*, about the existence of which there is great room for doubt; for as this is a nerve of motion and not of sensation, it is not easy to understand how it should be liable to be effected by a disease which is in general simply and purely painful. However it is still more difficult to deny the fact; numerous instances have occurred in which the disease has (to all appearance) been seated in this nerve, and several wherein the pain has not only followed its ramifications with great exactness, but has also been attended by convulsive twitchings of the facial muscles, and even by their paralysis. Dr. Elliotson (*Cyclop. of Pract. Med.*, art. 'Neuralgia') admits without scruple the possibility of the portio dura being affected; Mr. Cooper (*Diet. of Pract. Surg.*) inserts this species as the fourth division of the Tic Douloureux; and Dr. Good (*Study of Med.*) says that the nerve in question 'is more frequently the seat of affection than any of the branches of the fifth pair seem to be.' But Dr. Rowland (*Treat. on Neuralgia*, 1838) is still inclined to 'doubt whether this nerve is capable of being affected with neuralgia,' and rests his opinion partly on 'a case mentioned by Thouret (*Hist. de la Soc. Roy. de Méd.*, t. ii.), where the pains apparently followed the ramifications of the portio dura, commencing at the stylo-mastoid foramen, and spreading over the cheek. With the hope of effecting a cure, the facial nerve was divided at its exit from the cranium, but no mitigation of the sufferings followed; and the only result of the operation was paralysis of the muscles of that side of the face.' This must be admitted to be a very important fact, but there are others equally strong in direct contradiction as to the result, especially that most interesting case related at length by Dr. Darwin in the second part of his '*Zoonomia*,' where three branches of the facial nerve were successively divided, and each operation was attended with great relief. Upon the whole, if the possibility of this nerve being affected with neuralgia be admitted, the apparent contradiction involved is probably one of those of which, in the present state of science, a perfectly satisfactory explanation cannot be given.

But besides these external forms of neuralgia, the disease has sometimes been found to attack various internal organs. This was first suggested by Dr. John Fothergill in 1773, who says (in vol. v. of the '*Med. Observ. and Enquiries*') 'There are few physicians, I believe, who may not in reviewing many cases, which have occurred to them, of anomalous pains in different parts of the body, so as sometimes to counterfeit gouty, bilious, and other internal affections of the stomach and bowels, perceive some analogy between them and the complaint here pointed out;' but it is only lately that pathologists have begun to enumerate these 'anomalous pains,' and class them as so many distinct species of neuralgia. Sometimes the central mass of the nervous system is affected, and we find the terms '*Cerebralgia*' and '*Myalgia*' employed by some modern French authors to designate neuralgia of the brain and of the spinal chord. (Raciborski, *Précis du Diagnostique*, 1837.) Sometimes, instead of the branches of a nerve, the extreme filaments only are diseased, as would appear to be the case in many of those

* The meaning of the term 'Tic Douloureux' appears to be rather doubtful. In the '*Dictionnaire de Trévoux*,' the word 'Tic' is said to mean, first, a vicious trick that horses have of biting the manger; and secondly, 'a sort of convulsive movement to which some persons are subject.' These twitchings not being accompanied with pain, the epithet 'douloureux' was added to distinguish those in neuralgia from every other sort. Dr. Good however considers the word 'tic' to be 'an onomatopoeia, or sound expressive of the action it imparts.' The '*Tic Douloureux*' is called '*Dolor ardens Faciei*,' by Boerhaave; '*Ticinus Maxillaris*,' and '*Trismus Dolorifrons*,' by Sauvages; '*Neuralgia*,' by Swediaur; '*Névralgie Faciale*,' by Good; '*Angina Dolorosa*,' by Boerhaave.

kinds of pain commonly called 'rheumatic' (MM. Jolly and Piorry, quoted in Raciborski). To these have been added torticollis, lumbago, angina pectoris, neuralgia of the arteries, gastralgia, enteralgia, hepatalgia, nephralgia, hysteralgia, neuralgia of the heart, testicle, bladder, urethra, diaphragm, &c. (Raciborski, Rowland, Elliotson, &c.) It may perhaps be rather fanciful to give the name 'neuralgia' to all these cases, and it would take up too much space to describe each separately; but they are all more or less characterised by the same peculiar sort of pain, coming on and leaving off suddenly, extremely acute while the paroxysm lasts, and subject to intervals of complete cessation.

Of the remote or predisposing causes of neuralgia very little is known, but it has been supposed to attack females more frequently than males, the rich than the poor, those that live in towns rather than the inhabitants of the country. It is also most common among persons of a nervous temperament, and both infancy and old age are comparatively safe from its attacks. The immediate or exciting causes are very numerous, and sometimes extremely obscure. Among the most common may be mentioned, exposure to wet and cold, mental excitement and agitation in persons of an irritable temperament, and a deranged state of the digestive organs, though with respect to this last it should be noticed that some eminent pathologists seem inclined to think that this is seldom if ever the case. Local injuries of various kinds are another very frequent cause of the disease; such as the lodgement of any foreign body in the branch of a nerve, wounds, contusions, cicatrices, the too great distension of a nerve, carious teeth, &c. Sir Henry Hallford has published in his 'Essays' five cases showing that sometimes 'the disease is connected with some preternatural growth of bone, or a deposition of bone in a part of the animal economy where it is not usually found in a sound and healthy condition of it, or with a diseased bone;' and Sir Benjamin Brodie, in his 'Lectures on Local Nervous Affections,' mentions several where the pain was occasioned by the pressure of an aneurysmal or other tumour. Several other causes are enumerated by Dr. Rowland in his treatise on neuralgia, viz. diseases of the urinary organs, disorder of the heart and large vessels, uterine disorders, spinal irritation, organic diseases of the brain and spinal marrow, malignant diseases, chronic inflammation, malaria, and anæmia. In many cases however no exciting cause whatever can be discovered either during life or after death.

With regard to the seat of neuralgia, there can be little doubt but that it is in the nerve itself; but it is equally certain that the part where pain is felt is not always the part diseased. The pathology of the disease is extremely obscure and uncertain, chiefly from the difficulty of deciding the question of its supposed identity with neuritis; and this difficulty is much increased by an examination of the contradictory evidence brought forward on each side, by the men most eminent for talents and experience. Larrey ('On the Use of the Moxa') speaking of tic douloureux, describes it as 'a chronic and inflammatory turgescence of the neurilema, which envelopes the nerves of the part affected;' Sir Astley Cooper on the other hand, in his 'Lectures on Surgery,' admits that it is difficult to say what is the real nature of the disease, but goes on to declare that 'the nerves are not in an inflamed state most certainly, for under the most horrid suffering they are found of a natural colour; they are not increased either in their usual size, but on the contrary are found to be rather diminished.' Upon the whole, the truth seems to be that, in general, no signs of inflammation are found either during life or after death; but at the same time we cannot refuse to believe the positive evidence brought forward to show that in some cases the nerve has been found larger than usual and of a deeper colour, and the neurilema unnaturally thick and distended by serous infiltration. (See the instances collected by Dr. Rowland, *Treat. on Neur.*) Where these morbid appearances have been occasioned by acute neuritis, the course of the disease is so different from that of neuralgia, that the two affections can hardly be considered to be identical; where the case has been one of chronic inflammation, it may still be doubted whether we should not consider this to be one of the causes of neuralgia, rather than the disease itself to be of an inflammatory nature.

The diagnosis of neuralgia is not in general very difficult, for even when it does not follow the course of a nerve, it may commonly be distinguished from every other disease by the

peculiar character of the pain, its excessive violence during the paroxysm, and the absence of all symptoms of fever and inflammation. It may sometimes be difficult at first sight to distinguish neuralgia from neuritis, inasmuch as the two diseases resemble each other in some of their most prominent symptoms; but by observing the following diagnostic signs (derived from the general character of inflammation in all parts of the body), the danger of confounding them may be avoided. In neuritis the pain is continual, as is the case in all inflammations; in neuralgia it is never constant, but is subject to paroxysms and intermissions. In neuritis the pain is aggravated by the slightest pressure; in neuralgia, on the contrary, it is sometimes alleviated by it. To these it may be added that in neuritis we shall find the usual attendants of inflammation, viz. heat, redness, and swelling; while in neuralgia (as noticed above) these are rarely if ever present.

The prognosis will of course depend very much on the nature of the exciting cause of the disease, but still as a general rule it is extremely uncertain. Sometimes, when every remedy has been tried in vain, a cure will be effected by time alone, for it seems that all the sensitive part of the nervous system is liable to become dull and lose its powers by a long series of irritation; yet even this hope cannot be depended on, as there are some cases on record (quoted by Dr. Rowland) where the disease has continued even to the age of eighty-five.

With regard to the treatment of neuralgia, it would appear quite superfluous to say that it must be regulated by the circumstances of each particular case, if it were not notorious that no disease has been treated more blindly and empirically. The favourite remedy at present is the sesquioxide of iron, which was first brought into notice by Mr. Hutchinson of Nottingham ('Cases of Neuralgia Spasmodica, &c.' Lond., 1820), and which now occupies a place in public favour that has been successively held for a longer or shorter period by almost every active and powerful substance in the 'Pharmacopœia.' Yet every practitioner will readily be able to imagine cases, even if he has not met with them in his own practice, where the exhibition of this medicine must be entirely useless, and in no disease is there more truth in the maxim 'sublatâ causâ tollitur effectus.' When any foreign body presses upon the nerve, or when the pain can be distinctly traced to a carious tooth, the removal of the source of irritation will commonly be sufficient to cure the disease; though the practitioner should be especially warned against the danger of confounding neuralgia with the tooth-ache, an error that is not unlikely to occur in some cases of tic douloureux, and one that has often occasioned the loss of several teeth to the patient without any good effect. When (as is sometimes the case) the disease appears to be occasioned by the irritation arising from an old cicatrix, it will be expedient to try the effect of applications to the cicatrix itself, viz. either the nitrate of silver, or the actual cautery, or a blister, or a crucial incision over the part, or even its removal by the knife. And in the same way, when it can be distinctly referred to any other of the exciting causes enumerated above, the removal of that will probably be followed by the disappearance of the disease. But, as already observed, it very frequently happens that the exciting cause cannot be discovered, and in these cases the treatment must necessarily be in a great degree empirical. When the paroxysms are irregular in their duration and recurrence, perhaps the sesquioxide of iron is the best remedy at present known: it may be given in doses of half a drachm three times a day in twice its weight of treacle. When the pain recurs after certain regular intervals, those medicines which are found to be most efficacious in the treatment of ague may be exhibited with advantage. The disulphate of quina may be given in doses of four or five grains three times a day, though this medicine has sometimes been given in much larger quantities, and Sir Benjamin Brodie mentions one case where the patient took as much as half a drachm daily. (*Local Nervous Affections*, p. 28.) The liquor potassæ arsenitis is another excellent medicine which may be employed in this form of the disease; the dose is at the commencement four or five minims three times a day, which may gradually and cautiously be increased to eighteen or twenty. When there are any signs of inflammation present, that the disease may seem rather to deserve the name of neuritis than of neuralgia, it must be treated accordingly, and the usual anti-phlogistic remedies, both external and internal, may be

employed. In almost every case of neuralgia it will be advisable to exhibit some preparation of opium, both to relieve the pain, and also in order to procure the patient some sleep at night, at which time the paroxysms are often much aggravated; and especial care must also be taken not only to prevent the constipation caused by this drug, but also to keep up a free evacuation of the bowels, as in some cases the disease appears to have been cured by purgative medicines alone. A very interesting lecture on a case of neuralgia was delivered at St. Thomas's Hospital, Nov. 26, 1832, by Dr. Elliotson, which affords an example of the amount to which the doses of several powerful medicines may be carried in this disease. The sesquioxide of iron was increased to an ounce every three hours, to which was gradually added fifteen grains of the sulphate of iron. From this treatment the patient received some degree of benefit, but it was only temporary. In the same case strychnia was given to the amount of three-fifths of a grain three times a day, eight grains of the hydrochlorate of morphia twice a day, and nine minims of hydrocyanic acid three times a day, to prevent the sickness occasioned by doses of twenty minims of the liquor potassæ arsenitis. After remaining in the hospital more than six months, the patient went out nearly as bad as when he first came in. (*The Lancet*, No. 484.)

Among local applications may be mentioned the unguentum veratri, emplastrum opii, and empl. belladonnæ, or a lotion (recommended by Dr. Bennett, of Charleston in America), composed of four ounces of the aqua laurocerasi and one ounce of sulphuric æther, either alone or with half or one drachm of the extract of belladonna. (*British and Foreign Medical Review*, vol. i., p. 263.) Counter-irritants have often proved very efficacious, particularly the application of a common blister, and, after the cuticle has been removed, the sprinkling over the denuded surface a quarter or half a grain of the acetate or hydrochlorate of morphia. Moxas and issues have also been tried with success.

After all other remedies, both internal and external, have failed, the patient's last resource is the operation either of dividing the nerve or removing the limb; and even this will very often fail also. When the disease depends on some local irritation or resides in the extremity of the nerve, the operation is frequently successful; but when it proceeds from constitutional causes, or exists either in the brain itself or nearer to it than the point where the nerve can be divided, in this case it is manifest that, as no benefit can reasonably be expected from the operation, the experiment ought never to be tried but at the earnest request of the patient. Sometimes the nerve is simply divided, but in these cases the pain very often returns as soon as the two extremities are reunited; sometimes a portion of the nerve is removed, but even this appears only to obtain for the patient rather a longer respite. Latterly, after part of the nerve has been cut away, the two ends have been touched either with nitrate of silver or the actual cautery, and in some instances this plan appears to have succeeded where the simple section of the nerve had failed. When the operation of dividing the nerve in facial neuralgia is to be performed, the following are the directions given by Sir Astley Cooper, in his 'Surgical Lectures':—If it should be deemed requisite to divide the suborbital nerve, it should be done a quarter of an inch below the orbit: the nerve passes out of the foramen half an inch below; so that you are to divide it midway between the foramen and the edge of the orbit: if you divide it lower than this, you will leave some branches which will still continue the disease. The proper mode to adopt for dividing it is to introduce a sharp-pointed bistoury at the distance from the orbit already stated, and, carrying the point of the instrument close upon the bone, you hook up the nerve on its edge; then press upon the skin over the edge with your finger, and at the same time withdraw the knife through the opening by which it entered; in this way, as you take out the knife, the nerve will be divided. You ought to ask the patient if he feels a numbness of the upper lip, and if he should not, your operation will be incomplete. When necessary, the supra-orbital branch is to be divided in a similar manner by introducing the knife under the integuments of the superciliary ridge; cut through the nerve immediately as it emerges from the supra-orbital foramen, carrying the point of the knife from the nose outwards. When the submental nerve requires division, you need not make any incision

through the integuments, but may perform the operation by placing the knife within the mouth, and directing its point downwards to the mental foramen, where the nerve passes out, and by gliding the knife along the bone at that part, the nerve is sure to be divided. In performing this operation, you may direct your knife by the bicuspidati teeth, the anterior maxillary foramina being just below them.

(*Cooper's Dictionary of Practical Surgery*; *Good's Study of Medicine*; Dr. Elliotson, in the *Cyclopædia of Practical Medicine*; Franck, *Præces Medicæ Universæ Præcepta*, t. iv.; M. NEURITIS. [NEURALGIA.]

NEUROPTERA (from *νεῦρον*, a nerve, and *πτερόν*, a wing), one of the orders into which the class *Insecta* is divided. The insects composing this order may be distinguished by the following characters:—wings, four in number, membranous, generally naked, and more or less transparent, but sometimes hairy; the mouth is usually fitted for mastication, or furnished with mandibles and maxillæ; the larvæ are provided with six legs and are active, their metamorphosis is variable, but is usually semi-complete. The character which gave rise to the name, viz. the minute reticulation of the nervures of the wing, will also in most instances serve to distinguish the insects of the present order from others. The May-fly and dragon-fly afford familiar examples.

The order *Neuroptera* is divided by Latreille into three sections, to which he applies the names SUBULICORNES, PLANIPENNES, and PLICIPENNES, under which heads the characters of these sections are described.

NEUSOHL. [HUNGARY.]

NEUSS, a Prussian town in the government of Düsseldorf, is situated in 51° 18' N. lat. and 6° 45' E. long., at the commencement of the canal which is to unite the Rhine and the Meuse, and at the influx of the Kruse into the Erft, which latter river has been made navigable, for vessels of moderate burthen, from this town to its junction with the Rhine, over which there is, near this junction, a bridge of boats to Düsseldorf. The Rhine flowed in the thirteenth century close under the walls of the town, from which it is now half a league distant. Neuss is still partly fortified with gates and towers, but the ramparts have been converted into public walks and gardens. There are two Roman Catholic churches, of which that dedicated to St. Quirinus is a fine Gothic edifice, one Protestant church, a synagogue, an orphan asylum, a lunatic asylum, an hospital, and a handsome town-hall. The inhabitants now amount to 8000, most of whom are Roman Catholics, there being only 150 Lutherans, 100 Calvinists, and 50 Jews. Neuss is a flourishing town, and has manufactures of woollen cloths, kerseymere, baize, flannel, cotton, cotton-yarn, worsted, handkerchiefs, tape, and hats; likewise a manufactory of cotton-cards, one of starch, an establishment for dyeing Turkish-red, and a quill and pen manufactory, in which 200,000 quills are clarified every week. There are also vinegar-makers, soapboilers, four oil-mills, and one fulling-mill. The inhabitants of the town and circle are also extensively engaged in agriculture and breeding of cattle, and have a great trade in corn, mill-stones, stone for building, square timber, planks, slates, and coals.

The town is said to have been built by Drusus, brother of Tiberius, who had thrown a bridge over the Rhine; one of the gates of the town is still called Drusus-gate. In the thirteenth century Neuss joined the Hanseatic league, and is celebrated for its brave resistance, in 1475, to Charles the Bold, duke of Burgundy, who besieged it for nine months. To reward the townsmen, many important privileges were granted to the city by the emperor Frederick III., who came to its relief. The bronze statue of Frederick stands in the market-place. It was here that the allied armies passed the Rhine, on their march to Paris, in 1815.

NEUSTADT, commonly called *Wiener-* or *Wienerisch-Neustadt*, in 47° 50' N. lat. and 16° 15' E. long., is situated on the extensive plain of the Steinfeld, on the navigable canal to Vienna, and at the junction of the Kehrback

and the Little Fische, not far from the frontiers of Hungary. Next to Vienna, it is the most considerable town in Lower Austria, containing, together with the suburb Leopoldstadt, 10,000 inhabitants, besides the military and the students of the academy. The town is pretty regularly built, nearly in the form of a parallelogram, with four gates; it is surrounded with a wall with towers, and a broad and deep moat. It is divided into four quarters, and has in the centre a large and handsome square, surrounded with arcades. The principal building is the antient archducal palace, built in 1186 by Leopold the Virtuous, and assigned in 1762 by the empress Maria Theresa to the imperial military academy. It is a strong square edifice with a tower, and surrounded with ditches, which however are now dry, and have been converted into kitchen-gardens and plantations of fruit-trees. This academy has 36 professors and 500 pupils. The beautiful Gothic chapel of St. George, allotted to the academy, contains, among other monuments, that of the emperor Maximilian I., and some good paintings on glass of the fifteenth century. The academy has a good library, a collection of philosophical instruments, a school for drawing, an artillery-hall, containing a complete model of a fortress, a hall for gymnastic exercises, a manege, a winter bath, a refectory, with the portraits of distinguished Austrian generals, and a walled garden, 1400 yards long and 1200 broad, which was formerly a park, and is still so called. The church of Our Lady, formerly the cathedral while the place was a bishop's see, is a large stone edifice of the thirteenth century, with two lofty towers; it contains some good paintings, and, among other grave-stones, those of counts Zriny and Frangipani, who were beheaded for high-treason in 1671. Two other churches have been converted into warehouses. Of the other buildings, the chief are, a Cistercian abbey, which has a library of 20,000 volumes and a beautiful collection of minerals and shells; a military hospital, a civil hospital, and a gymnasium. There are manufactories of velvet, silk, cotton yarn, earthenware, and paper. Neustadt, being so advantageously situated on the high road from Vienna to Styria, and likewise an entrepôt for the commerce between Hungary and Italy, carries on a very brisk trade by water with Vienna, and by land with all the provinces of the Austrian empire. This place was built by Leopold the Virtuous between 1192 and 1194, and on account of its fidelity to its prince, which was particularly manifested under Frederic the Valiant in 1236, and Frederic IV., 1452, and in the siege by the Turks in 1529, has received the honourable appellation of 'Always Faithful.'

This flourishing town was nearly destroyed by a dreadful conflagration on the 8th September, 1834, which in a few hours burnt 500 houses and several public buildings. This calamity was fortunately followed by a mild autumn and winter, so that the rebuilding of the houses was not stopped. The emperor Francis, besides a very large sum from his privy purse, assigned 100,000 florins from the public treasury: all the members of the imperial family contributed amply, and immense contributions flowed in, not only from every part of the Austrian empire, but from foreign countries, both in money and clothing, provisions, &c., which, added to the sums paid by the insurance offices, enabled the inhabitants entirely to rebuild the town and to resume their usual occupations.*

NEUTER. [GENDER.]

NEUTRAL SALTS. Formerly this term included such salts as did not obviously contain an excess either of acid or alkali, and this was determined by their action upon vegetable colours. Such for example as had an alkaline or earthy base, and reddened litmus paper, were termed super or acidulous salts, and they had generally an acid taste; such a compound is that called cream of tartar, now termed bitartrate of potash: on the other hand, potash and soda, when combined with the smaller portion of carbonic acid which they are capable of uniting with, were called subcarbonates, because they render turmeric paper of a yellowish-brown colour, thus evincing an alkaline property.

At present the term neutral salt includes such compounds, whatever may be their action on coloured tests, and whatever may be their taste, as are composed of one equivalent

of each of their constituents; thus the subcarbonates of potash and of soda are now termed carbonates, notwithstanding their alkaline reaction, because they consist of one equivalent of acid and one of base.

NEUTRALIZATION is a term generally applied to the decomposition of the alkaline carbonates, as of potash and soda, by the gradual addition of some acid more powerful than the carbonic, and which of course expels it from the alkaline bases with effervescence. The process of neutralization by means of sulphuric acid is extensively adopted in the process of *alkalimetry*, or of determining the quantity of real alkali which samples of carbonate of potash or soda contain, by means of the quantity of sulphuric acid required to render them neutral to test-papers.

NEUWIED, situated in 50° 25' N. lat. and 7° 30' E. long., on the left bank of Rhine, was formerly the capital of a small principality which retained its independence till 1806, when it was mediatised, and assigned to Nassau. In 1814 it was transferred to Prussia, to which the sovereignty now belongs; it is in the province of the Rhine and government of Coblenz. Neuwied is a very regular well-built town with broad straight streets, and houses all of equal height. It contains 5500 inhabitants, consisting of Roman Catholics, Lutherans, Calvinists, Anabaptists, Moravians, Mennonites, Quakers, and Jews, and among the Protestants a few (about 40) who call themselves 'The Inspired,' and believe in the continued operation of the Holy Ghost: all these sects have their own places of worship. It is the capital of the circle and of the principality, and the residence of the Prince Augustus of Wied-Neuwied, who has a very fine palace with extensive gardens. The palace contains a good library, and an interesting collection of Roman coins, statues, &c. found in the neighbourhood, this having been the site of the standing Roman frontier camp against the Germans. There is likewise the collection of natural history made in Brazil by Prince Maximilian of Wied, and that which he brought from his travels in North America, especially among the Indian tribes of the Missouri and the Rocky Mountains. Among the public institutions there are a seminary for schoolmasters, a progymnasium, a school for mechanics, a society for the education of destitute children, several infirmaries and other establishments for the poor, a house of the Moravian Brethren with a boarding-school for boys and another for girls; five Protestant churches, of which that of the Moravians and that of the Calvinists are the most worthy of notice, a synagogue, and many manufactures. It is the seat of the government of the principality and of many public offices both of the king and the prince. The inhabitants are very active and industrious, and have manufactures of silk, cotton, wool, lace, thread, hats, carpets, leather, tobacco, stockings, and tape; a considerable manufactory of tin culinary utensils, stoves, and also a manufactory of musical clocks. There are breweries, distilleries, vinegar manufactories, and many others. The inhabitants carry on a profitable trade in their own manufactures, and in the products of the country, such as pipe-clay, timber, potash, iron, lead, corn, and wine. A league from the town and close to the Rhine are the ruins of the antient castle of Fredericks-stein, called by the watermen the Devil's Castle. (Stein, Hassel, and Müller's *Handbuch*, 1836.)

NEVA, River. [PETERSBURG.]

NEVA'DA, LA SIERRA (the Snowy Chain), is a chain of mountains in the kingdom of Granada, in Spain, running due east and west, between 37° and 37° 15' N. lat., and between 3° and 4° W. long. Its length is about 50 miles, and its greatest breadth about fifteen. It attains its greatest altitude in the centre, in the peaks of Mulahacen and Picacho de Veleta, the former being 11,658 feet and the latter 11,382 feet above the level of the Mediterranean. Maladeta, the highest peak in the Pyrenees, being 11,424 feet in height, the Sierra Nevada is, among European mountains, second only to the Alps in altitude. This chain is perpetually covered with snow above the line of 9600 feet. At its base, about 25 miles north-west of the Picacho de Veleta, lies the city of Granada.

The geological composition of the Sierra Nevada has not yet been thoroughly investigated. According to Colonel Silvertop (*Geol. Proceedings*, 1836), this chain consists of a central axis of gneiss and mica schist, with successively overlying zones, on each flank, of transition and secondary rocks, which on the south and along the shores of the Mediterranean are here and there covered with patches of tertiary marine deposits, containing subapennine shells;

* The above account is taken from the 'Austrian National Encyclopedia,' published at Vienna in 1833: as this was between three and four years after the fire, and several public buildings are specified as having been destroyed (which we have therefore not noticed), it may be presumed that article referred to describes Neustadt as it now is.

whilst on the northern flank of the chain, or toward the interior of Spain, the secondary rocks are succeeded by formations of lacustrine origin. The marbles quarried in the Sierra are much varied in colour, and are esteemed the best in Spain. The most celebrated are those of Lanjarron. On the southern side, in several spots, there are remains of Roman mines, none of which are now worked.

The base of the Sierra is partially clothed with wood on the north, but more abundantly on the south, where the lower slopes are adorned with orange and olive groves, and the vegetation peculiar to the south of Europe. Higher up, the mountains are either bare or scantily clothed with grass and low shrubs, though in a few of the most sheltered valleys are patches of trees and corn-land, surrounding cottages, or farms. Above the line of perpetual snow, vegetation, with the exception of a few mosses, ceases entirely. The botany of the Sierra is said to consist chiefly of the *artemisia glacialis*, *antirrhinum organifolium*, *arenaria tetraquetra*, *saxifraga tridactylites*, *festuca ovina*, and *jasion montana*: it is however but imperfectly known; for though Roxas de San Clemente, an eminent native naturalist, spent many years in investigating it, he unfortunately died before he could lay the result of his researches before the world.

The Sierra Nevada is almost uninhabited. The farms before mentioned are very few; they are the abode of the peasants, who tend the horned cattle and goats, which find pasturage in the glens that are watered by the streams of melted snow.

Bears formerly infested these mountains, but they have long been extirpated: wolves still abound: the ibex is said to have been seen, but the fact is doubtful. Game, particularly hares and rabbits, is very plentiful. Eagles, vultures, and ravens, with finches in great variety and abundance, are found in this Sierra.

The vast fields of snow on the summits of these mountains give rise, by their melting, to numerous streams, which impart fertility to the surrounding country. The principal of these is the Xenil, the Singilis of the Romans, which traverses the plain of Granada, and falls into the Guadalquivir at Palma. The snow also not only serves to temper the intense heat of the summer, but yields to the neighbouring cities an inexhaustible supply of ices.

Mulahacen, the highest peak, is inaccessible. The view from the summit of the Veleta is magnificent, embracing the greater part of the province of Andalucia, with parts of Murcia, Valencia, and Castile; the Mediterranean is to the south, bounded by the mountainous coast of Africa at the distance of 180 miles.

The above account is principally the fruit of personal observation.

(Miñano, *Diccionario Geografico-Estadístico de España y Portugal*; Antillon, *Geografía de España y Portugal*; Laborde, *Itinéraire Descriptif de l'Espagne*; Cook's *Sketches in Spain*; Semple's *Journey through Spain*; *Nuevos Puseos por Granada y sus Contornos*.)

NEVERS, a town in France, capital of the department of Nièvre, situated on the Loire, at the junction of the little river Nièvre, in 47° N. lat. and 3° 10' E. long., 133 miles in a direct line south by east of Paris, or 140 by the road through Fontainebleau, Montargis, and Cosne.

This town existed in the time of the Romans, and appears to have been known to them by the name of Noviodunum, and afterwards of Nivernum, or Nevirnum, from the river Niveris, or Noveris (Nièvre), on which it is situated. It was of little importance until the reign of Clovis, in whose time it belonged to the Burgundians. It afterwards came into the hands of the Franks, and was taken and burnt by Hugues le Grand in his quarrels with Louis d'Outremer. It suffered much in the wars of the English under Henry V. and VI., and in the disputes of the dukes of Bourgogne with the kings of France. In the middle ages it was the capital of the county of Nevers, which was raised by François I. to the rank of a duchy (A.D. 1539). The duchy was sold by Charles III. de Gonzague (Gonzaga), the last duke, to Cardinal Mazarin, and was, a few years afterwards (A.D. 1665), united to the crown of France. It constituted the province of Nivernois.

Nevers is situated on a slope on the banks of the Loire. This situation gives the town a fine appearance from a distance, but renders the streets inconveniently steep: they are also crooked and ill-paved. The houses are irregularly built, but there are some good ones. There are some remains of the old walls and towers of the city. The chief

P. C., No. 995.

public buildings are the cathedral, which owes more to its situation on the crown of the hill whereon the city is built, than to its architecture. The tower, which is square, and richly adorned with statues and sculpture, is the finest feature of the building. The old castle of the dukes of Nevers is also in the upper part of the city. There are barracks, an arsenal, and an ex-episcopal palace, now occupied by the prefect of the department. There is a public walk attached to the ducal castle, and a triumphal arch at the entrance of the town from Paris, bearing a pompous inscription.

The population of Nevers in 1828 was 15,782 for the commune; in 1831, 11,868 for the town, or 15,085 for the whole commune; in 1836 it was 16,967 for the commune. The inhabitants of the town and neighbourhood manufacture iron-wares of massive character, cannon and shot, chain-cables, anchors, chains for suspension bridges, &c. Some of the iron-works belong to government. The principal forges are at Guerigny, on the Nièvre, seven or eight miles from the town: they furnish employment to 400 or 500 workmen. Besides these larger wares, agricultural implements, files, and other tools are made; also earthenware, porcelain, enamel, cordage, violin-strings, glue, &c. There are dye-houses, glass-houses for bottles, and tan-yards. There is a commodious port for the river craft at the mouth of the Nièvre, and considerable trade is carried on in iron and steel, wood, coal, wines, leather, cattle, and manufactured goods. There are nine yearly fairs. There are at Nevers two seminaries for the priesthood, a high school, a school of linear drawing, a school of geometry and mechanics applied to the arts, a free-school for the arts, a public library of 7000 volumes, several hospitals, and a theatre.

Nevers is the seat of a bishopric; the diocese includes the department of Nièvre, and the bishop is a suffragan of the archbishop of Sens and Auxerre.

The arrondissement has an area of 875 square miles, and comprehends ninety-nine communes: it is divided into eight cantons or divisions, each under a justice of the peace. The population, in 1831, was 86,847; in 1836, 94,382.

NEVIS, one of the Lesser Antilles, in 17° 14' N. lat. and 63° 3' W. long., is separated from the south side of the island of St. Christopher by a channel about two miles wide, called the Narrows, which is navigable only by small boats owing to the numerous shoals in it. Nevis consists of a single conical mountain, of volcanic origin, rising at first with a gentle ascent from the sea-shore, and having its summit perpetually covered with clouds. The circumference of the island is about 24 miles, and its greatest elevation 2500 feet above the sea. The soil is for the most part a tenacious marl, and is very fertile. On the western side are two small streams. The sides of the mountain are covered with plantations, but the higher parts are rocky and sterile. The town, Charlestown, stands near the south-west end of the island, and has a tolerable roadstead, but it is somewhat difficult of approach on account of a shoal which stretches off the shore to the distance of half a mile. There has been no census of the population for a great number of years. The estimated number of inhabitants in 1836 was 9250, only a small proportion of whom were whites. The number of slaves on the island on 1st August, 1834, was 8815, for whom compensation was paid to their owners out of the parliamentary grant to the amount of 151,006*l.*, being at the rate of 17*l.* 2*s.* 7*d.* per head. Of this number, 5123 were attached to plantations, 176 were mechanics employed in the country, 1207 were domestic servants, 719 were mechanics employed in the town, 1261 were children under six years of age, and 329 were aged and diseased persons.

The exportable produce of Nevis consists almost wholly of sugar, molasses, and rum. The quantity of each of these articles exported in 1836 was 2,724,836 lbs. sugar, 37,120 gallons molasses, and 12,290 gallons of rum. The total value of the exports in that year was 34,885*l.*, and that of the imports—consisting chiefly of plantation stores, was 32,511*l.* The shipping by means of which this trade was conducted, and the countries from and to which the vessels proceeded, were as follows:—

Countries.	Inwards.			Outwards.		
	Ships.	Tons.	Men.	Ships.	Tons.	Men.
Great Britain	6	1372	..	6	1435	..
British Colonies	163	4857	..	180	5329	..
United States of America	6	698	..	6	698	..
Foreign States	75	1560	..	58	1991	..
Total	245	8487	1004	250	8746	1134

The island is divided into five parishes. It has a local legislature, consisting of a council, of eleven, and a House of Assembly, of fifteen members. Nevis was first colonised by the English in 1628; it has always followed the political fortune of the island of St. Christopher.

NEW BEDFORD. [MASSACHUSETTS.]

NEW BRANDENBURG is a pretty town in the grand-duchy of Mecklenburg-Strelitz. It is built nearly in the form of a circle, with broad straight streets, and stands in a pleasant country on the banks of a small river near the lake called the Tollensee. The grand-duke has a palace in this town, which also contains a gymnasium and several schools. The inhabitants, above 6000 in number, live partly by agriculture, partly by trade and manufactures. There are many brandy distilleries, manufactories of woollen cloths, playing-cards, paper, snuff and tobacco, and chemicals. Calico-printing is carried on to some extent. The Mecklenburg insurance-offices of household furniture against fire, and of the standing crop against damage done by hail, are in New Brandenburg. In each of these property to the amount of a million sterling is insured. There is a well attended annual wool-fair, and celebrated horse-races, which attract a great concourse of the lovers of those sports. Considerable quantities of tobacco and hops are grown in the surrounding country. About two miles from the town the grand-duke has a handsome country seat called the Belvedere, with grounds laid out in the English style.

NEW BRITAIN is a large island in the Pacific, situated between 5° and 7° 30' S. lat. and 148° and 153° E. long. Up to the year 1700 it was considered a part of New Guinea, or Papua; but in that year Dampier discovered the strait which separates both islands, and is still called after his name. This strait is about 40 miles wide. New Britain is separated by St. George's Channel from the island of New Ireland. New Britain is of a very irregular figure, and its southern shores have a coast-line of more than 350 miles. The surface is estimated at 24,000 square miles, or nearly half the extent of England. The interior of the island contains mountains of great elevation, as may be inferred from their being seen from sea at a great distance. Carteret observed smoke to rise from the highest summit. In several places the mountains come close to the sea, as at Capo Gloucester. Along the shores there are several plains of considerable extent, and also some good harbours. The declivities of the mountains are generally covered with trees. The island is fertile, and produces the cocoa-nut, sago, and other kinds of palms; also bananas, yams, ginger, sugar-cane, the bread-tree, bamboo, and many other plants and trees. Dogs, pigs, turtles, and fish abound. The inhabitants, who appear to be rather numerous, belong to the race of the Australian negroes, but rather resemble the inhabitants of Papua, or New Guinea, than those of Australia or Tasmania. They are stout and well made, of a very dark colour, with curly hair, and go naked. They are courageous and fond of war.

(Dampier's *Voyages and Travels*; Carteret's, D'Entrecasteaux's, and Dumont d'Urville's *Voyages round the World*.)

NEW BRUNSWICK, a British colony in North America, lies between 45° and 48° 5' N. lat. and 63° 48' and 67° 53' W. long. It is bounded on the north by the Bay of Chaleurs, and by the river Ristigouche, which in its whole course from its source to its æstuary in the Bay of Chaleurs separates this country from Lower Canada. On the east it borders on the Gulf of St. Lawrence, Northumberland Strait dividing it from Prince Edward Island; and on Nova Scotia, with which it is connected by the isthmus of Chignecto, which separates Northumberland Strait from Chignecto Bay, and is only ten miles wide. On the south it is washed by the Bay of Fundy. On the west it borders on the state of Maine, from which it is separated by a line beginning at Passamaquoddy Bay, and running along the course of the St. Croix river to the mouth of the Scodie river, whence it continues along the course of the Chiputnaticook and the lakes, in which the last-mentioned river originates. The remainder of the western boundary is formed by an imaginary line extending along the meridian of 67° 53' W. long., and separating New Brunswick from the northern part of Maine and Lower Canada. Its surface is estimated at 25,324 square miles, or about half the area of England, without Wales.

Surface and Soil.—New Brunswick may be divided into three regions, the Southern, Central, and Northern region.

The *Southern* region comprehends the country along the Bay of Fundy, and from 40 to 50 miles inland, and is divided from the Central region by a line drawn from the lakes of Chiputnaticook eastward to Bear Lake and the St. John river, which it intersects at the outlet of Washademoak Lake, and then continues along that lake and the river of the same name to the sources of the river Petcou-diac; it follows the course of this river to its mouth in Shepody Bay, a branch of Chignecto Bay. This region is divided into two unequal portions by the St. John river. The western section contains the greatest part of Passamaquoddy Bay, an extensive sheet of water, branching out into several inlets, and forming harbours for vessels of considerable size. It receives many rivers, of which the St. Croix is the most important, being navigable for large vessels to St. Stephen's, above which place it is interrupted by falls, yet timber is floated down. Passamaquoddy Bay contains several islands: Campobello, ten miles long and two wide, is separated by a narrow deep channel from Maine; and Deer Island is nearly seven miles long and three miles broad in the widest part. Before the bay lies Grand Manan Island, about fourteen miles long and six or seven wide. The coast of this section is everywhere rocky, but it does not rise to any considerable height. The surface is much broken, but as the rocks which constitute the substratum of the soil are generally covered with a deep layer of earth, it is clothed with high forest trees, and when cultivated yields good crops of grain. The most elevated part of this tract is intersected by several lakes, some of considerable extent, and probably 600 or 700 feet above the sea-level. That part of the Southern region which lies east of the St. John river is rather rocky and sterile. The rocky and elevated coast runs off in an almost continuous line, without any considerable break, so that the inlets along it may rather be called coves than harbours. At the back of this iron-bound coast the country rises with a rather steep ascent, and then extends in an uneven and broken plain, on which several hills rise to some elevation. The soil of this tract is very stony, and generally shallow. In its natural state it is chiefly covered with low trees, which do not supply timber. When cultivated it produces moderate crops of rye, barley, oats, and potatoes, but not wheat. There are however in this tract several depressions, extending in a longitudinal direction, and constituting valleys, in which the rivers flow, mostly to the St. John river. The lower part of these valleys is occupied by lakes, as Kenebekasis, Belleisle, and Washademoak. In the inner recesses of these lakes fine valleys begin, and extend many miles upwards along the rivers. These valleys are covered with large timber-trees, and when cultivated produce excellent crops of grain. In climate this tract differs from the country farther northward, being somewhat less cold, but much more humid, and exposed to thick and frequent fogs when the winds blow from the Atlantic. This circumstance, added to the strong tides in the Bay of Fundy [FUNDY], and the rocky iron-bound coast, renders the navigation very perilous, which disadvantages are hardly compensated by the harbours of this coast, especially those in Passamaquoddy Bay, being less encumbered with ice in winter than those of New England, and being accessible nearly all the year round.

The *Central* is divided from the Northern region by a line beginning on the west on the banks of the St. John river at Presqueisle, and running thence in a north-eastern direction to the mouth of the Little Nipisighet river in the Bay of Chaleurs. The shores of this region are low, and the rivers have sand-bars across their entrance, though there is usually a considerable depth of water on them. In many places the shores are fringed with sandy ridges or small islands, which produce only bent-grass, and within these islands are lagunes with shallow entrances. There are no deep harbours except at the mouths of the rivers. The level country, which extends several miles inland, has a sandy soil, and is clothed with dwarf spruce and birch trees, but it makes pretty good pasture-ground. The country begins to rise at from twelve to twenty miles from the shores, and continues to rise till about sixty miles, where it begins to descend rather rapidly towards the St. John river at a distance of about thirty miles from its banks. This more elevated tract has an uneven surface, extending in long broad-backed ridges, most of which run east and west. Hills occur in several places, but they do not attain a great elevation, and have generally gentle slopes. Their whole surface is still

covered with a continuous forest of heavy timber, the vigorous growth of which indicates a fertile soil. Along the banks of the St. John river extends a flat country, which on the east begins at the mouth of the Washademoak, and extends westward to Meductic, and thence northward to Presqueisle. The eastern portion is nearly a level, and contains the most fertile and best settled part of the colony; from Meductic northward its surface is undulating and even hilly, and though the soil seems not so good, it is covered in most parts with heavy timber.

The *Northern* region is very hilly, and even mountainous, especially on the banks of the river Ristigouche, and in that tract where the rivers Tobique and Nipisighet originate. The latter seems to form an elevated tableland, thickly studded with lakes. The interior of this region is very little known, with the exception of the tracts bordering on the river Tobique, which are covered with the finest forests of red pine, and furnish nearly all the timber which is exported from St. John. No settlements have yet been established, except on the Bay of Chaleurs, and the inhabitants live almost entirely on the produce of their fishing.

Rivers.—The largest river is the Looshtook, or St. John river, which rises far in the west, and flows for above 200 miles through Lower Canada. [CANADA.] It enters New Brunswick near 47° N. lat., and soon afterwards forms the Great Falls. By the most northern fall the river descends from 45 to 50 feet perpendicular. This is followed by some smaller falls, so that in half a mile the water descends 75 feet. Up to the foot of these falls the river is ascended by flat-bottomed boats of 20 tons burden. Below the falls the river often runs between abrupt banks, and its rugged bed renders navigation dangerous in many places. Several rapids occur, of which the most difficult are the rapids called Meductic Falls, situated where the river begins to run eastward. The last of these rapids occurs 6 or 7 miles above Fredericktown, at Saraye Islands. Where the river bends again to the south it is connected, by narrow channels, with several lakes, among which the largest is Grand Lake, whose channel joins it opposite Gagetown. This lake is 30 miles long and about three miles wide. The other lakes, Washademoak, Belleisle, and Kenobekasis, are somewhat smaller. All of them are navigable for sloops, as well as the rivers which fall into them. Sloops can ascend the St. John river to Fredericktown. About a mile above the town of St. John are the Rugged Narrows, where the river is interrupted by huge rocks, over and among which the waters roll and foam, and which render the navigation, except for four short diurnal periods, impracticable. The great rise of tide, which here attains from 25 to 30 feet, so far overflows these rapids that when the flood rises 12 feet at the foot of the town, sloops and schooners pass in safety for about 20 minutes, and for the same time when the tide ebbs to 12 feet. At Fredericktown the tide rises from 6 to 10 inches, and it is perceptible as high as the mouth of Keswick river. The whole course of the St. John river exceeds 400 miles, of which 220 lie within this colony.

The Petcoudiac, which falls into Shepody Bay, the western branch of Chignecto Bay, is about 70 miles long, and the tide flows up 40 miles. Ships occasionally proceed as far as Dorchester for timber; but the impetuous tides of the Bay of Fundy render the navigation difficult. The Miramichi, the most important river next to the St. John, drains the centre of the Central region with its numerous upper branches, and falls into the Gulf of St. Lawrence, after a course of more than 100 miles; it is navigable for large ships for about 40 miles. There is a sand-bar across its entrance, but the channel over it is broad, and has water for ships of from 600 to 700 tons. The Nipisighet river, which drains the Northern region, and runs nearly 100 miles, is much broken by falls and rapids, and does not appear to be navigable for any extent.

Climate.—The climate of this colony rather resembles that of the countries along the southern shores of the Baltic, than that of England. The spring is short, lasting only from the middle of April to the middle of May, and is characterised by raw weather. About the middle of May the summer sets in, and continues to the beginning or middle of September. The weather is warm, and rain not frequent, except during the thunder-storms, which are frequent. In September and October the weather is fine and pleasant, but in the two following months raw, and rain is very frequent. At the end of December or

beginning of January, the frost, which frequently is felt before, but only at intervals, becomes continual, and lasts to the end of March or the middle of April. The rivers generally break up about that time, so that the winter may be considered as lasting four months. The winter is colder and the summer hotter than under the same parallels of latitude in Europe; the daily variations of temperature are also greater, but the transitions from dry to wet weather are by no means so sudden as in England. The winds are subject to sudden and frequent variations, and as the temperature of the air depends on them, the variations of the atmosphere are as sudden. Northern and southern winds are rare. South-west winds prevail in summer and autumn. Westerly winds are, throughout the whole year, more frequent than any other. North-westerly winds are cold and dry; the winds from the north-east and east bring on snow-storms in winter, sleet and wet weather in spring, and heavy rains in summer and autumn. In July the thermometer rarely rises above 90° and in January it rarely sinks below 10° of Fahrenheit.

Productions.—The great commercial wealth of this country consists in its extensive forests, which are composed of pine, fir, spruce, hemlock, birch, beech, maple, ash, elm, and poplar; oak is also found, but it is not common. Pine is by far the most valuable for commercial purposes. Wheat, rye, oats, barley, beans, peas, buckwheat, and flax are cultivated with success, and Indian corn in the southern districts. Potatoes and the common esculent roots and vegetables are also grown. On the alluvial grounds which occur along the banks of the numerous rivers there are fine meadows and pasture-grounds. Apples, plums, and cherries grow well, but not the other fruit-trees of England.

Wild animals are by no means numerous, though there are still bears, wolves, foxes, racoons, minks, squirrels, and beavers: the moose deer is nearly extinct. Wild geese, ducks, partridges, and pigeons are the most common game. The rivers abound with salmon, eel, trout, perch, &c., and the sea near the shores with cod, haddock, mackerel, and herrings. A large number of families, settled in the country north of the mouth of the Miramichi river, gain their livelihood by fishing cod, mackerel, and herrings; the cod is sent to Spain and Italy.

The mineral riches are imperfectly known. Marble abounds on the banks of the lake Kenobekasis, and coal on those of Grand Lake, where it is worked. Iron-ore is said to be abundant. Gypsum occurs in large quantities all along the shores of the Bay of Fundy, and is exported to the United States, as well as grindstones, which are quarried in the vicinity of Shepody Bay.

Inhabitants.—The number of natives or Indians is very small. A few families belonging to the Mic-mac are found in the neighbourhood of the Bay of Chaleurs, and a somewhat larger number of Etchemins live in the forests and on the banks of the rivers above the Great Falls of the St. John river. It is curious that in a country so newly settled, and of which so small a portion is under cultivation, the aborigines should be so few. It appears indeed that they have never been numerous. These natives do not cultivate the ground; they live on the produce of their fishing and hunting, and pass continually from one river or lake to another. A number of families, settled mostly on the shores of the Bay of Chaleurs, are of French origin, or Acadians; the remainder are of British origin.

Towns.—Fredericktown, the capital, is built on the banks of the St. John river, 85 miles from its mouth, on a flat, surrounded by the river on two sides. Vessels of 50 tons burden may ascend to this town. The streets are regular, but the houses chiefly of wood. It contains a good government-house, and several other public buildings. The population is about 3000. St. John, the principal trading-place, has above 10,000 inhabitants; it is situated near the mouth of the St. John river, on the southern declivity of a peninsula, and on rocky and very irregular ground. It contains several good public buildings. St. Andrew's, a thriving place at the mouth of the St. Croix river, in Passamaquoddy Bay, has 3000 inhabitants. Newcastle, on the banks of the Miramichi, about 20 miles from its mouth, is a thriving place, well situated for the exportation of timber. (M'Gregor's *British America*; Bouchette's *British Dominions in North America*.)

The population of the colony, according to the latest census, taken in 1834, was as follows:—

District or County.	Sq. Miles.	Males.	Females.	Total.	Families.	Houses.
York	3,440	5,437	5,041	10,478	1,698	1,502
Carleton	4,050	4,934	4,509	9,443	1,542	1,419
St. John	646	10,389	10,279	20,668	3,630	2,188
King's County	1,328	6,305	5,890	12,195	1,926	1,849
Queen's County	1,502	3,747	3,477	7,224	1,175	1,056
Sunbury	1,224	9,061	1,777	3,834	536	505
Westmoreland	2,050	7,323	6,882	14,205	2,272	2,017
Northumberland	5,000	6,008	5,162	11,170	1,777	1,660
Kent	1,260	3,292	2,829	6,031	971	884
Gloucester	3,600	4,706	3,617	8,323	1,316	1,155
Charlotte	1,221	8,371	7,481	15,852	2,443	2,349
Total	25,324	62,513	56,944	119,457	19,345	16,434

In collecting the above numbers distinction was made between males and females who were above or under the age of 16, from which it appeared that there were—

	Males.	Females.	Total.
Above 16	52,845	28,291	61,136
Under 16	29,381	28,403	57,784
Age not ascertained } 	287	250	537
	62,513	56,944	119,457

The number of emigrants that arrived in the colony in each year, from 1832 to 1836, was as follows—

1832	6929
1833	3952
1834	7717
1835	3307
1836	5886

The militia returns of 1836 comprise 51 field-officers, 300 captains, 580 subalterns, 471 serjeants, 26 drummers, and 19,260 rank and file; in all 20,688.

The home government and the local legislature have been alike mindful of the subject of education. King's College in Fredericton is endowed by royal charter, and receives out of the crown revenues the yearly sum of 1000*l.*, in addition to 990*l.* from the provincial treasury, and 180*l.* arising from rent of lands with which the college has been endowed. There are no late returns of the number of students. In connection with the college and supported out of its funds is a grammar-school, conducted on the same plan as the school of Eton College, in which 61 scholars are taught. By an act of the provincial legislature, 90*l.* per annum are appropriated to the support of a grammar-school in each county of the province, on condition that the inhabitants subscribe 45*l.* per annum in addition. Under this act eight grammar-schools are supported in as many of the counties. Carleton and Gloucester are the only counties in the province without a grammar-school. Another act of the provincial legislature provides for the support of parish schools to the number of seven in a parish, by the grant of 20*l.* colonial currency per annum to each school, provided the inhabitants subscribe an equal sum and erect a school-house. Under this act there were, in 1836, throughout the province 480 schools, in which 6424 boys and 5078 girls received instruction. In addition to the schools thus established and endowed by the legislature there are numerous private schools, but no returns respecting them have been made.

For the religious instruction of the inhabitants there are appointed 24 rectors and 6 curates belonging to the Church of England; 10 clergymen in connection with the Church of Scotland; 14 preachers, who officiate by turns in 28 chapels belonging to the Wesleyan Methodists, besides Baptists, Independents, and Roman Catholic preachers.

The exports of the province are almost wholly confined to the produce of the forests and the fisheries. Out of 547,720*l.*, the total value of exports in 1836, the forests supplied to the amount of 475,431*l.*, and the fisheries 35,943*l.*, the remaining value being made up of coals, gypsum, corn, and provisions, and sundry articles re-exported. The value of imports during the same year was 863,783*l.*, of which grain and salt provisions amounted to 146,045*l.*; articles of apparel and woven goods to 314,334*l.*; metals and hardwares, 91,052*l.*; cordage, glassware, earthenwares, and other British manufactures, 87,937*l.*; colonial produce, 88,374*l.*; and the residue was made up of articles of foreign growth and production. The imports into the province are always to a larger amount than the exports, which must partly arise from the capital conveyed to it by settlers from the mother-country. The excess of imports during

the five years from 1832 to 1836 was 577,087*l.*, which is somewhat more than 20*l.* for each emigrant that landed.

The shipping that entered and cleared during 1836 was as follows:—

From and to—	Inwards.			Outwards.		
	Ships.	Tonnage.	Men.	Ships.	Tonnage.	Men.
Great Britain	612	157,862	..	688	219,259	..
Brit. colonies	1918	118,394	..	1789	108,435	..
United States	543	56,626	..	318	18,670	..
Foreign states	19	4,178	..	6	671	..

Total 2992 337,060 16,462 2801 347,035 16,059

Ship-building forms a considerable branch of industry in the province; and as many of the vessels constructed there are sold after discharging their first cargoes in British ports, their value in part makes up for the excess of imports as above described, but to what extent this kind of remittance is made there are no means of knowing. The number of ships built, with their tonnage, in the five years from 1832 to 1836, was as follows:—

Years.	Ships.	Tons.
1832	55	17,465
1833	97	17,837
1834	92	24,140
1835	94	23,058
1836	89	27,826

The amount of shipping that belonged to the province in 1836 was 587 vessels, of 84,425 tons, navigated by 3658 men.

The administration of the government of New Brunswick is confided to a lieutenant-governor (who is subordinate to the governor-general of the British provinces in North America), an executive and legislative council, of 12, and a House of Assembly, of 28 members. For the dispensing of justice there is a supreme court, with a chief-justice and three puisne judges. There are also a court of chancery, a vice-admiralty court, and a court for the probates of wills and granting of administration to intestates.

The public revenue of the province in 1836 amounted to 58,627*l.*, and was derived from the following sources:—

Specific duties on spirits, sugar, coffee, dried fruits, cattle, and ad valorem duties on the importation of manufactured goods	£19,728
Duties on sales by auction	1,545
Hawkers' and pedlars' licences	103
Customs' duties, levied under acts of the imperial parliament, transferred to the local treasury	7,251
	£58,627

The provincial expenditure during the same year was 52,414*l.*, under the following heads—

Collection of revenue	£3,227
Allowances to members of the legislature and expenses of legislative bodies	5,017
Dispensation of justice	484
For purposes of education	9,940
Bounties	232
Construction and repairs of roads and bridges	21,531
Construction and repairs of public buildings	3,535
Expenses of militia	910
Post-office charges	324
Relief of emigrants and other charitable objects	1,117
Miscellaneous charges	6,094
	£52,414

In addition to the foregoing, various expenses are defrayed by Great Britain. The sums thus paid, in 1836, were:—

For the civil and ecclesiastical establishments	£9,054
For the judicial establishment	3,835
Miscellaneous expenditure	150
	£13,039

NEW CALEDONIA, an extensive island in the Pacific, is situated between 17° 57' and 23° S. lat., and between 163° and 168° E. long. This island extends from north-west to south-east more than 400 miles, but is of inconsiderable width. In the broadest part it is hardly 60 miles wide. On all sides it is enclosed by coral reefs, which

connect innumerable small sandy islands or cliffs. These reefs extend in some places more than 50 miles from the shores, but they generally occur at a distance of from 4 to 10 miles from the coast. Hitherto only two openings have been found in these reefs by which the island can be approached by vessels. There are only two harbours in which large vessels can anchor with security; on the north-eastern shores, Port Balade, and on the south-western, Port St. Vincent. From the shores the country gradually rises inland to a mountain-range which traverses the island in all its length, and rises in some parts to 2000 or 3000 feet above the sea. This island is less fertile than most other islands of the Pacific. The declivities of the hills are partly bare and partly covered with coarse grass and low trees. Some flats along the shores are swampy; but others, as well as the valleys, have a fertile soil. The inhabitants live mostly on yams and fish. The sugar-cane and banana are cultivated to some extent. Cocoa-nut palms, bread-fruit-trees, and mango-trees abound on the shores. Among other minerals, a kind of steatite is found, which is eaten by the inhabitants, who belong to the race of the Austral negroes. They are stoutly made, have black and curly hair, and a very dark colour. They eat their enemies. Cook, who discovered this island in 1774, found them good-natured and friendly; but the French give a different account of their character. They speak a language which differs from that of the neighbouring islands, but it is supposed that it will be found to be only a dialect of the language spoken in Papua and New Britain.

(Cook's and D'Entrecasteaux's *Voyages*, and Krusenstern's *Mémoires*.)

NEW COLLEGE, Oxford, was founded in 1386, by William of Wykeham, bishop of Winchester and lord-high-chancellor of England, for a warden, seventy fellows and scholars, ten chaplains, an organist, three clerks, and sixteen choristers. The fellows and scholars are elected from the college of Winchester, where an election is held annually by the wardens of both colleges, two fellows of New College, and the sub-warden and head-master of Winchester College, to supply the vacancies which may happen in the course of the ensuing year at New College. The founder's kindred are actual fellows on their first admission, the others are scholars on probation till the expiration of two years. The visitor is the bishop of Winchester. The election from the college of Winchester usually takes place in the second week of July.

Of the benefactors to New College after its establishment, one only appeared during the founder's lifetime, John de Buckingham, bishop of Lincoln, who gave to the society the advowson of Swalcliffe church and some lands adjoining. Thomas Beckington, bishop of Bath and Wells, in 1440, Thomas Jane, bishop of Norwich, in 1494, and archbishop Warham, in 1509, were also contributors of landed property. John White, bishop of Winchester, was a benefactor in 1558.

The rectories of Akeley, Hardwick, Harwood Magna, Newton Longville, Radclive, and Tingewick, and the vicarage of Whaddon, in Bucks; the vicarage of Steeple-Morden in Cambridgeshire; the rectory of Abbotstoke in Dorset; the rectories of Birchanger and New Stampford, with the vicarage of Writtle with Roxwell chapel, and the chapelry of Rumford, in Essex; the vicarage of Marshfield in Gloucestershire; the vicarage of Hackfield with the chapelry of Mattingloy in Hants; the rectories of Saham Tony, All Saints Stratton, St. John Maddermarket in Norwich, and Weston Longville, and the vicarage of Witchingham, in Norfolk; the rectory of Paulespury in Northamptonshire; the rectories of Bucknell, Heyford Warren, Stanton St. John, and Wootton, with the vicarages of Adderbury and Chester-ton, and the vicarage of Swalcliffe with Epwell chapelry, in Oxfordshire; the rectory of Worthingham with the chapelry of Wolston in Shropshire; the rectory of Long-Ditton in Surrey; the rectory of Stockton in Warwickshire; and the rectories of Alton Barnes, St. John Berwick, Colerne, and Donhead St. Mary's, in Wilts, form the list of preferments in the college patronage.

Among the prelates educated in New College are Chichele and Warham, archbishops of Canterbury; bishop Beckington, already mentioned; Kenn, bishop of Bath and Wells; and bishop Lowth. Among the other scholars educated in the college may be named—Philpot, one of the first martyrs in Queen Mary's reign; Nicholas Harpsfield; Sir Henry Sidney, the father of Sir Philip;

Pits, the biographer; Herbert, earl of Pembroke; Wood, the author of the 'Institutes of the Laws of England'; Somerville, the poet; Smith, the translator of Thucydides; and Dr. Robert Holmes, the collator of the 'Septuagint.'

Most of the buildings of the founder in this college, after a lapse of more than four centuries, remain substantially entire. His whole design may be still traced throughout and the hall, chapel, cloisters, groined gateways, and even the original doors and windows, in many instances, remain undisturbed. The chapel was restored by Wyatt in 1789, and is rich both in ancient and modern painted glass: the west window, painted by Jervais from finished cartoons furnished by Sir Joshua Reynolds, and begun in 1777, is considered one of the finest works of art in Oxford: the other windows of the antechapel exhibit the original glass of the founder's time. The tower of this college, a pattern of massive strength, and one of the great features in the general view of Oxford, stands on the site of one of the bastions of the old city wall. The more recent buildings in what is called the garden court of the college were finished in 1684.

Among the curiosities preserved in this college is the superb and costly crozier of the founder, of silver, gilt and enamelled. Some of the ornaments of his mitre, his gloves, and ring, are also preserved in the muniment-room.

On the 31st December, 1839, there were 169 members upon the books of this college. (*Gutch's Colleges and Halls of Oxford*; *Chalmers's Hist. of the Colleges and Halls*; *Ingram's Memorials of Oxford*; *The Oxford Univ. Calendar*, 1839.)

NEW ENGLAND. [ENGLAND, NEW.]

NEW FOREST, situate in that part of Hampshire which is bounded on the east by Southampton river, and on the south by the British Channel, is the only forest belonging to the crown of which the origin is known. Domesday Book contains a distinct account of its afforestation, and the formation of it has added much to the load of reproaches laid on the memory of William the Conqueror. Our historians concur in accusing him of laying waste the country in Hampshire to a very large extent, of expelling the inhabitants from their houses, seizing their property, and even destroying churches, without giving the sufferers any compensation. Knyghton, who makes William Rufus a partner in the devastation with his father, represents opinion to have varied as to the number of churches destroyed, from twenty-two, beside dependent chapels, to fifty-two. (*Twysd., Script. Decem.*, col. 2354, 2373.) The fact of the destruction is allowed by the Conqueror's own chaplain, William of Jumieges, who, speaking of the deaths of William Rufus and his brother Richard, in the forest, says, 'Ferunt autem multi, quod ideo hi duo filii Willicelni Regis in illa silva judicio Dei perierunt: quoniam multas villas et ecclesias, propter eandem Forestam amplificandam, in circuitu ipsius destruxerat.' (*Hist. Norm. Script.*, fol. par. 1619, p. 296.)

Gough, in his edition of Camden, and Warner, in his 'Topographical Remarks relating to the South-Western parts of Hampshire' (8vo. London, 1793, vol. i., p. 182-189), gave, each, a tabular estimate of the amount of injury which William was supposed really to have occasioned to the population and agriculture of this part of England by the afforestation, abstracting the quantity of land in hides, virgates, and acres, with the respective values of the different allotments of property in the Confessor's and the Conqueror's reigns; A third tabular arrangement was made by the late Rev. William Bingley, among his preparations for a history of Hampshire. As a resident in the forest, Mr. Bingley had better opportunities than either Gough or Warner for comparing the text of the record of Domesday with the face of the county; and it appears from his tables that at least a hundred and forty hides had been afforested between the time of Edward the Confessor and that of the survey. These, reckoning four virgates in each hide, and thirty acres to make a virgate, amount to nearly seventeen thousand acres. Gough's table was the least extensive of the three already mentioned; it took in only that part of the survey which in itself purported to relate immediately to the New Forest and its environs, and omitted all the other parts of the survey of the county in which lands are stated to have been afforested: thus reducing the quantity of land really added by the Conqueror almost one half.

In justice to the Conqueror's memory however it should be stated that an anterior forest certainly existed here, and

is mentioned by several writers under the name of Ytene. The Conqueror enlarged its circuit to the extent stated, and gave it a fresh name, thus ensuring to himself a lasting reproach. Domesday Book is the earliest record which designates this tract as the *New Forest*. The destruction of numerous habitable places within its limits is evident from the names of many of them terminating in *ham* and *ton* or *tune*: as Truham, Groteham, Adlingeham, Wolnetune, Bermintune, and others, all indicating former villages or hamlets. Mr. William Stewart Rose, in the notes to his Romance of 'The Red King,' enumerates others, and refers to different spots within the present circuit of the forest where the ridges and inequalities of surface, and the fragments of building materials found upon digging within them, show marks of former foundations.

The oldest perambulation of this forest now preserved is in the Chapter-house at Westminster, of the 8th Edward I., the boundaries described in which include all the country from Southampton river on the east to the Avon on the west, following the sea-coast as the southern boundary between those rivers, and extending northwards as far as North Chardeford, or North Charford, on the west, and to Wade and Orebrugge, or Owerbridge, on the east. Another perambulation was made in the 29th Edward I., which leaves out a great part of the country contained in the former. This perambulation is preserved among the records in the Tower, and confines the forest to limits which appear to have been followed in the 22nd Charles II., when the forest was again perambulated. By the Charta de Foresta, all lands not belonging to the crown which had been afforested by Henry II., Richard I., or King John, were to be disafforested; but as no provision was made for the reduction of the more ancient afforestations, it is not easy to account for the great diminution of this forest in the reign of Edward I., who was not a prince likely to submit to any encroachment on his rights.

The perambulation of the 22nd Charles II. is the last on record, and contains the present legal bounds of the forest. According to this perambulation the forest extends from Godshill on the north-west, to the sea on the south-east, about twenty miles; and from Hardley on the east to Ringwood on the west, about fifteen miles; and contains within those limits about 92,365 acres statute measure. The whole of that quantity however is not forest land, or now the property of the crown; there are several manors and other considerable freehold estates within the perambulation belonging to individuals, to the amount of 24,797 acres; about 625 acres are copyhold, or customary lands, belonging to her majesty's manor of Lyndhurst: about 1004 acres are leasehold, under the crown, granted for certain terms of years, and forming part of the demised land revenue, under the management of the office of woods and works; about 901 acres are purprestures, or encroachments on the forest; about 1193 acres more are enclosed lands, held by the master-keepers and groom-keepers, with their respective lodges; and the remainder, being about 63,845 acres, are the woods and waste lands of the forest.

In each species of the property above mentioned the crown has different rights or interests.

By an act passed in the 9th and 10th Will. III., for improvement of this forest, certain rights of common, of pasture, pannage, and fuel, claimed by the proprietors of estates within or adjacent to the forest, under certain limitations, were saved and reserved to them, and the rights of the crown were defined and ascertained.

By that act the crown was empowered to enclose two thousand acres of the waste lands of the forest; one thousand acres forthwith, and the remaining thousand immediately after the first session of parliament after the year 1699; and also two hundred acres more yearly for twenty years following, making in all six thousand acres, 'to remain in severalty in the actual possession of the crown for ever, freed and discharged from all manner of right, title, and pretence whatsoever, and to be called, made, and kept a nursery for wood and timber only;' and the crown was likewise empowered, so soon as the trees in all or any part of such enclosures should be past danger of being hurt by cattle or deer, to throw open the same, and in lieu thereof to enclose an equal quantity in any other part of the forest; keeping in this way six thousand acres constantly enclosed as a nursery for timber. The crown has also a right to keep deer on the unenclosed part of the forest at all times, without any limitation or number.

By the same act it was provided 'that all persons having any right of pasture or pannage, or any privileges within the forest, should hold and enjoy the same; that is to say, their right of pannage between the 14th of September and the 11th of November yearly (old style), and their right of common of pasture in and through the waste grounds of the forest, at such time and times as the same should not be enclosed, the time of the fence-month (that is to say, fifteen days before and fifteen days after Midsummer, yearly), and the time of winter haining (that is to say, from the 11th of November to the 23rd of April yearly, old style), excepted, under and subject to the forest laws; saving also to the several adjacent inhabitants their ancient right of fuel, provided that such inhabitants should not sell or otherwise dispose of any part thereof, nor that any person or persons presume to receive or take the same in other manner than they ought, nor by reason of any claim or pretence of any right that was not allowed, according to the laws of the forest before the 27th year of queen Elizabeth.'

The right to fuel-wood is limited and ascertained by a decree of the Court of Exchequer, dated the 19th of June (26th Eliz.), by which it was ordered 'that no inhabitant of any house newly built, since the beginning of the queen's reign, should be allowed any wood in the said forest to be spent in any such new-built house.' This has ever since been held to be the rule for judging whether the inhabitant of any house claiming fuel-wood is entitled to it or not; and the claims for fuel-wood, with every other claim on the forest, are to be found in the Records of the Proceedings of the last Justice Seat for this forest, begun at Lyndhurst, and adjourned from thence to Winchester, the 29th of September, 1670, before the earl of Oxford, lord chief-justice in Eyre; in which claims are also set forth the small rents payable to the crown by the claimants for pasture and fuel, together with the rates payable annually for the pannage of swine.

For local purposes the New Forest is divided into nine bailiwicks, viz. Burley, Fritham, Godshill, Lynwood, Bat-tramsley, South East, the Nodes, Inn, and North. These bailiwicks are subdivided into fifteen walks, viz. Burley, Holmsley, Bolderwood, Eyeworth, Ashley, Broomy, Rhinefield, Wilverley, Whitley Ridge, Lady Cross, Denny and the Nodes, Ashurst, Ironshill, Castle Malwood, and Bramblehill.

Its officers are a lord-warden, lieutenant, riding-forester, bowbearer, two rangers, woodward, under-woodward, four verderers, high-steward, under-steward, twelve regarders, nine foresters or master-keepers, being one to each bailiwick, and usually fifteen under-foresters or groom-keepers; but at times a smaller number.

The lord-warden is appointed by letters patent under the great seal, during the royal pleasure. This officer has a general superintendance and command over the forest in all matters relative to vert and venison; and appoints the bowbearers, rangers, steward, and all the master-keepers and groom-keepers, to continue during his pleasure, except for the bailiwick of Burley, which has been in grant to the Bolton family for more than a century, by letters patent, renewed from time to time; and the walks of Bolderwood and Ironshill, of which grants were made for the lives of prince William and princess Sophia, the son and daughter of his royal highness the duke of Gloucester, brother of king George III. The lord-warden, by his patent, has the manor of Lyndhurst and hundred of Redbridge, or New Forest hundred, and the office of keeper of the decoy-ponds, with the herbage and pannage, and rents of free tenants. He has also possession of the king's house at Lyndhurst, with an allowance of 70*l.* per annum for repairs. The emoluments arising to the lord-warden amount to 214*l.*, and to his steward 48*l.*, besides the 70*l.* before mentioned.

The riding-forester (a place which has been abolished, we believe, during the present year) is, or rather was, also an appointment by letters patent, during the royal pleasure. His office was to ride before the king when he went into the forest. The salary 500*l.* per annum, with a fee buck and doe yearly.

The bow-bearers' duty is to attend the sovereign with a bow and arrow when in the forest. Salary 40*l.* per annum, with a fee buck and doe yearly.

The rangers are to drive the deer which stray into the purlieus back again into the forest. Salary 2*l.* 10*s.* 4*d.* per annum; 4*l.* per annum in lieu of wood formerly allowed; and one fee buck and doe yearly to each ranger.

The woodward is appointed by letters patent from the crown, during pleasure. He has 200*l.* per annum for himself, besides the salary of the deputy. He has also certain perquisites, arising chiefly from the timber, and an assignment of four loads of fuel-wood.

The vorderers and regards are chosen by the freeholders of Hampshire. The vorderers have no salary, emolument, or perquisite, besides a fee buck and fee doe yearly. The regards, who attend the marking of all trees to be felled, value the timber for sale, and attend the sales, are paid by a fee of 2*s.* 6*d.* per day when on actual duty.

The master-keepers' and groom-keepers' duty is to preserve the vert and venison in their respective bailiwicks and walks; to prevent any destruction of either, and all encroachments on the forest. The master-keepers have neither salary nor emoluments except a fee buck and doe each annually; while the under-keepers have small salaries, and, now, limited perquisites.

Another act for the improvement and regulation of this forest was passed in 1800, the enactments of which have not only effected the correction of various minor abuses committed within its limits, but are calculated to make it a permanent benefit to the country, by furnishing an abundant, and not as formerly, a very scanty supply of timber for our navy. The quantity of timber actually delivered for naval purposes, from the year 1761 to 1786, was 23,000 loads of oak and 7003 loads of beech, as appears by the Commissioners' Reports in 1789.

(*Reports of the Commissioners on the Woods, Forests, and Land Revenues of the Crown*, fol., Lond., 1787-1792; Gough's edit. of Camden's *Britannia*, fol., 1804, vol. i., p. 179-187; Ellis's *Introl. to Domesday Book*, vol. i., p. 105-110.)

A Plan of the New Forest, laid down from the surveys taken by Thomas Richardson, William King, and Abraham and William Driver, by order of the Commissioners of the Land Revenue, was published by Faden, in 1789, ten sheets, folio.

NEW GEORGIA ARCHIPELAGO, also called *Solomon's Islands*, constitutes one of the most extensive groups of islands in the Pacific. They extend from north-west to south-east, between 5° and 10° 50' S. lat., and between 154° 35' and 162° 25' E. long. They were discovered by the Spanish seaman Mendana, in 1567; visited for the second time by Carterot, and afterwards by several French and English navigators. Many parts of these islands have not yet been seen by any navigator. The most northern island is Winchelsea or Anson, and the most southern Ronnell. The largest islands from north to south are—Bougainville's Island, which is about 60 miles long; Choiseul, which is perhaps as long; S. Isabella, perhaps the largest of the group; Georgia, which extends 40 miles from east to west; Guadalcanar, which is 70 miles long; and San Cristoval, which is about the same size. Besides these there are several islands of less extent, and a great number of small islands. The shores are mostly very steep, and rise to a considerable height. The interior is rugged, and frequently mountainous. Mount Lammor, on the island of Guadalcanar, is compared in elevation with the Peak of Teneriffe. The hills and mountains are generally covered with lofty trees, and the valleys are generally well cultivated and very fertile. Bananas, yams, sugar-cane, and ginger are extensively cultivated. The most common fruit-trees are the bread-fruit, cocoa-palms, cabbage-tree, a kind of almonds, and Indian kale (*Caladium esculentum*). The clove-tree is also found here. Fowls abound, as well as several wild birds. The inhabitants belong to the Australian negroes, and seem to have made some progress in civilization; but they are cannibals.

(*Carterot's Voyage round the World*, and Krusenstern's *Mémoires*.)

NEW HAMPSHIRE, one of the United States of North America, is situated between 42° 41' and 45° 11' N. lat., and between 70° 45' and 72° 30' W. long. On the east it is washed by the Atlantic for about 20 miles; the remainder of the eastern boundary-line is contiguous to Maine, and about 150 miles in length. On the north it borders on Lower Canada for about fifty miles. It is separated by the river Connecticut on the west from Vermont, for about 170 miles. The boundary between it and Massachusetts, which lies south of it, is about 80 miles. The length of this state is about 174 miles. Its breadth varies: along 45° N. lat. it is 90 miles wide, but farther north it

grows narrower, so that on the parallel of 45° it hardly measures more than 25 miles. Its mean breadth is about 50 miles, and its area is about 8700 square miles. According to some authorities the area is nearly 9500 square miles.

Surface and Soil.—The shores are rather low, and the country along them, to the distance of 20 or 30 miles inland, is in general level; but the land rises imperceptibly, so as to arrest the tides within 20 miles from the sea, though they rise to about 18 feet. This flat tract has a sandy soil of inferior fertility. At the back of it the surface becomes broken and hilly, and the hills gradually rise in elevation as they proceed farther inland, until, at a distance of about 10 miles from the banks of Connecticut river, they constitute a continuous range, running nearly due south and north. Some of the summits attain a considerable elevation. Mount Monadnoc, about 10 miles from the boundary of Massachusetts, rises to the height of 3254 feet, and Moosehillock, farther north, to 4636 feet. On approaching 44° N. lat. the chain expands into an extensive mountain-group, which projects considerably towards the east, and is known by the name of the White Mountains. The highest summit of this group, Mount Washington, is the highest mountain in the United States east of the Rocky Mountains, and attains a height of 6234 feet above the sea-level. Several other summits rise to between 4000 and 6000 feet; as Mount Adams, 5328 feet, Mount Jefferson, 5058 feet, Mount Madison, 4866 feet, Mount Franklin, 4711 feet, and Mount Monroe, 4356 feet. From the northern side of the White Mountains the chain continues on both sides of the Androscoggin river, but it does not attain a great elevation. The country between this northern portion of the chain and the Connecticut river is hilly, rocky, and very thinly settled, on account of the severity of the climate owing to its elevation above the sea, and also an account of the barrenness of the soil. But south of the White Mountains the soil on the declivities of the lower hills and in the valleys between them is good, and that along the banks of the rivers, which is subject to be overflowed annually, is of excellent quality: but in general this state is better calculated for pasturage than for tillage.

Rivers and Lakes.—The Connecticut rises near the northern border of the state, in Lower Canada, in several small branches, but soon begins to form the boundary-line between New Hampshire and Vermont. Though its current is considerably obstructed by falls, rapids, and shoals, the navigation has been so much improved by dams, locks, and short canals, that boats of considerable tonnage may ascend it to Haverhill, near 41° N. lat., a distance of nearly 200 miles from its mouth in a straight line, and even to Fifteen-Mile Falls above Haverhill. [MASSACHUSETTS.] The Merrimack, which rises in the White Mountains and traverses the central districts of the state by a southern course, has also many falls and rapids, but the navigation of this river also has received great improvements, so that it is navigable from its mouth to Concord. The advantages which arise from this circumstance are still increased by the Middlesex Canal. [MASSACHUSETTS.] The Piscataqua, which for about 40 miles forms the boundary between this state and Maine, rises near the southern declivity of the White Mountains in a small lake, and runs south-south-east about 60 miles in a straight line. As a navigable river, it is of small importance, as its course is very rapid, and the tide ascends it only a short distance from the sea; but it forms the fine harbour of Portsmouth.

This state contains several lakes. The largest is Lake Winnepisseogee, which is 25 miles in length, and from one to 10 miles wide. Squam Lake, north-west of the former, is five miles long and four wide. In the northern districts is Umbagog Lake, through which the boundary-line between New Hampshire and Maine passes.

Climate.—The climate of the lower districts may be compared with that of the countries along the eastern shores of the Baltic. Frost occurs sometimes towards the end of September and usually in October, but it is slight. In November the weather is variable, and the frost moderate and not continuous. In December it begins to be intense and lasting. In January a thaw of several days sometimes occurs, but otherwise in this month, as well as in February, the frost is severe. Snow falls to the depth of from two to four feet, and does not disappear before April. In winter the prevailing wind is from the north-west, which rarely blows in summer. From the middle of November to the middle of May the cattle must be kept in stables. The winter does

not last longer in the hilly and mountainous districts, but it is more severe. At Keene, in the south-western part of the state, the thermometer has sunk to 24° below zero, Fabr. In these districts night-frosts are often experienced in June and August, so that July is the only month quite free from frost. This is also the case in the mountainous districts of Sweden, near 60° N. lat. In New Hampshire these districts are probably more than 1000 feet above the sea-level. The heat in summer is great, but we have not found any exact observations on the temperature.

Productions.—The low lands along the rivers yield rich crops of wheat and rye, also flax, hemp, and culinary plants. Barley, oats, peas, and beans are also grown. The uplands produce only moderate crops. Each farmer has an orchard of apple and pear trees, and good cider is made. In most districts Indian corn is grown, but it is sometimes destroyed by the night-frosts in June and August. Horned cattle are abundant, and the dairies very good. The cattle are of a large size. Sheep and pigs are also common; but horses are not numerous, and they are of a small size.

The hills and mountains are still almost entirely covered with extensive forests, consisting of pine, fir, oak, cedar, hemlock, beech, maple, balsam, poplar, birch, hickory, spruce, chesnut, and larch. The most valuable is the white pine, for masts, yards, and planks of vessels. The most common animals in the forests are the black bear, the wolf, fox, wild cats, racoons, and grey, striped, and flying squirrels; but the moose deer, the beaver, and black squirrel have become rare. Several kinds of birds abound; the wild turkey has become rare. The bays and rivers abound with halibut, cod, salmon, shad, eels, and trout. This state is rich in minerals, among which are iron, copper, galena, and plumbago.

Inhabitants.—The natives, who formerly seem to have been numerous and frequently were at war with the settlers, have long since disappeared. The present population consists of the descendants of British who have settled here during the two last centuries. There are a few free coloured people among them. In 1820 the population amounted to 244,155 individuals, among whom were 786 free coloured people. The census of 1830 gave the number at 269,328, or about 30 individuals to each square mile. They are mostly occupied with agriculture, but a considerable number are employed in preparing timber for market. There are manufactures of cotton, broad-cloths, and carpets in several towns, particularly Somersworth and Dover.

Political division.—New Hampshire is divided into eight counties. The capital of the state is Concord, situated on the river Merrimack, where it begins to be navigable. It is a small place, which in 1830 contained 3727 inhabitants. Portsmouth is on the estuary of the Piscataqua, which forms an excellent and spacious harbour, deep enough for vessels of the largest size. Owing to the great rise of the tides, it is rarely impeded by ice, and never freezes over. The town, which is about three miles from the mouth of the river, carries on a considerable commerce, and contains about 8000 inhabitants. Many vessels are built here. The general government has a navy-yard on an island in the harbour. Dover, not far from the Piscataqua, has more than 5000 inhabitants, and some commerce. There are a few other towns with from 2000 to 3000 inhabitants. Dartmouth College, at Hanover, is a respectable institution. The common schools, which are above 1500 in number, are supported by an annual tax.

Commerce.—The foreign commerce of the state is concentrated in the harbour of Portsmouth. From the 1st of October, 1832, to the 30th of September, 1833, the imports amounted to the sum of 167,754 dollars, and the exports to 155,258; of the latter, the goods of foreign produce amounted only to 9903 dollars. Only American vessels were employed in it. The vessels which entered the port amounted to 10,347 tons, and those which departed to 6002 tons. Formerly the commerce with the West Indies was considerable, but it has much declined since 1812. The state has from 60 to 70 vessels employed in the fisheries.

History.—New Hampshire was first settled in 1623, and the progress of the colony in the beginning was very slow. It had to sustain many distressing wars with the natives who inhabited its present territory. From the middle of the last century its progress was more rapid. In 1776 the provincial convention declared the royal government dissolved, with the view of separating entirely from Great Britain.

This took place before the declaration of independence. In 1776 the first provincial congress was established, under the name of a House of Representatives, but the present constitution dates from the year 1792. The legislature, called the *General Court*, is composed of two bodies, the Senate and House of Representatives. The senators, twelve in number, are elected annually by the citizens who pay taxes. The number of representatives depends on the population, and is at present 234. The executive power is vested in the governor, who is annually elected by the citizens of twenty-one years of age. This state sends two members to the Senate and six to the House of Representatives at Washington.

(Darby's *View of the United States*; Warden's *View of the United States of America*; Pitkin's *Statistical View of the Commerce of the United States of America*; *American Almanac for 1839*.)

NEW HANOVER. [NEW IRELAND.]

NEW HEBRIDES is an extensive group of islands in the Pacific, situated, if Banks's Islands are included among them, between 13° 15' and 20° 5' S. lat. and between 166° 40' and 170° E. long. Banks's Islands, the most northern group of the New Hebrides, were discovered by Captain Bligh in 1789; they consist of five small islands and one larger island which is more than 20 miles in circumference. South-west of these islands is the largest of the whole group, Tierra del Espiritu Santo, which was discovered by Quiros in 1605. It extends more than 70 miles from north-north-west to south-south-east, with an average width of 25 miles. It contains a wide bay with good anchorage on its eastern side. Farther south is Mallicolo, which is more than 60 miles long, and about 28 wide, and has a good harbour called Port Sandwich, on the east side near its southern extremity. The islands l'Isle des Lepreux, Aurora, Pentecôte, Ambrym, Paom, and Apee, which are situated east of Tierra del Espiritu Santo and Mallicolo, are not so large. Farther south is the large island Erromango, which is more than 80 miles in circumference, and the smaller island of Tanna, which is about 20 miles long. Besides these eleven larger islands there is a considerable number of smaller ones, which lie dispersed between and about them. These islands, or at least some of them, are of volcanic origin. An active volcano exists on the island of Tanna. These islands consist mostly of hills of moderate elevation, which however in some of them rise to the height of mountains. The valleys between these hills and also the level tracts along the coasts are very fertile. The uncultivated declivities of the hills are covered with trees. These islands are very rich in vegetable productions. It is said that more than forty different kinds of plants and trees are cultivated. The banana, sugar-cane, yam, arum, batata, and curcuma are grown in regularly divided fields, and with great care. The cocoa-nut, bread-fruit, the cabbage-tree, a kind of figs, almonds, and oranges are common. Bamboos, pepper, and mastic are abundant, and the nutmeg-tree occurs likewise. The domestic animals are hogs, pigs, and fowls. The inhabitants eat their enemies who fall in battle. They belong to the race of the Australian negroes, but have made greater advances in civilization than most of the other tribes of that race, as the state of their agriculture evinces. It seems that they do not speak one language, it being said that on the island of Tanna three different languages are used. This island is the best known, since Cook remained there some time, when he discovered most of these islands in 1774. (*Cook's Voyages*; and Krusenstern's *Mémoires*.)

NEW HOLLAND. [AUSTRALIA.]

NEW IRELAND is an island in the Pacific, situated between 2° 40' and 4° 52' S. lat. and 150° 30' and 152° 50' E. long. It is more than 170 miles long from south-east to north-west, but on an average not much more than 12 miles wide. It was considered as a part of New Guinea by its discoverers Schouten and Lo Maire; and after Dampier, in 1700, had discovered Dampier's Strait, which separates New Britain from New Guinea, it was thought to be a portion of New Britain, until, in 1767, Carteret discovered the strait which separates both islands. Dampier had taken it for a bay, and called it St. George's Bay, a name which Carteret changed into St. George's Channel. The strait which divides it from New Hanover was called by Carteret, Byron's Strait. Near the southern extremity, Cape St. George, there is a good harbour, called Port Prasin. The island has a hilly surface, and some summits rise into mountains, but all of them

are covered with wood. The lower tracts are well cultivated, and produce bananas, sugar-cane, batatas, ginger, yams, bread-fruit, cocoa-nuts, sago, figs, bamboos, and many other plants and trees. Dogs, pigs, and turtles are abundant. The inhabitants belong to the Australian negroes, and resemble in every respect their neighbours the inhabitants of New Britain. New Hanover is situated farther west, and is about 30 miles long from east to west; it is likewise very hilly, and even mountainous, but contains many cultivated tracts. (Carteret's *Voyage round the World*; and Krukenstorn's *Mémoires*.)

NEW LONDON. [CONNECTICUT.]

NEW MEXICO. [MEXICAN STATES.]

NEW RIVER. [MIDDLETON, SIR HUGH.]

NEW SIBERIA. [SIBERIA.]

NEW SOUTH SHETLAND is a group of islands situated south-south-east of and about 600 miles from Cape Horn, between 61° and $63^{\circ} 30'$ S. lat. and 53° and 63° W. long. They extend from east-north-east to south-south-west, over a space of nearly 300 miles, and consist of twelve islands of moderate extent, and a great number of rocks and cliffs. They were discovered in 1819 by Captain Smith, and have frequently been visited since that time for the purpose of taking fur-seals and sea-elephants, with which the shores abound. The largest of the islands from east to west are Clarence, Elephant, King George, Strachan, Mitchell, Sartorius, Livingston, Low, and Smith. The interior of these islands consists of high hills or mountains. A mountain on Smith's Island attains the height of 6600 feet above the sea. They are almost entirely covered with snow all the year round, and only after Midsummer (in January) a few tracts, which are free from snow, are overgrown with lichens and mosses, in some places intercepted with a sort of straggling grass. The only inhabitants of these cold regions are numerous sea-fowls, as the albatross, penguin, &c., and the animals above mentioned. The surrounding sea abounds in whales and fish. Most, if not all, of these islands are of volcanic origin. Captain Weddel observed smoke issuing from the rocks of Bridgman Island, and the Island of Deception has the form of a horse-shoe, resembling in that respect the islands of the Pacific, which are formed by madreporas. The deep depression in the middle of Deception Island, which is 97 fathoms deep and makes an excellent harbour (Port Foster), is doubtless a crater, and this island may, as to form, be compared with the island of Nisita in the Bay of Naples. The high rocks which enclose this crater are volcanic, rise to more than 800 feet above the sea, and are partly covered with ice. South of these islands is a wide strait, called Bransfield Strait: the coasts which constitute the southern shores of this strait appear to form an extensive country, which has lately attracted the attention of navigators. [SOUTH POLAR COUNTRIES.] (Weddel's *Voyage* and Foster's *Voyage*.)

NEW TESTAMENT. [GRIESHACH; TESTAMENT.]

NEW-YEAR'S-DAY. Of the customs formerly practised at the opening of the new-year, none appear to have been so universal as feasting and sending presents, both of which the moderns appear to have derived from the Romans. Suetonius (*August.*, § 57, edit. varior., 8vo., 1647, p. 198) alludes to the practice among the Romans of bringing presents to the Capitol on new-year's-day, whether the emperor was present or absent; and Tacitus speaks of an order of Tiberius, forbidding the giving or demanding of new-year's-gifts unless it were on the calends of January. The early Fathers of the church condemned this practice as superstitious, because the gifts were considered as omens of success for the ensuing year.

New-year's-day with us, like many others, in modern times, has lost much of the ceremonials of its observance. In a volume of 'Miscellanies,' printed in Queen Anne's time, we read,—'January. On the first day of this month will be given many more gifts than will be kindly received or gratefully rewarded. Children, to their inexpressible joy, will be drest up in their best bibs and aprons, and may be seen handed along streets, some bearing Kentish pippins, others oranges stuck with cloves, in order to gain a blessing of their godfathers and godmothers.'

Gifts at new-year's-tide formed a charge of no small amount in the privy-purse expenses of royalty, from very early times to the time of Charles II.: they were mostly made in plate.

Moresin, who published his 'Papatus' in the time of James I., tells that in Scotland it was then the custom to

send new-year's-gifts on new-year's-eve; and on new-year's-day they wished each other a happy day, and asked a new-year's-gift. When Brand wrote his 'Popular Antiquities,' it was still usual in Northumberland for persons to ask for a new-year's-gift on that day.

The modern Jews, on the first day of the month Tisri, which may be considered as their new-year's-day, usually have a splendid entertainment, and wish each other a happy new-year.

Hospinian says, that at Rome on new-year's-day (he speaks of modern practices) no one would suffer a neighbour to take fire out of his house, or anything of iron, or lend anything. (Brand's *Popular Antiq.*, vol. i., p. 8-18, &c.)

NEW YORK is one of the largest and the most important of the states which compose the North American Union. It is situated between $40^{\circ} 40'$ and 45° N. lat., and between 73° and 80° W. long. It extends in length from south to north more than 300 miles, and in width, along the parallel of 42° N. lat., 340 miles. Its surface is estimated at more than 46,000 square miles, or about 4000 miles less than that of England without Wales. To the north and west of New York lie the Canadas, from which it is separated by the parallel of 45° , called the Canadian Line, and by the river St. Lawrence, Lake Ontario, Niagara river, and Lake Erie. On the south it is bounded by the states of Pennsylvania and New Jersey, and the Atlantic Ocean; the Delaware river forms the boundary-line between it and Pennsylvania for 65 miles. On the east it borders on Connecticut, Massachusetts, and Vermont. Lake Champlain constitutes the boundary-line for 105 miles between New York and Vermont.

Surface and Soil.—None of the United States presents a greater variety of surface than New York, a circumstance owing to its including portions of two large mountain-systems, the Appalachian and Acadian Mountains, and to its containing also a mountain-system of its own, the Essex Mountains. These three mountain-systems are divided from one another by wide valleys, mostly of a peculiar description and from the lakes Erie and Ontario by a plain of considerable extent.

The Appalachian Mountains in Virginia, in 39° N. lat., occupy, with their numerous parallel ridges, hardly more than 100 miles in width. But near 40° N. lat. they begin to widen, and at 41° N. lat. they are above 200 miles in width. This extension is produced by the eastern and central ridges turning to the east and east-north-east, whilst the western ridges (the Laurel Hills and Chesnut Ridge) continue in the general direction of the system north-north-east. These western ridges grow lower and less distinct as they approach 42° N. lat., and north of that parallel they are lost in an elevated plain or table-land, which has a hilly surface. The eastern ridges continue as distinct mountain-masses eastward to $74^{\circ} 40'$, or a distance of from twenty-five to thirty miles from the banks of the river Hudson, where they may be said to terminate; but their extremities are here united by a mountain-ridge whose general direction is north and south. This ridge forms a continuous range between 41° and 42° N. lat. Its southern extremity, which lies within the state of New Jersey, is known by the name of the Kittatinny Mountains, but the whole has not yet been designated by a name. We should propose the appellation of Tuscarora Mountains, to perpetuate the name of that tribe of the Six Nations, to whose memory no geographical monument exists. This Tuscarora range continues beyond the union of the ranges northward to 43° N. lat., where it turns westward, and after extending in that direction nearly fifty miles, terminates at the eastern extremity of the table-land on which the western ranges of the Appalachian Mountains are lost. But all the eastern chains of the Appalachian Mountains do not unite with the Tuscarora Mountains. The most southern, known in New Jersey under the name of the Blue Ridge, is divided from them by the valley in which the Pawling and Wallkill rivers flow south-west and north-east. This last-mentioned ridge continues in a north-eastern direction to the very banks of the Hudson river, where it terminates with the Mattewan Mountains or Highlands, between West Point and Newburg.

Opposite the Highlands and east of the Hudson river rise the Fishkill hills, which constitute the south-western extremity of that extensive mountain-region which occupies a considerable portion of New England, and extends through Lower Canada to the very mouth of the St. Lawrence river.

Though commonly considered as a portion of the Appalachian Mountains, it claims a distinct consideration, and ought to be designated by a particular name, for which we propose that of Acadian Mountains, as the greatest part of this mountain-region was formerly known by the name of Acadia. The Fishkill hills run from the banks of the Hudson north-east and north through New York, until they arrive at its eastern boundary-line, where the states of Connecticut and Massachusetts meet, and where they take the name of Taghkanic range. From this point, continuing to the east of north, they constitute the boundary between Massachusetts and New York, until, by declining more to the east, they enter the first-named state, and proceed into Vermont, where they are called the Green Mountains. Between them and the Tuscarora range extends the valley of the middle Hudson.

The Essex Mountains are situated entirely within the limits of New York, and have only lately and partially been explored. They occupy the country between $43^{\circ} 20'$ and $44^{\circ} 30'$ N. lat., enclose Lake George, extend along the western shores of Lake Champlain, and reach westward probably to $74^{\circ} 30'$ W. long., so that they extend about fifty miles in width. West of them is an elevated table-land, which seems to run to $75^{\circ} 40'$ W. long., and which on the south terminates in the valley of the Mohawk river, which valley separates it from the Tuscarora range, where this range runs east and west.

New York contains seven regions, different in configuration of surface and in fertility, and to a considerable degree also in climate—the hilly region of the Susquehanna and Delaware rivers, the elevated table-land, the declivity of the table-land towards Lake Ontario, the northern region, the valley of the Mohawk river, the valley of Lake Champlain, and the vale of the Hudson river, to which the island of Long Island and Staten Island are to be added.

The region of the Susquehanna and Delaware rivers comprises the country which is surrounded on the east and north by the Tuscarora range, and is drained by the upper branches of the Delaware and those of the eastern branch of the Susquehanna; it extends westward to about 76° W. long. The mountain range which surrounds it probably in no part exceeds in absolute elevation 2000 feet. The valleys which descend from the Tuscarora range, chiefly in a south-western direction, contain rather wide and extensive bottoms of great fertility, which in their natural state are overgrown with forests of sugar-maple, black walnut, elm, beech, and other trees, indicating a strong soil. The declivities of the mountains are rather steep, and their soil of inferior quality; they are mostly overgrown with pine, among which oak, chestnut, and hemlock are intermixed. The valleys, when cultivated, yield rich crops, and hence this region is comparatively well settled.

West of this region, along the boundary-line of Pennsylvania, lies the elevated table-land on which the western ridges of the Appalachian Mountains terminate, and the western branch of the Susquehanna, the Alleghany river, an affluent of the Ohio, and the Genessee river originate. It is from 20 to 30 miles wide, terminating on the north at the southern extremity of the lakes Cayuga and Seneca. Its surface is broken and hilly, but the hills are scattered over the country, and not disposed in ridges. Towards the western extremity, two short ranges, the Cattaraugus and Chataugue hills, rise to a considerable elevation. At the eastern extremity the table-land seems not to exceed 1000 feet in elevation, but at the sources of the Genessee and Alleghany it probably rises to 1300 feet, or more than 800 feet above Lake Erie. The deepest depression seems to occur between Lake Seneca and the village of Elmira on the Tioga, an affluent of the western branch of the Susquehanna, and in this direction the summit level does not exceed 885 feet, but it lies in a valley. The country is almost entirely covered with wood, mostly pine, and is at present very thinly settled. Some sheltered tracts between the hills exhibit a considerable degree of fertility.

From this table-land the country slopes towards Lake Ontario; but it can hardly be called a slope, as there is a rise, though not a considerable one, towards the shores of the lake. Between the table-land and this rise there is a slight depression extending in the form of a trough east and west: it is called the Lake Country. At the eastern extremity of this depression, between Lake Erie and the river Genessee, the country seems gradually to descend from 1000 feet and upwards to 565 feet, which is the Erie level of the Grand

Canal. Where the country descends from the table-land, there are numerous lakes, of which the most considerable are Canandaigua (685 feet), Crooked Lake (700 feet), Seneca (440 feet), and Cayuga (400 feet). These numbers, indicating the elevation of the lakes above the sea, show that the depression lowers in its course from west to east. The surface of this depression is generally either level or undulating, and rarely hilly, but the lakes lie deep under the general surface in wide chasms, and the beds of the rivers are likewise much depressed. In its natural state this country is covered with high forest trees, and, when cultivated, yields most abundant crops. It is the most fertile portion of the state, and as it is contiguous to the Grand Canal, cultivation is extending rapidly, and the population has, in the last twenty years, probably doubled twice. The central portion of the canal passes through the depression, but the western part passes over the higher grounds which separate it from Lake Ontario.

The higher ground, which occurs north of this region, and about ten or twelve miles from the shores of Lake Ontario, does not appear to be much more elevated than the Lake Country. Its surface is uneven and broken, and the soil partly stoney and gravelly, and in general of indifferent quality. From this higher ground the country descends uniformly and gradually to Lake Ontario, except that, between Niagara and Genessee rivers, a distance of 80 miles, it is traversed in its whole length by what is called the Ridge Road or Alluvial Way. This elevated tract is composed of common beach sand and gravel stones, apparently worn smooth by the action of water, and the whole is intermixed with small shells. Its general altitude above the neighbouring land is 30 feet, and its width varies considerably. At the Niagara and Genessee rivers it is found to be about 120 or 130 feet above their level, and thus it appears that it is about 150 feet above Lake Ontario, from which it is 6 or 10 miles distant. It is conjectured that it once constituted the shores of that lake, which by some change in its outlet has sunk about 150 feet below its ancient level. As the country on both sides of this extraordinary ridge is thickly wooded, but the ridge itself without vegetation, the first settlers chose it as the line of road, whence it derives its name. We find no mention of a similar elevation east of the river Genessee. The country traversed by the Alluvial Way seems to be of indifferent quality.

The northern region comprehends the country lying north of Lake Oneida and of the valley in which the Mohawk river flows, as far east as the mouth of the East Canada creek. Farther east its southern boundary is formed by a line drawn from the last-mentioned place to Glens Falls on the Hudson river, which occur where the river flows from west to east. It is separated from Lake Champlain by the deep depression in which that lake lies. Northward it extends to the Canadian line, the St. Lawrence, and westward to Lake Ontario. It comprehends the Essex Mountains, as well as an elevated and extensive table-land lying to the west of the mountains, and the declivities with which the mountains and table-land descend to the south, west, and north. It comprehends about one-third of the surface of the state, and a great portion of it, perhaps one-half, is uninhabited. The mountains occupy the eastern part of the region: they begin on the south, between Glens Falls on the Hudson river and the southern extremity of Lake George. A lower ridge separates that lake from Lake Champlain, but the more elevated portion of the mountains extends along the western shores of Lake George northward. In its southern parts this range does not appear to rise to a great elevation; but north of 44° N. lat., and especially between $44^{\circ} 5'$ and $44^{\circ} 10'$, some of its summits rise above the line of trees. The most elevated, called the High Peak of Essex, or Giants' Mountain, attains an elevation of 5467 feet, or above 1800 feet more than Mount Catskill, the most elevated summit of the Appalachian Mountains whose height has been determined, and only about 800 feet less than Mount Washington, the highest summit of the White Mountains in New Hampshire. Mount MacIntyre, west-north-west of the Giant Mountain, attains 5183 feet, and several other peaks rise to between 4000 and 5000 feet. The snow does not disappear from the summit of the Giants' Mountain till after the middle of July. The valleys embosomed between these higher ranges are from 2000 to 3800 feet above the sea-level, and of course uninhabited and uninhabitable. In the Alps, valleys of such an elevation are only inhabited during some weeks in the summer. The valleys are however covered with pine, spruce, and birch trees,

Towards the summit of the mountains, these trees become dwarfish, and are interwoven with each other by their numerous horizontal branches. On the highest summits however the trees disappear entirely, and are replaced by mosses, lichens, and small alpine plants.

The climate of this elevated region is so cold, that ice is formed during the night in the beginning of August. Towards the south the valleys are much lower, and a few settlements have been made. It is not exactly known how far the mountains extend westward, but probably they reach to $74^{\circ} 30'$ W. long., enclosing the numerous upper branches of the Hudson river. West of this mountain-region lies a table-land of an uneven surface: as no settlements have been formed here, it is little known, except that it does not contain ridges of high mountains, that a portion of it is covered with swamps, and a still greater part intersected with lakes. As the numerous rivers which originate on it descend by a succession of rapids and cataracts, its elevation above the sea must be considerable and the climate extremely severe, a circumstance which will account for the entire want of settlements east of $75^{\circ} 30'$, and northward only at a distance of from 20 to 25 miles from the banks of the river St. Lawrence. On the south this elevated region is bounded by a range of hills, which constitutes the northern border of the valley of the river Mohawk, and separates it from the upper course of Black River, of Lake Ontario, and of the Sacandago river. It extends between $74^{\circ} 15'$ and $75^{\circ} 30'$ W. long., from east by north to west by south, and is called the Sacandago Hills. According to a vague estimate of Darby, these hills rise from 1200 to 1500 feet above the sea-level, but they are probably higher. The declivity of this elevated region seems to begin on the west about 20 or 30 miles from the shores of Lake Ontario and the St. Lawrence river, where the settlements commence. In the valley of Black River they extend to a greater distance, probably because the bottoms of this river are more sheltered and more extensive than those of the other rivers. These settlements however occur at great distances and only on the banks of the rivers, the remainder of the region being entirely covered with woods. The climate of these declivities is very severe, as they are exposed to the prevailing cold winds which blow from the north-west.

This region is divided from the Tuscarora range by the valley of the river Mohawk. This valley may be said to begin at Rome, to which place this rapid river runs in a ravine from north to south. From Rome the river flows south of east, and the valley along its banks may be said to extend about 60 miles to Amsterdam, where it opens upon the vale of the Hudson river. The valley is in general from three to six miles wide; but at 75° W. long. it is traversed by a ridge of rocks which connect the Tuscarora Mountains with the Sacandago Hills, and running across the river cause it to form some cataracts, which are called the Little Falls. The bed of the river above the falls is more than 400 feet higher than the sea, but below the falls it is 40 feet less. The country which separates the Mohawk from Lake Oneida does not attain a height of more than 431 feet above the sea. That portion of the valley which lies above the falls is very fertile, and in this respect resembles the Lake Country. The Herkimer and German Flats, which are contiguous to the rocks forming the falls, are an alluvial tract noted for fertility. The lands below the falls are more hilly and less fertile, but still fertile enough to repay the labour bestowed on their cultivation. The whole valley is well settled, and the Grand Canal traverses it in its length.

Lake Champlain lies along the foot of the Essex Mountains on their eastern side, and on the east of the lake are the Green Mountains of Vermont, but they are at a much greater distance from the lake. The higher parts of both ranges are from 25 to 30 miles apart. Two-thirds of this space belong to Vermont, and the remainder is occupied by the lake and a very hilly country which lies between it and the Essex Mountains. The valleys and flats between the hills and on the borders of the lake are not distinguished by fertility, but give good crops when cultivated with care. From the southern extremity of Lake Champlain a glen extends between the hills which cover the country to the Hudson river below Glens Falls. The highest level of this glen is only 140 feet above the tide-water in the Hudson river, and 50 feet above the level of Lake Champlain. Through this glen the Champlain Canal has been made,

which unites the river to the lake. As the outlet of the lake, the river Chambly, falls into the St. Lawrence river, a water communication has thus been opened between the St. Lawrence and the Hudson.

The vale of the Middle Hudson begins near $43^{\circ} 20'$ N. lat., where the river, after issuing from the Essex Mountains, forms Glens Falls, and begins its southern course. It extends, with a width of from 60 to 80 miles, between the Tughkanic Range on the east and the Tuscarora range on the west to the Fishkill Hills and the Mattewan Mountains, a distance of nearly 150 miles. The mountain-ranges which enclose it do not appear in any part to rise to much more than 2000 feet above the sea-level. The slope on the east of the river is rapid but regular. The surface frequently rises into hills, but they do not attain a great elevation, and their declivities generally admit cultivation. The soil possesses a considerable degree of fertility, and to this circumstance, united to the advantages offered by a river navigable for large vessels, must be ascribed the fact that this portion of New York is one of the most populous and best cultivated. That portion of the vale which lies west of the river presents a greater variety in surface and fertility. At two places it is traversed by offsets from the Tuscarora range. North of 42° N. lat. are the Catskill Mountains, three ranges which lie east and west, and extend from 10 to 25 miles from the Tuscarora Mountains eastward. The most northern and shortest rises, in the Roundtop, to 3804 feet, and the southern and longest, which properly is called Mount Catskill, to 3486 feet. These summits are the most elevated in the Appalachian Mountains, with the exception perhaps of the Peak of Otter in Virginia, whose elevation is estimated at 4000 feet. Farther south, near $41^{\circ} 20'$ N. lat., another ridge branches off from the southern extremity of the Tuscarora Mountains, and advances to within 10 miles from the river in a north-eastern direction. It is properly the prolongation of the Kitatinny Mountains of New Jersey, but in New York bears the name of the Shawangunk Range. It probably does not attain the height of 2000 feet. On the western, as on the eastern side of the Hudson, only a few alluvial tracts occur on the banks of the river, and they are of very small extent. The country generally rises from the west banks with a rather rapid ascent to 200 feet and more, and then extends in a broken and hilly surface to the base of the mountains, though flat tracts occur in some places. The soil is in many places stoney, but it generally possesses a considerable degree of fertility, though it is somewhat inferior to that on the east side of the river. At the most south-western extremity of this region, between the Shawangunk Range and the Mattewan Mountains, in the valley of the river Wallkill, is a tract of exuberant fertility, called the Drowned Lands. Its southern extremity lies within the county of Sussex in New Jersey, but the greater portion is in Orange County in New York. It is from 35 to 40 miles in length and from 5 to 7 wide, and seems to have been a lake. It is flat and marshy, and some small lakes are scattered over it. In spring it is subject to inundation.

The vale of the Lower Hudson extends from the Mattewan Mountains and Fishkill Hills to the very mouth of the river, a distance of about 60 miles. The Fishkill Hills rise to a considerable elevation, Beacon Hill attaining 1471 feet, and New Beacon, or Grand Sachen, 1685 feet above the sea-level. The Mattewan Mountains west of the river, though high, do not attain so great an elevation. Both ridges terminate on the banks of the river in high rocks, which extend on each side for about 20 miles. The prevailing character of the surface and soil of this region is rocky, especially on the west of the river. The Mattewan Mountains terminate on the banks of the river with very high and precipitous rocks, which from Newburg extend to West Point, and even south of the last place. The higher lands recede to a distance from the river, and slope to the banks with a rather gentle declivity. This gentle slope continues along Tappan Bay; but from Tappan to a distance of about 8 miles from the town of New York, the Palisadoes, as they are called, extend along the river: they consist of enormous masses of rocks, from 20 to 500 feet in height. In some places they rise almost perpendicularly from the shore, forming for many miles a solid wall of rock, diversified only by an occasional fishing-hut on the beach at their base, and sometimes by an interval of a few acres of arable land, affording an opening for a landing-place, and a steep road leading to

their top. The highest part of the rocks lies contiguous to the river, from which they descend towards the interior of the country. The whole tract south of the Mattewan Mountains has a very rocky soil, and the cultivable land is only a small portion of it. The country east of the river also rises with a bold and broken shore, but it is less high and precipitous, and the surface of the country farther back is varied by ascents and descents. It contains a much larger portion of cultivated land, but the soil is rocky and of inferior quality, so that the country is rather thinly settled, notwithstanding the neighbourhood of the populous city of New York.

Long Island is about 115 miles long from west to east, and on an average between 9 and 10 miles wide: in some places it is 20 miles across. At the eastern extremity a shallow inlet, called Peconic Bay and Gardner's Bay, separates it into two peninsulas, of which the southern extends farthest east, and terminates with Montauk Point. A ridge of low hills extends along the northern shores of the island, and from their base to the southern shores there is an alluvial margin from one to five or six miles wide. Along the southern shores, and from one to two miles from it, extend long, narrow, low, and sandy islands. The intermediate space between these islands and the shores is occupied by shallow sounds. The soil is everywhere sandy and light, but within the hilly tract, especially at the western extremity, and from 20 to 30 miles eastward, it is of considerable fertility. The largest portion of the eastern districts is still covered with pine. The level tract along the southern shores is generally sterile and in some parts not worth cultivation. The area of Long Island is about 1200 square miles.

Staten Island is separated from Long Island by the strait called the Narrows, which forms the entrance into New York Bay. Staten Island is about 14 miles long and 8 wide, with an area of 77 square miles.

Rivers, Lakes, and Long Island Sound.—On the elevated table-land which extends along the northern boundary of Pennsylvania all the large rivers rise which fall into the Atlantic west of the mouth of the Hudson and east of the innermost recess of Chesapeake Bay. This region contains the sources of the Delaware [DELAWARE] and Susquehanna [PENNSYLVANIA], and also those of the Alleghany, one of the principal branches of the Ohio. On the same table-land, and probably in the most elevated portion of it, between the upper branches of the Alleghany and Susquehanna, and within the limits of Pennsylvania, rises the Genessee, which runs in a general northern direction about 125 miles, measured along its course. In its middle course, which lies in the Lake Country, it traverses a deep and wide valley of great fertility, and forms at Rochester, 5 miles from its mouth, a cataract 95 feet high. But above this impediment the river is navigable about 70 miles for boats.

Not far from the eastern banks of the Genessee river commences that remarkable series of lakes, which extend nearly 100 miles farther eastward, and are from 20 to 30 miles distant from Lake Ontario. These lakes extend in length from south to north, or rather, lines drawn from their most northern extremity, in the direction of their length, to Lake Ontario, cut the shores of that lake at right angles. The most considerable of these lakes, from west to east, are, Lake Canandaigua, which is 14 miles long, and from one to two wide; Crooked Lake is 18 miles long, and about $1\frac{1}{2}$ miles wide; Seneca Lake is 35 miles long and from 2 to 4 miles wide; Cayuga Lake is 38 miles long and from 1 to 4 miles wide; Skeneatiles Lake is 15 miles long and from $\frac{1}{2}$ to $1\frac{1}{2}$ mile wide; and Oneida Lake, the most northern, is about 20 miles and 4 miles wide. Onondaga Lake, which lies between Skeneatiles and Oneida lakes, is 6 miles long and two wide, and remarkable for the copious and strong salt springs, which occur at a distance of a mile from its eastern banks. All these lakes, except the most western, that of Canandaigua, discharge their water by one river, the Seneca. This river issues from the northern extremity of Lake Seneca, which receives the waters of Crooked Lake by a narrow channel, and winds with numerous bends through the Lake Country, running in a general north-eastern direction. Each lake discharges its waters by a separate channel into its bed. In approaching the western extremity of Oneida Lake it is met by the channel issuing from that lake, and after their union the river is called Oneida or Onondaga River.

Black River rises on the western declivities of the Essex mountains, and descends from the table-land of the northern region first by a south-western and afterwards

by a north-western course. About 36 miles from its mouth it turns west, and discharges its waters into Sackets Harbour, a small bay on Lake Ontario. This river runs about 120 miles, but in many parts of its course it consists of a series of cataracts and rapids. The lower falls, which are 7 or 8 feet in perpendicular height, occur at Brownville, eight miles, measured along the channel, above Sackets Harbour.

The table-land west of the Essex Mountains contains many lakes, and some of considerable extent, but our information respecting this region is still very scanty. The most eastern ridges of the Essex Mountains contain Lake George, which extends from south-south-west to north-north-east 33 miles, with a width varying between 1 and 7 miles. It is enclosed on all sides by high rocks, and contains many small rocky islands. It is 200 feet above Lake Champlain, into which it discharges its water by a channel at Ticonderoga. Lake Champlain extends northward into Lower Canada. [CHAMPLAIN.]

The largest river of New York, and perhaps the most important river of the United States, next to the Mississippi, is the Hudson. It is formed by two branches. The eastern branch rises, according to the most recent information, between $44^{\circ} 5'$ and $44^{\circ} 10'$ N. lat., on the northern declivity of Giants' Mountain, 4747 feet above the sea-level, and enters by a western course a wide valley which is 3711 feet above the sea. After some windings in the mountain-valleys, it takes a regular course to the west of south, until it turns a little to the west and meets the western branch. The western branch rises in the western ridges of the Essex Mountains, and runs south and east of south until it meets the eastern branch near $43^{\circ} 30'$ N. lat. As both branches descend from a very elevated region, their current is very rapid, and frequently interrupted by rapids and cataracts. The united river runs southward for some distance, and where it begins to turn to the east, it is precipitated over a ledge of rocks, and forms the Great Falls. Twenty miles lower down are Glens Falls, where the river turns again to the south, which direction it maintains with slight deviations to its mouth. Below Glens Falls the river becomes navigable, though the current continues to be rapid to the mouth of the Mohawk river. The tide ascends the river as far as the mouth of the Mohawk, and below this point the river is wide, but still its mean breadth does not amount to a mile. In some places it widens considerably and appears like a lake, as above Newburg, and still more above Tappan. The latter enlargement, called Tappan Bay, is from two to five miles wide, and continues for eight miles. About 30 miles from its mouth, which is between Sandy Hook in New Jersey and the western extremity of Long Island, the river divides into two arms, which enclose the island of Manhattan. The eastern and more narrow arm is called Haerlem River, and after it has united to Long Island Sound, East River. Where the river meets Long Island Sound is a dangerous strait in which it forms whirlpools and eddies; this pass is called Hell-gate, or Hurlgate. At the city of New York the East River unites again with the West River or proper Hudson, and the spacious bay of New York is formed. But before the river enters the sea, it sends off another arm to the westward, which surrounds Staten Island, under the names of Newark Bay, the Kills, and Amboy Bay. The Hudson is navigable for ships to Albany, 120 miles from its mouth, and to Troy, 36 miles farther up for sloops. It may be ascended by boats to Glens Falls, but this navigation is now superseded by the Champlain Canal, which extends along its western banks. The whole course of the river probably exceeds 350 miles. After issuing from the mountain-region the Hudson is not joined by any considerable tributary, except the Mohawk river, which rises on the table-land west of the Essex range, near $75^{\circ} 30'$ W. long., and runs southward. About 14 miles north of Utica it forms the Trenton Falls, by which the river descends 387 feet in a space of less than 5 miles. Some miles below these falls the Mohawk turns to the south-east. Below the village of Herkimer are the Little Falls, by which the river descends more than 30 feet in the distance of a mile. A mile above its mouth are the Cohoes Falls, 40 feet in perpendicular height. The tide ascends to the last-mentioned falls. At Waterford the Mohawk joins the Hudson, after a course of about 120 miles.

Long Island Sound, or the strait which divides Long Island from the continent, is about 120 miles long, with a

varying width. The eastern portion, extending as far west as Stamford in Connecticut, and Lloyd's Neck on the island, has an elliptical form, widening from about 8 miles at each extremity to about 20 miles in the middle. West of Lloyd's Neck it gradually contracts, and at its western extremity varies between half a mile and 2 miles for a distance of eight miles, until it joins East river. In the western and more narrow portion of the strait, the channel is rocky and much interrupted by small islands and projecting points. But the strait has, in general, depth sufficient for the largest vessels.

Climate.—The mean annual temperature of the city of New York is between 52° and 53°, which is only 2° or 3° higher than that of London, though it is more than 10° nearer to the equator. But this city has a milder climate than any other part of the state except Long Island. The vale of the Hudson river is much colder than any part of Great Britain. In December the cold increases gradually, and the winter lasts to the end of March. In January and February the thermometer sometimes sinks to 2° Fahr. Snow lies on the ground several feet deep, and the river is passed on the ice. The ice usually does not break up before the end of March. The spring months are raw, chilly, and damp. In summer the thermometer ranges, in general, between 60° and 80°: it sometimes rises to 85° and for a few days to 90°, but rarely higher. In September the weather is fine, but there are a few severe storms about the equinox. In October and November the weather is dry and clear, but some night-frosts occur, and towards the end of the latter month snow begins to fall. But the temperature is subject to great and sudden variations, even in the same day. These variations sometimes amount to 20° and even 30° of Fahrenheit. Such is in general the climate of the vale; but the cold is much more severe towards its northern portion in the vicinity of the mouth of the Mohawk river, which is ascribed to the prevalence of the north-western winds, which blow with considerable force through the valley of the Mohawk. The same winds render the climate of the valley of the last-mentioned river colder than the countries farther east or west. The Lake Country, on the contrary, enjoys a milder climate, its temperature being generally at least three degrees higher than that of the valley of the Mohawk. But it is subject to dense fogs, and is considered the most unhealthy portion of the state. In summer south-western winds prevail in this country. The northern region has very severe winters, so that during six months the country is covered with snow and the rivers frozen. In the high valleys of the Essex Mountains it freezes even in August.

Productions.—The cultivated cerealia are maize, wheat, rye, barley, oats, and buck-wheat. Artificial grasses are cultivated in some parts, especially in the neighbourhood of New York. Potatoes and turnips are generally cultivated. Immense quantities of melons are raised. Peas and beans succeed very well. Apples, peaches, and cherries are plentiful, but pears and plums are not so abundant. Currants and strawberries are cultivated near New York. In some parts flax and hemp are grown, especially in the Lake Country. All the domestic animals of England are reared in New York with success.

A considerable part of the state is still covered with forests, which consist of oak of different species, ash, walnut, pine, maple, beech, chesnut, birch, poplar, elm, cedar, hemlock, and hickory. The most extensive forests occur in the northern region.

The panther is rare, except in the Essex Mountains, which also contain the moose-deer. Deer are still frequent in the western districts and northern region. Other wild animals are, wolves, bears, grey and red foxes, racoons, skunks, minks, beavers, otters, squirrels, and hares. The musk-rat and marten have nearly disappeared. The wild turkey has become rare, even in the western districts, but swans, wild geese, ducks, and pigeons are abundant. The sea and the lakes abound in fish.

Several minerals occur in abundance, but only iron, salt, limestone, and marble are worked. Coal does not exist, at least not in such quantity as to be worked; and it is imported from various places, especially from Nova Scotia.

Political Divisions and Towns.—The state of New York is divided into fifty-six counties, having an aggregate area of about 46,085 square miles.

There are nine incorporated cities, viz. New York, Al-

bany, Troy, Hudson, Schenectady, Utica, Buffalo, Rochester, and Brooklyn. Their relative importance may be inferred from the amount of their population severally at the last census, viz.:—

New York	. 202,589	Buffalo	. . 8,653
Albany	. . 24,209	Utica	. . 8,323
Brooklyn	. . 15,396	Hudson	. . 5,392
Troy	. . . 11,605	Schenectady	4,258
Rochester	. . 10,885		

There are also 124 incorporated villages,* many of which contain from 3000 to 5000 inhabitants.

Brooklyn, on the East River, on Long Island, is opposite to New York, and may be considered as a suburb of that city. The two places are three-quarters of a mile distant, and communication is kept up between them by steam and horse-ferry boats. The population of Brooklyn is now 15,396. [BROOKLYN.]

There are many flourishing towns and villages on both sides of the Hudson river. Newburg, on the west side of the river, is 61 miles north of New York, and has a population of 6424. Poughkeepsie, on the east side of the Hudson, 74 miles from New York, has a population of 7222. Catskill, on the west side of the river, and near the Catskill Mountains, about 108 miles from New York, has a population of 4860. Hudson, on the east side of the Hudson, nearly opposite to Catskill, is a large manufacturing town, and has about twelve ships engaged in the whale fishery: the population is 5392. Albany, on the west side of the Hudson, and the seat of government, is the second city in the state. Next to James-town in Virginia, it is the oldest settlement in the United States. Since the completion of the Erie and Champlain canals, its growth has been very rapid. [ALBANY.] Six miles above Albany, on the opposite bank of the river, is the town of Troy, which is at the head of the sloop navigation, and has a considerable trade, with a population of 11,605.

The following are the principal towns on the Mohawk and the Erie canal:—Schenectady, on the south bank of the river, 15 miles north-west of Albany, is the seat of Union College, and has a handsome covered bridge over the Mohawk, 1000 feet in length: the population is 4258. Utica, on the south bank of the same river, 94 miles west of Albany, has a population of 8323. At this point, the Mohawk river, the Erie canal, and the great western road meet. Syracuse, 133 miles from Albany, is extensively engaged in the manufacture of salt. Canandaigua, on the lake of the name, has a population of 6162. Rochester is on the Genessee river and on the Grand Canal, which passes over a noble aqueduct of stone at this town. It is 236 miles from Albany, 7 miles from Lake Ontario, and has a ship navigation within two miles of the town. Owing to the falls of the Genessee river, this place enjoys the advantage of abundant water-power for putting mills in motion and other purposes. Rochester was founded in 1812, and in 1830 it contained 10,885 inhabitants. Buffalo is at the north-eastern corner of Lake Erie, at the termination of the Grand Canal, and at the head of Niagara river. It carries on a considerable trade on the lake. [BUFFALO.] In the western part of the state there are numerous towns equal in magnitude to some of those which have been mentioned. They are all in a thriving condition, and owe their prosperity mainly to the Erie canal. In this district the traveller meets with numerous well-built villages, only a few years old, in a country which, not long since, was an uninhabited wilderness. The numerous lakes in this part of the state contribute to the beauty and variety of the landscape. Plattsburg, on the west side of Lake Champlain, has a population of 4913. Sackett's Harbour, near the mouth of Black River, at the east end of Lake Ontario, is considered to be the best harbour in that lake: the population is about 2938.

Population.—The population of the state of New York at each enumeration since the acknowledgement of American independence was as follows:—

	Free.	Slaves.	Total.	Increase per cent.
1790	340,120	21,324	361,444	
1800	586,756	20,343	607,099	67.96
1810	959,949	15,017	974,966	60.59
1820	1,372,812	10,088	1,382,900	41.84
1830	1,918,608	75	1,918,683	39.74

* Incorporated villages are governed by a president and trustees, who are annually chosen by the people. They differ from cities only in having more limited powers and jurisdiction. The term 'town,' in the New York law, is synonymous with 'township.'

The increase, comparing 1830 with 1790, has been 433½ per cent., or at the rate of 10½ per cent. annually.

At the last census, in 1830, the population was ascertained in classes, as under:—

Free white population:—

	Males.	Females.	Total.
Under 5 years old ..	158,077	151,868	309,945
From 5 to 10 years ..	137,071	133,084	270,155

Constitution, &c.—The present constitution of the state of New York was adopted in 1821. The executive administration is entrusted to a governor and a lieutenant-governor, who are elected by the people for two years. The legislature consists of a senate, of 32 members, who are chosen for four years; and an assembly, of 128 members, elected annually. The lieutenant-governor acts as president of the senate. For the election of senators the state is divided into eight districts, each of which sends four members, one of whom is elected every year. The members of the House of Assembly are elected by counties, in numbers proportioned to their population. The elections must be held in October or November, and the legislature must meet for business at Albany on the first Tuesday of January in every year.

The right of suffrage in the election of public officers belongs to every white male citizen of twenty-one years of age and upwards who has been an inhabitant of the state for one year and of the county for which he offers his vote for six months next preceding the election. Free men of colour, at least twenty-one years old, may vote if possessed of an unincumbered freehold estate worth 250 dollars.

For the administration of justice there are:—a chancellor and vice-chancellor; a supreme court, with a chief-justice and two associate-justices; and eight circuit-courts, one for each of the eight senatorial districts, with a judge for each. The judges are all appointed by the governor with the consent of the senate; they hold their offices during good behaviour, and until they shall be sixty years of age. Courts of common pleas are likewise held in each county in the state, for which purpose a first judge and four assistant-justices are appointed, each of whom holds office during five years.

With the exception of certain judicial and civil functionaries, ministers of religion, teachers in schools and colleges, and students, all able-bodied free white male citizens, between the ages of eighteen and forty-five, are subject to the performance of military duty in the militia. The number enrolled in the militia of the state at the beginning of 1839 was 176,115 men.

Inland Communication.—Great exertions have continually been made to extend the means of internal communication through the state, for which purpose the public money has been freely expended, and loans have been raised on the credit of the state. In the Report of the Canal Board, made to the legislature in 1837, it is stated that the length of canals,

the property of the state, then finished and in operation, was 655 miles, the cost of which was 11,962,711 dollars. The state legislature began about twenty years ago this system of internal improvements, which has been carried on extensively and with great success. The first both in point of time and importance of its undertakings was the Erie Canal, which was begun in 1817 and finished in 1825. This canal, which connects the Hudson river with Lake Erie, is 360 miles in length, in the course of which an aggregate rise and fall of 662 feet is overcome by means of 81 locks: the difference of level between the Hudson and Lake Erie is 564 feet, the ascent of the canal to its summit-level being 613 feet, and the descent only 49 feet. The canal is throughout made 40 feet wide at the surface, 28 feet wide at the bottom, and 4 feet deep. Its course is as follows:—Beginning at Albany on the Hudson, it runs to the north along the west bank of that river to near the mouth of the Mohawk river, along the south bank of which it passes to the west through the counties of Albany, Schenectady, Montgomery, Herkimer, and Oneida to Rome; it then takes a south-west direction into Madison county, turns to the west, and passes through Onondaga county to within a mile of the Onondaga or Salt Lake, enters Seneca county, and crosses the Seneca river at Montezuma. Proceeding still to the west, it passes Lyons and Palmyra, and crosses the Genesee river at Rochester: its course is still to the west for 60 miles, when, turning to the south, it joins Tonawanta Creek, 11 miles from the river Niagara. The Tonawanta is used for 11 miles, when the canal leaves it and takes a southerly direction along the east bank of the Niagara to the termination of the canal at Buffalo on Lake Erie; thus connecting New York with the western states of the Union. New York is mainly indebted for this great work to Governor Clinton. [CLINTON.] The Champlain Canal joins the Erie Canal where its westerly course begins, near the confluence of the Hudson and Mohawk rivers; its course is nearly due north to Lake Champlain, comprising 4½ miles of cutting and 15½ miles of natural channel rendered navigable. The cost of these two works was 9,123,000 dollars, which occasioned a debt by the state of 7,771,000 dollars. The tolls in the first year after they were opened amounted to half a million of dollars, and have since progressively increased, until, in 1838, they reached 1,518,300 dollars. There were at the time the Report of the Canal Board was made (1837) in progress towards completion other canals 168 miles long, the estimated cost of which was more than 3,000,000 dollars; and beyond this an enlargement of the Erie Canal had been authorised by the state legislature at an estimated expense of fifteen millions of dollars. There were also private canals finished to the extent of 122 miles, and in progress 28 miles. Of railroads finished, in progress, and authorised, belonging to private companies, there were, in 1838—

	Miles.	Cost.
Finished ..	218	5,063,000 dollars
In progress ..	938	16,000,000 ..
Authorised ..	1704	31,064,000 ..

The state derives a considerable and constantly increasing yearly revenue from its canals. The surplus tolls of the Erie and Champlain canals, after defraying all expenses, were, in 1829, 478,694 dollars, and in 1838, 901,999 dollars: the average annual profit of the ten years was 806,704 dollars.

Property.—The value of real and personal estate within the state, as assessed for taxation, was, in 1838—

Real estate ..	502,864,006 dollars
Personal ..	126,680,778 ..
Total ..	629,544,784 ..

and the amount of taxes levied upon the same for general and county expenditure was 2,860,478 dollars. This was a little short of one-half per cent. on the assessed value, and considered with reference to the population, not quite a dollar and a half (6s. 3d. sterling) for each individual.

Education.—The subject of education has long received the greatest attention on the part of the state legislature. For this purpose the state is divided into 10,583 school districts, which are required to make yearly returns of the number of scholars and the various expenses attending the same. In the year ending 30th of September, 1838, returns were made, by which it is shown that of 539,747 children between 5 and 16 years old, residing in those districts, there were taught in schools 528,913, or 46 in every 49. The amount

of public money appropriated to the schools in that year was 335,882 dollars, or equal to 70,000 $\frac{1}{2}$.

There are in the state several public institutions for the purpose of education, in addition to those established in the city of New York. Among these the following are the most important:—

Union College, at Schenectady, was incorporated in 1794, and derives its name from the circumstance of several religious denominations having combined for its establishment. The buildings are two brick edifices, each 200 feet long and four stories high. Each building has two wings 150 feet wide. This college is liberally endowed. It has a library of nearly 6000 volumes, besides the students' library of 9000 volumes. The number of students is usually between 200 and 250.

Hamilton College, at Clinton, 9 miles from Utica, was erected in 1812. It is a large building four stories high, with a library of 6000 volumes. The number of students is about 100.

Geneva College, situated at the town of that name, was founded in 1825. The number of students is 44.

Hamilton Literary and Theological Seminary, situated in Madison county, 25 miles south-west of Utica, was founded by the Baptists, and incorporated in 1819. This building is of stone, four stories high, 100 feet long by 60 feet deep. The number of students is about 100.

The Theological Seminary at Auburn was founded by the Presbyterians in 1821. It has 54 students and a library of 1500 volumes.

The Hartwig Theological Seminary was founded under the will of the Rev. J. C. Hartwig, a Lutheran minister, who bequeathed a large estate in land for that purpose. It contains 90 students and has a library of 1000 volumes.

The United States Military Academy, at West Point on the Hudson, was established in 1802, on a tract of 250 acres of land ceded by the legislature of New York to the United States. The staff, including the superintendent and commandant, professors and teachers, comprises 40 persons, and the number of cadets is limited to 250. The regular course of studies occupies four years. Each cadet is appointed by the president of the United States.

Prisons, &c.—The prison discipline adopted in this state has attracted considerable notice on the part of foreign governments, many of which have sent commissioners to the United States for the purpose of acquiring information upon the subject. [AUBURN.]

Asylums for the insane poor have been founded in the state, one of which, the State Lunatic Asylum at Utica, is calculated for the accommodation of 1000 patients.

Paupers are supported by a tax on the inhabitants of the counties to which they respectively belong, and are placed under the care of superintendents specially appointed for the purpose. The several counties are provided with poor-houses, to which a farm is attached, and in which the paupers are collected. The whole number of paupers relieved or supported during the year 1836 was 37,959, of whom 20,554 belonged to the city of New York. The sum expended for their relief was 396,100 dollars (82,520 $\frac{1}{2}$), one-tenth part of which was repaid by the produce of their labour. Among the number just stated, there were 6874 foreigners, 786 lunatics, 271 idiots, and 77 deaf and dumb. The number who were in the poor-houses on the 1st of December, 1836, was—males 3714, females 3294; together 7008.

Public Debt.—The public debt of the state of New York, as it stood in June, 1838, amounted to 18,262,406 dollars, nearly the whole of which has been incurred for the promotion of public works, chiefly canals and rail-roads. The revenue derived from the state canals has been sufficient during the last six years to defray all expenses of repairs, to pay interest on the whole amount of the state debt, and to provide towards its extinction an average surplus of 610,000 dollars. About four millions and a half of dollars have been thus paid off since 1825.

(*Darby's View of the United States; Warden's Account of the United States of North America; Fowler's Journal of a Tour in the State of New York; Redfield's 'Account of two Visits to the Mountains in Essex County,' in Journal of Science and Arts, vol. xxxiii.; American Almanac for 1839; Official Papers and Reports.*)

NEW YORK, the largest city in the state of New York, and the commercial capital of the United States of America, is built on the point of Manhattan Island, at

the confluence of the Hudson and East rivers, in 40° 41' N. lat. and 74° 1' W. long.—It was founded in 1609, by a party of Dutch merchants, to whom the states general of Holland had granted a patent for the exclusive trade to Hudson's river, then called by the Indians the Manhattan; the same name was also then given to the island of New York. In 1621 an extensive but undefined territory on both sides of the Hudson was granted to the Dutch West India Company, and the city of New Amsterdam was built on the site of the former settlement. In 1664 a charter was executed by Charles II., conveying to the Duke of York the whole territory, from the eastern shore of the Delaware to the western bank of the Connecticut, and an armament was sent without delay from England to take possession of the country. At this time the Dutch and English were at peace, and this proceeding was justified on the ground that the whole territory of right belonged to the crown of England, having been discovered by the Cabots in the previous century, and that the Dutch settlers were intruders. After fruitless remonstrances on the part of the Dutch governor of New Amsterdam, Stuyvesant, the English obtained possession of the city and territory, and immediately changed the name of both to New York. The town at this time is said to have been handsome and well built, and to have contained 3000 inhabitants. Holland made no attempt at the time nor during the subsequent war to regain possession of the settlement, and at the peace of Breda it was formally ceded to England. In 1673, when England was again at war with Holland, the town was taken by a small Dutch squadron, not without suspicion of treachery, and without a shot being fired on either side. Peace being concluded in the following year, New York was restored to England. In 1682, the inhabitants having petitioned the Duke of York to give them some share in the management of their affairs, the same form of government was given to them as was already enjoyed by the other British plantations; a council was appointed by the proprietor, consisting of ten members; and a House of Assembly, composed of eighteen members, was chosen by the inhabitants, but the laws passed by these two bodies were to have no force until confirmed by the proprietor.

The citizens of New York early took part in the troubles that ended in the separation of the American plantations from England, and sent delegates to attend the general congress at Philadelphia, in September, 1774. In the summer of 1776 the English fleet under Admiral Howe, and the army under General Sir William Howe, having defeated the Americans under General Washington on Long Island, took possession of New York and retained it until the acknowledgement of American independence. The city was evacuated by the English on the 25th November, 1783, and was occupied by an American garrison the same day.

The island upon which New York stands is 15 miles long and from one mile to three miles broad. The city occupies the south part of the island; it extends along the Hudson about two miles, and along the East River, which divides it from Long Island, about four miles. The south-west part of the town, which was the earliest built, is ill-arranged, but the more modern parts are laid out with much regularity, and are well paved and lighted. Broadway, the principal street, which runs through the centre of the town, is three miles long and eighty feet wide. It contains several handsome churches, many of the principal hotels, and a great variety of elegant shops. Wall Street, which branches off from Broadway, contains the Exchange and most of the city banks, as well as the greater part of the merchants' and brokers' counting-houses, and the insurance offices. The City Hall, the front of which is of white marble, is 216 feet long, 105 feet wide, and 60 feet high. It contains the courts of law and the places of meeting for the municipal bodies. The building was begun in 1803, and finished in 1812, at the cost of half a million of dollars. The Merchants' Exchange, which was destroyed by the great fire that occurred on the 16th December, 1835, was also built of white marble; its front in Wall Street was 114 feet wide, and it extended in depth 150 feet; the basement was occupied by the Post-office. The Exchange which occupied the centre of the building, was of an oval form, 85 feet long, 55 feet wide, and 45 feet high, surmounted by a dome, through which light was admitted. The building was begun in 1824 and finished in 1827. The fire by which it was destroyed began near Wall Street; the

number of buildings demolished was 529, valued at four millions of dollars, and the merchandise and other moveable property destroyed was valued at more than thirteen millions of dollars.

The population of the city in the years 1820, 1830, and 1835, as given in Williams's 'State Register,' was as follows:—

1820	123,706
1830	202,589
1835	270,089

The value of the real estate assessed for taxation in 1835 was	Dollars.	143,732,425
And of the personal estate		74,991,278
Together		218,723,703

The amount of taxes levied in that year for public and municipal expenses was 1,095,994 dollars. This is equal to one half per cent. on the value, and to four dollars on each individual of the population.

It appears from the bills of mortality printed in the city, that the deaths in proportion to the population were, in 1835, one in 38; and in 1836, one in 34. The ages at which the deaths occurred in 1836, were,

Under 1 year (including 506 still-born).	2292
1 and under 2 years	1014
2 " 5	841
5 " 10	315
10 " 20	303
20 " 30	927
30 " 40	945
40 " 50	551
50 " 60	309
60 " 70	233
70 " 80	148
80 " 90	75
90 " 100	16
Total	7969

Of this number 4352 were males, and 3617 were females. The deaths in the first six months amounted to $\frac{7}{10}$ and in the last six months to $\frac{2}{10}$ of the number. Among the deaths 1514 were caused by consumption, 506 were still-born, 142 were the direct result of intemperance, 262 arose from accidents and violence, 33 were suicides, and only 131 are attributed to old age.

The mortality of the city would be lessened by the construction of sewers to carry off the filth which accumulates in all populous places. Some parts of the town are better cleansed and ventilated than others, and it has been remarked that the fever by which New York is sometimes visited always first shows itself in the most confined and dirtiest parts of the town. The situation of the town is by nature favourable to healthiness. The constant ebb and flow of the tide prevent all stagnation of the air, and while it is sufficiently protected from the occasional violence of the sea breezes, they are not prevented from visiting the town. The strength of the tide would greatly facilitate the removal of all noxious matters. The city is very ill supplied with water, but measures are in progress for remedying this deficiency.

The situation of New York as a commercial port is admirable. New York Bay, which is completely land-locked, is about 8 miles long and from $1\frac{1}{2}$ to 5 miles wide, and affords a perfectly safe anchorage. It is easy of approach, and is very rarely closed by ice. The entrance between Long Island and Staten Island, by a channel called the Narrows, is protected by forts, while the approach to it is facilitated by lighthouses, one of which is placed on a long tongue of land on the New Jersey shore called Sandy Hook; two others are erected about four miles south from Sandy Hook, and their lights, being 250 feet above the level of the sea, can be seen in fair weather at 40 or 50 miles distance. A fourth light-house is placed on Staten Island, at the narrowest part of the entrance to the harbour. The bay contains several small islands, which have been surrendered to the general government as sites for fortifications. There is sufficient depth of water, both in the Hudson and East rivers, for ships of large burthen to load and unload at the wharfs. The commercial intercourse with the interior and with the western states of the Union is secured by means of the Hudson and the system of canals which has already been noticed.

The tonnage of vessels that entered and cleared in each of the ten years from 1827 to 1836, was as follows:—

Year	Entered.			Cleared.		
	American.	Foreign.	Total.	American.	Foreign.	Total.
1827	261,301	39,242	300,543	239,968	33,375	273,343
1828	256,750	44,505	301,255	217,113	42,373	259,486
1829	259,322	30,219	289,541	219,674	32,855	252,529
1830	298,434	35,344	333,778	229,341	36,574	265,915
1831	315,973	77,719	393,691	254,331	72,444	326,775
1832	329,842	116,481	446,323	242,749	101,967	344,716
1833	454,218	161,949	616,167	384,175	153,565	537,741
1834	451,289	243,633	694,922	361,606	238,650	600,256
1835	676,173	357,575	1,033,748	589,855	343,078	932,933
1836	895,390	367,436	1,262,826	477,524	355,691	833,215

The value of imports and exports (stated in dollars) during the same period was as follows:—

Year	Imports.		Exports.	
	Foreign Goods.	American	Foreign.	Total.
1827	38,719,644	13,920,627	9,913,510	23,834,137
1828	41,927,792	12,363,015	10,415,634	22,777,649
1829	31,743,307	12,036,561	8,082,450	20,119,011
1830	35,624,070	13,618,278	6,071,705	19,697,983
1831	57,077,417	15,726,118	9,809,026	25,535,144
1832	53,214,403	15,057,250	10,943,695	26,000,945
1833	55,918,449	15,411,296	9,983,821	25,395,117
1834	73,188,594	13,849,469	11,662,545	25,512,014
1835	88,191,305	21,707,967	8,637,397	30,345,264
1836	119,233,416	19,816,520	9,104,118	28,920,638

The disparity between the value of the imports and exports here exhibited is compensated by disparity in the opposite direction, in the commercial dealings of other parts of the American Union. A great part of the returns from foreign countries for the produce of Louisiana, Alabama, Georgia, Carolina, and Virginia, which is shipped direct from the ports of those states, is made through New York.

There are in the city of New York 21 banks, with capitals amounting in the aggregate to 18,111,200 dollars. Three have severally a capital of 2 millions of dollars; two have each $1\frac{1}{2}$ millions; two have 1 million each, and the remaining 14 have each capitals from 750,000 to 200,000 dollars. The liabilities of the whole in the month of December, 1837, including their capitals, amounted, according to a report made by commissioners to Congress, to 55,620,834 dollars. There are also 28 fire-insurance companies, with capitals amounting in the aggregate to 10,250,000 dollars, and 13 marine insurance companies, whose united capitals amount to 4,550,000 dollars.

New York contains several learned and scientific societies. Among these are,—

The New York Historical Society, founded in	1804
New York Literary and Philosophical Society	
American Academy of Fine Arts, founded in	1808
National Academy of Design, founded in	1826
American Lyceum, founded in	1831
Medical Society of New York	

The University of New York, incorporated in 1831, has a capital of 120,000 dollars, raised in shares of 25 dollars. It is governed by a council, consisting of the mayor of the city, 4 members of the common council, and 32 persons elected by the shareholders from among their own body. The University comprehends two departments, one of which embraces the higher branches of literature and science, and the other provides instruction in classical, philosophical, and mathematical knowledge, with a course of study in English literature. There were in 1837, in the two departments, 17 professors and 226 students.

Columbia College, which is an institution for general literary instruction, in the city of New York, was founded in 1754, under the name of King's College. There are also the College of Physicians and Surgeons, the Theological Institution belonging to the Episcopal Church, and the New York Theological Seminary.

The earliest newspaper published in New York, the 'New York Gazette,' appeared first in 1725 (some accounts say 1733), and was issued weekly. There are now fifty-three newspapers published in the city, eleven of which appear daily, ten twice a week, twenty-six are published weekly, six semi-monthly, and one monthly. The number of sheets printed annually is estimated at 9,536,000. A list was given in 1834 of fifty-one weekly, monthly, and quarterly journals, magazines, and reviews, devoted to science and literature, which were published in the city of New York; many of these have no doubt been discontinued, and others may have since supplied their places.

NEW ZEALAND. [ZEALAND, New.]

NEWARK-UPON-TRENT, a town in Nottinghamshire, having a separate jurisdiction, though locally in the southern division of the wapentake of Newark, on an arm of the Trent, $19\frac{1}{2}$ miles north-east of Nottingham, and 124

from London, by Biggleswade, Norman Cross, Stamford, and Grantham.

Newark was considered by Dr. Stukely to have been a Roman town; but the correctness of this opinion is doubtful, though many Roman antiquities have been discovered here. The Dr. considered it to have been the Sidnacester of the Saxons, which others place elsewhere. The first undoubted mention of it is in the time of Edward the Confessor, when it had already acquired the name of New-erk, or New Work, in contradistinction to some town or building of older date in the neighbourhood. The manor at an early period belonged to the see of Lincoln, and Alexander, bishop of that see, built or perhaps enlarged and strengthened the castle of Newark in the early part of the twelfth century. The castle came, a short time after, into the possession of the crown, and in the time of king John was besieged by the barons in the interest of Louis the Dauphin. John, coming to its relief, died at Newark, A.D. 1216. On the conclusion of the treaty between Henry III. (son and successor of John) and the Dauphin, some of the English adherents of the latter, fearing punishment, seized the castle of Newark, where they were besieged by the king's guardian, the earl of Pembroke, and obliged to surrender. The castle was subsequently restored to the see of Lincoln, and, with the exception of a short interval in the reign of Edward III., appears to have continued in its possession until the reign of Edward VI., by whom the town was incorporated. It was at Stoke, near Newark, that Henry VII. defeated Lambert Simnel and his supporters, A.D. 1487. In the civil war of Charles I. the townsmen zealously supported the king, and received a garrison from the forces of the marquis of Newcastle, of from 4000 to 5000 foot and above 500 horse: there were plenty of cannon on the walls. The incidents of that war are noticed elsewhere. [NOTTINGHAMSHIRE.]

The town is seated on the right bank of a stream, which is usually regarded as an arm of the Trent, but ought rather to be considered as belonging to its tributary the Devon. Two small islands, with water-mills on them, opposite the town, are in the borough limits.

The borough comprehended, in 1831, the parish of Newark and a very small portion of the adjacent parish of East Stoke, viz. the site of the castle, and the islands with the mills. It had an area of 2080 acres, with 2022 houses, inhabited by 2087 families; the population was 9557, a very small portion agricultural. The commissioners for regulating the boundaries of municipal corporations have recommended a new boundary-line, excluding a rural district comprehended within the former limits, but for parliamentary purposes the former boundary remains unaltered.

Newark is irregularly laid out, and consists of several streets, with a market-place near the centre of the town. It extends in length about a mile along the bank of the river, and in some parts about half a mile in breadth from the bank inland. It is well paved, and lighted with gas, under the provisions of local acts, and is well supplied with water. The houses built of late years have been mostly of an inferior class.

The church is one of the largest and most elegant in the kingdom: it was in great part rebuilt in the time of Henry VI. and Henry VII.; but there are in it some remains of a previous edifice of Norman character. It is a cross church, and consists of nave and chancel, with large aisles, transepts, and some chapels, with a tower at the west end, surmounted with a lofty and elegant spire. The general appearance of the exterior is of perpendicular character; some portions however rather partake of the decorated character. The length of the church is 218 feet, the breadth of the nave and of the chancel, with their respective aisles, 77 feet, and the breadth between the extremities of the transepts 117 feet. The height to the summit of the steeple is 240 feet. The interior has some good wood screen-work, some antient stained glass, and some brasses and other antient monuments.

The antient castle stood near the bank of the river: the south-western angle, the western wall washed by the river, a considerable part of a tower at the north-western angle, and parts of the north side of the building, remain. The western wall exhibits three distinct stories or tiers of apartments. The architecture varies with the period of erection of the various parts: some of it is Norman, but other portions were probably erected just before the civil wars of Charles I. Part of the inner area of the castle is used as a bowling-green, and the remaining portion has been recently

P. C., No. 1000.

converted into a large and commodious cattle-market. Just below the castle is a neat bridge of seven semicircular arches over the river, built of brick and faced with stone. The approach to Newark from the north is by a causeway a mile and a half long, carried over the flat island formed by the main channel of the Trent and the Newark branch, and leading to the bridge: in this causeway are several bridges and arches, to give free passage to the waters when the floods are out.

There are a court-house, where the quarter-sessions for the division are held; a handsome town-hall, for the corporation business, the borough sessions, and assemblies; several dissenting meeting-houses and schools, &c., and St. Leonard's hospital or almshouses, built about the time of Charles I. There are some walls of an antient Augustine friary, now converted into a dwelling-house. The chapel of the antient hospital of the Knights Templars, converted into a dwelling-house, is yet standing.

The principal trade of Newark is in corn, malt, flour, coal, cattle, and wool. The market, which is on Wednesday, is well supplied with butcher's meat, fish, and poultry, and is one of the principal corn-markets in that part of the kingdom. There are six considerable yearly cattle-fairs. Large quantities of gypsum and lime-stone are obtained in the neighbourhood: the gypsum is burnt and pulverised for the use of plasterers and sculptors, and sent by water-carriage to London. Seventy men and boys are employed in plaster-pits and stone quarries. Bricks and tiles are also made, and there are two large iron and brass foundries in the town. The arm of the Trent which passes by Newark is navigable: there is a lock in it close to the town.

The corporation, under the Municipal Reform Act, consists of 6 aldermen and 18 counsellors; the borough, by the same act, was divided into three wards, the previous boundaries of the borough being retained; but the municipal boundary commissioners recommend narrower limits, and have proposed a new division into two wards. The corporation have no property of their own. There are valuable charity estates, from which the church is kept in repair, and the salaries of the church officers, including the organist and singing-boys, are paid. Out of these funds also the town is lighted and paved, a dispensary is partly maintained, and the grammar-school, including two exhibitions to one of the universities, besides the national schools for boys and girls, and an almshouse, containing 12 men and 12 women, are supported. The town returns two members to parliament. The right of voting, before the Reform Act, was in the inhabitants paying scot and lot: 1362 voters polled in 1830. The number of 107. houses is above 500, and the number of registered electors in the year 1835-6, including 107. householders and the remaining scot and lot voters, was 1293.

Borough sessions are held every quarter, and petty sessions twice every week; there is a court of record for civil suits under 300*l.*, and a court of requests, obtained in the last session of parliament, for the recovery of debts under 5*l.* The borough gaol is small and very defective in its arrangement. Its abolition has been recommended by the inspectors of prisons.

The court of election for the southern division of the county is held at Newark, which is also a polling-station.

The living of Newark is a vicarage in the archdeaconry of Nottingham, formerly in the diocese of York, but now in that of Lincoln, of the clear yearly value of 325*l.*, with a glebe-house. It is in the gift of the crown.

There were in 1833 one dame-school with 13 children; the endowed grammar-school with 37 boys; two national schools, one each for boys and girls, with 246 scholars; and nineteen other day or boarding and day schools with 760 to 780 children; one day and Sunday school held at the workhouse, with about 12 to 15 children in the week and 25 on Sundays; and five Sunday-schools, with 1157 children.

(Dickinson's Newark; Parliamentary Papers; Communication from Newark.)

NEWBURG. [NEW YORK.]

NEWBURY, a corporate town and parish in the hundred of Faircross and county of Berks, is seated on the right bank of the river Kennet, 16 miles west by south from Reading, and 80 west by south from London, direct distances. The town is antient, being supposed to have originated from the Roman station Spinae, which name is still preserved in that of Spoonhamland, a hamlet in the parish of Speen, and contiguous to the town of Newbury. An early

VOL. XVI.—2 B

At the time of William the Conqueror it was called Newbir or Newbyrig, and under that name was granted by the Conqueror to Ernulph de Hesdin. The principal streets are broad and well paved, and the town is lighted with gas. The church is a plain stone building, erected in the reign of Henry VII. There are several large maltings and corn-mills, and there were formerly some woollen manufactories of importance; but they have long since disappeared.

In the great council convened at Westminster in the reign of Edward III., concerning trade and manufactures, Newbury had three representatives.

The average annual export of flour, malt, and unmanufactured grain is estimated at 7000 tons. The corn-market is held on Thursday. The fairs are held five times in the year. That in October is a statute fair for hiring servants. (Lysons.) The Kennet and Avon Canal passes through the town.

The police of the town was described in 1835 as insufficient, and considerable inconvenience was said to arise from the circumstance of the hamlet of Speenhamland forming part of the town without being subject to the jurisdiction of the corporate magistrates. The earliest charter of incorporation extant is that of 28 Elizabeth; the charter under which the corporation acted previously to the Municipal Reform Act is dated in the first year of the reign of James II. The revenue of the corporation, derived chiefly from the manor of Newbury, is only 120*l.* Prior to 1818 the corporation derived a considerable income from a toll upon all grain which passed through the town; but this was contested in the above year, and has not since been paid.

The population of the parish in 1831 was 5959. The parish is in the diocese of Salisbury. The living is a rectory, in the gift of the crown, and valued at 455*l.* per annum.

The 'corporation school,' as it is called, originated from a bequest of Mr. John Kindrick, in 1624, of the sum of 4000*l.*, to be applied by the corporation in furnishing employment to the poor of Newbury. Part of the revenue thence arising was first appropriated to the education and clothing of 20 boys in 1706. The funds of this charity were augmented in 1715 by certain landed property named in the will of Mr. Richard Cowslade, the rental of which in 1819 amounted to 97*l.*, and the number of boys clothed and educated was in consequence increased to 28. In 1790 there was a further bequest, by James Kimber, of funded property, yielding an annual dividend of 531*l.*, which he directed should be employed in the education, clothing, and apprenticing of ten boys. The boys on these three foundations form what is called the Newbury Blue-coat School. They meet in a room adjoining the church, and are taught by the same master reading, writing, and arithmetic. It is to be regretted that so little good should have been effected with such ample means. In 1819 none of the boys had been apprenticed; the master, who had held his situation for many years, was complained of as being neglectful of his duties. The annual expenditure on account of the charity had not exceeded 150*l.*, and the appropriation of the residue could not be satisfactorily accounted for in consequence of the funds of the charity not having been kept distinct from those of the corporation. For the other charities of Newbury, which include several almshouses, the reader is referred to the 'First Report of the Commissioners on Charities,' page 41.

In the reign of Edward I. Newbury returned two members to parliament. (Lysons' *Magna Brit.*, i., p. 319, given by him on the authority of Willis's *Notitia Parliamentaria.*) At what period it was disenfranchised does not appear. It is here that the Easter quarter-session for the county is held. The vicinity of Newbury is remarkable for the battles fought there in 1643 and 1644, between Charles and the parliamentary forces. (*Beauties of England; Parliamentary Papers, &c.*)

NEWBURY, PORT. [MASSACHUSETTS.]

NEWCASTLE, distinguished from other places of the same name as *Newcastle-upon-Tyne*, is locally in Castle Ward, in the county of Northumberland, of which county it is the assize-town. It is 274 miles from London, by Hatfield, Baldock, Stamford, Newark, Doncaster, Borough-bridge, Darlington, and Durham.

Newcastle appears to have derived its origin from Pons Ælii, the second station from the eastern extremity of the Roman wall. Several Roman remains furnish decisive proofs that it occupies the site of a station. Many coins were found in the piers of the old bridge thrown down by a

flood in 1771, and the remains of a Roman well, two altars, fragments of walls, and large quantities of pottery, in digging the foundations of the new county court-house, A.D. 1810. Previous to the Conquest the place went by the name of Monkchester, from the number of monastic institutions. The town was also the resort of numerous pilgrims who came to visit the holy well of Jesus' Mount, now Jesmond, a mile north-east of the town. One of the principal streets in Newcastle is still called Pilgrim Street. There are considerable remains of the Black or Dominican Friary near Low Friar Lane. Another antient town, called Pampeden, appears to have been included in the limits of the modern Newcastle: this place was in the manor of Byker; its name is retained, though in a somewhat altered form, in the modern Pandon Hall, Pandon Bank, Pandon Dean, &c. It was from a fortress built by Robert, eldest son of William the Conqueror (A.D. 1079 to 1082), on his return from an expedition into Scotland, to which, in contrast to some more antient erection, the name of the *New Castle* was given, that the town derived its present name. In the rebellion of Mowbray, earl of Northumberland, against William Rufus, this fortress was taken by the king (A.D. 1095). In the reign of Stephen it came into the hands of the Scots, but in the reign of Henry II. (A.D. 1174), and John (A.D. 1213), it was repaired and strengthened. In the reign of Edward I., John Baliol did homage at Newcastle for his crown of Scotland. The town had been early incorporated, probably by William Rufus, but the first mayor was appointed in the reign of Henry III. (A.D. 1251). Edward I. gave the lands and tenements of Pampeden to the burgesses (A.D. 1299). The walls of the town, which had been erected perhaps in Rufus's time, were rebuilt on the eastern side, and it is likely that a portion of the old Roman wall of the station Pons Ælii was incorporated with them. Several of the early Anglo-Norman kings coined money at Newcastle.

In the reign of Edward III. the town was attacked, but without success, by David Bruce (A.D. 1342), in his invasion of England. At the siege of Calais (A.D. 1346) Newcastle furnished 17 ships and 314 mariners, a greater force than any other northern port except Yarmouth. In the wars with Scotland; Newcastle was a frequent place of rendezvous to the English forces, and it was the scene of several diplomatic meetings. In 1636 above 5000 persons died of the plague at Newcastle, an indication of the extent and population of the town. In 1640 it was deserted by the king's forces and occupied by the Scots, who had invaded England. In 1641 the Scots quitted the town, which in the ensuing civil war supported the king with great zeal. In 1644 it was besieged by the Scots, who had come to the support of the Parliamentarians, and taken by storm. In 1646 King Charles was brought hither from Newark by the Scots, to whom he had surrendered himself. In the Rebellion of 1715 the townsmen armed for the support of the government, and the place was occupied by a body of troops under General Carpenter. In 1740 a serious riot took place on account of the dearness of provisions. In the Rebellion of 1745-6 the town was occupied by the militia of the county, and by a regular military force under Marshal Wade.

The town has been more than doubled in size, and nearly so in population, during the present century. It is situated on the summit and declivities of three lofty eminences, rising from the north bank of the Tyne, and ten miles from its mouth. It extends about two miles along the bank. The town of Gateshead, in the county of Durham, occupies the opposite bank, and may be regarded as a sort of suburb of Newcastle. [GATESHEAD.] The limits of the municipal borough formerly included the town and county of the town of Newcastle, having an area of 2000 acres. The Boundary Act added to this, for parliamentary purposes, the townships of Elswick, Westgate, Jesmond, Heaton, and Byker; and these townships have been since added to the municipal borough, making the total area 4986 acres. The population, in 1831, was as follows:—County of the town of Newcastle, 42,760; townships of Elswick, 787; Westgate, 2996; Byker, 5176; Heaton, 601; Jesmond, 1393; total, 53,613. The population of Gateshead at the same time was 15,177: making a total of 68,790. At present, taking into account the rapid increase of buildings, the population of Newcastle and Gateshead, with the adjacent villages, comprising a dense population, chiefly of colliers, may be estimated at 100,000.

In the central part of the town, which is the oldest, the streets are inconveniently narrow, and lined with old houses. Considerable improvements have however been made, and now streets have been opened in this part. In the upper and more modern parts of the town are spacious streets and squares, with regular ranges of elegant buildings. The most splendid of these streets, superior indeed to most streets in other provincial towns, is Grey Street, so named in honour of Earl Grey. The whole is well paved, and lighted with gas; the paving and lighting, which are described in the Municipal Commissioners Reports as indifferent, in many parts have been much improved since their visit. (*Municipal Commissioners' Reports.*) The principal improvements have been on the northern side of the town, where the corporation have erected a new market-house, and entire streets have been built of shops and houses of a superior description. A group of entirely new and uniform buildings, called Branding Place or Village, has been erected in Jesmond township, north of Newcastle; and there is another assemblage of new and respectable houses on Rye Hill, in Westgate and Elswick townships, west of the town. The additions to the town eastward, along the bank of the river, are chiefly for commercial or manufacturing purposes. The improvements effected within the last five years have been very great, and many of them, as well as of preceding improvements, owe their origin to the skill and enterprise of a single individual, Mr. Grainger, a builder of Newcastle. The town is connected with Gateshead by an elegant stone bridge of nine elliptic arches, erected (A.D. 1776-1781) in place of a former bridge destroyed (A.D. 1771) by a great land-flood. It was widened in A.D. 1801. There are two streams running into the Tyne, one of which, the Pandon Burn, flows on the north side of the town, and is crossed by the high north road at Barras Bridge, and then, turning south, runs through or rather under one part of the town (for it is arched over) into the Tyne, about a quarter of a mile below the Tyne bridge; the other, the Ouse Burn, runs on the east side of the town, dividing the township of Jesmond from those of Heaton and Byker, and is crossed in several places by bridges over which roads lead from Newcastle to the places adjacent. It joins the Tyne half a mile below the Pandon Burn. A handsome bridge of three arches, built A.D. 1812, spans the deep and narrow valley of Pandon Dean.

Newcastle is adorned by a variety of public buildings. The church of St. Nicholas, in the centre of the town, is a large and handsome cross-church, 245 feet in length: it is chiefly of decorated English character. The steeple, which is at the west end, 201 feet high, is the most beautiful feature in the building, and is of late perpendicular. At the corners of the tower are bold buttresses, crowned by octagonal turrets with crocketed pinnacles: from the base of these turrets spring four flying buttresses, crocketed and peculiarly graceful in their forms; and on the intersection of these is placed a lantern crowned with a crocketed spire, and four crocketed pinnacles at the corners. This steeple has been imitated in those of St. Giles at Edinburgh, and St. Dunstan's in the East in London, and in other places; but the imitations fall far short of the original. The choir of the church, 110 feet long and 64 feet wide, is enclosed for service; the nave, 110 feet long and 74 feet wide, is without seats; the interior is adorned by a painted east window representing Christ bearing the cross, an altar-piece of the Last Supper, and several monuments. St. Andrew's church, on the north-west side of the town, is a very ancient structure, part of it being of Norman architecture, but it has undergone repeated alterations and repairs. St. John's, near the west gate, is a large cross-church, chiefly of early English character, with a square embattled tower. It contains an ancient font and several ancient monuments. All Saints church, near the centre of the town, is a modern edifice of Grecian architecture, with a steeple 202 feet high. The interior is an ellipse 80 feet by 60. St. Ann's chapel is a plain building, with a light steeple, on the east side of the town, near the Ouse Burn. St. Thomas's chapel, lately erected in the Magdalene Meadows, near Barras Bridge, on the north road, in place of a chapel near the Tyne Bridge, now pulled down, is a beautiful building in the early English style, with a lofty tower. There are a number of dissenting places of worship, but none of them have any architectural claims to notice. The Guildhall, Exchange, and Merchants' Court, or hall of the incorporated company of hostmen, form an extensive range of buildings, erected, altered, and

enlarged at various periods: they contain several portraits of historical interest. The Mansion-house, a commodious brick building, near the river Tyne, is now disused as the residence of the mayor, and let for a warehouse. The town and county gaol is a massive stone building of modern erection, large and commodious, and admitting the requisite classification. The moot-hall, or County Court-house, erected in part of the precincts of the ancient castle, is a building of elegant proportions, adorned with a fine portico of six Doric columns on the south front, and a similar portico of four columns on the north front. The architectural details are from the temple of Theseus at Athens. Much of the old castle, which was formerly used as a county prison and for holding the assizes, is yet standing; many alterations have been made in it within the last twenty or thirty years, but by no means in harmony with the original architecture of the building, which is Norman. The walls have a thickness varying from 14½ to 17 feet.

The Infirmary is a commodious and handsome building in the Westgate township: the institution is well managed, and all requisite accommodations for the patients are provided. The in-door patients average about 800; the out-patients about 700. There are a dispensary, a small lying-in hospital, a lunatic asylum under good management and well provided with accommodations, several ranges of almshouses, and other charitable institutions: the keelmen's hospital, for poor keelmen; Jesus' hospital, for decayed freemen, their widows and children; the Trinity almshouses; and the Westgate hospital (the last founded in commemoration of the peace of 1814), are the principal of these. The Literary and Philosophical Society, instituted A.D. 1793, occupies a handsome building of Doric architecture, comprehending a museum, a library, and other apartments. This society owes its origin chiefly to the Rev. Wm. Turner, a dissenting minister in the town. It was established in 1793; and the present building was erected 1822-25. Adjoining the library of the Literary and Philosophical Society are the rooms and museums of the Natural History Society of Northumberland, Durham, and Newcastle, and of the Antiquarian Society of Newcastle. There are a handsome theatre, assembly-rooms, and a riding-school, formerly a circus; public baths near the head of Northumberland Street, and a stand upon the race-course north of the town. There are extensive barracks, enclosed within a stone wall, north-west of the town. The royal arcade, an extensive pile of building, lately erected, is occupied by shops and offices. Two public cemeteries have been formed of late years near the suburbs of the town.

The commercial importance of Newcastle arises from its situation on a river navigable thus far by sea-borne vessels of 400 tons. The Tyne forms the haven, and is under the care of the corporation. The river side is lined with warehouses and extensive quays. The chief business is in the shipment of coals, the produce of the surrounding coal-pits. The coals are brought down the river in broad vessels called keels. The boatmen are called keelmen. The yearly export of coal in the ten years ending with 1832 averaged above 700,000 chaldrons sent coastwise, about half to London; the export over sea to the different countries of the Continent rose from about 45,000 to above 70,000 chaldrons in the same period. In 1833 the quantity sent coastwise was 1,921,848 tons; in 1834, 2,017,452 tons; in 1835, 2,261,401 tons; in 1836, 2,280,713 tons; in 1837, 2,392,494 tons; and in 1838, 2,450,778 tons; the exports to foreign parts in the same years were 230,434, 227,444, 309,536, 415,849, 476,157, and 554,175 tons respectively. The other chief articles of export are lead, the trade in which has much increased; cast and wrought iron; glass and pottery, copperas and other chemical productions; soap, colours, grindstones, salt, and pickled salmon. The imports are wine, spirituous liquors, and fruit from the south of Europe; corn, timber, flax, tallow, and hides from the Baltic; and tobacco and various other articles from North America. The gross receipts at the custom-house for the years ending 5th January, 1836 to 1838, were 307,274*l.* 1*9s.* 3*d.*, 413,796*l.* 17*s.* 6*d.*, and 379,360*l.* 19*s.* 8*d.* respectively; the net receipts of the same years were 293,087*l.* 7*s.* 7*d.*, 396,533*l.* 2*s.* 6*d.*, and 361,311*l.* 8*s.* 8*d.* These receipts were not exceeded by those of any other ports in Great Britain, except London, Liverpool, Bristol, and Hull, in England; and by Greenock, Leith, and Glasgow, in Scotland. The number of ships which entered the port in the years 1832-8 was as follows.—

Years.	British.		Foreign.		Total.	
	Vessels.	Tonnage.	Vessels.	Tonnage.	Vessels.	Tonnage.
1832	432	68,975	323	33,402	755	102,377
1833	506	80,285	261	31,804	767	112,089
1834	425	69,293	445	45,458	870	114,751
1835	466	75,352	348	37,159	814	112,511
1836	702	113,992	585	58,703	1207	172,695
1837	921	140,704	688	76,404	1609	217,108
1838	944	145,940	891	96,064	1835	242,004

Three or four vessels are sent every year to engage in the Davis's Straits whale-fishery. The salmon-fishery on the river has much declined. A number of steam-boats ply between Newcastle and Shields.

The chief manufactures are of glass-bottles and plate and crown glass, chiefly carried on in the township of Byker; this manufacture employed, in 1831, 350 men. The manufacture of steam-engines, mill-work, and other machinery employed from 130 to 140 men in 1831; and the different branches of the manufacture of leather, about 200 men. A number of persons were engaged in ship and boat building, block, mast, and sail making, flax-dressing, rope-making, coach-building, &c. There are several multi-houses, breweries, flour-mills, cooperages, printing-offices, and iron and lead-works, and chemical works. The lofty chimneys of these last, rising from 150 to 300 feet, form a striking feature of the town, and from the flatness of the surrounding country are seen at a great distance. (*Pop. Returns for 1831.*) Fire-bricks, coal-tar, and brown paper are made. Thirty years ago, the bricklayers' and slaters' labourers were chiefly females.

The inland trade of the town is considerable: there are two weekly markets, Tuesday and Saturday: the corn-market is a very important one; the market for wheat and rye, and that for oats, are held in different places; there is a handsome and commodious fish-market under the merchants' court, and large and commodious markets for butcher's meat and vegetables have been lately erected. There are several yearly fairs for woollen cloth, hardwares, leather, horses, and cattle. There are rail-roads from Newcastle to Carlisle, to North Shields, and to South Shields and Sunderland. Parliamentary sanction has been obtained for a railway from Newcastle to York. A Chamber of Commerce has been established for many years.

By the Municipal Reform Act, the borough was directed to be divided into seven wards; the corporation to consist of fourteen aldermen and forty-two councillors; by the revising bars, agreeably to the permission given in the act, the number of wards was fixed at eight, but the alteration was not approved by the king in council. The revenue of the corporation averages from 30,000*l.* to 35,000*l.* per annum: the principal sources are rents (about 9000*l.*), a duty on coals and other goods exported (about 11,000*l.* of which 7000*l.* is coal duty), payments for liberty to deposit ballast (8000*l.*), tolls (nearly 2000*l.*), &c. The chief expenditure is for port and harbour charges (8000*l.* to 9000*l.*), repairing and cleansing the streets (4500*l.* to 5000*l.*), annuities and interest (about 8000*l.*), and charges on hospitals, schools, clergy, &c. (about 2500*l.*), the mayor's salary and expenses (above 3000*l.*), other salaries (about 3500*l.*), general repairs and improvements (above 2500*l.*), &c. (*Rep. of Municip. Commissioners.*)

Newcastle-upon-Tyne is a town and county; the assizes and the Epiphany quarter-sessions for the county of Northumberland are held in the Moothall, which is built on a piece of ground in the jurisdiction of Northumberland, though surrounded by the buildings of Newcastle. Assizes and quarter-sessions for the borough are held in the Guildhall at the usual periods; the recorder presides. There are a mayor's court and a sheriff's court, which have jurisdiction in suits of unlimited amount; a court of conscience for small debts under 40*s.*; and a court of conservancy for the river. There is a police force of 7 serjeants-at-mace and 80 constables, and a night-watch.

St. Nicholas is the mother-church of Newcastle: the benefice is a vicarage (united with the curacy of Gosforth) of the clear yearly value of 753*l.* with a glebe-house; and the vicar has the right of presentation to the perpetual curacies of All Saints (clear yearly value 330*l.*), St. Andrew (227*l.*), St. Ann (110*l.*), St. John, and St. James (244*l.*).

Besides the Philosophical Society and Antiquarian Society, there are a literary, scientific, and mechanical institution, an institution for the promotion of the fine arts, a Botanic and Horticultural Society, a Law Society, a Natural History

Society, and a Philharmonic and Choral Society. There are several libraries connected with various public bodies, beside subscription news-rooms.

The total number of the day-schools of all classes (including boarding-schools) in the town and county of the town, in 1833, was ninety-six; of Sunday-schools twenty-one; in the added townships there were twenty-seven day-schools and nine Sunday-schools: making a total of one hundred and twenty-three day-schools and thirty Sunday-schools. The free grammar-school (in which the late lords Eldon, Stowell, and Collingwood, the poet Akenside, and other eminent persons received the earlier part of their education) was founded by Thomas Horsley, who was mayor of Newcastle in 1525. The Jubilee school is a Lancasterian school, established on occasion of the Jubilee, A.D. 1809, and supported by subscription, with a handsome school-house and a good library: the clergy Jubilee school, built to commemorate the fiftieth year of the prelate of Dr. Shute Barrington, bishop of Durham, is a national school supported by an endowment and by subscription. There are several endowed schools and schools supported by subscription, including three infant-schools. There are a number of other benevolent societies.

(Brand's *History of Newcastle; Guide to Newcastle and its Environs*, by T. Sopwith, 1838; *Historical and Descriptive View of Northumberland*, Newcastle, 1811; Rickmans' *Gothic Architecture; Parliamentary Papers.*)

NEWCASTLE-UNDER-LYME,* a borough, market-town, and parish of Staffordshire, in the hundred of Pirehill, 150 miles from London on the road by Daventry, Coventry, and Lichfield, to Liverpool.

This place is of considerable antiquity, and was a corporate town as early as the reign of Henry II. It is referred to as such in a charter granted in that reign to Preston in Lancashire. The earliest extant charter to Newcastle is dated 19 Henry III., 1235. At a later period of the same reign a castle was built (or probably rebuilt) here by Edmund earl of Lancaster, the king's second son. The records of the borough are extant from 1386.

The town is situated about two miles from the right or west bank of the Trent, not far from the source of that river, and consists of several streets irregularly laid out, but well paved, and lighted with gas. It is supplied with good water. The houses are mostly old, but not deficient in neatness or uniformity. High-street along the Liverpool road is tolerably spacious. The town has two churches. One was rebuilt early in the last century, but has a lofty square tower of much greater antiquity, built of red-sandstone. The other church was built a few years since. There is a Catholic chapel, built in 1834, which is a Gothic building, constructed of ornamental bricks; and there are meeting-houses for Independents, Baptists, Unitarians, and several branches of the Methodists. There are a guildhall, having a clock with an illuminated dial, and a public office for the mayor and magistrates. There is a range of almshouses for twenty alms-women, founded by Christopher Monk, duke of Albermarle, son of the famous George Monk. There are no vestiges of the antient castle except only a portion of the mound on which it was built, the rest having been levelled into the moat for purposes of cultivation.

The population of the borough, which is coextensive with the parish, was, in 1831, 8192; at present it is probably about 10,000. In 1831, 784 men were engaged in manufactures. The chief manufacture is that of hats. There are three silk-mills, a cotton and a paper-mill, the latter chiefly for the manufacture of a tissue-paper used in the potteries for printing the ware. A small portion of the inhabitants are engaged in the potteries. Markets are held on Monday and Saturday in the High-street. Besides the five annual fairs there are now five additional moveable cattle-markets held during the year. The town was formerly regarded as the capital of the pottery district, which is immediately

* Old records point to an antient forest, or woodlands, originally separating Cheshire from the rest of England called *Lime*, probably from its standing on the *limes*, or border. It has been conjectured, with much probability, that a number of places situated on or near the tract formerly occupied by these lime woodlands have derived the addition of *lyme* (which is the most antient and authentic form), *lyne*, or *line*, to their names from such proximity.

Besides Newcastle-under-Lyme we have Ashton-under-Lyme, now under-Lime, Burnlem, antiently Bury-wades-lime (the Saxon word *Bur* signifying a tower, cottage, or dwelling; *Wades*, towards; and *lime*, the woodland tract). Mately-under-Lyme, Whitmore-under-Lyme, Norton in Salop (described in the Cartulary of St. Peter's Abbey, Shrewsbury, as *Juxta nemus quod Lima dicitur*), Hellen-under-Lyme, and Audlem (Old Lyme).

adjacent; but this connection has been gradually diminishing of late years, much to the detriment of Newcastle. A still more serious loss to the town has arisen from travellers being now nearly altogether diverted from it to the Grand Junction Railway.

There is a branch canal from this town to the Grand Trunk (or Trent and Mersey) Canal, which passes through the neighbourhood; and a canal from the coal-mines in Apedale, which affords a supply of coals to the town at a cheap rate.

The corporation, under the Municipal Reform Act, consists of six aldermen and eighteen councillors. The borough, by the same act, was divided into two wards, and the municipal boundaries were made coextensive with the parliamentary boundaries, which had been somewhat enlarged by the Boundary Act. The borough has a commission of the peace, and a good police: quarter-sessions and petty-sessions are regularly held. The corporation revenues are about 600*l.* per annum, a sum which is inadequate to meet the annual expenditure of salaries, rent charges in satisfaction of charitable bequests, &c.

Newcastle has returned members to parliament from 27 Edward III., and probably from an earlier date. The constituency, previous to the Reform Act, consisted of the resident freemen; the number was about 800. The number of houses, in 1831, assessed at 10*l.* annual value, was 267; the number estimated to be of that value was 360. Amongst other privileges, the burgesses have an exclusive right of pasturage on about 205 acres of fertile land, divided into four large fields, which were allotted to them under the Enclosure Act of 1816, in lieu of their antient right to one-third of the pasturage of about 600 acres, called the Town Fields. At the same time five acres, bordering the town on its eastern side, were set apart for public walks, together with funds for their support, and are now planted and laid out in an ornamental manner, to the great advantage of the inhabitants.

The living is a rectory, of the clear yearly value of 285*l.*, with a glebe-house, built in 1698.

There were, in 1833, in the borough, an infant-school, with 100 children; an endowed free grammar-school; four other schools, partly supported by endowment, with 118 children; nineteen other day-schools, with 499 children; one boarding-school, with 43 children; one national day and Sunday school, partly supported by endowment and partly by subscription, with 408 children in the week, and 625 on Sunday; and five Sunday-schools, with 1106 children. A Lancasterian school has been opened since these returns were made. There are a theatre; a permanent Book Society, established in 1815, having a library of upwards of 1500 volumes; and a Literary and Scientific Institution, founded in 1836, which also possesses a library. (*Communication from Newcastle-under-Lyme.*)

NEWCOME, WILLIAM, born 1729, died 1800, one of the eminent divines of the eighteenth century belonging to what was called the Liberal school, to which such men as Law, Paley, and many others belonged. The scene of his labours lay for the most part of the active period of life in Ireland, where he attained the highest dignity in the Church, being appointed archbishop of Armagh during the short administration of Earl Fitzwilliam in 1795.

His father was a clergyman at Abingdon, and he was educated at the grammar-school in that town, from whence he passed to the university of Oxford, where he became in due time a Fellow and tutor of Hertford College, where he had Charles James Fox for one of his pupils. In 1765 he became Doctor in Divinity, and in that year accompanied his patron, the earl of Hertford, when he went lord-lieutenant to Ireland. He went as chaplain, and a bishopric in that country soon falling vacant, he was placed in it: it was the see of Dromore. Entering the episcopal order thus early in life, it is not extraordinary that he had several translations, which were first to Ossory, then to Waterford, and finally to Armagh. A writer of some account of his life assures us that he 'diligently and faithfully discharged the duties of his episcopal office, and secured the respect of all parties and of all religious persuasions by the affability, prudence, candour, and moderation which were the invariable guides of his conduct.'

But the best praise of this eminent prelate is, that he was during the whole of his life a most assiduous biblical student, and that he did not suffer those studies to end in themselves, but laid before the world results which ensued

upon them. He did not begin to lay these results before the public till he had maturely considered them, for he was nearly fifty before he printed any considerable work; but when he had begun, he showed that it was his great object to promote the knowledge and study of the Scriptures. His first work was 'The Harmony of the Gospels,' a work the title of which affords but an inadequate idea of its nature and contents, as, besides containing the results of his inquiries on a very difficult and important point of sacred history, it contains a great mass of valuable criticism and useful information. Out of this work arose a controversy with an acute antagonist, Dr. Priestley, on the duration of the ministry of our Saviour; Bishop Newcome contending for three years, and Dr. Priestley limiting the time to one year. In 1782 he published his 'Observations on our Lord's Conduct as a Divine Instructor, and on the Excellence of his Moral Character,' a work of great beauty; and in 1785 a new version, with critical remarks, of the Twelve Minor Prophets: This was followed in 1788 by a similar work on the prophet Ezekiel. In 1792 he published his 'Review of the Chief Difficulties in the Gospel History relating to our Lord's Resurrection;' and in the same year, 'An Historical View of the English Biblical Translations.' This was his latest publication, except an Episcopal Charge; but after his death there was given to the world a very important work, which he had himself caused to be printed four years before his decease, entitled, 'An Attempt towards revising our English Translation of the Greek Scriptures,' in which he set the example of taking the benefit in an English version of those changes in the Greek text which the critical examination of existing manuscripts has shown to be expedient and necessary.

NEWFOUNDLAND, an island belonging to the British, is situated in the Atlantic Ocean, not far from the eastern shores of North America, between 46° 40' and 51° 37' N. lat. and 52° 25' and 59° 15' W. long. It is nearer to Europe than any of the islands, or any part of the continent, of America, the distance between St. John's and the harbour of Valencia in Ireland being only 1656 sea-miles. On the north-east, east, and south it is surrounded by the Atlantic Ocean. On the west of it lies the Gulf of St. Lawrence, which communicates at the northern extremity of the island with the Atlantic by the strait of Belle Isle, which is about 60 miles long and 12 broad, and deep and safe as a passage to and from the Gulf of St. Lawrence. Cape Rays, the south-western point of the island, is about 70 miles from North Point in Cape Breton; and this wide expanse of water unites the Gulf of St. Lawrence to the Atlantic on the south side of the island. The surface of Newfoundland is estimated at nearly 60,000 square miles, or something more than the area of England and Wales together. Its form approaches to that of a triangle.

The shores are rocky and high, and indented by broad and deep bays, which enter from 40 to 60 miles into the body of the island. The lands adjacent to the sea are bleak, rugged, and nearly destitute of trees or bushes; but at the heads of the bays and near the mouths of the rivers there are flats of some extent covered with trees. The interior of the island is nearly unknown: it seems to be diversified by hills, rivers, and numerous lakes. Towards the eastern coast the hills are low, and there are many trees of small growth; but towards the western coast it is more rugged, and the hills frequently rise to the height of mountains, and have little wood until within a few miles of the coast. The most elevated part is the northern peninsula, which lies along the Strait of Belle Isle. Towards the centre of the island there are flats of considerable extent, swampy, and mostly covered with peat. The hills and mountains do not generally form ridges, but each elevation seems to have its own peculiar base.

The climate of Newfoundland is influenced by its geographical position, by its exposure to the atmosphere of the Atlantic, and by the large fields of ice which, during the months of March, April, and May, are on their way from the northern shores towards the south, and cover the sea adjoining the island to a great distance. Great humidity prevails whenever the wind blows from the sea; and though the cold during the winter is severe, the harbours are not frozen so long as the most southerly of those within the Gulf of St. Lawrence. The cold is rather greater on the western coast and in the interior, but the atmosphere is generally clear and pure. During the summer months the days and nights are, with few exceptions, very pleasant.

At mid-day it is frequently very hot, and even oppressive; but in the mornings and evenings, and at night, the air is exceedingly agreeable. The most disagreeable periods are the setting-in and the breaking-up of the winter, and especially when the great islands of ice appear off the coast.

The climate is not too severe to allow cultivation, but it has hitherto been attempted only on a moderate scale. At the heads of the bays and along the lower course of the rivers there are many tracts of alluvial soil, which, with some outlay, could be converted into meadows, and if drained of the water which covers them when the snow dissolves, would yield good barley, oats, and potatoes. In many parts there is rich pasturage. Trees of any considerable size are only found within the bays, near the water, and along the rivers. On the Atlantic coast there is little wood of any value, except for fuel and the building of small boats. Spruce, birch, and larch compose the woods. Pine is rare and of small growth: mountain-ash is still less common. On the high unwooded grounds wortleberry-bushes predominate.

Deer are numerous, but beavers are not so common as they were formerly. Foxes are still numerous along the rivers and sea-coast. Fishing is at present almost the only occupation of the inhabitants: they take seals on the floating ice-fields in the spring, and cod in the summer along the eastern and southern coasts of the island, the coast of Labrador, and the Great Bank. The salmon, herring, and mackerel are also taken.

Coal, gypsum, and limestone are found in several districts, especially on the western coast, near St. George's Bay.

In the interior of the southern districts there is still a native tribe, the Mic-mac, who also occupy the peninsula of Gaspe, in Lower Canada, and extend into New Brunswick. The northern districts were formerly occupied by another tribe, called the Red Indians; but notwithstanding the careful search which was made some years ago to find out some individuals belonging to this tribe, none have been found, and it seems that the tribe is entirely extinct. The European settlers, all of whom are employed in the fisheries, are established on the coast, and especially on the peninsula of Avalon, which is united to the main body of the island by a low isthmus little more than three miles wide. This isthmus separates Trinity Bay from the bay of Placentia. The settlements on the other coasts are few and at a considerable distance from one another.

The port and town of St. John's is on the east side of the island. The entrance of the harbour is so narrow, that two large ships can hardly pass abreast with safety. There are twelve feet water in the middle of the channel. The harbour is spacious, and sheltered on all sides by high rocks: its fortifications are rather strong than extensive. The town runs along nearly the whole of the north side of the port, but there can scarcely be said to be more than one street, the others being irregular lanes. A few of the houses are of stone or brick, and some of the buildings are handsome, but the greater part are of wood. The public and government buildings are tolerably extensive. The population in summer hardly exceeds 10,000, but on the return of the fishermen it is increased to 15,000. Harbour Grace, the next town in importance, has a population of 5000; it is situated on the western shores of Conception Bay, and the harbour is safe, but rather intricate. The other settlements are small, and chiefly consist of a few wooden houses.

The Great Bank of Newfoundland is the most extensive submarine elevation that is known to exist in any ocean. It is about 600 miles long, and in some places 200 broad. The soundings on it are from 26 to 95 fathoms. The whole appears to be a mass of solid rock; its edges are abrupt, and deepen suddenly from 25 to 95 fathoms. The shallowest parts are the Cape Race, or Virgin Rocks; although there is about four fathoms on the shoalest parts, yet during a heavy sea, a ship would be immediately dashed to pieces on them. The best fishing-grounds on this bank are between 42° and 46° N. lat. The Outer Bank seems to be a continuation of the Great Bank at a lower elevation. It lies between 44° 15' and 46° 24' W. long. and 44° 10' and 47° 30' N. lat. The soundings on it vary from 100 to 160 fathoms. Between the Outer and Great Bank the soundings vary from 120 to 218 fathoms. From the Great Bank to Nova Scotia there is a continuation of banks. The temperature of the water on the Great Bank is from 40 to 12 degrees colder than that of the surrounding sea; and

when it comes into contact with the warm waters of the Gulf-stream, at its southern extremity, the difference amounts to 16 or 18 degrees. It is supposed that the fogs which generally hang over the banks, and hover along the coasts of Nova Scotia, Cape Breton, and Newfoundland, are produced by the vapours which arise from the meeting of the warm waters of the Gulf-stream with those which are brought down from the polar regions by the prevailing north-eastern winds. [FISHERIES.]

The first discovery of Newfoundland is due to some Norwegians, who, before the year 1000, sailed on a voyage of discovery from Greenland, and visited various parts of North America. Indeed it seems pretty well established that during the tenth and eleventh centuries the Northmen discovered and visited a great part of the eastern coast of America. (*London Geog. Journal*, vol. 8.) The existence of Newfoundland however seems to have been forgotten until its re-discovery, on the 24th June, 1497, by John Cabot, then in the service of England. The name Newfoundland was given by Cabot to the whole of the territories discovered by him. The continent and other islands have since received other specific names, while that of Newfoundland has been confined to this island.

Cabot, on his return to England, having reported the great abundance of fish discovered on the coasts of Newfoundland, many private adventurers shortly after proceeded to the spot; and it appears that so early as the year 1500, 'the fishery was carried on by Portuguese, French, Biscayans, and other nations, on the banks or shallows, and on the coast to the east and south of the island of Newfoundland.' At that time the island contained great numbers of bears, beavers, otters, red foxes, martens, and hares, and a profitable trade was carried on with the Indians for the skins of these animals, which were shipped to Europe. No attempt was made to form a settlement on the island until 1536, when a London merchant, Mr. Hoare, attempted, together with the crew of his ship, to pass the winter there, but, after undergoing great hardships, they returned to England before the winter was over. The next attempt was made in 1583, when Sir Humphrey Gilbert, half-brother of Sir Walter Raleigh, having obtained from Queen Elizabeth a grant of 200 leagues round any point on the island where he might choose to settle, proceeded there with 200 people in five small vessels. He formed his settlement in the Bay of St. John, but some of his people became dissatisfied and returned to England, and the remainder having embarked with him on an exploring expedition to the south part of the island, more than 100 of them were lost in one of the ships in a storm. Upon this, with the rest of his followers, he was proceeding towards England, when another storm overtook them, and their vessel foundered. Several attempts to form settlements were afterwards made and successively abandoned, until in 1623 Sir George Calvert, afterwards Lord Baltimore, formed a colony in the south-eastern part of the island, which he called Avalon, and appointed his son the governor. The nature of Sir George Calvert's title does not appear. Soon after the formation of the colony, he proceeded thither, in order that he might freely enjoy the profession of the Roman Catholic religion. Ten years later, a colony was sent from Ireland by Lord Falkland, then lord-lieutenant of that part of the kingdom; and in 1654 Sir David Kirk went there with a few settlers, under the authority of a parliamentary grant. In the meanwhile the French had established a colony in Placentia Bay, and constant disputes arose between them and the English settlers. The permission of the French colony was confessedly a matter of favour on the part of the English government, to which the French fishermen for some time paid a tribute of five per cent. on the value of the fish taken. This payment was relinquished by Charles II. in 1675, and the French fishery thereupon increased rapidly. In the declaration of war against France issued by William III. shortly after he was called to the throne of England, it was stated as one cause of that measure, 'that it was not long since the French took licences from the governor of Newfoundland to fish upon that coast, and paid a tribute for such licences, as an acknowledgement of the sole right of the crown of England to that island; but of late, the encroachments of the French upon that island and his majesty's subjects, trade, and fishery there, had been more like the invasion of an enemy than becoming friends who enjoyed the advantages of that trade only by permission.'

During this war, and in that which followed, considerable damage was done by the French and English forces to the settlements of their respective countrymen on Newfoundland. In 1708 the French attacked and nearly destroyed the town of Saint John, and succeeded in obtaining possession of nearly every settlement; but at the treaty of Utrecht the island was declared to belong wholly to England, the French being allowed to fish under certain regulations, and to occupy the small islands of St. Pierre and Miquelon at the entrance of Placentia Bay, but a garrison of only 50 men was allowed to be kept in each. The subject of fishery rights on the shores and banks of Newfoundland has since been the cause of some disagreement between the English and French governments; and at this time (1839) is far from being placed on a satisfactory footing; but the sovereignty of the island as settled by the treaty of Utrecht has remained undisputed.

The population of Newfoundland has always been very fluctuating. The sole inducement to settlers is offered by the fisheries, for the prosecution of which many persons take up their abode on the island only during the fishing season, and leave it during the winter. By a census taken in 1763 it appeared that the number of inhabitants was then 13,112 of both sexes and all ages. The population in 1806 was estimated at 26,500. A census has since been taken in each of the years 1823, 1828, and 1836, showing the following results:—

	Males.	Females.	Total.
1823 . . .	31,746	20,411	52,157
1828 . . .	34,617	23,471	58,088
1836 . . .	41,467	32,238	73,705

The population in the several districts in 1836 was as follows:—

Districts.	Males.	Females.	Total.
Saint John	10,239	8,687	18,926
Conception Bay	12,842	10,373	23,215
Trinity Bay	3,751	3,052	6,803
Ronavista Bay	2,898	2,285	5,183
Fogo	2,131	1,366	3,497
Ferryland	3,330	1,781	5,111
Placentia and St. Mary	2,644	2,057	4,701
Burin	1,775	1,365	3,140
Fortune Bay	1,857	1,272	3,129
Total	41,467	32,238	73,705

The produce of the fisheries at different periods will show the increasing importance of this colony. In 1763 there were taken and cured 386,274 quintals of codfish and 694 tierces of salmon. There were further exported 1598 tuns of train-oil, and furs to the value of about 2000*l*. In 1795 the fishery employed 400 sail of ships, of the aggregate burthen of 38,000 tons. The produce was 500,000 quintals of codfish, 3700 frails of salmon, 1000 barrels of herrings, 3300 tuns of cod and seal oil, and 4900 seal skins. There were also employed 2000 boats. In 1836 there were produced 860,354 quintals of codfish, 1534 barrels of herrings, 1847 tierces of salmon, 384,321 seal skins, and 9485 tuns of cod, seal, and whale oil, the value of the whole being 808,066*l*.

The inhabitants are in a great degree dependent for provisions upon importation. Salt provisions are sent from Ireland and Germany; large quantities of biscuit are also sent from Germany, flour is imported from the United States of America and from the north of Europe, and Indian corn meal from the United States. The agricultural return for 1836 states the number of acres in cultivation to be 11,052, and their produce 10,300 bushels of oats, 1,168,127 bushels of potatoes, and 6,975 tons of hay. The number of horses in that year was 1551, of horned cattle 5835, and of sheep 3103. The number of shipping that arrived at and departed from the colony in that year was as follows:—

Countries.	Inwards.		Outwards.	
	Ships.	Tons.	Ships.	Tons.
Great Britain	186	26,646	145	18,546
British Colonies	323	29,718	376	42,144
United States	39	5,720	18	2,157
Foreign States	262	36,746	246	32,710
Total	809	98,830	785	

The total value of imports in 1836 was 579,799*l*., and of exports 787,099*l*.

(MacGregor's *British America*; Bouchette's *British Do-*

minions in North America; Chappell's *Voyage to Newfoundland*, 1818.)

NEWFOUNDLAND DOG, a well-known and fine variety of the dog, seldom seen in a state of purity, when it is comparatively small, but very muscular and strong, and generally black. The large, and, it must be confessed, handsome dogs, which are so often seen in this country, and pass for Newfoundland Dogs—"Dogs"—it is Col. Hawker, if we recollect right, who so designates them—"as big as a jackass and as hairy as a bear"—are very different from the compact and moderate-sized animals which, in their native country, are employed in drawing sledges and little carriages laden with wood, fish, or other commodities. Some of these true Newfoundland Dogs we have seen, and they make admirable retrievers. We have also seen the great and less pure *English Newfoundland Dogs*, so to speak, employed in the field for the same purpose with great success. One of the leading qualities of both, when so broken in, is the gallant manner in which they will face and penetrate cover, however thick and rough, in pursuit of the lost object. Whether it be furze, bramble, or blackthorn, in they dash, and almost always persevere till they have recovered the lost piece of game. As water-dogs they are above all praise. Their zeal, their devotedness, their entire abandonment of self when they rush to the rescue of some drowning wretch, are admirable; to be sure, in their eagerness to save, they sometimes encumber those with help who do not need it; and there have been instances where they have nearly destroyed the swimmer by their kindness. Directly they see anybody, or indeed any animal whatsoever, struggling in the water, in they jump, and seem to think that it is their duty never to leave them till they have got them out. They have been employed most successfully in wrecks; and will work against the most heavy sea; not always with success however. There is a case on record where the compact frame and indomitable courage of a bull-dog succeeded in carrying him through breakers which proved fatal to the Newfoundland breed. During a heavy gale a ship had struck on a rock near the land. The only chance of escape for the shipwrecked was to get a rope ashore, for it was impossible for any boat to live in the sea then running. There were two Newfoundland Dogs and a Bull-dog on board. One of the Newfoundland Dogs was thrown overboard with a rope tied round him, and perished in the waves. The second shared a similar fate; but the Bull-dog fought his way through that terrible sea; and arriving safe on shore, rope and all, became the saviour of the anxious people on the wreck.

The Newfoundland Dog is confiding, very sagacious, and capable of the warmest attachment to his master. The attacks of little dogs are generally either coolly looked down upon, as if hardly understood, or treated with marked contempt; but there are exceptions to this lofty behaviour: we saw a harmless and very affectionate pug receive his mortal hurt from one of these dogs, and that without the slightest provocation on the part of the poor little pug. This however was a bad-tempered exception to the general rule; and the Newfoundland Dog may, notwithstanding, be pronounced to be as generous as he is brave.

NEWHAVEN. [SUSSEX.]

NEWHAVEN. [CONNECTICUT.]

NEWMARKET is a market-town, situated principally in the county of Suffolk, though some part, including the whole of the race-course, is in Cambridgeshire. Its direct distance from London is 55 miles north-north-east, and from the town of Cambridge 12 miles west. The main street is long and wide, well lighted, but only partially paved. There is a filthy watercourse running directly through the heart of the town. The houses for the most part are modern and well built. The greater part of the town was destroyed by fire in 1623, and again in the early part of the last century. The destruction of property on the former occasion was estimated at 20,000*l*. Horse-racing does not appear to have been introduced here till about the close of the sixteenth century, when some of the horses which had escaped from the wrocks of the Spanish Armada are said to have been exhibited here, and to have astonished the spectators by their extraordinary swiftness. Soon after the accession of James I. to the English throne horse-racing became a fashionable diversion, and a house was erected at Newmarket for the accommodation of him and his court. This house having been much injured during the civil war, in-

structions to rebuild it were given by Charles II., who was a distinguished patron of the turf. Part is still standing, the rest having been pulled down: adjoining are the extensive stables formerly used for the royal stud. The race-course is on the western side of the town. It extends four miles in length, and is considered the finest in the world. The prosperity of the place is mainly dependent upon the company which the races never fail to attract, and the training of horses, many of which are exported or otherwise disposed of at high prices. The training-ground is on a gentle acclivity on the southern side of the town, and for its purpose is even superior to the race-course, preference being given to it for training horses destined to run in the most distant parts of England. The weekly consumption of oats by the horses, which are here during the greater part of the year, is estimated at 500 quarters. The races which take place during the year are seven in number, namely, the Craven meeting, on Easter-Monday; the two Spring meetings, which follow with one week's interval between each; the July meeting; and the three meetings in October, the last of which is the Houghton. The accommodations afforded by the hotels, inns, and coffee-houses is of the first class. Three plates are annually given by the king, and one under very curious conditions by the will of a Mr. Perram. The market-day is Tuesday. The fairs are held on Whit-Tuesday and on the 8th of November.

Newmarket consists of two parishes, All Saints and St. Mary's. The former is in Cambridgeshire, and in 1831 its population was 714; the latter is in Suffolk, and its population in the same year was 2134: making a total of 2848 persons. The living of All Saints is a perpetual curacy of 37*l.* per annum; that of St. Mary is a rectory, consolidated with the vicarage of Wood Ditton, which are together valued at 375*l.*, and are in the gift of the duke of Rutland. Both are in the diocese of Norwich.

The sum of 25*l.* was formerly paid annually by the Exchequer to the parochial authorities, under a donation, as it is understood, of Queen Anne, for the support of charity-schools at Newmarket, but it was withdrawn about three years ago. After deducting 8*l.* 15*s.* for office-foes, the residue was equally divided between the master and mistress of the national school, who are appointed by the rector of St. Mary's, and whose duty it was to afford gratuitous instruction to 21 boys and the like number of girls. The school is now supported by voluntary contributions, and 72 boys and 53 girls are educated according to the principles of the established church; the number on Sunday being increased to 91 boys and 85 girls.

The other charities of Newmarket, which are numerous, though of small amount, are mentioned in the 'Twenty-second Report of the Charity Commissioners,' pp. 173-5.

(*Beauties of England; Population Returns.*)

NEWPORT. [MONMOUTHSHIRE; WIGHT, ISLE OF.]

NEWPORT PAGNELL, a market-town in the parish of Newport Pagnell, hundred of Newport, and county of Buckingham, 12 miles north-east by east from the town of Buckingham, and 45 miles north-west by north from London (direct distances). It is seated near the junction of the rivers Ouse and Ousel, by the latter of which it is divided into two unequal parts, and over which there is an elegant iron bridge, erected in 1810. The streets are ill paved, and only occasionally lighted with gas. The water for the use of the inhabitants, till within the last fifty years, was supplied by means of machinery from the Ouse, but is now derived from a town pump situate in the High-street. The parish church has lately undergone thorough repair. It is a spacious building of considerable antiquity, dedicated to St. Peter and St. Paul, and stands upon an eminence from which there is a fine view of the surrounding country. The living is a vicarage in the diocese of Lincoln, and in the gift of the crown, with a net annual income of 230*l.* There are in the town three other places of worship; the Independent Chapel was found by John Gibbs, who was ejected from the vicarage, and in which the Rev. Wm. Bull, the 'Delphic Oracle' of Cowper, preached for half a century. It is not a little singular that there are four private burial-grounds in this parish, only one of which is consecrated, namely, the one situated in the gardens of Tickford Abbey. The only manufacture of the town is that of bone lace, which, though not carried on to so great an extent as formerly, still forms a staple trade. There is a market every Saturday, and seven fairs are held in the year, four of which are supposed to have been chartered by Alfred the Great.

About the time of the Norman Conquest the manor of Newport was in the possession of William Fitzansculf, a powerful baron and ancestor of the Paganells, from whom the name Pagnell is derived. During the civil war the town was garrisoned by Prince Rupert, but was subsequently taken by the parliament, and retained by them during the remainder of the war. Sir Samuel Luke, conjectured to be the prototype of Hudibras, was its governor in the year 1645. (Lysons, i. 612.)

There are four schools, a national and a Lancasterian school, a girls', and an infant school, which are supported by voluntary donations. There is also a foundation for teaching twenty girls to read, write, and work, endowed by Dr. Atterbury with 10*l.* per annum; and a charity school for girls, supported by Mrs. Van Hagen. There is a Mechanics' Institution; and an academy, supported by the dissenters, for the education of young men for the Christian ministry. The principal charities of the place are Revis's almshouses and Queen Ann's hospital, so called from Ann, consort of James I., by whom it was refounded. The revenue of the former, 164*l.* per annum, is partly applied to the support and clothing of the seven aged persons appointed by the trustees to be the occupants of the almshouses, and partly towards defraying the expense of certain weekly stipends and distributions of bread, &c. The annual income of the hospital is 261*l.*, and is appropriated to the support of a master and six poor men and women, and an allowance of 20*l.* per annum to the vicar as master thereof.

The entire parish of Newport Pagnell, in the year 1831, contained a population of 3385 persons.

(*Lysons' Magna Britannia; Beauties of England and Wales; Twenty-seventh Report of the Commissioners on Charities*, pp. 148-175, &c.; *Communication from Newport Pagnell.*)

NEWRY, a town in Ireland, partly in the lordship of Newry in the county of Down, partly in the barony of Upper Orior, in the county of Armagh. It is on the Newry Water, which divides it into two parts, 38 English miles south-south-west of Belfast, and about 64 north of Dublin by Drogheda and Dundalk. The Newry Water flows into Carlingford Bay.

There was in ancient times a monastery here, and a castle built by Sir John de Courcy, one of the early Anglo-Norman conquerors of Ulster; which castle was destroyed by the Scotch in their invasion of Ireland under Bruce. Being rebuilt, it was again destroyed in the rebellion of Shane O'Neal; but was a second time restored by Bagnal, Marshal of Ulster, who also rebuilt the town and re-peopled it with Protestant settlers. Newry suffered in the civil war of 1641, and was destroyed by the army of James II. in their retreat from the north in 1689, only the castle and six houses being left standing.

The greater part of the town is on the eastern bank of the Newry Water in the county of Down, and is connected with the remaining part in the county of Armagh by several bridges over the Newry river or the Newry canal. The borough limits include a considerable rural district: there were, in 1831, 1992 houses, inhabited by 2566 families; the population was 13,065: the entire parish, which also extends into O'Neilland West barony in the county of Armagh, had a population of 25,117: nearly 400 men were employed in manufactures. The town is well built in the modern part, and is lighted with gas; it is increasing in wealth and extent. The main street consists of good houses: four of the bridges are of stone; there are spacious assembly-rooms; a neat and commodious custom-house; a church of Gothic architecture, built twenty years since at a cost of more than 12,000*l.*, with a tower and spire 190 feet high; a chapel-of-ease, formerly the parish church; two Catholic chapels, one of which is considered to be the diocesan chapel of the Catholic bishop of Dromore; a friary, which is also a seminary preparatory to the college of Maynooth; two Presbyterian meeting-houses, one of them large and elegant; some other dissenting places of worship; a barrack for 700 men; and an hospital capable of accommodating 30 or 40 patients.

There are at Newry iron-foundries on an extensive scale, and forges for making shovels, spades, and other iron goods; flint-glass and cordage are manufactured, and there are in and about the town a distillery and several flour or oatmeal mills. The trade of the town is great, and it has lately much increased, especially in the export of grain and the import of timber; it communicates with Carlingford Bay

five miles distant, by a ship canal, and with Lough Neagh by a boat canal, both parallel or nearly so to the river in that part of their course which is near the town. Lower down the ship canal opens into the river, by the bed of which it communicates with the bay; and the boat canal unites with the river Bann, by the bed of which it enters Lough Neagh. On the east side of the canal is a line of quays with warehouses; and northward from them is a dock for boats to take in or discharge their cargoes. The gross receipts of duties at the custom-house were in 1836 more than 58,000*l.* The chief trade of the port is with Great Britain. Irish produce, especially corn and cattle, and Irish manufactures, are sent to Liverpool and Glasgow; the imports are timber, coal from Lancashire and Scotland, tea, sugar, salt, British hardware, and other manufactured goods. The chief foreign trade is with the United States and British North America, the Mediterranean, Odessa, the Baltic, and Archangel. There is communication by steam-packets with Liverpool and Glasgow. The steam-boats do not go up to Newry, but to Warren Point, about six miles below, where also the larger trading vessels discharge their cargoes. A great number of labourers embark at Newry for the harvest in England, and few come back without 6*l.* or 7*l.* earned by their labour in England. There are markets on Tuesday, Thursday, and Saturday; the first is for grain, the last is for meat. There are two yearly fairs.

Newry was incorporated 10th James I. The corporation has however become extinct, but the town retained the privilege of returning two members to parliament up to the Union, when the number was reduced to one. It was, before the Reform Act, a scot and lot borough. The number of voters, 5*l.* (Irish) and 10*l.* householders, registered in 1832, 1833, and 1834, was 1156; but the former class of voters will be allowed to become extinct on the death or removal of those who at present possess the suffrage. The seneschal of the manor of Newry is the returning officer.

There is a manorial court held by the seneschal of the manor, having jurisdiction in suits under 100 marks. The quarter-sessions for the Newry division of the county of Down are held here twice in the year; quarter-sessions for the county of Armagh are also held twice in the year in that part of the town which is in Armagh county. Petty sessions are held weekly. The police force consists of detachments of the constabulary of the two counties. The parish of St. Mary, Newry, is a donative in the gift of the Earl of Kilmorey, who is impropiator of the tithes, and exercises (as lay abbot, or representative of the former abbots of a Cistercian abbey, which existed in the town prior to the Reformation), episcopal jurisdiction, holding ecclesiastical courts, and granting probates of wills and licences for marriage, subject only to the metropolitan jurisdiction of the archbishop of Armagh. The vicarage is endowed by the Earl of Kilmorey with 400*l.* per annum, but the net revenue is diminished to one half by the payment of curates' salaries. There is no glebe-house. The church and chapel-of-ease are attended by about 1000 to 1100 persons, chiefly in the morning. Three Catholic chapels in the parish are attended, chiefly in the afternoon, by about 3600 or 3700 persons; the various Presbyterian meeting-houses by nearly 2000 persons; and the other congregations by about 700 persons, chiefly in the evening. There are several schools, most of which are aided or supported by endowments or donations.

NEWSPAPERS. Some persons are of opinion that the origin of newspapers may be traced to the 'Acta Diurna' of the Romans. [ACTA DIURNA.] However this may be, it was not till the sixteenth century that anything at all approaching to the nature even of the 'Acta Diurna' existed in modern times. The war which the Republic of Venice waged against the Turks in Dalmatia gave rise, in 1563, to the custom in Venice of communicating military and commercial news by written sheets, which were read in a particular place to those desirous to hear them, and who paid for this privilege in a coin no longer in use, called *gazzetta*, a name which, by degrees, was transferred to the newspaper itself in Italy and France, and passed over into England. The Venetian government eventually gave these announcements in a regular manner once a month; but they were too jealous to allow them to be printed. Only a few written copies were transmitted to various places, and read to those who paid to hear. Many volumes of these manuscript newspapers exist in the Magliabecchiana library at Florence.

It is to England, or rather to Lord Burghley, the able minister of Queen Elizabeth, that the honour of commencing

P. C., No. 1001.

ing printed sheets of public intelligence is now generally ascribed. The earliest of those which remain (copies are preserved among Dr. Birch's Historical Collections in the British Museum, No. 4106) relate to the descent of the Spanish Armada upon the English coasts; but as they are numbered 50, 51, and 54, in the corner of their upper margins, it has been not improbably concluded that a similar mode of publishing news had been resorted to considerably earlier than the date of that event, though, as far as we know, none of the papers have been preserved. 'The English Mercurie, published by authority for the contradiction of false reports,' was the title of these papers, and the last number contains an account of the queen's thanksgiving at St. Paul's for the victory she had gained over the enemies of England. It is probable that when the great alarm of the Armada had subsided, no more numbers were published. It must not however be concealed that doubt is entertained of the genuineness of these papers. Two of them are not of the time, but printed in modern type; and no originals are known: the third is in manuscript of the eighteenth century, altered and interpolated with changes in old language such only as an author would make.

From the time that 'The English Mercurie' (if genuine) was given up, we find no continued vehicle for political intelligence with a fixed title in England for many years. In the reign of James I., packets of news were published in the shape of small quarto pamphlets occasionally. The earliest we have met with, preserved in the second volume of the series of newspapers purchased with Dr. Burney's library (also in the British Museum), is entitled 'News out of Holland,' published in 1619 for N. Newbery, followed by other papers of news from different countries in 1620, 1621, and 1622. There can be no doubt of the genuineness of those. In 1622, when the Thirty Years' War and the exploits of Gustavus Adolphus excited curiosity, these occasional pamphlets were converted into a regular weekly publication, entitled 'The News of the Present Week,' edited by Nathaniel Butler. This seems to have been the first weekly newspaper in England.*

About this period newspapers began also to be established on the Continent. Their originator at Paris is said to have been one Renaudot, a physician, who had found that it was conducive to success in his profession to be able to tell his patients the news. Seasons were not always sickly, but his taste for collecting news was always the same, and he began to think that there might be some advantage in printing his intelligence periodically. His scheme succeeded, and he obtained a privilege for publishing news in 1632. It would appear that not long after this time there were more newspapers than one in England.

Upon the breaking out of the civil war in Charles the First's time, great numbers of newspapers, which had hitherto been chiefly confined to foreign intelligence, were spread abroad by the different parties into which the state was then divided, under the titles of 'Diurnals,' 'Special Passages,' 'Intelligencers,' 'Mercuries,' &c., mostly in the size of small quarto, and treating of domestic matters. Nearly a score are said to have come out in 1643, when the war was at its height. Heylin, in the address prefixed to his 'Cosmographie,' enjoins the reader not to think himself unsatisfied in his expectation, if he find not in it 'the situation and affairs of each town of war or the quartering-place of every company or troop of soldiers, which are presented to him in the weekly news-books.' Hence we find some papers entitled 'News from Hull,' 'News from the North,' 'The Last-printed News from Chichester, Windsor, Winchester, Chester,' &c., and others too numerous to mention. We also find 'The Scots Dove' opposed to 'The Parliament Kite,' or 'The Secret Owl.' Keener animosities, as D'Israeli remarks, produced keener titles: 'Heraclitus Ridens' was met by 'Democritus Ridens,' and 'The Weekly Discoverer' was shortly met by 'The Discoverer Stript Naked.' 'Mercurius Britannicus' was grappled by 'Mercurius Mastix faithfully lashing all Scots, Mercuries, Posts, Spies, and others.' Mercurius was the favourite name, with another word to indicate the character of the party from which it emanated. Whenever any title however grew popular, it was stolen by the antagonist, who

* Before the introduction of printed newspapers, it appears that great families had a sort of gazetteers in London, who transmitted to them the news of the day in written letters. This custom accounts for the following memorandum preserved in the Clifford family: 'To Captain Robinson, by my lord's command, for writing letters of news to his lordship for half a year, five pounds.' (Whitaker's *Hist. of Craven*.)

thus conveyed his opinions to those who would not have received them had he not worn the appearance of a friend.

D'Israeli, in his 'Curiosities of Literature,' gives an account of the two principal persons who were at this time concerned in the newspaper press, Marchant Needham and Sir John Berkenhout. 'Marchant Needham,' he says, 'the great patriarch of newspaper writers, was a man of versatile talents and more versatile politics, a bold adventurer, and most successful because the most profligate of his tribe. From college he came to London; was an usher in Merchant Taylors' school; then an under-clerk in Gray's Inn; at length studied physic and practised chemistry; and finally he was a captain, and, in the words of honest Antony à Wood, 'siding with the rout and scum of the people, he made them weekly sport by railing at all that was noble in his intelligence, called Mercurius Britannicus, wherein his endeavours were to sacrifice the fame of some lord, or any person of quality, and of the king himself, to the beast with many heads.' He soon became popular, and was known under the name of Captain Needham of Gray's Inn; and whatever he now wrote was deemed oracular. But whether from a slight imprisonment for aspersing Charles I., or some pique with his own party, he requested an audience on his knees with the king, reconciled himself to his majesty, and showed himself a violent royalist in his 'Mercurius Pragmaticus,' and galled the Presbyterians with his wit and quips. Some time after, when the popular party prevailed, he was still further enlightened, and was got over by President Bradshaw as easily as by Charles I. Our Mercurial writer became once more a virulent Presbyterian, and lashed the royalists outrageously in his 'Mercurius Politicus:' at length, on the return of Charles II., being now conscious, says our friend Antony, that he might be in danger of the halter, once more he is said to have fled into Holland, waiting for an act of oblivion. For money given to a hungry courtier, Needham obtained his pardon under the great seal. He latterly practised as a physician among his party, but lived universally hated by the royalists, and now only committed harmless treasons with the College of Physicians, on whom he poured all that gall and vinegar which the government had suppressed from flowing through its natural channel.' In buffoonery, keenness, and boldness, Sir John Berkenhout, the other principal news-writer of the day, was not inferior, nor was he at times less an adventurer than Needham. His 'Mercurius Aulicus' was devoted to the court, then at Oxford. Beside newspapers, he was the author of numerous small political pamphlets abounding in wit and satire.

In 1662 the 'Kingdom's Intelligencer' was commenced in London, which contained a greater variety of useful information than any of its predecessors. It had a sort of obituary, notices of proceedings in parliament and in the law courts, &c. Some curious advertisements also appear in its columns. In 1663 another paper, called 'The Intelligencer, published for the satisfaction and information of the people,' was started by Roger (afterwards Sir Roger) L'Estrange, who warmly espoused the cause of the crown on all occasions, and infused into his newspapers more information, more entertainment, and more advertisements of importance than were contained in any succeeding paper whatever previous to the reign of Anne. L'Estrange continued his journal for two years, but dropped it upon the appearance of the 'London Gazette,' first called the 'Oxford Gazette,' owing to the earlier numbers being issued at Oxford, where the court was then holding and the parliament sitting, on account of the plague being in London. The first number of what has still continued to the present time, as the 'London Gazette,' was published at Oxford, February 4th, 1665. So numerous did these little *books of news*, as they were called, become at this time, that between the years 1661 and 1668 no less than seventy of them were published under various titles.

On the 12th of May, 1680, L'Estrange, who had then started a second paper, called the 'Observer,' first exercised his authority as licenser of the press, by procuring to be issued a 'proclamation for suppressing the printing and publishing unlicensed news-books and pamphlets of news, because it has become a common practice for evil disposed persons to vend to his majesty's people all the idle and malicious reports that they could collect or invent, contrary to law; the continuance whereof would in a short time endanger the peace of the kingdom; the same manifestly tending thereto, as has been declared by all his majesty's

subjects unanimously.' The charge for inserting advertisements (then untaxed) at this period, we learn from the *Jockey's Intelligencer*, 1683, to be 'a shilling for a horse or coach, for notification, and sixpence for renewing;' also in the 'Observer Reformed' it is announced that advertisements of eight lines are inserted for one shilling; and Morphey's 'Country Gentleman's Courant,' two years afterwards, says, that 'seeing promotion of trade is a matter that ought to be encouraged, the price of advertisements is advanced to two pence per line.' The publishers at this time however were sometimes puzzled for news to fill their sheets, small as they were; but a few of them got over the difficulty in a sufficiently ingenious manner. The 'Flying Post,' in 1695, announces, that 'if any gentleman has a mind to oblige his country friend or correspondent with this account of public affairs, he may have it for two-pence of J. Salisbury, at the Rising Sun in Cornhill, on a sheet of fine paper, *half of which being blank*, he may thereon write his own private business, or the material news of the day.' Again, 'Dawker's News-Letter:' 'This Letter will be done upon good writing-paper, and blank space left, that any gentleman may write his own private business. It will be useful to improve the younger sort in writing a curious hand.' Another publisher had recourse to an expedient for filling his sheet, curious enough; wherever there was a dearth of news, he filled up the blank part with a sufficient proportion from the Bible.

It was not until the reign of Anne that the Londoners enjoyed the luxury of a newspaper every day. The first was issued in 1709, and called 'The Daily Courant,' being published every day but Sunday. There were at this time seventeen others published thrice a week, and one twice. Among them was the 'British Apollo,' the 'General Post-script,' the 'London Gazette,' the 'Postman,' the 'Evening Post,' and the 'City Intelligencer.'

It was about this time that a new species of publication came out, which, although it would scarcely be regarded as belonging to the family of newspapers now, was held to be so then; and in fact, for a considerable time after it was commenced, it included articles of news along with its other matter. We allude to those admirable publications, the 'Tatler,' 'Spectator,' 'Guardian,' &c., which formed the models of so many subsequent publications of the same kind. The first number of the 'Tatler' was published on the 23rd of April, new style, 1709; the last on the 2nd of January, 1711. Much space was occupied in each by advertisements, and the price of each number was a penny. The publication of the 'Spectator' began March 1, 1711, at the same price; but upon the imposition of the halfpenny stamp-duty, which began August 1, 1712, the price was raised to two-pence. The halfpenny tax is conjectured to have been the cause of the 'Spectator' being stopped in the beginning of 1713. It was however immediately followed by the 'Guardian,' the first number of which appeared on March 2nd, 1713. This paper soon dropped, and was succeeded by the 'Englishman' in October the same year (professedly political). The 'Englishman' lasted for two years, and was in its turn supplanted by the 'Freeholder,' on December 23rd, 1715; the latter work being almost the sole production of Addison.

It may be sufficient to notice in few words two or three of the more remarkable journals only which have since succeeded. The 'Public Advertiser' was first printed under the title of the 'London Daily Post and General Advertiser,' so far back as 1726, and assumed its later name only in 1752. This paper was the vehicle through which 'Junius's Letters' were given to the world. The 'St. James's Chronicle' is another of our oldest papers; at its first publication it was an amalgamation of two papers (the 'St. James's Post' and the 'St. James's Evening Post'), both of which began in 1715. The 'North Briton,' edited by Wilkes, first appeared in 1762; and in the same year the 'Englishman' was established. The 'Englishman' attracted much notice about 1766, on account of the insertion of several satirical articles in it by Burke.

The following account of the origin of the newspaper stamp is given by Cooke, in his 'Life of Bolingbroke.' 'Queen Anne, in one of her messages to parliament, declared that, by seditious papers and factious rumours, designing men had been able to sink credit, and that the innocent had suffered; and she recommended the House to find a remedy equal to the mischief. In obedience to the Queen's desire, and at the instance of her secretary, the

parliament passed a bill, in 1712, imposing a stamp duty upon pamphlets and publications. At its origin the amount of this stamp was a halfpenny; and it is curious to observe what an effect this trifling impost had upon the circulation of the most favourite papers. Many were entirely discontinued, and several of those which survived were generally united into one publication. The act which imposed this duty is 10 Anne, c. xix. It is to this act that Swift alludes in his Journal to Stella, under August 7, 1712: 'Do you know that all Grub Street is dead and gone last week?'

By the 6th and 7th Wm. IV., c. 76, the stamp-duty on newspapers, which had been gradually raised to 4d. (with a discount of 20 per cent.), was reduced to 1d. (without any discount), a discount of 25 per cent. being allowed for Ireland. The quantity of letter-press on a sheet of paper bearing a stamp of 1d. is limited to 1530 square inches on one side. If it exceeds 1530 square inches, but does not exceed 2295, the stamp is 1½d.; above 2295, it is 2d. A supplement not exceeding 765 square inches of print on one side published with any newspaper, is chargeable with a duty of ¼d. The title of every newspaper is now printed on its stamp, it having been found that in the returns the stamps entered as used by one paper were frequently used by another; and the stamp returns may now be relied upon as shewing the actual circulation of each newspaper.

In 1836, when the stamp-duty was 4d., the total number of stamps issued for the United Kingdom was 35,576,000.

In 1838 the total number of 1d. stamps issued was, in round numbers, as follows:—

London	28,500,000
English provincial papers	15,500,000
Welsh papers	350,000
<hr/>	
England and Wales	44,350,000
Scotland	5,117,000
Ireland	5,225,000
<hr/>	
Total	54,692,000

From the 5th July, 1833, the duty on advertisements was reduced from 3s. 6d. to 1s. 6d. in Great Britain, and to 1s. in Ireland. The following statement of the total number of advertisements, and total amount received therefrom, will show the results of this reduction:—

Year.	England and Wales.		Ireland.		Scotland.	
	Advts. No.	Duty. £.	Advts. No.	Duty. £.	Advts. No.	Duty. £.
1833	783,557	137,122	121,991	15,248	104,447	18,278
1838	1,315,680	98,668	178,200	8,910	176,411	13,230

The London newspapers are now divided into three classes: the daily, the twice or thrice a week, and the weekly; the daily are again divided into morning and evening papers. The expense attending the establishing and carrying on of a London daily newspaper is very great. To establish a morning paper requires a capital of from 50,000l. to 60,000l.; and the risk is so great that a single individual would hardly venture on such a speculation. It is assumed that capital to the amount of 500,000l. at least is invested in the daily press of London, of which two-thirds, or nearly so, may be represented by the morning papers.

Previous to the reduction of the newspaper stamp-duty at the end of 1836, the general price of the London daily papers was 7d.: it is now 5d. Previous to the reduction of the advertisement duty in July, 1833, the lowest price of an advertisement in a London daily paper was 7s.: it is now 5s.

The 'Times,' the largest of the London newspapers, since the reduction of the newspaper stamp-duty at the end of 1836 has issued daily a double paper, that is, eight pages of six columns each. The printed area of the whole paper (both sides) is more than 19½ square feet, or a space of nearly 5 feet by 4. On a rough estimate it contains about 113,000 words, which is equal to about 70 pages of the 'Penny Cyclopædia.' Compared with an 8vo. volume having a page of print of 3½ by 6½ inches, the area of the 'Times' is equal to more than 120 of the 8vo. pages; and, allowing for difference of size in the type, to perhaps 200 of the printed 8vo. pages.

The 'Times' is printed by a machine worked by steam-power, which is capable of printing 2500 in an hour perfect, that is, on both sides; so that an impression of 12,500 can be completed in five hours. The paper is generally put to

press at five in the morning, at half-past six publication commences, and at ten the whole impression is ready to be issued to the public. Mr. Babbage, after describing the manner in which eight and forty columns are formed into eight pages and placed on the platform of the printing-machine, says, 'Ink is rapidly supplied to the moving types by the most perfect mechanism: four attendants incessantly introduce the edges of large sheets of white paper to the junction of two great rollers, which seem to devour them with unsated appetite; other rollers convey them to the type already inked, and having brought them into rapid and successive contact, redeliver them to four other assistants, completely printed by the almost momentary touch.'

Fifteen or sixteen gentlemen are employed by the 'Times' for the purpose of reporting the debates in parliament, others are engaged to report the trials in the courts of law, and examinations and convictions before police magistrates, and to furnish accounts of all public meetings of any interest or importance both in London and in the provinces. To show the manner in which the parliamentary proceedings are reported, let us suppose that an important debate is expected in each house of parliament, and that four reporters are engaged for the Lords and four for the Commons, the process of reporting being the same in each house. The first reporter takes notes for an hour, before the end of which time the second reporter is by his side and ready to succeed him. The first then hastens to the 'Times' office to write out his notes at length for the compositors; the second remains for an hour, and then hurries away like the former, while the third is taking notes for another hour, and he is followed in the same manner by the fourth. The first reporter is now ready to succeed the fourth; he takes notes for an hour, and is followed by the second, and so on till the house breaks up. The time of taking notes is frequently limited to three-quarters of an hour or even less. By this process the whole of a series of debates which began at four or five in the afternoon and continued till three or four in the morning, is issued to the public within a few hours of the time when the debate terminated. Reporters on all turns after the first are allowed cab or coach hire. The distance between the houses of parliament and the printing-office has been calculated to cost the newspapers about two reporters each; that is, the time occupied in going backwards and forwards is equal to the employment of two reporters on each paper. Short-hand is not much used in parliamentary reporting; indeed some of the best reporters never use it, the notes being used rather as an assistance to the memory in giving an abstract of the speeches than in reporting them as they were spoken. All the other London daily papers have an establishment of reporters similar to that of the 'Times,' but on a somewhat smaller scale, and extra reporters are engaged during the session of parliament.

The lowest price charged for an advertisement in the 'Times' is 5s., with the exception of servants wanting places, which are only 4s. If it exceeds four lines, 6d. is charged for every additional line till it reaches the length of about 20 lines. When it exceeds this length, the rate of charge is increased, the longest advertisements being charged at the highest rate.

One hundred persons at least are employed on the establishment of the 'Times.' There are three editors, fifteen or sixteen reporters, at a very liberal annual salary, three or four readers, three or four clerks, twelve attendants on the machinery, about fifty compositors, besides foreign correspondents, news-collectors, and agents.

We subjoin a list of the London newspapers, showing the sale of each publication and the number of advertisements contained in it, formed on an average of the whole of the year 1838, and drawn from accounts furnished by the Stamp-office, and printed by order of the House of Commons:—

Besides these there are a few weekly journals of a purely literary character, the principal of which are the *Athenæum* and the *Literary Gazette*.

The four papers which are published three times a week are made up from the columns of four of the daily papers, the advertisements being omitted and a selection made of the most interesting matter. The *English Chronicle* belongs to the *Morning Herald*; the *Evening Chronicle* to the *Morning Chronicle*; the *Evening Mail* to the *Times*; and the *St. James's Chronicle* to the *Standard*.

The earliest local provincial newspaper in England is said to have been the 'Norwich Postman,' published in 1706, at the charge of a penny, but 'a halfpenny not refused;' followed by the 'Norwich Courant, or Weekly Packet,' in 1714,

price three half-pence. Previous to 1720 the 'York Mercury' appeared, followed in that year by the 'York Courant,' which still exists. In this year also a 'Leeds Mercury' was established; and about the same time a 'Gloucester Journal.' In 1730 a 'Manchester Gazette' was published. The 'Oxford Journal' began in 1740; a 'Preston Journal' in 1745, and 'Billinge's Liverpool Advertiser' in 1765.

In the year 1838 the total number of English provincial newspapers was 240, and of Welsh 10, with a sale of about 15,500,000 for the whole year. They are all weekly papers, with the exception of two or three, which are published twice and three times a week. Some of them are very large, and have an extensive circulation and a great number of advertisements. The 'Leeds Mercury,' for instance, is as large as the 'Times,' has a weekly sale of 9000, and an average weekly number of 245 advertisements. The 'Liverpool Mercury' has a weekly sale of 6400, and averages about 280 advertisements.

In Scotland the newspaper-press was first introduced during the civil wars in the seventeenth century. When a party of Cromwell's troops arrived at Leith in 1652, for the purpose of garrisoning the citadel, they brought a printer, named Christopher Higgins, to reprint a London diurnal, called 'Mercurius Politicus,' for their amusement and information. The first number was issued on the 26th October, 1653; and in November the following year, the establishment was transferred to Edinburgh, where this reprinting system was continued till the 11th April, 1660. On the 31st December, 1660, appeared at Edinburgh 'The Mercurius Caledonius,' purporting to comprise 'the affairs in agitation in Scotland, with a survey of foreign intelligence.' It was a small quarto of eight pages. The last number was dated March 22 to March 28, 1661. It was succeeded by 'The Kingdom's Intelligencer.' In 1669 an 'Edinburgh Gazette' was published by authority, followed in 1705 by the 'Edinburgh Courant.' 'The Caledonian Mercury,' which still exists, was first published on April 28, 1720. After Edinburgh, the next place at which the publication of a newspaper was attempted in Scotland was Glasgow, where the first number of the 'Glasgow Courant' appeared November 11, 1715. 'The Glasgow Journal,' begun in 1729, still exists. An 'Aberdeen Journal, or North British Magazine,' began in 1746; the first number gave an account of the battle of Culloden; this paper still continues. The 'Dumfries Journal' commenced in 1750. The 'Kelso Mail' was established in 1797; the 'Dundee Courier,' in 1800; the 'Dundee Advertiser,' 1801; followed by the 'Dundee Chronicle;' the 'Ayr Advertiser,' and the 'Greenock Advertiser,' in 1802; an 'Inverness Journal,' in 1807; and the 'Perth Advertiser,' in 1808; in 1811 the 'Montrose, Arbroath, and Brechin Review' was established. Somewhat subsequent to this the 'Fife Herald' was established, and in 1833, the 'Fifeshire Journal.' In 1820 a 'Stirling Journal' was instituted, followed by a 'Stirling Advertiser,' but both have been since united in one paper. Scotland has also three other country newspapers, viz. the 'Elgin Courier,' the 'Paisley Advertiser,' and the 'Western Independent.' In 1838 there were 64 newspapers circulated in Scotland, of which 16 belonged to Edinburgh. There were no daily papers. The total sale was 5,117,000.

In Ireland, as in England and Scotland, newspaper intelligence originated during civil commotion. As far back as 1641, at the breaking out of the Rebellion of that year, there was printed a news sheet called 'Warranted Tidings from Ireland;' but from that time to the beginning of the eighteenth century, we have no notice of any other print of the kind, although it is not improbable that there may have been some. About the year 1700, a newspaper called 'Pue's Occurrences,' named after the proprietor, was established in Dublin, and maintained itself for more than half a century. This was the first newspaper published in the Irish capital. The next Dublin print was 'Falkener's Journal,' established in 1728—both were daily papers. Waterford appears to have followed Dublin in publishing news, by the establishment of a paper in 1729, entitled 'The Waterford Flying Post.' In November, 1766, the 'Waterford Journal' came out; and 'Ramsay's Waterford Chronicle' about the same time. The present 'Waterford Mirror' was started in 1801. The oldest existing newspaper in Ireland is the 'Belfast News Letter,' started in 1737. Among the other existing Dublin papers may be mentioned the 'Evening Post,' which has now existed about sixty years. In 1838 there were 84 newspapers circulated in Ireland, of

which 26 belonged to Dublin. The total sale was 5,225,000. There are five daily papers in Dublin.

The newspapers of Great Britain have much improved within the last twenty or thirty years. Before that time, few of them contained any original articles or essays beyond occasional or local paragraphs. But all the English newspapers are still too exclusively devoted to the support of some particular political party, or to some particular object; and it is not easy to find in any one of them a full and impartial discussion of any great question affecting the general interest, free from party bias and direct abuse or oblique censure of individuals whose views differ from those of the newspaper writer. In the comprehensiveness of their views, their just estimation of the value of general principles, and in their sober and critical application of them to the solution of political questions which affect the interest of the community, the best French newspapers have a decided superiority over the English. Some of the French provincial newspapers occasionally contain articles which deserve to find a place among a collection of political essays.

Newspapers are now as common in the British dominions abroad as in England; and in British India six gazettes are published in the Bengal language. In Van-Diemen's Land no fewer than six papers are published at Hobart's Town, namely, the 'Hobart Town Gazette,' the 'Hobart Town Courier,' 'True Colonist,' the 'Tasmanian and Austral-Asiatic Review,' 'Colonial Times,' and 'Bent's News and Tasmanian Threepenny Register;' and two at Launceston, the 'Cornwall Chronicle' and the 'Launceston Advertiser.' In New South Wales there are five newspapers, published at Sidney. At Perth in Western Australia there is now a weekly paper. The 'South Australian Gazette' is published at Adelaide; the first number was printed in England, and carried out, with printing materials, to Australia. It has been followed by another, the 'South Australian;' and a newspaper has been commenced this year (1839) at Port Lincoln. Two newspapers have also been commenced within the present year at Melbourne, in the newly-explored territory of Australia Felix. The first New Zealand Colony, which sailed in September, 1839, carried out the materials for printing a newspaper, of which the first number was printed in England.

In Germany newspapers originated in the 'Relations,' as they were termed, which sprung up at Augsburg and Vienna in 1524, at Ratisbon in 1528, at Dillingen in 1569, and at Nürnberg in 1571, and which appeared in the form of letters printed, but without date, place, or number. The first German newspaper in numbered sheets was printed in 1612. Of the Italian journals, the 'Gazzetta di Milano,' 'Gazzetta di Venezia,' and 'Giornale del Regno delle due Sicilie' are daily; the 'Diario di Roma,' 'Gazzetta di Firenze,' 'Giornale di Commercio di Livorno,' 'Gazzetta di Bologna,' 'Gazzetta Piemontese,' 'Gazzetta di Genova,' 'Voce della Verità' of Modena, 'Gazzetta di Parma,' 'Gazzetta di Lucca,' 'Osservatore Veneziano,' and some others, appear two or three times a week, and a much greater number weekly. The whole number of journals in Italy, including all periodicals, political, literary, and scientific, exceeds two hundred. Madrid has its 'Gaceta;' and Lisbon has also a paper for the publication of official documents and communications. In Belgium and Holland there are, in French and Dutch respectively, a considerable number of daily and weekly papers. In 1830 Switzerland had twenty-four weekly papers, and five others which appeared once a fortnight: the number is since increased. Most of them are written in German. Some are in French, one or two in Italian, and one in the Romansh or Grisons language. The first Russian paper was published in 1703, under Peter I. In 1829 the number of papers and periodicals published in the Russian empire was seventy-three; but the only important political journals are the 'Gazette de St. Petersburg' and the 'Journal de St. Petersburg.' In Sweden the newspapers are not much devoted to political discussion. Denmark has about eighty journals, of which twenty-three are devoted to politics and twenty-five to the sciences. The Greeks have several newspapers in their own language. A journal is published at Corfu, one at Athens, and another at Smyrna. The 'Moniteur Ottoman' is published at Constantinople, in French, under the sanction of the sultan, and the viceroy of Egypt has his official paper printed in the same language, at Boulak near Cairo.

In the United States the increase of newspapers has been

more rapid than in England. In the year 1704, the first Anglo-American newspaper, called the 'Boston News Letter,' was published at Boston. In 1719 the first newspaper was published in Pennsylvania; and in 1733 the first newspapers were published in New York and Rhode Island. Now there is hardly a petty town in any of the twenty-six states without its newspaper, and in the large cities, such as New York, several are published daily. In Pennsylvania a considerable number of newspapers are printed in the German language and distributed among the numerous German settlers in that state. One German newspaper at least is also published in Maryland, and perhaps more. In Louisiana, some papers are printed both in French and English.

The largest collection of newspapers in England is in the British Museum. This collection was commenced by a considerable number being sent there, at the time when the Museum was established, with the library of Sir Hans Sloane. Another collection, of itself valued at 1000*l.*, was purchased in 1813 with the library of the late Dr. Charles Burney. At the end of two years from the time of publication the commissioners of stamps now transfer to the British Museum, for public use, copies of all the stamped newspapers, both of town and country.

The newspapers of 1837 delivered to the British Museum from the Stamp-office were, London papers 89, country papers 201, British Islands 15, Scotch papers 52, Irish 67.

(Chalmers's *Life of Ruddiman*, 8vo., London, 1794, pp. 106-124, with his Appendix, No. 6, pp. 404-441; Nichols's *Literary Anecdotes of the Eighteenth Century*, vol. i., p. 312; vol. iv., pp. 33-97; vol. viii., pp. 495-499; *Encyclopædia Americana*, vol. ix., 8vo., Philad., 1832, pp. 253-263; Chambers's *Edinburgh Journal*, vol. iii., fol., London, 1835, articles in pp. 113, 130, 146, 193, 242, 306, 322, 389; see also various articles in the *Companion to the Newspaper*, fol., 1833-1836.)

NEWTON, ISAAC, was born 25th December, 1642, old style, at Woolsthorpe, a hamlet in the parish of Colsterworth and county of Lincoln, eight miles south of Grantham. From the pedigree registered upon oath in the Herald's office, by Newton himself, in the year 1705, it appears that he was descended from a family of that name, which was resident at Westby in Lincolnshire until about the year 1370 ('Biog. Brit.'). when it became possessed of the manor of Woolsthorpe. His father, Isaac Newton, married the daughter of James Ayscough of Market Overton in Rutlandshire, and the subject of this article was their only child. The mother was left a widow during her pregnancy, and appears to have given premature birth to her child, which was of extremely diminutive size. Mrs. Newton, whose income was little more than 80*l.* per annum, soon contracted a second marriage with the Rev. Barnabas Smith, rector of North Witham, whereupon young Isaac, then about three years old, was confided to the care of his maternal grandmother, by whom he was sent to two day-schools at Skillington and Stoke, until he attained the age of twelve years, when he was admitted into the free grammar-school of Grantham. While here he evinced considerable aptitude for mechanical contrivances, and among other things he constructed a windmill and water-clock, but in the prosecution of his regular scholastic studies he for some time took little interest, and accordingly stood very low in the school. At length however 'the boy who was above him, having one day given him a severe kick upon the stomach, from which he suffered great pain, Isaac laboured incessantly till he got above him in the school, and from that time he continued to rise until he was the head boy.' (Brewster's *Life*.) The decease of Mrs. Newton's second husband, in 1656, induced her to return to the manor of Woolsthorpe, and in that year Isaac was taken from school to assist in the management of the farm. Accordingly on market-days he was sent to Grantham, accompanied by an aged domestic, either to dispose of farm produce, or to purchase such things as were needed by the family. But on these occasions it more frequently happened that Isaac stopped by the way-side, watching the motions of a water-wheel or some other piece of machinery, or if he reached the town of Grantham it was only to resort to the apothecary's garret in which he had resided while he attended the grammar-school, and where a few old books afforded him ample entertainment until his trusty companion summoned him to return home. These and other instances having shown the inutility of thwarting his studious disposition he was shortly after sent back to Grantham school. How

long he remained at school this second time does not appear, but when he had attained his seventeenth year it was determined to send him to Trinity College, Cambridge, at the recommendation of his uncle, the Rev. W. Ayscough, who had been himself educated there. His matriculation took place 5th June, 1660, the year in which Dr. Barrow was appointed to the Greek professorship.

It is a matter of regret that no definite information exists as to the order in which Newton pursued his mathematical studies before entering the university. Biot gives an unauthenticated although very probable anecdote to the effect that while Newton was yet a lad 'one of his uncles found him beneath a hedge, wholly absorbed in the solution of a mathematical problem;' but we find no mention of any mathematical work which had occupied his attention, with the exception of the 'Elements' of Euclid. It has been asserted that a glance at the fundamental propositions was immediately followed by a knowledge of the numerous consequences which may thence be deduced. But the fame of Newton is not enhanced by stating as true what is in the highest degree improbable. There is no doubt that he had read the 'Elements,' though not perhaps with that attention which he afterwards acknowledged their importance deserved. As to his knowledge of natural philosophy, his water-clock, windmill, and sundials may be considered as evidence of his early acquaintance with the principles of mechanics and with the doctrine of the sphere, for it is difficult to suppose that a mind such as his, so ardent in the pursuit of truth, could have contented itself with following a few rules of authority without understanding the reasons upon which they were based. But if these considerations be not thought conclusive, we have only to look to the nature of his discoveries during the first six years of his residence at Cambridge, that is, before the completion of his twenty-fourth year, in order to be convinced that he must either have pushed his studies to a very considerable extent before entering the university, or that his subsequent progress was perfectly unparalleled; for in this period of six years he invented his Binomial Theorem, established the fundamental principles of his doctrine of Fluxions, and demonstrated the law of the force in virtue of which the planets gravitate towards the sun, although, in consequence of the erroneous measurement of the earth then in use, it was not till afterwards that he was able to show that the same law holds with respect to the moon, and that the force manifested at the earth's surface in the fall of a pebble is identical, as to its nature, with that which pervades the whole planetary system.

Descartes had already laid open a vast field of research by the successful application of algebra to geometry, and his writings, both mathematical and speculative, were then much read at Cambridge. After the perusal of Saunderson's 'Logic' and the 'Optics' of Kepler, the attention of Newton was directed to the 'Geometria' of Descartes, a work which, doubtless, exercised considerable influence over his subsequent pursuits, by furnishing him with general methods of direct investigation, such as, till the time of Descartes, were totally unknown. Upon the whole however he was much less indebted to the analytical writings of Descartes than he was to those of his countryman Wallis. He seldom read without making comments upon the text or marginal notes of such parts as appeared to him susceptible of extension or improvement. In this way he completed the perusal of Descartes's 'Geometry,' after which he passed on to the 'Arithmetica Infinitorum' of Wallis. In this work the author had suggested a method of obtaining the quadrature of the circle, the practicability of which depended upon an interpolation. Newton set about effecting this, notwithstanding the discouraging declaration of Wallis, that he believed it to be impracticable. The attempt however proved not merely successful, but in the course of his inquiry he was led (1663-4) to a discovery of greater moment, the history of which is given under BINOMIAL THEOREM. This theorem, combined with the previous labours of Wallis and others, supplied Newton with a method of determining the area and rectification of curves, the surface and content of the solids formed by their revolution, and the position of their centre of gravity; and by similar means he solved with comparative ease a number of problems which had hitherto baffled the attempts of mathematicians, or of which solutions had been obtained only under particular circumstances, whereby the real difficulty had been rather evaded than overcome. The almost indefinite application

which he continued to make of this method, computing even the numerical values of the formulæ to which his investigations gave rise, as if he regarded the occupation rather as a source of amusement than of labour, may possibly have been suggested by the view, as novel as it was important, which he took of the mode whereby magnitudes of every kind may be conceived to be generated, and by the notion he early entertained of the possibility of deducing the definite value of a variable magnitude from the velocity of its increase or diminution.

The fluxionary calculus to which this opinion gave rise was invented by Newton in or before the year 1665. Its history is given in the article FLUXIONS. The following year he composed his 'Analysis per Equationes Numero Terminorum Infinitas,' a tract which afterwards caused much discussion as to the extent to which it contained the method of fluxions. For some reason which it is now difficult to assign, he thought proper to conceal the substance of this tract from the public and even from his friends. However on the appearance of Moreator's 'Logarithmotechnia' in 1668, in which work Newton having recognised two of the many results to which his binomial theorem had previously conducted him, namely, the development of $\log(1+x)$ and the determination of the quadrature of the hyperbola, he communicated the tract above mentioned to his friend Dr. Barrow. This was not till the month of June, 1669. The 31st July following, Barrow, with Newton's permission, transmitted the MS. to Mr. Collins, at the same time acquainting him that it was the production of a young friend of his who possessed a fine genius for such inquiries. Collins took a copy of the MS. and returned the original to Dr. Barrow. The copy was afterwards found among Collins's papers, and attested the year in which the original treatise had been composed. It was first formally published in 1712, but long previous to that its contents must have been pretty widely diffused through Collins's correspondence with many of the principal mathematicians of the day, both in England and upon the Continent.

Newton was admitted sub-sizar in 1661, became scholar in 1664, and took his degree of B.A. in 1665. In 1664-5 he was a candidate with Mr. Robert Uvedale for the law-fellowship of Trinity College; when Barrow, having found the candidates on an equality as regarded attainments, conferred the appointment on Mr. Uvedale, he being the elder. In 1667 he became junior fellow, took the degree of M.A., and became senior fellow in 1668. He succeeded Dr. Barrow as Lucasian professor of mathematics in 1669.

The raging of the plague, in 1665-6, induced Newton to quit Cambridge and retire to Woolsthorpe. Here it was that he began to reflect more particularly upon the nature of the force by which bodies at the earth's surface are drawn towards its centre, and to conjecture that the same force might possibly extend to the moon, and there be of sufficient intensity to counteract the centrifugal force of that satellite, and thereby retain it in its orbit about the earth. To compare this hypothesis with observation, it was necessary to determine the law according to which the intensity of such a force would vary with the distance from the earth's centre; for although no sensible variation can be detected within the narrow limits of direct observation, namely, the summit of the highest mountains or the bottom of the deepest mines, it was reasonable to presume that some variation would be appreciable at the distance of the moon, and in such case only could the force be just sufficient to counteract the centrifugal tendency of the revolving satellite. To a mind so habituated to generalise, it was a natural extension of his hypothesis to suppose that the same kind of force which incessantly deflects the moon from a rectilinear path might likewise act upon the planets so as to retain them in their orbits about the sun. Now the assumption of an attractive force emanating from the sun was at this time far from being a novelty, and it had even been asserted by Bouillaud that if such a force really existed, its intensity would vary inversely as the square of the distance from the attracting body; but neither Bouillaud nor those who entertained similar opinions had given any proof, either empirically or otherwise, of what they had asserted; and certainly none appear to have attempted to establish that the forces which retain the planets in their orbits were identical, as to their nature, with that which draws a stone, when let fall, to the surface of the earth. Newton showed that the law of the inverse square of the distance is

that which really exists in nature; and further, that this law was a necessary consequence of the analogy already discovered by Kepler between the periodic times and the mean distances of the planets. The following will convey a notion of the line of reasoning by which Newton arrived at this result. The intensity of the force, whatever may be its nature, which counteracts the centrifugal force of a planet, is proportional to the versed sine of the arc described in a given time; so that if the time be small, the force will be proportional to the square of the arc divided by the planet's mean distance, or to the square of the linear velocity by the distance. If therefore for the velocity we substitute the ratio of the mean distance to the periodic time, which is proportional to it, we shall find that the force varies as the distance by the square of the periodic time, that is, by Kepler's law, as the distance by the cube of the distance, that is, inversely as the square of the distance. Having thus established the law whereby the planets gravitate towards the sun, he proceeded to examine whether the same law regulated the gravitation of the moon towards the earth. At this point it is that Newton's reasoning first rests upon conjecture, namely, that the force manifested at the earth's surface in the fall of a stone, is identical with that which is constantly deflecting the moon towards the centre of the earth, and that the law of its variation was the same as that which he had determined for the planets. If such were the case, the distance fallen through by the moon in one second of time ought to bear the same ratio to the distance fallen through by a body at the surface of the earth in one second, which the square of the earth's radius bears to the square of the moon's mean distance. The length of the earth's radius, which, entered as a necessary element in the verification of his conjecture, was at that time very imperfectly known (a degree of latitude being estimated at only 60 miles instead of 69½ miles, its more correct length); the consequence of which was, that the result of his calculation indicated a force at the distance of the moon greater, by nearly one-sixth, than that deduced from direct observation. This difference, which many would have considered sufficiently small to establish the correctness of the hypothesis, was regarded by Newton rather as a direct refutation of its truth. He therefore laid aside further consideration of the subject, suspecting, says Whiston ('Memoirs' of himself), that some unknown cause, perhaps similar to the vortices of Descartes, modified, in the case of the moon, the law which he had satisfactorily established with regard to the planets.

In 1666, the plague having subsided, he returned to Cambridge, but without mentioning to any of his friends the interesting inquiry which, during his absence, had occupied so much of his attention. In this way the discarded hypothesis lay dormant for sixteen years. In 1682, when attending a meeting of the Royal Society, he casually heard of the measurement of an arc of the meridian which had been executed by Picard three years before. Having taken a note of the result, and thence deduced the length of the earth's radius, he resumed his former calculation; but in the course of the work, observing that the conclusion he had formerly anticipated was about to be realised, his ardour is said to have brought on a state of excitement and nervous irritability which precluded his further progress, so that the completion of the calculation was confided to a friend. The following year he transmitted to London a few propositions on the motion of bodies acted on by centripetal forces, which were shortly after communicated to the Royal Society, and constitute the leading propositions of the 'Principia.' The manuscript of this work, entitled 'Philosophiæ Naturalis Principia Mathematica,' was presented to the Royal Society by Dr. Vincent in 1686. Its perusal gave rise to many remarks from Dr. Hooke respecting the deduction of the law of the inverse square of the distance from the second law of Kepler, to which he laid claim. Hooke's pretensions upon this head were never made out; and from the known mediocrity of his mathematical attainments, as well as his general disposition to appropriate every new discovery to himself, they are looked upon as very doubtful. Newton however having apparently replied to his remarks with more warmth than discretion, he (Newton) afterwards expressed a willingness to compromise the dispute by the insertion of a scholium (lib. i. prop. iv. cor. 6), wherein the controversial deduction is attributed independently to Sir Christopher Wren, Hooke, and Halley. The printing of the 'Principia' was superintended by Dr. Halley, and the expense defrayed by the Royal Society.

It appeared in 1687, London, 4to. For an account of this memorable work, the reader is referred to PRINCIPIA.

The theory of universal gravitation advanced by Newton, wherein each particle of matter is supposed to attract all other matter in the direct proportion of its mass, and inversely as the square of the distance, is, from its nature, insusceptible of direct demonstration, and could only be established by showing that the phenomena of nature were in no instance opposed to such a supposition, and that it was sufficient to the explanation of those phenomena. Newton did much towards this; but the completion of the proof required the labours of many succeeding mathematicians and astronomers, and this may, in some measure, account for the qualified reception which the theory met with at the hands of Huyghens, who, though he acknowledged the mutual gravitation of the masses of matter, refused his assent to the assumed attraction between their ultimate particles. The opposition to the theory made by Leibnitz, the erroneous and unphilosophical principles which he endeavoured to substitute in its stead, and the meanness with which he sought to injure the reputation of Newton by designating the theory subversive of true religion, are equally prejudicial to his scientific and moral fame. The long interval that elapsed before the writings of Newton began to be generally understood and his doctrines appreciated, is attributable exclusively, as regards England, to their inherent abstruseness. On the Continent they had further to contend with established prejudices in favour of the doctrines of Descartes.

The latter half of the seventeenth century is not less remarkable for its optical discoveries than for the zeal with which the physical sciences generally were prosecuted. The proportionality of the sines of the angles of incidence and refraction, which furnishes an easy explanation of all the circumstances attending the simple refraction of homogeneous light, had been discovered, and the discovery attributed to Descartes, though now known, on the authority of Vossius and Huyghens, to have been due to Snell, a Dutch physician, who died in 1626. From this law Descartes had been able to explain the theory of the refracting telescope, but had fallen into error by attributing the defects of such instruments solely to the spherical aberration of the lenses employed in their construction. Had such been the case, it is obvious that the whole of the aberration might have been removed by merely varying the form of the lenticular surface. Descartes accordingly, in his 'Dioptrice,' published in 1629, and James Gregory, in his 'Optica Promota,' published in 1663, had investigated the forms which they believed it would be necessary and sufficient to give to the lenses, in order that parallel rays transmitted through them should converge to a point or focus with mathematical accuracy. The aberration of sphericity was however but a trifling impediment to the perfection of dioptrical instruments, compared with what is now designated chromatic aberration, or the aberration of refrangibility, which arises from the then undiscovered fact that light is not a homogeneous substance, but composed of rays, some of which are more susceptible of refraction than others. In the year 1666 we learn ('Letter of Newton to Oldenburg,' *Phil. Trans.*) that Newton, in common with many other philosophers at that time, occupied himself in the attempt to grind object-glasses in conformity with the precepts of Descartes and Gregory, and while thus occupied he seems to have conjectured that the defects of refracting telescopes might arise from some other cause than that which had hitherto been exclusively assigned. Either this conjecture or accident led him to consider the phenomenon of the prismatic spectrum (vol. ix., p. 20), which was then well known to philosophers, although it had been explained by none. In doing so he remarked that the angle subtended at the aperture of his shutter by the length of the spectrum was considerably greater than that subtended by the sun's diameter, though, according to the received law of refraction, these angles ought to have been sensibly equal. After modifying the experiment in various ways, and assuring himself that this discrepancy did not arise from any irregularity in his prism, the thought fortunately suggested itself of trying the separate effect of the prism upon each of the coloured lights of the spectrum. Accordingly, having transmitted them successively through a second prism at the same angle of incidence, he found—1, that the colour was in no degree affected by this second refraction; 2, that the spectrum formed by each colour occupied a distinct position on

the screen, so that the deviation from the direction of the primitive ray was different in all, being greatest in the violet and least in the red. He therefore came to the important conclusion 'that light was not homogeneous, but composed of rays, some of which were more refrangible than others.' This discovery must have been made subsequent to the publication of Wallis's optical lectures, which appeared in 1669, for otherwise it is improbable that Newton, to whom the revisal of the MS. was confided, and who receives the author's acknowledgements for having 'corrected several oversights, and made some important corrections,' would have permitted his friend to promulgate views so erroneous.

In the above year however Newton began to deliver a course of lectures on optics at Cambridge, and the composition of white light formed part of the course. Seeking the complete development of the consequences of his discovery, 'he was conducted,' says M. Biot, 'to a multitude of observations no less admirable for their novelty and importance, than for the sagacity, address, and method with which he contrived, executed, and linked them one with the other. He thence composed his system of optics, wherein the fundamental properties of light were for the first time unveiled and established, and classed according to pure experience alone, without the slightest intermixture of hypothesis; a method of procedure which was then as surprising and as little heard of as the properties themselves:....both the physical and natural sciences were at this time so mixed up with mere opinions, that few persons were capable of discriminating between a vague conjecture and a precise idea, between a physical hypothesis and a law of nature rigorously demonstrated.'

Although Newton had been thus successful in his optical inquiries, and had detected the principal source of indistinctness in refracting telescopes, he not only did not see how this indistinctness might be removed, but even designated all attempt as 'desperate' (*Optics*, lib. i., prop. 7); and the long interval which elapsed before the discovery of the achromatic telescope may be attributed to the unmerited reliance which in this instance was placed in his decision. He regarded as a self-evident truth, which it therefore needed neither reason nor observation to confirm, that the spectra formed by different refracting media were always of equal length whenever the refraction of the mean ray was the same; in other words, that the dispersive powers of different media were the same where their indices of refraction corresponding to the mean ray were equal; and although the fact was controverted by some of the more respectable continental philosophers who assailed his doctrines, the circumstance appears to have neither shaken his belief, nor to have suggested the propriety of convincing his opponents by an appeal to experiment. An apparent analogy also between the lengths of the colours of the spectrum and the divisions of the harmonic chord, led him to suppose that the refractive indices of any medium corresponding to the different coloured rays might be deduced from a knowledge of the index of refraction corresponding to the mean. Had he happened to have repeated his experiments with different refracting substances, he could scarcely have failed to recognise the difference of their dispersive powers even when the refraction of the mean ray is the same. Many of his experiments he did repeat with a prism of water, but in this instance he mixed with the water 'a little sugar of lead' (Brewster), his object being merely to increase the refractive power of the water; but he thereby unknowingly also increased its dispersive power, and probably rendered it sensibly equal to the dispersion of the glass prism previously employed. By these mistakes he was induced to forego all attempts to perfect the refracting telescope, and directed his attention to the construction of reflecting telescopes on the principles pointed out by James Gregory, in his *Optica Promota*.

In 1668-9 he had succeeded; and in 1671 he executed a second telescope 'with his own hands,' which is still carefully preserved in the library of the Royal Society. For the investigations of Newton relative to the colours of thin transparent substances the reader is referred to *Thin Plates*. It was in order to explain the phenomena exhibited by such substances, and the partial reflexion and transmission of light incident upon diaphanous surfaces, that Newton devised his theory of 'fits of easy reflexion and transmission.' [LIGHT.] Speaking of Newton's theory of colour, Sir John Herschel remarks, 'It is a theory of extraordinary boldness

and subtlety, in which great difficulties are evaded by elegant refinements, and the appeal to our ignorance on some points is so dexterously backed by the weight of our knowledge on others, as to silence if not refute objections which at first sight appear conclusive against it.' (*Encyc. Metrop.*, art. 'Light,')

In 1672 Newton was elected member of the Royal Society. In 1675 he received a dispensation from Charles II. to continue in his fellowship without taking orders. About the year 1687 he was appointed one of the delegates to defend the privileges of the university of Cambridge against the attacks of James II. In 1688 he took his seat in parliament as one of the representatives of the university, and was resident in London until the dissolution of parliament, which took place the following year. He was again returned in 1703, but lost his election in 1705. On no occasion does he appear to have taken any conspicuous part in the debates of the house. Prior to the year 1695, when he was appointed warden of the mint, with a salary of from 500*l.* to 600*l.* per annum, his pecuniary circumstances are said to have been rather straightened, and whatever may have been his own expectations, his friends seem to have reckoned upon some token of liberality from Charles II. and his successor. The profligate reign of the former, and the opposition which Newton had given to the wishes of James, sufficiently account for their expectations having been disappointed. His sole income is stated to have been derived from his Lucasian professorship, and from the produce of the manor of Woolsthorpe, the amount of which, though aided by habits remarkably temperate and abstemious, ill accorded with the natural generosity of his disposition and the frequent occasions which he probably had of relieving the necessities of his poorer relations. His fellowship however must have been an additional source of income, though we find no mention of its amount, and the notion of his having been in narrow circumstances most probably arose from the fact that in the Journal of the Royal Society there is entered an order in council, dated January 28, 1674-5, whereby he is excused from making the customary payment of one shilling a week 'on account of his low circumstances, as he represented.' (Birch, *Hist. of Royal Society*, iii., p. 179.) Four years after receiving the appointment of warden of the mint, he was promoted to the mastership of that establishment with a salary of from 1200*l.* to 1500*l.*, and at his death his personal estate was valued at 32,000*l.*

About the year 1676, Leibnitz having heard of many new results obtained by Newton by means of an infinite series (the Binomial Theorem), he expressed to Oldenburg his wish to be made acquainted with it. This led to a correspondence between Newton and Leibnitz, wherein the former also communicated many beautiful theorems on the quadrature, rectification, &c. of curves, to which he had been led by the aid of his method of fluxions, but at the same time withheld all information concerning the principles of that method except in the form of anagrams, which were very unlikely to be deciphered. The letters of Leibnitz in reply showed that he was already in possession of a method analogous to that of fluxions, and equally extensive in its applicability. An account of the dispute which afterwards arose between the English and foreign mathematicians, relative to the claims of Leibnitz as an independent inventor of the calculus, and the part which Newton himself took in the controversy, will be found in the article *FLUXIONS* (vol. x., pp. 331-3), and in *COMMERCIIUM EPISTOLICUM* (vol. vii., p. 329).

The five years preceding Newton's appointment to the wardenship of the mint were passed chiefly at Cambridge. During parts of the years 1692 and 1693 he suffered under temporary mental aberration, although it was between December, 1692, and February, 1693, that he wrote his four celebrated letters on the existence of the Deity, at the express request of Dr. Bentley.

Mr. Van Swinden, while examining the MSS. and autograph letters of Huyghens, met with a small journal in the hand-writing of the latter. It is deposited in the library of Leyden, and contains the following note, communicated by Mr. Van Swinden to M. Biot, and first published by the latter in the *Biographie Universelle*. '29th May, 1694. Mr. Colin, a Scotchman, informs me that the illustrious geometer Isaac Newton has been insane for the last eighteen months, either from excess of study, or from the grief occasioned by the destruction of his chemical laboratory, together with many important MSS., by fire. Mr.

Colin adds, that when he came to the archbishop of Cambridge, his conversation indicating an alienation of mind, he was immediately taken care of by his friends, confined to his room, and remedies applied, by means of which he has now so far recovered as to again be able to comprehend the Principia.' Huyghens having mentioned this circumstance to Leibnitz, the latter, in his reply, dated 23rd June, 1694, expresses his gladness at receiving the account of Newton's convalescence at the same time that he received that of his illness, and adds, 'It is to men like you and him, Sir, that I wish a long life.' Sir David Brewster has been at considerable pains to determine how far the foregoing statement is consistent with fact, and has succeeded in bringing to light many interesting documents which bear immediately upon this and other points. Among these is a manuscript diary of Mr. Pryme, a student at Cambridge, at the time that Newton was fellow of Trinity, which manuscript is now in the possession of his collateral descendant George Pryme, Esq., professor of political economy at Cambridge. It commences in the year 1685, and under 3rd February, 1692, the writer mentions having that day heard of the destruction of Newton's MSS. on the theory of colours, 'established upon thousands of experiments which he had been twenty years of making, and which had cost him many hundred of pounds,' and he goes on to say that it took place on a winter's morning while Newton was at chapel, adding that 'when Newton had come back and seen what was done, every one thought he would have run mad; he was so troubled thereat, that he was not himself for a month after.' Another version of the story is, that Newton left in his study a favourite dog, which overturned a lighted taper upon his papers, and on his return, finding the extent of his loss, he exclaimed, 'Oh, Diamond, Diamond, little do you know the mischief you have done me!' The above extract from the diary of Mr. Pryme, while it in some degree corroborates the statement in the Journal of Huyghens, seems to show that the indisposition of Newton was neither so intense nor of so long continuance as has been supposed, and that 'insanity' was inapplicable in the strict sense of that word, although there certainly existed some doubt as to what state of mind he was really in. This view is supported by letters in the hand-writing of Newton, of Mr. Pepys (secretary of the Admiralty), and of Mr. Millington (of Magdalen College, Cambridge), which have also been published by Sir David Brewster from the originals in the possession of Lord Braybrooke. Among these is the following from Newton to Pepys, excusing himself from fulfilling a promise he had made to see the latter when next in London. Pepys entertained a very high esteem of Newton, and appears to have been very anxious for his health and longevity. 'September 13, 1693. Sir,—Some time after Mr. Millington had delivered your message, he pressed me to see you the next time I went to London. I was averse; but upon his pressing consented, before I considered what I did, for I am extremely troubled with the embroilment I am in, and have neither ate nor slept well this twelvemonth, nor have my former consistency of mind. I never designed to get anything by your interest, nor by King James's favour, but am now sensible that I must withdraw from your acquaintance, and see neither you nor the rest of my friends any more, if I may but leave them quietly, &c.,—Isaac Newton.' The wording of this letter excited in Mr. Pepys the suspicion that Newton was suffering from 'discomposure of head or mind, or both,' and he in consequence addressed himself for explanation to Millington, who in reply says, '..... he (Newton) told me of his own accord that he had writt to you a very odd letter, at which he was much concerned; added that it was a distemper that much seized his mind, which he desired I would represent to you and beg your pardon, he being very much ashamed he should be so rude to a person for whom he hath so great an honour. He is now very well, and though I fear he is under some degree of melancholy, yet I think there is no reason to suspect it has at all touched his understanding, and I hope never will.' While labouring under the same melancholy and nervous affection, he had characterised the writings of Locke as immoral, and designated their author a Hobbit. In a letter to Locke, dated 'At the Bull in Shoreditch, September 16, 1693,' he says, 'Being of opinion that you endeavoured to embroil me with women, I was so much affected by it, that when one told me you were sickly and would not live, I answered, "were better if you were dead." He then asks

P. C., No. 1002.

forgiveness for this uncharitableness, and for the ill opinion he had entertained of his writings, and concludes, 'I beg your pardon also for saying or thinking that there was a design to sell me an office, and am your most humble and unfortunate servant, Is. Newton.' In 1694 he appears to have recovered his former tranquillity and strength of mind; for in that year we find him actively occupied in testing his lunar theory by the observations of Flamsteed, with whom he had hitherto been on the most intimate terms. The quarrel which subsequently took place between Newton and the astronomer royal is noticed under FLAMSTEED.

In 1699 Newton was chosen foreign associate of the Royal Academy of Sciences at Paris; in 1703 he was elected president of the Royal Society, to which office he was annually re-elected till his death; and in 1705 he was knighted by Queen Anne. In 1722 he became subject to a disorder of the bladder, accompanied with cough and gout. He presided for the last time at the Royal Society on the 28th of February, 1727, and died at Kensington on the 20th of March following, in the eighty-fifth year of his age. His body was interred in Westminster Abbey, the funeral being attended by several of the nobility and the principal members of the Society. In 1731 a magnificent monument, designed by Kent and sculptured by Rysbrack, was erected in the abbey at the expense of his relatives. It is situated immediately behind the organ, and bears an appropriate inscription ending with 'Sibi gratulentur mortales tale tantumque exstitisse humani generis decus.' It is not true that the binomial theorem is also engraven upon it, though it is so stated under 'Binomial Theorem,' on the authority of several writers. The same year a medal was struck at the Tower, bearing on one side the head of Newton, with the motto 'Felix cognoscere causas;' and on the reverse a personification of the mathematical sciences. In 1753 a full-length statue, by Roubilliac, was erected in Trinity College chapel, bearing the word Newtonus with the inscription from Lucretius, 'Qui genus humanum ingenio superavit.' There is also a bust of Newton in Trinity College library, by the same sculptor. Besides these memorials of Newton there exist several portraits of him by Vanderbank, Ritts, Sir Godfrey Kneller, and Sir Peter Lely: the last was taken when Newton was a B.A. The manor-house of Woolsthorpe, recently visited by the writer, is built of stone, and seated in a valley on the west side of the river Witham. It was repaired in 1798 by Mr. Turner, the late proprietor, by whom also a marble tablet was placed over the mantelpiece of the room in which Newton was born. It bears the inscription, 'Sir Isaac Newton, son of Isaac Newton, lord of the manor of Woolsthorpe, was born in this room on the 25th of December, 1642.' At foot are the lines from Pope,

'Nature and nature's laws lay hid in night:
God said, "Let Newton be," and all was light.'

In a room on the same floor is preserved his oaken study, converted by the present occupant into a lumber closet. The two dials engraved upon the southern wall are still very distinct, but the styles of both are wanting. The larger dial is about a foot in diameter. The celebrated apple tree, the fall of one of the apples of which is said by Pemberton to have turned the thoughts of Newton to the subject of gravitation, was thrown down by the wind about five years since. A drawing has been preserved of it in its prostrate position, and another tree grafted on its stock.

In his person Newton was short, but well set, and inclined to corpulence. His hair was abundant, and white as silver, without baldness. His eye was bright and penetrating till within the last twenty years of his life; but his countenance, though thoughtful, seldom excited much expectation in those to whom he was unknown. In his conversation there appears to have been little either very remarkable or agreeable; but we have the testimony of Dr. Pemberton that 'neither his age nor his universal reputation had rendered him stiff in opinion, or in any degree elated.' Ascribing whatever he had accomplished to the effect of patient and continuous thought rather than to any peculiar genius with which nature had endowed him, he looked upon himself and his labours in a very different light from that in which both he and they were regarded by mankind. 'I know not,' he remarked, a short time before his death, 'what I may appear to the world; but to myself I seem to have been only like a boy playing on the seashore, and diverting myself in now and then finding a smoother pebble or a prettier shell than ordinary, whilst

VOL. XVI.—2 D

the great ocean of truth lay all undiscovered before me.' (Turner's *Collections relative to the Town of Grantham*.) But while he thus contrasted the littleness of human knowledge with the extent of human ignorance, he was fully conscious of the importance of his own labours, when compared with those of his predecessors and contemporaries, and evinced a natural readiness to assert and vindicate his rights whenever occasion might require. It were to be wished that, by an earlier publication of his discoveries, he had adopted the most eligible mode of establishing the undoubted priority of his claim. Such a course, by changing the current of events, would have left him less open to the charge of having disregarded the claims of others, or of having suffered their reputations to be prejudiced by his silent acquiescence in the acts of his colleagues. To judge of Newton from the life of him recently published by Sir David Brewster, we could only infer that his moral character had suffered from no one instance of human infirmity, and that every action had been dictated by feelings of benevolence and the love of truth. These were indeed the general motives by which he was actuated. The unrefuted disingenuousness of his behaviour towards Leibnitz, relative to the discovery of the calculus, and the yet more discreditable part which he took in the persecution of Flamsteed by the Royal Society, are exceptions. Sir David Brewster considers Leibnitz to have been the only aggressor, Newton the only sufferer. The MS. autobiography of Flamsteed was not discovered by Mr. Baily till the year following that in which Sir D. Brewster published his life of Newton.

The following is a list of the works of Newton, in the order of publication:—

1. 'Principia,' 1687, Lond., 4to.; 1713, Camb., 4to., edited by Cotes; 1726, Lond., 4to., edited by Pemberton; 1730, Lond., 2 vols. 8vo., illustrated by Donick; 1729, Lond., 2 vols. 8vo., Englished by Motte. Besides these, several editions have been published on the Continent. The best edition is that of MM. Le Seur et Jacquier, 1739-42, Genov., 4 vols. 4to., comprising a valuable running commentary on the text, and generally known as the 'Jesuits' edition.' The same, 1760, Colon. Allobrog.; the same, 1822, Glasgow, 4 vols. 8vo., edited by Wright. (Horsley, tom. ii. and iii.)

2. 'Optics,' Lond., 1704, 4to. To the first edition, written in English, were appended two Latin treatises, viz. 'De Quadratura Curvarum,' containing an exposition of his method of fluxions; and 'Enumeratio Linearum tertii Ordinis,' containing an elegant classification of seventy-two curves of the third order, with an account of their properties, but without any information as to the method whereby those properties had been investigated. These treatises, which had little connection with the principal work, were omitted in the subsequent editions. A Latin translation of the 'Optics,' by Dr. Clarke, appeared in 1706, Lond., 4to., for which Newton presented the doctor with 500*l*. The other editions are, in English, Lond., 1714, 1721, 1730; in Latin, Lond., 1719, 1721, 1728, Lausanne, 1740, Padua, 1773. (Horsley, tomes i. and iv.)

3. 'Arithmetica Universalis,' 1707, Camb., 8vo., comprising the algebraical lectures delivered by Newton at the university, printed under the inspection of Whiston, and, according to some authorities, without the author's consent. Translated by Raphson, 1728, Lond., 8vo. There are several later editions, both English and foreign. That by Castillon, Amst., 1760, is in 2 vols. 4to. (Horsley, tom. i.)

4. 'Analysis per Equationes Numero Terminorum Infinitas,' 1711, Lond., 4to. Translated by Stewart, 4to., Lond., 1745. This work was written by Newton, about the year 1672, and intended as an introduction to Kinckhuysen's 'Algebra,' of which he had undertaken to publish a new edition. Motives now unknown induced him to abandon this design. (Horsley, tome i.)

5. 'Methodus Differentialis,' a small tract on interpolation. (Horsley, tome i.)

6. 'De Mundi Systemate,' 1728, Lond., 4to. This is a popular account of the truths contained in the third book of the 'Principia.' An English translation from the original MS. had been published the previous year in 8vo. There are later editions. (Horsley, tome iii.)

7. 'The Chronology of Antient Kingdoms amended: to which is prefixed a Chronicle from the first memory of things in Europe to the conquest of Persia by Alexander the Great,' 1728, Lond., 4to. It had been surreptitiously translated and published at Paris, in 1725. The reader will

find an able review of this work, by M. Daunon, appended to Biot's Life of Newton in the 'Biographie Universelle,' tome xxi., pp. 180-6. (Horsley, tome v.)

8. 'Table of Assays,' printed in Dr. Arbuthnot's 'Tables.'

9. 'Optical Lectures,' 1728, Lond., 8vo., comprising those delivered in the years 1669-70-71. Translated into Latin, 1729, Lond., 4to. (Horsley, tome iii.)

10. 'Observations on the Prophecies of Daniel and the Apocalypse of St. John,' 1733, Lond., 4to. (Horsley, tome v.)

11. 'A method of Fluxions and Analysis by Infinite Series,' translated into English from the original Latin by John Colson, to which is added a Commentary by the translator, 1736, Lond., 4to.

12. 'An Historical Account of two notable Corruptions of Scripture,' written prior to 1691, but first published in 1754, Lond., under the title of 'Two Letters from Sir Isaac Newton to M. Le Cierc.' (Horsley, tome v.) Newton contributed some papers to an edition of Varenus's 'Geography,' printed at Cambridge in 1672, 8vo.

The papers communicated by Newton to the Royal Society are comprised in vols. vii.-xi. of the 'Transactions.' The principal works of Newton were collected and published by Dr. Horsley, under the title of 'Newtoni Opera quæ extant omnia,' 1779-85, Lond., 5 vols. 4to. In the foregoing list, where a work had been reprinted in Horsley's edition, reference is made to the volume. The following were, with few exceptions, first printed in Horsley's edition:—Tome i., 'Excerpta quædam ex Epistolis Newtoni ad Series Fluxionesque pertinentia;' 'Artis Analyticæ Specimina, vel Geometria Analytica.' Tome iii., 'Theoria Lunæ.' Tome iv., 'Letters on various Subjects in Natural Philosophy, published from the Originals in the Archives of the Royal Society;' 'Letter to Mr. Boyle on the Cause of Gravitation;' 'Tabulæ ducæ, Calorum altera, altera Refractionum;' 'De Problematibus Bernouillianis;' 'Propositions for determining the Motion of a Body urged by two Central Forces;' 'Four Letters to Dr. Bentley;' 'Commercium Epistolicum D. Johannis Collins, et aliorum, de Analsi Promota' (first published by the Royal Society in 1713: a new edition appeared in 1722); 'Additamenta Commercii Epistolici.' Tome v., 'A short Chronicle from a Manuscript, the property of the Rev. D. Ekins, dean of Carlisle.' The minor works of Newton have been collected and published under the title of 'Opuscula Mathematica, Philosophica, et Philologica; collegit partimque Latine vertit ac recensuit Joh. Castillioneus;' Laus. et Genev., 3 tomes 4to. After the death of Newton, Dr. Pellet was appointed by the executors to examine his manuscripts and papers, and to select such as he deemed adapted for publication. They are eighty-two in number, and consist of a great number of sheets. But many of those on theological subjects are mere copies over and over again, with very slight variations. Of these MSS., the only ones which Dr. Pellet deemed fit to be printed were 'The Chronology' and 'An Abstract of the Chronology,' the former in ninety-two, the latter in 12 half-sheets folio. At the same time he recommended for further consideration those entitled 'De Motu Corporum;' 'Paradoxical Questions concerning Athanasius;' 'History of the Prophecies;' and a bundle of loose mathematical papers. A catalogue of these MSS. was appended to a bond given by Mr. Conduit to the administrators of Newton, wherein he binds himself to account for any profit he may make by their publication. A list of them will be found in Hutton's 'Dictionary.' Those on theological subjects are at present, we believe, in the possession of the family of the earl of Portsmouth. In addition may be mentioned the valuable and hitherto unpublished collection of letters between Newton and Cotes, relative to the publication of the second edition of the 'Principia,' preserved in the library of Trinity College, Cambridge; the Correspondence of Newton with Mr. Pepys and Mr. Milington, in the possession of Lord Braybrooke; and other MSS. in the Bodleian library, Oxford.

NEWTON'S PRINCIPIA. [PRINCIPIA.]

NEWTON, THOMAS, born 1704, died 1782, having been for the last twenty years of his life bishop of Bristol, and for the last fourteen dean of St. Paul's; a prelate of not very remarkable powers, natural or acquired, but a man without reproach, acceptable in the society of the great, and possessed of a certain amount of general and professional knowledge.

He is chiefly known by two works: an edition of the 'Paradise Lost,' with notes, first published in 1749, and his 'Dissertation on the Prophecies,' of which the first volume appeared in 1755. Both had a certain, perhaps a high, celebrity in their day, but we look in them in vain for much of either acuteness or learning. Both however may be perused by those who do not profess to be themselves critical scholars with advantage; and the critical scholar in English or in biblical literature may meet occasionally with useful suggestions. It is perhaps unfortunate for the bishop that a comparison is provoked between his work on Milton and the edition (a model of works of that class) of the minor poems by Warton.

Bishop Newton's course of life was very like that of other divines who have risen to the episcopal bench. He was the son of a person engaged in trade, was a pupil in the grammar-school at Lichfield, and afterwards at Westminster, from whence he removed to Trinity College, Cambridge; was for some years a city preacher, and tutor in the Tyreconnel family, and in 1744 presented by Pulteney earl of Bath, who was his great friend and patron, to the living of St. Mary-le-Bow. He next became lecturer at St. George's, Hanover Square, prebendary of Westminster, dean of Salisbury, sub-almoner, bishop of Bristol, and finally dean of St. Paul's.

NEWTOWN STEWART, a town in the parish of Ardstraw, barony of Strabane, county of Tyrone, and province of Ulster. It is seated on the left bank of the Moyle, or Mourne, 9 miles (English) north by west from Omagh, and 116 miles (English) north-west by north from Dublin (direct distances). It derives its name from Sir William Stewart, to whom the adjacent lands were granted by Charles I. Being surrounded by the mountains of Munterloney, and commanding the only pass in this mountainous district, it was formerly regarded as a place of some importance. In 1689 it was burnt by order of James II., and remained a mere heap of ruins till 1727, when it was restored by the Stewart family. The parish church, 'a handsome building,' was erected the same year, at the expense of Dr. Hall, the then vicar of Ardstraw, and subsequently bishop of Dromore. Young, in 1780, described this place as 'a row of neat stone and slate cabins.' It now consists of three streets, which are tolerably well built and paved, and contains one or two inns. Its population, in 1831, was 1737, that of the entire parish of Ardstraw being 18,617. Many of the inhabitants are employed in the neighbouring quarries. The market-day is Monday. The fairs are held on the last Monday in every month.

(Young's *Tour in Ireland*, Lond., 1780, 4to.; *Population Returns*.)

NEWTOWN. [MONTGOMERYSHIRE.]

NEXT OF KIN. [CONSANGUINITY; INFESTACY.]

NIAGARA RIVER AND FALLS. The Niagara river unites lake Erie with lake Ontario, which is 334 feet lower than lake Erie. The river descends through this difference in level in the space of about 33 miles. Near the place where it issues from lake Erie the river runs through a level country, and its banks are not much elevated above the surface of the water. The current is gentle, hardly exceeding two miles and a half an hour. The width of the river is about one mile, and it preserves this width until it arrives at Grand Island, by which it is divided into two arms. About ten miles lower down, at Navy Island, both arms re-unite, and at this place the river is about two miles wide. A little lower down, at the mouth of the Welland or Chippeway river, it suddenly contracts to less than a mile, and its current rapidly increases from three to seven or eight

miles an hour. The course of the river in this part is nearly due west, and its banks begin to rise first to ten or twelve feet, and soon to twenty, thirty, and fifty feet above the surface of the water. This rising of the banks is not the effect of a rise in the surrounding country, which in fact preserves its level in a continuous plain, but it is owing to the bed of the river descending on an inclined plane. The waters are borne down with great force against the Canadian side, and driven back by the high rocky banks, for at this point the river suddenly turns to a course which is east of north, and immediately afterwards the great volume of water is hurled down over a perpendicular height of 160 feet into a terrific gulf. Goat Island divides the cataract. This island is about 320 yards wide. The cataract between it and the American side is 320 yards wide, and 162 feet high; but between the island and the Canadian side it is 700 feet wide and 150 feet high. Both falls unite before they are lost in the gulf below. The American cataract descends nearly in a perpendicular line, and is divided into two cataracts by a small rock. The fall between this rock and Goat Island is only ten yards wide, and is called the cataract of Montmorenci. The Canadian cataract rolls over a precipice projecting about fifty feet beyond its base, and the falling water forms a curve, between which and the rock itself persons may safely proceed thirty or forty yards. This is called the Horse-Shoe Fall. To accommodate the travellers who visit the falls, a wooden bridge has been thrown across the American Fall to Goat Island, a few yards above the very crest of the cataract, and on the Canadian side a platform has been extended so far as to enable the traveller to look immediately over the awful abyss. Below the Falls the river flows with considerable rapidity between banks from 200 to 300 feet high. These banks are perpendicular for about half their descent, but towards the base they form a slope composed of the fragments which have fallen from above. Four miles below the Falls, in a semicircular basin, there is a terrific whirlpool formed by the water, which descends into the vortex with furious impetuosity, and rushes out between a narrow passage formed by perpendicular cliffs. Not far from this place the river passes the low ridge called Queenston Heights, and enters the level country which surrounds lake Ontario.

This enormous volume of water is thrown over a mass of limestone rock, which lies in horizontal strata: below the limestone there is a thicker mass of soft shale, which crumbles away rapidly; so that the limestone above overhangs it forty feet or more, and fragments of the superior rock fall down from time to time. Thus the cataracts are slowly changing their position, and moving nearer to lake Erie. The deep channel in which the river flows below the Falls seems to owe its origin to the same cause that is now in operation; and it is not improbable that the Falls were once at Queenston, which is now seven miles below the cataract. The high table-land extends from Queenston to lake Erie

The Niagara descends—

From lake Erie to the head of the Rapids above the Falls	15 feet
By the Rapids above the Falls	51 "
By the Great Fall on the American side	162 "
From the base of the Falls to Queenston	104 "
From Queenston to lake Ontario	2 "

334 feet

To obviate the interruption which the Falls of the Niagara cause to navigation, the Welland Canal has been made on the Canadian side. [CANADA.]

Hist.*, xii.)

NIAS. [SUMATRA.]

NICÆA. [ANATOLIA.]

NICANDER, a physician, poet, and grammarian, of whose life very few particulars are found in ancient authors, and even those few are doubtful and contradictory. Upon the whole it seems most probable that his father's name was Damnaeus (*Eudociæ Viol.*, ap. *Villois. Anecd. Gr.*, vol. i., p. 308, and *Anonymi Scriptoris, Vita Nic.*); that he lived about Ol. clxi., ii., 135 B.C., in the reign of Attalus III., the last king of Pergamus, to whom he dedicated one of his poems which is no longer extant (Suidas; *Eudoc.*,

Viol.; *Anon. Vita*); that he was a native of Claros (Nican-
dri *Theriaca*), a small town near Colophon, whence he
is commonly called *Colophonius* (Cic., *De Orat.*, lib. i.,
cap. 16; Suidas, *Anthol. Gr.*); and that he succeeded his
father as hereditary priest of Apollo Clarius (Eudoc., *Viol.*;
Anon. Vita). He appears to have been rather a volumi-
nous writer, as the titles of more than twenty of his works
have been preserved; but of all these we possess at present
only two in a perfect state, with a few fragments of some of
the others. The '*Theriaca*' is a poem consisting of nearly
1000 lines in hexameter verse, on the wounds caused by
different venomous animals, and the proper treatment of
each: it is characterised by Haller (*Biblioth. Botan.*) as
'longa, incondita, et nullius sibi farrago.' It contains
however several curious passages relating to natural history,
of which the following may serve as a specimen. He men-
tions (v. 147, &c.) a species of serpent, called *σινψ*, which
always assumes the colour of the ground over which it
crawls.* He places (v. 183, &c.) the venom of serpents in
a membrane surrounding the teeth, which is not very far
from the truth. He describes the ichneumon (v. 190, &c.)
and the asp, and the way in which the former fights with
the latter and destroys its eggs; all of which is described
in very nearly the same terms by Pliny (*Hist. Nat.*, lib.
viii., cap. 35, 36), and in a great measure confirmed by
modern naturalists. (See Cuvier's notes on the above-
mentioned chapters of Pliny, in the French translation, 20
vols. 8vo., Paris, 1829-33.) In speaking of the amphis-
bæna, he falls into the vulgar error of his day, and describes
it as having two heads (v. 372, &c.). The same error is
found in Pliny (*Hist. Nat.*, lib. viii., cap. 35). He divides
scorpions into nine species, distinguishing them chiefly by
their colour (v. 769, &c.), a mode of division probably
taken from Apollodorus (Pliny, *Hist. Nat.*, lib. xi., cap. 30),
and followed by Ælian (*De Nat. Anim.*, lib. vi., cap. 20).
He is the first person who describes the moths that flutter
about a candle at night, and calls them *φάλαρα* (v. 759, &c.).
He gives a fabulous account of the basilisk (v. 396, &c.),
which is followed, as might be expected, by Pliny (*Hist.*
Nat., l. viii., cap. 33, and l. xxix., c. 19), and by Ælian (*De*
Nat. Anim., lib. ii., cap. 7), though it should be observed
that the animal spoken of by them could not be the same
that is called by that name by modern naturalists, which is
found only in America. [BASILISK; COCKATRICE.] He
declares the bite of the field-mouse to be poisonous (v. 815,
&c.), and that the animal dies if it should fall into a wheel-
rut; both which circumstances are repeated by Pliny (*Hist.*
Nat., lib. viii., cap. 83) and Ælian (*De Nat. Anim.*, lib. ii.,
cap. 37). He is one of the earliest writers who mentions
the fable of the salamander (v. 817, &c.). See Pliny, *Hist.*
Nat., lib. x., c. 86, and Ælian, *De Nat. Anim.*, lib. ii., c. 31.
He says that wasps (v. 738, &c.) are generated by the pu-
trifaction of the carcass of a horse (comp. Pliny, *Hist. Nat.*,
lib. xvii., cap. 18, and Ælian, *De Nat. Anim.*, lib. i., cap. 28),
and bees by that of an ox (comp. Ælian, *De Nat. Anim.*,
lib. ii., cap. 57).

The '*Alexipharmaca*' is a rather shorter poem, written in
the same metre, on poisons and their antidotes, and may
be considered as a sort of continuation of the '*Theriaca*.'
Haller's judgment on this work is as severe as on the pre-
ceding. He says of it, '*Descriptio vitænulla, symptomata*
fusè recensentur, et magna farrago et incondita plantarum
potissimum alexipharmacarum subjicitur.' Among the
poisons of the animal kingdom he mentions (v. 115, &c.)
the cantharis of the Greeks, which is not the *Lytta Vesica-*
toria, but the *Melœ Chicorii*; the buprestis (v. 335, &c.),
Carabus Bucidon; the blood of a bull (v. 312); the coagu-
lated milk in the stomach of mammiferous animals (v. 364,
&c.); a species of tetraodon (v. 465, &c.), *Tetraodon La-*
gocephalus; the leach (v. 495, &c.), *Hirudo venenata*;
and a species of gecko, *σαλαμάνδρα* (v. 550, &c.). Among
the vegetable poisons we find the aconite (v. 12, &c.),
'*Aconitum Lycactonum*;' the coriander (v. 157, &c.), which
has sometimes been fatal in Egypt; the hemlock (v. 186,
&c.), '*Conium*;' the colchicum (v. 249, &c.), *ἰσήμερον*; the
Lotos dorychnium (v. 376, &c.); the henbane (v. 415, &c.),
'*Hyoscyamus*;' opium (v. 433, &c.); and the different spe-
cies of fungi (v. 521, &c.), the growth of which Nicander
attributes to fermentation. Of mineral poisons he mentions

only white lead, or carbonate of lead (v. 74, &c.), and
litharge, or protoxide of lead (v. 607, &c.).

To counterbalance in some degree Haller's unfavourable
opinion of Nicander's extant works, it ought in justice to
be stated that his knowledge of natural history appears to
be at least equal to that of other writers of his own or even
of a later age, while on the subject of poisons he was long
considered a great authority: Galen several times quotes
him, and Dioscorides, Aëtius, and Johannes Actuarius have
borrowed from him largely.

With respect to his merits as a poet, the most opposite
opinions are to be found both in antient and modern
writers. In the Greek anthology Colophon is congratulated
for being the birth-place of Homer and Nicander (t. iii., p.
270, ep. 567, ed. Brunck.). Cicero (*De Orat.*, lib. i., cap.
16), alluding to his '*Georgics*' (a poem not now extant),
praises the poetical manner in which he treats a subject of
which he was entirely ignorant; while Plutarch (*De Aud.*
Poëtis, cap. 2) says the '*Theriaca*' only escapes being prose
because it is put into metre, and will not allow it to be
called a poem, because there is in it 'nothing of fable or
falsehood.' This very point Julius Cæsar Scaliger thinks
worthy of especial commendation, and says, '*Magna ei*
laus quod ne quid ineptum aut ineptè dicat.' (*Poëtices*,
lib. v., cap. 15.) He goes on to praise the accuracy of his
expressions and versification, and declares that among all
the Greek authors a more polished poet is hardly to be
found. M. Merian, on the other hand, in an essay '*Com-*
ment les Sciences influent dans la Poësie' (*Mém. de l'Acad.*
Roy. de Berlin, l'an 1776, p. 423) mentions Nicander to
show the antipathy that exists between the language of
poetry and the subjects of which he treated. He calls him
'a grinder of antidotes, who sang of scorpions, toads, and
spiders,' and considers his poems as fit only for the apotheca-
ries. Probably his poetical genius has been a good deal
cramped by the prosaic character of the subjects that he
has chosen for his theme; and we may fairly say that his
writings contain quite as much poetry as could be expected
from such unpromising materials. As for his style and
language, probably every one who has ever read half a
dozen lines of either of his poems will agree with Bentley,
who says that he studiously affected obsolete and antiquated
words, and must have been an obscure writer even to his
contemporaries. (*Cambridge Museum Crit.*, vol. i., p. 371.)

The '*Theriaca*' and the '*Alexipharmaca*' were first pub-
lished in Greek, with the Scholia to both poems, by the
elder Aldus, Venet., 1499, fol., at the end of his edition of
Dioscorides. The last and best edition is Schneider's, who
published the '*Alexipharmaca*' in Greek and Latin, with
the Scholia and copious notes, Halmæ, 1792, 8vo. The
'*Theriaca*,' edited in the same manner, and containing also
the fragments of Nicander's other poems, appeared in 8vo.,
Lips., 1816. The '*Theriaca*' was published in the '*Cam-*
bridge Museum Criticum,' with Bentley's emendations, vol.
i., p. 370, &c. There is extant a Greek paraphrase in prose
of both poems (printed in Schneider's editions) by Eutechnius,
of whom nothing is known, except that he has done the
same to Oppian's '*Cynegetica*' and '*Haliëutica*.'

NICANDER, KARL AUGUST, a recent Swedish poet
of considerable celebrity, was born at Stregnäa, on the 20th
March, 1799, and educated at the university of Upsala,
where he made his literary début in 1820, first under the
pseudonym 'August,' in the '*Kalender för Dame*,' and
almost immediately afterwards by his '*Runesvärdet, eller*
den förste Riddarn' (The Runic Sword, or the First
Knight), a tragedy which manifested great power. His
next production, which was illustrated with designs by his
friend Baron von Hamilton, was that entitled '*Runor*'
(the Runes), a series of sixteen legendary 'romants,'
among which that which has for its subject Erik Vasa is
the most interesting. Another production of the same
kind, though founded not upon northern but southern
story,—namely, his '*Enzio*,' an historical lyric in eleven
romants, appeared in a collection of poems by him in
1825-6; and in each of those years he obtained a prize me-
dal from the Swedish academy, the latter of which was
for his poem on the '*Death of Tasso*,'—a subject previously
treated with great beauty and energy by the Russian poet
Batiushkov. Admirable and touching as are the strains in
which the tragic tale of '*King Enzio*' are poured forth,—
deep as is the pathos, rich as is the poetic colouring, pure
and graceful as is the language, this piece did not become
a favourite with the public. It was however translated into

* Compare Pliny, '*Hist. Nat.*' lib. viii., cap. 35. The same account of the
σινψ is found also in Aristotle (*De Mirab. Auscult.*, c. 178), and in Ælian (*De*
Nat. Anim., l. xvi., c. 40).

German by Mohnike (1829), and the collection in which it appeared procured for its author the applause and patronage of the academy, which enabled him to travel and visit Italy in 1827. Of this journey the literary fruit was the poet's 'Minnen från Södern' (Recollections of the South, after a Tour through Denmark, Germany, Switzerland, and Italy). Its chief merit lies in the poetical pieces with which it is interspersed. Among his minor poetical compositions, that on 'Silence' is a piece of singular beauty and pathos. Nicander died February 7, 1839.

NICARAGUA. [CENTRAL AMERICA.]

NICCOLA DI PISA, or **PISA'NO**, is a celebrated name in the history of art. He was among the very earliest restorers of sculpture: he quitted the hard, dry, and mechanical manner of his predecessors, and introduced a style which, though it falls short of the antique, was based upon similar principles, and in which he displayed a vigorous mind and much feeling, if not always the most refined taste. None of his biographers have been able to ascertain the precise date either of his birth or death, but the former must have been very near the commencement of the thirteenth century, as he was greatly advanced in age, and became quite decrepid in the year 1273, after which date no certain mention of him can be traced. That he had attained to great skill in his profession in 1225 may be taken for granted, as he was in that year employed to execute the *arca* or tomb of San Domenico at Bologna, which he embellished with a series of bas-reliefs and figures truly admirable for that time. Several of these subjects are given by Cicognara, in his 'Storia della Scultura,' and many of the heads and countenances are finely expressed. This work clearly shows that Niccola had diligently studied the antique, and also that he must then have been almost in the maturity of his powers. For a description of and remarks on this masterly production, we refer to Cicognara and to Moronna's 'Pisa Illustrata.'

Niccola appears to have continued at Bologna till 1231, when he began the celebrated church of San Antonio, or Il Santo, at Padua, which acquired for him no less fame as an architect. He had previously given evidence of his skill in architecture by the church and convent of San Domenico at Bologna, which were designed by him during his residence in that city, and supposed to have been his first works of the kind. Immediately after completing the building at Padua, he was engaged to erect the church Dei Frari at Venice, and his reputation as an architect became so great that he was successively employed on many other buildings at Florence, Pistoja, Volterra, Naples, and in his native city. Among those which he executed at Florence, the most celebrated is the church and of monastery Santa Trinita, which edifice was extolled by Michel Agnolo as one of surpassing excellence for its simple grandeur and the nobleness of its proportions. He begun the cathedral of Pistoja in 1240, and likewise improved and embellished that at Volterra. At Arezzo, the convent of S. Domenico,—at Viterbo, the church and convent of the Dominicans, where he did much in the way of repairs and restorations,—and at Naples, the church of Lorenzo, besides the magnificent abbey on the plain of Tagliacozzo, erected by Charles I. of Anjou (1268) in commemoration of his decisive victory over Corradino, and thence called Santa Maria della Vittoria,—testify to the repute in which his architectural talents were held and how extensively he was employed. Besides the Palazzo degli Anziani and S. Michele, among the edifices by him at Pisa the most noted is the campanile of S. Niccola, or the Augustines, which is an octangular structure externally, except at its upper story, which has sixteen sides, with as many arches springing from columns, and forming an open gallery around it, and above this is a lesser story crowned by a short spire, or rather a steep roof, where the octagonal form is resumed. The interior is circular, and forms an open well-staircase with arches resting upon columns, of which latter there are altogether four and twenty, fifteen of oriental granite, and the rest of various marbles. Moronna gives an elevation and section of this structure, but they are so wretchedly executed, that they cannot be relied upon for anything further than the general idea and shape of the design.

Another very celebrated work by him at Pisa, though of a different class, is the pulpit in the Baptistery, a hexagon supported on seven columns, there being one in the centre beneath it, besides those at the angles. It was executed by him in 1266; and in 1266 he was employed to make another

for the cathedral at Sienna, which latter is considerably larger and richer, and octagonal in plan, so that instead of five, there are seven sides occupied with compartments in bas-relief, and likewise nine columns instead of seven. Had he produced nothing else, these two works alone (as to which Cicognara enters into a minute description), would suffice to establish Niccola's fame as a sculptor, and show the great perfection to which he advanced the art from what he found it in the hands of his immediate predecessors. Another work, of which the historian of Italian sculpture speaks at great length, is the representation of the Last Judgment and Inferno, in the façade of the Duomo of Orvieto, which has been generally attributed to Niccola, but is asserted by that critic to have been the production of

GIOVANNI DI PISA, the son and pupil of Niccola, who may have been born somewhere about 1235, as at the time of his death, in 1320, he is said to have been 'vecchissimo,' exceedingly old. We may at least suppose him to have been nearly twenty-five when he was invited to Perugia to erect a splendid monument to Urban IV., who died in that city in 1264. That work gave such satisfaction, that he was employed also upon the embellishments of the fountain in front of the Duomo, wherein he displayed extraordinary ability in the architecture, the sculpture, and the bronzes. Scarcely had he completed this work, when his father died, and he returned to Pisa in order to take possession of his patrimony. One of the first tasks committed to him by his fellow-citizens was that of adorning the small but celebrated church of S. Maria della Spina, one of the richest and most remarkable specimens of its peculiar Gothic style in Italy. For the façade and other parts of the exterior he executed a number of statues, bas-reliefs, and other ornaments of sculpture, and is said in one of the figures to have portrayed his father Niccola. What he there did however were merely the embellishments to a building, in which others shared with him; but it was not long before opportunity was afforded him of displaying his architectural ability on an ample scale, for in 1278 he began, and in 1783 completed, the renowned Campo Santo, or cemetery, one of the most remarkable monuments of its period, and that which, together with the adjacent cathedral, campanile, and baptistery, offers a most interesting group of studies to the architect. The edifice is of marble, and forms a cloister of sixty-two arches (five at each end and twenty-six on each side), inclosing the inner area or burial-ground; but neither this latter nor the exterior is a perfect parallelogram, the cloister being fifteen feet longer on one side than on the other, viz. 430 and 415 feet, and consequently the ends not at right angles to the sides. This defect would almost seem to have been occasioned by oversight, as it could not have been worth while to sacrifice regularity for the sake of a few feet.

After this, according to Vasari, he went to Sienna, where he made a model or design for the façade of the Duomo; this however is questionable. One of the first commissions he received after finishing the Campo Santo was from Charles I. of Anjou, who invited him to Naples, where he erected the Castel Nuovo, and built Santa Maria Novella. In 1286 he was employed to erect the high altar in the Duomo at Arezzo, an exceedingly sumptuous work, in the Tedesco style, with a profusion of figures and sculptures, all in marble. This work, and his Virgin and Child, on one side of the cathedral at Florence, are reckoned by Cicognara as his best productions; but another of great celebrity is the marble pulpit by him in the church of S. Andrea, at Pistoja, which, like that by Niccola in the Duomo at Pisa, is a hexagon supported by seven columns. He also executed many of the sculptures of the Duomo of Orvieto, where he employed various assistants and pupils, some of the latter of whom afterwards became celebrated, particularly Agostino and Agnolo di Sienna. At the instance of the Perugians, he returned to their city, and executed the mausoleum of Benedict XI. He was also invited by the citizens of Prato, in 1309, to build the Capella della Cintola, and to enlarge their Duomo. Loaded with honours and distinctions as well as years, he closed his life in his native city, and was there buried within that monument which he had himself constructed about forty years before, the Campo Santo, which for others was a burying-place, for himself a mausoleum.

NICE, the County of (*Contado di Nizza*), a province of the Sardinian dominions in Italy, is situated between the Maritime Alps and the sea, at the western extremity of the

Riviera of Genoa. It is separated on the west from France by the river Var, and on the north from the plains of Piedmont by the Col de Tende, 5887 feet above the sea, over which passes the carriage road from Nice to Turin. The river Roia, a rapid stream coming from the Col de Tende, crosses the eastern part of the county of Nice, near the borders of the former republic and now duchy of Genoa, and after a course of about 30 miles enters the sea near Ventimiglia. The greatest length of the county of Nice, from the sources of the Tinea, an affluent of the Var, in the lofty recesses of the Alps, to the sea-coast, is nearly 50 miles; and its breadth varies from 30 to 40 miles. The country appears like a section of a vast amphitheatre, the lower part of which consists of gentle hills and small valleys and plains, with a southern aspect. Being sheltered from the northern winds by the Alps, it enjoys a very genial climate, and is made productive by cultivation, especially of olives, figs, grapes, oranges, lemons, and other fruit. But the climate of Nice is not so mild in winter as that of Villafranca, Mentone, San Remo, Nervi, and other favoured spots on the Riviera of Genoa; and the lemon-tree, which in these last-mentioned places thrives in the open fields, is reared at Nice on espaliers against walls facing the south. (Foderé, *Voyage aux Alpes maritimes*.) The mountains, which are mostly barren and naked, occupy about two-thirds of the territory of Nice.

The principal articles of exportation are, oil, which is very fine, and in good years to the amount of 2,500,000 francs; silk, 160,000 francs; oranges and lemons, 75,000 francs; timber, 106,000 francs. Nice imports corn, wine, and cattle, and manufactures of various kinds. The population of the whole county is 104,000. The whole province is 'Porto franco,' that is to say, foreign goods are introduced without paying duty. (Bertolotti, *Viaggio nella Liguria marittima*, 1834.)

The principal towns are—Nizza; Sospello, 3600 inhabitants; Villafranca, with a good harbour and docks for the Sardinian navy, and a strong castle on the hill above, and 2500 inhabitants; Saorgio, in a strong position, often mentioned in the last wars between the French and Sardinian troops, has 2200 inhabitants; Tenda, at the foot of the mountain of the same name, has 2000 inhabitants.

The county of Nice, although subject to the royal constitutions or legislative code of the Sardinian monarchy, still retains some local regulations and privileges, which date from the time of its former Anjou sovereigns. It has its own senate or supreme court of justice, independent of the senates of Genoa and Turin, and having under its jurisdiction the provinces of Oneglia and S. Remo. The county of Nice is divided into fourteen mandamenti, or administrative districts, and contains eighty-seven communes.

Nice in the twelfth century was a municipal commonwealth, and allied to Pisa; but the kings of Aragon, having become masters of Provence, established their supremacy over Nice, leaving to the town however its elective consuls and its other municipal franchises, A.D. 1188. But Provence having passed from the Aragonese to the dominion of the counts of Anjou, in consequence of the marriage of Beatrix, daughter of Raymond Berlinghieri IV. of Aragon with Charles of Anjou, brother of Louis IX. of France, in 1246, the county of Nice became subject to the Anjou dynasty of Provence and Naples.

During the war of the disputed succession of queen Joanna I. of Naples, the people of Nice had recourse for protection to Amadeus VII. of Savoy; and in 1402 king Ladislaus of Naples, and soon after his competitors of the house of Anjou, renounced their claims upon Nice to Amadeus VIII. duke of Savoy and prince of Piedmont. The county of Nice has remained ever since, with brief interruptions of temporary conquest, subject to the house of Savoy, under which it has attained its present state of prosperity.

The county of Nice has produced several distinguished men, among others the amiable poet Passeroni, who died at Milan at the end of the eighteenth century; the painters Brea and Vanloo; Papon, author of a valuable *Histoire Générale de Provence*; Marshal Massena, well known in the wars of Napoleon; and the naturalist and traveller Pacho, who wrote a description of Cyrenaica and Marmarica, and died at Paris in 1828, at an early age.

The language of Nice is a dialect of the Langue d'Oc, or Provençal, but through its vicinity to and connection with Italy, Italian terminations and words have in many instances superseded those of the old language of the troubadours.

It has been used by several native poets. The following is a specimen, describing a sanctuary raised on the ruins of the ancient town of Cemenelum:

Enfin, en achen luec destruc e sollari
Un mortal aspirat bustieu un santuari;
Don era Glupier e sent dieu ompulsant,
L'estendant de la crous s' eleva trionfant.

The annual arrivals of vessels in the port of Nice are reckoned at about 2000, being chiefly small craft, and mostly French or Italian. (Serristori, *Saggio Statistico*.)

NICE (in Italian, *Nizza*), a town in Italy, formerly capital of an Italian county, subject to the duke of Savoy, now king of Sardinia, afterwards incorporated with the French empire, and now again subject to its former sovereign. It is on the coast of the Mediterranean, about 10 miles east of the Var, which separates Italy from France; and 92 miles south by west of Turin, and as far south-west of Genoa, in 43° 41' N. lat. and 7° 16' E. long.

Nice was founded by the Greeks of Massilia, and fortified by them to repress the neighbouring tribes and secure the navigation of the adjacent sea. Its name was written in Greek *Nikasia* (Strabo, p. 184. Casaub.). It continued subject to the Massilians after the establishment of the Var as the boundary of Gaul and Italy, though it was within the boundary of Italy. In the middle ages it was a strong fortress. It was besieged, A.D. 1543, by the French, under François I., on the land side, and by the Turkish fleet, under Barbarossa, on the sea side. It was taken and plundered, except the citadel, which held out. The town was again taken by the French in 1691, 1706, and 1744. It was seized by the French, without resistance, in 1791, and annexed to the republic, being made the capital of the department of Alpes Maritimes. By the new arrangements of territory, in 1814-15, it reverted to Sardinia.

Nice is pleasantly situated, being bounded on the north by the Maritime Alps, and open on the south to the sea. The citadel of Mont-Albano, on a high and pointed rock, overhangs the town, and the Paglion, a mountain torrent, passes it on the west side, separating it from the suburb called La Croix de Marbre (the marble cross), or sometimes the English quarter, from the number of English who resort to it in time of peace. In this suburb the houses are painted externally in fresco, and surrounded with gardens containing standard orange and lemon trees. The town itself is divided into two parts, distinguished respectively as the old and new towns. The streets of the former are narrow; the latter is better laid out, and the houses are painted, like those of the English quarter. There are two squares, one of them surrounded with porticos, and very handsome. Adjacent to the other is a raised terrace, which serves for a defence of the town against the sea and for a public walk. On this terrace is a poorly-executed statue of Catherine Seguiran, a heroine, who assisted in the defence of Nice against the Turks. The ramparts of the town, on the land side, form another promenade. The cathedral or church of Santa Reparata is the chief public building.

The climate of Nice has been much celebrated for its mildness, but has been probably over-praised. The neighbourhood of the Alps, and the prevalence of the *Vent de Bise*, a keen searching wind, renders the air frequently very cold, and even frosty in winter and spring; and the heat in summer is excessive. It is however much resorted to by invalids and other strangers, especially English. The influx of visitors greatly augments the population of the place, which in 1824 consisted of 25,851 inhabitants (*Calentario Sardo*); but it appears to have increased considerably since, as Bertolotti (*Viaggio nella Liguria marittima*, 1834), reckons the population of Nizza at nearly 30,000. The walks and rides in the neighbourhood of the town are agreeable. There are many pleasant country-houses on the slope of the adjacent hills, and near the town are the ruins of the ancient Cemenelum, now the hamlet of Cimiez. There are a theatre, baths, good inns, cafés, a public library, and agreeable society. Provisions (except game) are good and plentiful; the wine and oil are excellent. There are in the town some silk, cotton, and paper mills, a great number of oil mills, and a tobacco manufactory. Soap, liquors, essences, and perfumery are also made. The port, which is protected by a mole, is spacious and secure. Vessels of 300 tons can enter it. The chief trade is in silk, oranges and other fruit, and in the manufactures of the town. The roadstead would afford anchorage to a hundred vessels of the line. Nice is a bishop's see.

NICE, THE COUNCIL OF, was the first and most

important œcumenical council held in the Christian church. It was convened by the emperor Constantine, for the purpose of settling the Arian controversy, after he had in vain attempted to reconcile Arius and Alexander, the leaders of the two opposing parties in that dispute. The council met at Nicæa in Bithynia, in the year 325 A.D., and sat probably about two months. It was attended by bishops from nearly every part of the East; but few came from Europe, and scarcely any from Africa, exclusive of Egypt. According to Eusebius, there were more than 250 bishops present, besides presbyters, deacons, and others. Some writers give a larger number. The account generally followed is that of Socrates, Theodoret, and Epiphanius, who state that 318 bishops attended the council. Some account of the bishops who composed this assembly is given by Socrates, Sozomen, and Theodoret. It is uncertain who presided, but it is generally supposed that the president was Hosius, bishop of Corduba (Cordova) in Spain. Constantine himself was present at its meetings.

The chief question debated in the council of Nice was the Arian heresy. Eusebius of Cæsarea proposed a creed which the Arian party would have been willing to sign, but it was rejected by the council, and another creed was adopted as embodying the orthodox faith. The most important feature of this creed is the application of the word *consubstantial* (*ὁμοούσιος*) to the Son, to indicate the nature of his union with the Father; this word had been purposely omitted in the creed proposed by Eusebius. The creed agreed upon by the council was signed by all the bishops present, except two, Secundus, bishop of Ptolemais, and Theonas, bishop of Marmarica. Three others hesitated for some time, but signed at last, namely, Eusebius of Nicomedia, Theognis of Nicæa, and Maris of Chalcedon. The council excommunicated Arius, who was immediately afterwards banished by the emperor. The decision of this council had not the effect of restoring tranquillity to the Eastern church, for the Arian controversy was still warmly carried on, but it has supplied that mode of stating the doctrine of the Trinity (as far as relates to the Father and the Son), in which it has ever since been received by the orthodox. [ARIUS.]

The time for the celebration of Easter was also fixed by this council, in favour of the practice of the Western church. [EASTER.] It also decided against the schism of Meletius.

The only documents which have been handed down to us from this council are its creed, its synodical epistle, and its twenty canons. These canons contain no catalogue of the books of the Bible.

The Second Council of Nice, held in the year 786, declared the worship of images to be lawful.

(Lardner's *Credibility*, pt. ii., chap. 71, and the authorities quoted by him; Mosheim's *Ecclesiastical History*; Neander's *Kirchengeschichte*.)

NICENE CREED, THE, is one of the three creeds received by the church of England. It consists of the creed drawn up by the first council of Nice, with the addition of that part which relates to the divinity of the Holy Ghost. It was adopted in its present shape at the second general council of Constantinople, A.D. 381.

NICEPHORUS I., emperor of Constantinople, was Logotheta, or intendant of the finances of the empire, under the reign of the empress Irene and of her son Constantine VI., in the latter part of the eighth century. Irene, having deprived her son of his eyes, usurped the throne. After reigning alone for six years a conspiracy broke out against her, headed by Nicephorus, who was proclaimed emperor, and crowned at Santa Sophia, A.D. 802. He banished Irene to the island of Lesbos, where she lived and died in a state of destitution. The troops in Asia revolted against Nicephorus, who showed himself avaricious and cruel, and proclaimed the patrician Bardanes emperor, but Nicephorus defeated and seized Bardanes, confined him to a monastery, and deprived him of his sight. The empress Irene had consented to pay an annual tribute to the Saracens, in order to stop their incursions into the territories of the empire; but Nicephorus refused to continue the payment, and wrote a message of defiance to the caliph Harun al Rashid. The caliph collected a vast army, which devastated Asia Minor, and destroyed the city of Heraclea on the coast of the Euxine. Nicephorus was obliged to sue for peace and pay tribute to the caliph. In an attack which the emperor made on the Bulgarians he was utterly defeated by them and killed, July 31. His son Stauracius suc-

ceeded him, but reigned only six months, and was succeeded by Michael Rhangabe, master of the palace.

NICEPHORUS II. (called Phocas, but who must not be confounded with the usurper Phocas, who reigned in the beginning of the seventh century) was descended of a noble Byzantine family, and distinguished himself as a commander in the field. After the death of Romanus II., A.D. 959, his widow Theophano, who was accused of having poisoned him, reigned as guardian to her infant son, but finding herself insecure on the throne, she invited Nicephorus to come to Constantinople, and promised him her hand. Nicephorus came, married Theophano, and assumed the title of Augustus, A.D. 963. He repeatedly attacked the Saracens, and drove them out of Cilicia and part of Syria. In 968, Otho I., emperor of Germany, sent an embassy to Nicephorus, who received it in an uncivil manner. [LIUTFRANDUS.] But his avarice made him unpopular, and his wife, the unprincipled Theophano, having formed an intrigue with John Zimisce, an Armenian officer, conspired with him against her husband. Zimisce, with other conspirators, was introduced at night into the bedchamber of the emperor, whom they murdered, A.D. 969.

NICEPHORUS III., called Botaniates, an old officer of some military reputation in the Byzantine army in Asia, revolted against the emperor Michael Ducas, A.D. 1078, and with a body of troops, chiefly composed of Turkish mercenaries, marched to Chalcedon, upon which Michael resigned the purple, and Nicephorus was proclaimed emperor at Constantinople. Michael was sent to a monastery with the title of archbishop of Ephesus. Another aspirant to the throne, Nicephorus Bryennius, was defeated, taken prisoner, and deprived of his sight. A fresh insurrection, led by Basiliscus, was likewise put down by the troops of Nicephorus under the command of Alexis Comnenus. Alexis himself, who had an hereditary claim to the throne, was soon afterwards proclaimed emperor by the soldiers. Having entered Constantinople by surprise, he seized Nicephorus and banished him to a monastery, where he died in a short time, A.D. 1081. [ALEXIS COMNENUS.]

NICEPHORUS, made patriarch of Constantinople in the year 806, warmly defended the worship of images against the Iconoclasts, and was consequently banished to a convent in Asia by the emperor Leo the Armenian, A.D. 816. He died in his retirement in the year 828, being seventy years of age. He wrote several historical and theological works: 1, 'Chronographia Brevis,' being a short chronicle of events from the beginning of the world to the time of the author's death, with the series of kings, emperors, patriarchs, bishops, &c. It was translated into Latin, and published with notes, by Father Goar, Paris, 1652. 2, 'Breviarium Historicum,' or historical abridgment from the end of Maurice's reign, A.D. 602, till the beginning of the reign of Irene and her son Constantine, A.D. 760. Father Petau published a Latin translation of it in 1616, and President Cousin has given a French translation of it in the third volume of his 'History of Constantinople.' Both the above works of Nicephorus form part of the collection of the 'Byzantine Historians.' 3, 'Stichometria Librorum Sacrorum,' or enumeration of the books of Scripture, with the number of verses in each; inserted in the eighth volume of the 'Critici Sacri.' 4, Several treatises against the Iconoclasts. 5, Seventeen canons inserted in the Collection of Councils and other 'Opuscula.' The Life of the patriarch Nicephorus, by Ignatius, a contemporary writer, has been translated into Latin, and inserted in the 'Acta Sanctorum.' Nicephorus is numbered among the saints both of the Greek and Roman church.

NICE'RATUS, a physician mentioned by Dioscorides (*Præf.*, lib. i., p. 2, ed. Spreng.) as one of the followers of Asclepiades, who attended particularly to materia medica. None of his writings remain, but his prescriptions are several times mentioned by Galen (*Opera*, ed. Kühn, t. xii., p. 634; t. xiii., pp. 87, 96, 98, 110, 180, 232, 233; t. xiv., p. 197), and once by Pliny (*Hist. Nat.*, l. xxxii., c. 31). We learn from Cælius Aurelianus (*Morb. Chron.*, l. ii., c. 5) that he wrote also on cataplexy. He flourished about the year 40 B.C.

NICE'TAS, a physician of Constantinople, supposed to have lived in the reign of Isaac Comnenus, about the middle of the eleventh century, of whom nothing is known, except that he formed the collection of surgical works that bears his name. It exists at present only in manuscript, of which there are three copies, one at Florence and two at Paris; but part of it was published at Florence, 1754, fol., with the title 'Græcorum Chirurgici Libri, Sorani unus de

Fracturarum Signis, Oribasii duo de Fractis et de Luxatis : e Colloctione Nicetæ ab antiquissimo et optimo codice Florentino descripti, conversi, atque editi ab Antonio Cocchio, &c. Perhaps he is the person to whom Theophylact's fifty-fifth letter is addressed, who is styled 'Physician to the King,' *ιατρος βασιλικος*. (Fabr., *Bibl. Gr.*; Haller, *Bibl. Chirurg.*)

NICHE (from the Italian *nicchia*, signifying also a nook), a small recess, or concavity in the face of a wall for the purpose of containing a statue. The use of niches seems to have originated with the Romans, for scarcely any thing of the kind occurs in the architecture of the Greeks themselves, who rarely employed statues in any way as external decorations to their edifices, sculpture being so applied by them only as friezes or within pediments. In Italian architecture, on the contrary, niches are of very frequent occurrence, and often enter very largely into a design as principal features in the composition.

Niches are usually semicircular in plan, and round-headed, that is, covered by the quarter of a hollow sphere, owing to which the shadow within the concavity produces a highly beautiful curve. They are however occasionally made square in plan, in which case they are square-headed (as in the front of the National Gallery, London); but square-headed niches are sometimes made circular in plan, though round-headed ones are never made square. Niches exhibit still greater diversity in the modes of decorating them: in this country it has usually been the fashion to leave them quite plain, and, oftener than not, quite empty also; although a niche without a statue, vase, or some piece of sculpture in it, is rather a questionable feature, suggesting to the spectator the absence of the object which it is intended to receive; therefore, as has been remarked, not very much better than an empty picture-frame hung up in a room, the only thing which diminishes the impropriety being that though the frame can be hung up when the picture is provided for it, a niche must be provided first, and a statue can be placed in it afterwards at any time.

When niches are decorated they are usually placed within a square-headed panel, having architraves and other dressings like those of windows, and therefore admit of as much variety of design as windows themselves. Many Italian architects have given them columns, and thus converted them into small tabernacles (as in the upper order of the side elevations of St. Paul's), or have otherwise bestowed so much enrichment upon them that the statues within them are almost lost.

As to the relative size of niches, that must depend upon the circumstances of the design. When decorated like windows they are generally of the same dimensions as the windows themselves, if there are any in the composition; but cases may occur where it may be advisable to make a niche in the centre of a design a more important feature than any of the windows in it. On the other hand, small plain niches between windows, when the intervals between the latter are very considerable, may be employed with good effect, and so as to produce a pleasing degree of variety and contrast without confusion, and also afford the opportunity of introducing mezzanine windows over them; for instance, five windows in width below would give four such niches between those of the principal floor, and four attic or mezzanine windows above them, making nine in all for that story, which might therefore be divided off into small rooms.

NICHOLAS I., a deacon of Rome, was elected pope, mainly through the influence of the emperor Louis II., who was then at Rome, in April, A.D. 858, and was consecrated in St. Peter's church in presence of the emperor. The new pope sent legates to Constantinople to urge the emperor Michael III. to restore Ignatius to the patriarchal see, into which Photius had intruded himself, and at the same time to reclaim the dioceses of Illyricum, Apulia, Calabria, and Sicily, which the court of Constantinople had detached from the see of Rome during the schism of the Iconoclasts, and which, after that schism had been put down by the Eastern emperor, had not been restored. (Thomassin, *Discipline de l'Eglise*, vol. i.) The allegiance paid by the Roman pontiffs to Charlemagne and his successors as emperors of the West had greatly widened the breach between the Roman see and the Byzantines, and the schism of Photius completed the separation of the two churches. Nicholas excommunicated Photius, who in return, at a council assembled at Constantinople, anathematized Nicholas and his followers, asserting at the same

time, that 'since the seat of the empire had been removed from Rome to Constantinople, the primacy and privileges enjoyed till then by the Roman see had become transferred unto that of the new capital.' The legates of Nicholas returned to Rome without effecting anything. In the year 865 Nicholas had the satisfaction of receiving into the bosom of the church Bogoris, king of the Bulgarians, with part of his nation. But on the other side he involved himself in a serious dispute with his former patron the emperor Louis, on account of Lotharius, king of Lorraine, having repudiated Theotberg his wife and married his concubine Waldrada. The pope had appointed the archbishops of Treves and Cologne as his legates to examine into the affair; but the legates, in a council held at Metz, A.D. 863, obtained a decision in favour of Lotharius, upon which Nicholas assembled a council at Rome, A.D. 864, in which the two archbishops were deposed, and Lotharius's divorce and marriage were declared null. The emperor Louis took the part of the archbishops, and marched with troops to Rome to oblige the pope to revoke the sentence. An affray took place in front of St. Peter's church between the soldiers of the emperor and the Pope's followers, but the emperor soon after consented to withdraw his troops. In the year 867, Basil the Macedonian, having murdered the emperor Michael, succeeded him on the throne, and shortly after restored Ignatius to the patriarchal see and banished Photius. Nicholas himself died at Rome in the same year, and was succeeded by Adrian II. Nicholas has left a number of letters upon questions of church doctrine and discipline, which are inserted in Coleti's 'Collection of Councils.'

NICHOLAS II., Gerard of Burgundy, succeeded Stephen IX. as pope, A.D. 1059. An opposite faction chose John bishop of Velletri, who took the name of Benedict X., but the council of Sutri disavowed him, and Benedict was obliged to resign his claim. Nicholas assembled a council at Rome, which passed a decree concerning the mode of electing the pope. This important decree is in the collection of councils, and also in Muratori's 'Rerum Italicarum Scriptores.' Nicholas entered into negotiations with the Normans, who had occupied Southern Italy, and bestowed on Robert Guiscard the duchy of Apulia and Calabria, as a fief of the Roman see. He died soon after, in 1061, and was succeeded by Alexander II.

NICHOLAS III., Giovanni Gaetani, of a noble Roman family, succeeded John XXI. in 1277. He prevailed on the emperor Rudolf of Habsburg, who was little acquainted with Italian affairs, to confirm the various grants of territory alleged to have been made to the see of Rome by former emperors, and the Exarchate of Ravenna among the rest. (Fontanini, *Del Dominio Temporale della Santa Chiesa*, and his controversy with Muratori on the subject.) Nicholas quarrelled with Charles of Anjou, king of Naples, and deprived him of the dignity of senator of Rome. He has been accused of nepotism; that is to say, of having enriched his nephews and other relatives. He died A.D. 1280, and was succeeded by Martin IV.

NICHOLAS IV., a Franciscan monk, and a native of Ascoli in the Marches, was raised to the papal see after the death of Honorius IV., A.D. 1288. He favoured the pretensions of Charles II. of Anjou upon the island of Sicily, and excommunicated James of Aragon and his partisans in that island. He received an embassy from a Tartar khan who promised to assist the Christians in the recovery of Palestine. Nicholas died in 1292, and was succeeded by Celestine V. Nicholas left several theological works.

NICHOLAS V., Tommaso da Sarzana, was elected pope after the death of Eugenius IV. in 1447. He soon after terminated the schism in the Western church by prevailing upon Felix V., who had been elected pope by the council of Basle in 1439, to abdicate in his favour, and thus restore peace to the Christian world: Felix did this with a good grace in the year 1449. [AMADRUS VIII.] At the same time, as if influenced by the example of the heads of the church, the sovereigns and states of Italy seemed to forget their feuds, at least for awhile, and Italy enjoyed several years of internal peace, a rare occurrence in the history of the middle ages. The pope, who was a patron of learning, availed himself of this period of repose to collect books and MSS., and to have translations made of the Greek classics and of the fathers of the Eastern church; he received and patronized learned men from various countries, and especially from Greece, at that time overpowered and devastated by the Turks; and he embellished Rome with sumptuous as

well as useful buildings. He enlarged the university, restored the bridges as well as the aqueduct of the *Acqua Vergine*, and founded the Vatican library. In 1450 he proclaimed a jubilee, which drew a prodigious number of strangers to Rome. In March, 1452, Frederic III. of Germany came to Rome, where he was crowned by the pope with the crown of Lombardy; after the coronation he married Leonora of Portugal, and both Frederic and his consort received the imperial crown from the hands of the pontiff. In the following year, 1453, the news of the taking of Constantinople by the Turks deeply affected Nicholas, who had urged the Christian princes to succour the Byzantines, and who now impressed with great earnestness upon the Italian and other states the necessity of giving up their mutual jealousies and forming a league for their common defence against the Ottomans. He also corresponded with Mahomet II. [MONTECASINO.] Nicholas died in March, 1455, at 57 years of age. He is one of the most distinguished individuals who have filled the Papal chair, and he was free from the charge of nepotism. He was succeeded by Calixtus III.

NICHOLS, JOHN, the printer, born 1745, died 1826, one of the most respectable, valuable, and useful men of the age in which he lived.

He was born and educated at Islington, and originally intended for the navy, but the death of a relation led his friends to change their design, and when not quite thirteen he was placed with Bowyer, who has been called the last of the really learned printers of England. He soon gained the confidence of his master, and was intrusted by him with the management of his printing-office. In 1766 he was taken into partnership by Mr. Bowyer, and Mr. Bowyer dying, in 1777, the whole business fell into his hands.

From this period may be dated the commencement of that career of literary exertion which was pursued with an ardour that was unabating to the close of his life, for the few things which he had published in the life-time of Mr. Bowyer scarcely deserve a notice. It is not our intention to enumerate all the works of which he was the author or editor as well as printer (for according to his own enumeration they had amounted, in 1812, to fifty-seven), but only those which are more prominent and celebrated.

In 1782 he published a quarto volume, entitled '*Biographical and Literary Anecdotes of William Bowyer, Printer, F.S.A., and of many of his Learned Friends*,' a work which, far more than any other work of his time, and far more than any work which had appeared since the '*Athenæ Oxonienses*' of Anthony Wood, abounded in biographical information at once authentic and original. This work, many years after, was recast and greatly enlarged, appearing in six octavo volumes, entitled '*Literary Anecdotes of the Eighteenth Century*,' in 1812, to which two supplementary volumes were added, and they have been followed at intervals by five large octavo volumes more, of the same kind of material, with the new title, '*Illustrations of Literary History*.' These works will be the great fund on which critics in time to come will draw for accounts of the men in the eighteenth and beginning of the nineteenth centuries, just as the '*Athenæ*' is the fund of biographical knowledge for the men of the sixteenth and seventeenth centuries. But after all something more is wanted than both these works supply.

We regard this as the work on which Mr. Nichols's literary reputation will chiefly rest; and next to it may be placed his '*History of the County of Leicester*,' which is in six large folio volumes. This was in the course of publication from 1795 to 1811. The faithfulness with which he corrected any mistakes into which he had been led is worthy of imitation. The work is in general very exact and accurate, and the chief defect seems to be that the worthy author seems not to have known so well what might be omitted in a work of that nature, as what ought to find a place in it. To the people of the county it must be invaluable.

In 1788 he published, in two volumes quarto, '*The Progresses and Processions of Queen Elizabeth*,' an original and happy conception affording an opportunity for the introduction of much minute historical information, and which that illustrates the manners of a period on which we always look with a peculiar kind of interest.

In 1797 he published '*Illustrations of the Manners and Expenses of Antient Times in England*.'

Having mentioned these, we shall forbear to notice any works of which he is rather to be considered in the light

of an editor than an author, or where a large share of the labour was borne by some of his many literary friends. Few men had more friends of this description or deserved them better.

It will be seen by what has been said that the turn of Mr. Nichols's mind was to that species of literature which is called antiquarian, but which is in fact minute or refined history, dealing with equal attention with things of modern and of antient date. The same turn of mind is perceptible in two other publications of Mr. Nichols's, for such they may be regarded. The first of these was entitled by him '*Bibliotheca Topographica Britannica*.' It consists of tracts in English history and topography, printed by him from originals, and extends, when the set is complete, to eight or ten quarto volumes, bound variously; and there is a Supplement, which may or may not be regarded as part of the work. The other work, which was strictly periodical, is '*The Gentleman's Magazine*,' which passed, in a great measure, into the hands of Mr. Nichols in 1778, and continued under his direction till the time of his death. He greatly raised the reputation of the work, and during the more vigorous period of his management it was remarkable for the value of some of the articles which it contained, and for the preservation of a multitude of minute pieces of information, which will be valuable to the future inquirer into the literary or political history of the period.

Mr. Nichols passed a life honourable as it was useful, and happy as it was industrious; experiencing only one calamity besides such as ordinarily fall to the lot of human nature, but that a severe one,—the destruction by fire of his printing-office and warehouses, with the whole of their contents, on the 8th of February, 1808.

NICIAS is the name commonly given to the physician of Pyrrhus, king of Epirus, who went to Fabricius, the Roman consul, offering for a certain reward to take off his master by poison, A.U.C. 474, B.C. 280. Fabricius not only rejected his offer with indignation, but immediately sent him back to the king with notice of his treachery; and Pyrrhus, upon receiving the information, is said to have cried out, 'This is that Fabricius whom it is harder to turn aside from justice and honour than to divert the sun from its course.' (Eutropius, lib. ii., cap. 14.) Zonaras adds (*Annal.*, tom. ii., p. 50, l. 10, ed. Basil., 1557) that Nicias was put to death, and his skin used to cover the seat of a chair.

Historians (as was hinted above) are not agreed as to the traitor's name. He is called Nicias by Claudius Quadrigarius (ap. Aul. Gell., lib. iii., cap. 8) and Zonaras (tom. ii., p. 48, l. 45), and Cineas by Ehan (*Var. Hist.*, lib. xii., cap. 33). But Ammianus Marcellinus (lib. xxx., cap. i.), Valerius Antias (ap. Aul. Gell., lib. iii., cap. 8), and Valerius Maximus (lib. vi., cap. 5, § 1) tell the story of one of the friends of Pyrrhus, whom the first-named author calls Demochares, and the two others Timochares.

NICIAS. [SYRACUSE.]

NICKEL. This metal was first described by Cronstedt in 1751. For nice purposes the metal may be obtained in a state of purity by the following process:—roast the native sulphuret of nickel to expel the sulphur and oxidize the metal; dissolve the residue in a mixture of four parts of sulphuric acid and one part of nitric acid moderately diluted with water; evaporate the clear solution till crystals are formed, which are sulphate of nickel, of a fine emerald green colour; redissolve these, and separate any copper they may contain by a plate of iron, and add excess of ammonia, which dissolves the oxide of nickel and any oxide of cobalt that may be mixed with it; to the clear solution add potash dissolved in water, which throws down hydrate of nickel of a green colour, and this, after washing and drying, is to be mixed with black flux, and reduced into the metallic state by a strong heat in a wind-furnace.

The properties of nickel are, that it has a white colour with a yellowish tint; its lustre is considerable, and it is both malleable and ductile. Like iron, it is attracted by the magnet, and may, like it, be rendered magnetic at common temperatures, but it loses this power when heated to 630° Fahrenheit. The specific gravity of fused nickel is about 8.28, and by hammering it is increased to almost 9.0. It is nearly as hard as iron.

Nickel suffers little or no change by exposure to the air and moisture at common temperatures; it is very difficult of fusion, but melts at a lower temperature than iron; at a red heat it absorbs oxygen gradually from the air, and also decomposes water at this temperature. Nitric acid is the

only acid which readily acts upon nickel. Nickel occurs in meteoric iron and aërolites. [AEROLITES.]

The uses of nickel are very limited, and until within a few years it was scarcely employed at all; but it is now very usefully employed, and to a considerable extent, in forming an alloy with copper and zinc, known by the name of German silver. Its oxides impart a green colour to glass and porcelain.

The ores of nickel are few in number:—

Sulphuret of Nickel. Capillary Nickel.—This occurs in regular hexagonal capillary crystals. Primary form a rhomboid; colour brass-yellow or greyish; lustre metallic; hardness, scratches mica, and is scratched by felspar. Opaque, brittle.

It is soluble in nitric acid, and before the blow-pipe, when strongly heated, gives a malleable and metallic button.

It occurs in Wales, Cornwall, Saxony, &c.

Analysis by Arfwedson:—

Sulphur	.	.	34.26
Nickel	.	.	64.35
			98.61

Arseniuret of Nickel. Copper Nickel.—Occurs crystallized, botryoidal, reniform, and amorphous. Primary form a right rhombic prism; structure compact, fibrous; fracture uneven, conchoidal, splintery; hardness 5.0 to 5.5; colour yellowish and greyish red; lustre metallic. Opaque. Specific gravity 7.655.

Before the blow-pipe on charcoal emits an alliaceous smell, and melts.

It is found in Cornwall, Saxony, Bohemia, &c., and also in South America.

Analysis by Pfaff:—

Nickel	.	.	48.90
Arsenic	.	.	46.42
Iron	.	.	0.34
Lead	.	.	0.56
Sulphur	.	.	0.80
			97.02

Sulpho-arseniuret of Nickel. Nickelglanz. Grey Nickel.—Occurs massive. Structure granular; fracture uneven. Easily frangible. Colour pale lead-grey. Opaque. Specific gravity 6.129.

Found in Sweden and in the Harz, &c.

Analysis of a specimen from Loos, in Nelsingland, by Berzelius, which was mixed with some mispickel:—

Nickel	.	.	29.9
Arsenic	.	.	43.4
Sulphur	.	.	19.3
Cobalt	.	.	0.9
Iron	.	.	4.1
			97.6

Silicate of Nickel. Pimelite.—Occurs massive, and investing other minerals. Colour apple or yellowish green. It is earthy, dull, opaque, soft and greasy to the feel. It is infusible before the blow-pipe, but becomes of a dark-grey colour.

It is found in Sweden and the Harz.

Analysis by Klaproth:—

Silica	.	.	35
Oxide of Nickel	.	.	15.62
Alumina	.	.	5.10
Lime	.	.	0.40
Magnesia	.	.	2.25
Water	.	.	37.91
			96.26

Arseniate of Nickel.—Occurs powdery on the surface of arseniuret of nickel, and massive. Colour greenish white and green. Opaque.

Found in Allemont, Hesse, &c.

Analysis by Stromeyer:—

Arsenic acid	.	.	36.97
Oxide of Nickel	.	.	37.35
Water	.	.	24.32
			98.64

We proceed now to the artificial compounds of nickel.

Oxygen and Nickel combine in two proportions, forming the protoxide and sesqui-oxide or peroxide.

Protoxide of Nickel may be obtained by adding potash or

soda to a solution of any salt of nickel, by which a green hydrate is precipitated; this, heated to redness, loses water and becomes of a dark colour. It may also be procured by heating nitrate of nickel to redness. It is insoluble in water, readily dissolved by most acids, and yields green solutions. It is not reducible to the metallic state by heat alone, and is not attracted by the magnet. Oxide of nickel is insoluble in potash or soda, but readily dissolves in ammonia; the solution has a fine azure-blue colour, and is decomposed by potash or soda. It is the base of all the salts of nickel.

It is composed of

One equivalent of oxygen	.	.	8
One equivalent of nickel	.	.	28
			—
Equivalent			36

Peroxide of Nickel may be obtained by adding a solution of chloride (or hypochlorite) of lime to one of nitrate of nickel, or by transmitting chlorine gas through water in which hydrate of nickel is suspended. The peroxide thus obtained is of a black colour, insoluble in dilute acids, potash, or soda. When added to a mixture of ammonia and its carbonate, azotic gas is evolved, and the peroxide, becoming protoxide, is dissolved. At a red heat it yields oxygen gas, and with hydrochloric acid gives out chlorine gas, and forms chloride of nickel.

It is composed of

One and a half equivalent of oxygen	.	.	12
One equivalent of nickel	.	.	28
			—
Equivalent			40

Chloride of Nickel is formed by dissolving either the protoxide or peroxide of the metal in hydrochloric acid. Its colour is a fine emerald-green; and by evaporating the solution, green filamentous crystals containing water are formed. This salt deliquesces in a moist atmosphere. When deprived of water it has a yellow colour and a micaceous appearance; it is volatile, and may be sublimed at a high temperature. The solution is decomposed by the alkalis and their carbonates, but ammonia added in excess redissolves the precipitate at first formed.

Chloride of nickel is composed of

One equivalent of chlorine	.	.	35.5
One equivalent of nickel	.	.	28
			—
Equivalent			64

The fluoride, bromide, and iodide of nickel are not much known, and are of but little importance.

Sulphur and Nickel combine in two proportions, forming the sulphuret and disulphuret.

Sulphuret of Nickel is prepared either by heating metallic nickel or the oxide with sulphur; or it may be procured by adding a hydrosulphate to a solution of nickel, or to a certain extent by passing hydrosulphuric acid gas into a neutral solution of nickel. The precipitated sulphuret is nearly black, dissolves in hydrochloric acid with the evolution of hydrosulphuric acid gas; the sulphuret procured in the dry way is of a greyish-yellow colour, and requires aqua regia (or nascent chlorine) for solution.

Sulphuret of nickel consists of

One equivalent of sulphur	.	.	16
One equivalent of nickel	.	.	28
			—
Equivalent			44

Disulphuret of Nickel may be prepared by transmitting hydrogen gas over sulphate of nickel at a red heat. Its colour is lighter, and it is more fusible than the sulphuret, and consists of

One equivalent of sulphur	.	.	16
Two equivalents of nickel	.	.	56
			—
Equivalent			72

Phosphuret of Nickel is formed by the action of phosphorus upon nickel heated to redness; the resulting compound is whitish, brittle, and is decomposed when exposed to heat and air. It is more fusible than the metal, and, according to Pelletier, is composed of 17 phosphorus + 83 nickel; while Lampadius states its composition to be 13 phosphorus + 87 nickel.

Cyanide of Nickel is prepared by adding a soluble cyanide to a solution of nickel, or when hydrocyanic acid is mixed with acetate of nickel.

Ferrocyanide of Nickel is a greyish or greenish com-

pound, which is precipitated when ferrocyanide of potassium is added to the salts of nickel.

ALLOYS OF NICKEL. — *Arsenic* readily combines with *Nickel*, and the compound remains undecomposed at a very high temperature. It does not obey the magnet.

Potassium and Nickel combine by fusion.

Antimony and Nickel form an alloy of a lead-colour.

Zinc and Nickel form a white brittle alloy, which enters into the composition of the *packsong* of the Chinese.

Tin and Nickel give rise to a white brittle alloy, which burns at a high temperature.

Iron and Cobalt unite with nickel, but the resulting alloys are but little known.

Mercury and Nickel have not been combined.

Copper, Zinc, and Nickel form a white alloy, of late years much employed under the name of German silver.

The salts of oxide of nickel are of course numerous, but we shall describe only a few of them:—

Nitrate of Nickel may be prepared by dissolving either the metal or its oxide in dilute nitric acid. The solution is of a fine green colour, and by evaporation yields a deliquescent salt, which is not applied to any particular purpose. It probably consists of 1 equivalent of nitric acid 54 + 1 equivalent of oxide of nickel 36 = 90; the crystals however contain a considerable quantity of water, but chemists are not agreed as to the exact proportion.

Sulphate of Nickel is easily procured by dissolving the oxide or hydrate in dilute sulphuric acid; a green salt is obtained, which readily crystallizes, and in two different primary forms; the cause of the difference has not been ascertained. The crystals consist of nearly

One equivalent of sulphuric acid	40
One equivalent of oxide of nickel	36
Seven equivalents of water	63
Equivalent	139

Carbonate of nickel is an insoluble compound readily decomposed both by heat and acids.

Nickel forms double salts with potash and with ammonia.

The peculiar properties of the salts of nickel are, that they are decomposed by the alkaline carbonates, and the precipitate is redissolved by ammonia, forming a beautiful blue solution, which is decomposed by potash and soda, but not by their carbonates.

NICOBAR ISLANDS, THE, are situated in the Indian Ocean, between 6° 50' and 9° 20' N. lat. and 92° 50' and 94° 10' E. long. They consist of nine larger islands and some smaller ones, and are on that account called by the Malays *Sambilang*, that is, *Nine Islands*. The two most southern are called *Great and Little Nicobar*. *Great Nicobar* is more than twenty miles long, and eight miles across in the widest part. *Little Nicobar* is not half as large. Farther north are six smaller islands. The best known are *Noncowry* and *Camorta* or *Nicovari*, which are separated from one another by a strait, forming one of the safest harbours in India, in which ships of all sizes may ride with the greatest security, sheltered from all winds, about half a mile from shore. At its eastern entrance is the island of *Trincutta*. This harbour has the great advantage of two entrances from the east and west respectively, so that ships may get in and out either with a north-east or south-west monsoon. The other three islands are *Katshall*, *Teresa*, and *Tillanjong*. The most northern island is much farther to the north, and is called *Car Nicobar*. The surface of these islands is hilly, and the hills in some places are rather high. They are in general covered with wood, and only a few tracts along the shores are cultivated. The impenetrable forests with which the hills are covered are considered to be the cause of the great unhealthiness of these islands to Europeans. The soil is very fertile and capable of producing all the fruits and vegetables of intertropical countries. The islands abound in cocoa-nuts, papayas, bananas, limes, tamarinds, betel-nuts, and the *mellors*, a species of bread-fruit; yams and other roots are cultivated, but rice is unknown. The mangosteen-tree and the pine-apple grow wild in the woods (Colebrooke), but their fruits are delicious. The animals are hogs, dogs, and fowls. The woods contain timber in plenty, and some of it supplies excellent materials for building or repairing ships. The sea abounds with exquisite fish, shell-fish, and turtle. *Ambergris* and the edible bird-nest are common, and supply the only articles of exportation; the Chinese and Malays annually visit these islands to procure them. The inhabitants probably do not exceed

3000 or 4000: if we may form a judgment from their physical appearance, they belong to the Malay race, and the ground-work of their language confirms this opinion. They erect their houses along the shore upon piles, to the height of six or eight feet above the ground, and sometimes so near the margin of the water as to admit the tide to flow under them. In the interior of the island of *Great Nicobar* a tribe is said to exist which differs from the other inhabitants; they are probably the aborigines, and belong to the Australian Negroes, as these people are found in many of the islands of the Indian Archipelago and in the Andaman Islands. The Danes twice tried to form a settlement in the harbour of *Noncowry*, in 1756 and in 1678, but they abandoned it after a few years, on account of the unhealthiness of the climate. Some missionaries remained there till 1792, but as they did not succeed in the conversion of the natives, they returned to *Tranquebar*.

(Hamilton; Fontana; Colebrooke, in *Asiatic Researches*, vols. ii., iii., iv.)

NICOLAI, CHRISTOPHER FREDERICK, a writer to whom German literature is greatly indebted, not only on account of what he himself contributed to it from his own pen, but also what he did for it by establishing several critical journals, and exciting the talents of others. He was born at Berlin, March 18th, 1733, where his father was a bookseller. At the age of sixteen, just as he was beginning to make some proficiency in his studies, he was obliged to abandon them, being sent to Frankfort on the Oder for the purpose of learning the bookselling trade; yet such was his eagerness for information, his love of reading, and his perseverance, that he employed every moment of leisure, his evenings, and the early part of every morning, in study, and, without other assistance than that of books, made himself a proficient in Greek, Latin, and English, and likewise acquired a knowledge of some parts of mathematics and philosophy. He was an instance of what may be accomplished by self-instruction, which, great as may be the disadvantages it has to contend with, has that in its favour which all advantages can hardly make amends for, namely, willingness and resolution to learn; while at the same time, if it occasionally may lead astray, self-instruction leads also to numerous inquiries that never present themselves to those who merely proceed along the path chalked out for them.

On his return to Berlin, in 1752, his attention to business did not interrupt his self-imposed studies, of which both English and German poetry then formed a considerable share; and in 1755 he produced his '*Letters*,' wherein he impartially discussed the pretensions of the two literary sects headed by *Bodmer* and *Gottsched*. This work excited considerable attention, and led to his intimacy with *Lessing* and *Moses Mendelsohn*. After the death of his father, he withdrew himself from the business, leaving it to his brother, and determined to content himself with his own slender means, in preference to the pecuniary advantages to be reaped by sacrificing his literary leisure and enjoyments. The unexpected death however of his elder brother, in 1758, put an end to this short interval of tranquil study, he being obliged to carry on the business for the benefit of the family in general. But while on the one hand this only increased his diligence and economy of time, it led, on the other, to entering upon literary plans which he had before projected. In conjunction with *Mendelsohn*, he had already commenced (1757) the '*Bibliothek der Schönen Wissenschaften*,' one of the earliest and best belles-lettres journals in the language, which was afterwards continued, till the end of 1805, under the title of the '*Neue Bibliothek*,' &c. With *Lessing* and *Mendelsohn* he established, in 1759, the '*Briefe der Neuesten Litteratur*;' and in 1765 projected the '*Allgemeine Deutsche Bibliothek*,' of which periodical he continued to be editor till it reached its 107th volume. He did not contribute much to it himself, but the management alone of such a periodical, so eminently useful in its day, shows him to have been most indefatigable, as in the meanwhile, notwithstanding all his other avocations, he produced many original works. Among them are his '*Anecdotes of Frederick the Great*,' 1788; a most excellent and elaborate '*Description of Berlin and Potsdam*,' 3 vols., 1786; the '*Life and Opinions of Sebaldus Nothanker*,' 1793, a sort of novel, which went through many editions, and was translated into English, French, Dutch, Danish, and Swedish; '*Life and Opinions of Sempronius Gundibert*,' 1793, intended to set the doctrines of *Kant* and his disciples in a ridiculous light. Besides these, his '*Essay on the Templars*,' his '*Re-*

marks on the History of the Rosicrucians and Freemasons, his 'Tour through Germany,' &c., to say nothing of a number of smaller pieces contributed by him to different journals, prove the variety of his information and the activity of his mind. He died in 1811, at the age of 78.

NICOLAÏTANS, a sect of heretics, who arose in the first century, and are mentioned with strong disapprobation in *Rev.*, ii. 6, 15. They appear, from the statements of the early writers, to have held the doctrines of the Gnostics, and to have lived impurely. It is generally supposed that 'the doctrine of the Nicolaitans' (*Rev.* ii. 15) is the same as 'the doctrine of Balaam' (v. 14), namely, 'to eat things sacrificed to idols, and to commit fornication.' Indeed some critics suppose the name Νικόλαος in this passage to be merely translated from *נִיְלָאִי* and used symbolically, deriving the former

word from *νικάω* and *λαός*, and the latter from the synonymous Hebrew words *נִיְלָאִי* and *נִיְלָאִי*. (Robinson's *Greek*

Lexicon to the New Testament.) The early writers trace the origin of this sect to Nicolas the Deacon (*Acts*, vi. 5), but some of them acquit him of holding the sentiments of the Nicolaitans, and ascribe the rise of the heresy to an improper advantage taken of some incautious expressions which he had used.

(Mosheim's *Ecc. Hist.*; Winer's *Biblisches Realwörterbuch*; Neander's *Kirchengeschichte*.)

NICOLAÛS MYREPSUS (Gr., ὁ μυρεψός, 'the ointment-maker'), author of a work, 'De Compositione Medicamentorum,' written in Greek, but of which hitherto only a Latin translation has been published. Very little is known of the events of his life, and of this little the greater part is to be gleaned from hints and expressions scattered up and down in his own work. He is generally considered to be the last of the Greek medical writers (if indeed, as Friend says, his barbarous language deserves to be called Greek), and his date can be ascertained with tolerable precision. His work was probably compiled towards the end of the thirteenth century, A.D., as he is quoted by Petrus de Abano, who died in 1316, and also by Matthæus Sylvaticus and Franciscus de Pede Montium, both of whom were physicians to Robert king of Naples, and wrote very early in his reign, which began in 1309. He himself mentions Mesue (sec. xxxii., cap. 117), who lived in the twelfth century; Michael Angelus, who is probably the first emperor of the Palæologi, and began to reign A.D. 1260 (sec. i., cap. 295); Pope Nicolas (sec. ii., cap. 9), who seems to be the third of that name, and who died A.D. 1280; and Joannes Actuarius (called *Dominus* Joannes, sec. x., cap. 103; and *Magister* Joannes, sec. xxxii., cap. 99), who is generally supposed to have flourished in the thirteenth century. He appears to have visited or lived at Nicæa (sec. xxiv., cap. 12) and Alexandria (sec. i., cap. 241; sec. xvii., cap. 17; sec. xxiv., cap. 85), whence he is sometimes called Nicolaus *Alexandrinus*; he afterwards settled at Constantinople, where he attained the dignity of Actuarius* (Georg. Acropol.). Several passages in his work prove that he practised as a physician (sec. i., cap. 66; sec. xvii., cap. 17, &c.), and Georgius Acropolita, his contemporary, mentions him (*Hist. Byz.*, ed. Paris, fol. 1651, cap. 39, p. 34) as eminent in his profession, but as very ignorant of natural philosophy.

He was evidently a person of great piety, as appears throughout the whole of his work, though in many places it deserves rather to be called the most absurd superstition. He orders the patient in some places (sec. i., cap. 419, and sec. i., cap. 405) to repeat three *Paters*, *Credos*, and *Aves*; he often prescribes the baptismal water (sec. vii., cap. 6; sec. xiv., cap. 8, &c.) as a powerful medicine; he directs a verse out of the Psalms (sec. i., cap. 405) to be 'written on paper on the first day of the week before sun-rise, and to be tied on the right arm,' as a remedy against menorrhagia; and many other examples of the like or even greater absurdity might be given (sec. xxxvii., caps. 66 and 67; sec. i., cap. 405, &c.). Though a great part of the work is sensible enough, yet upon the whole it is not of much value. It consists of an immense number of medical formulæ, arranged alphabetically, and divided into forty-eight sections; it is almost entirely a compilation from other works, espe-

* Actuarius, Gr. Ἀκροβάτιος, a title of the court of Constantinople, given apparently only to physicians, and quite distinct from the use of the word found in the earlier Latin authors. See Du Cange, *Gloss. Græc.*, tom. i., p. 46; and Ponsini, *Gloss. ad Pachym. Hist. Andronici*, tom. i., p. 366, seq., and tom. ii., p. 469. Besides Joannes the son of Zacharias, who is better known by his title of Actuarius than by his real name, several other physicians are recorded as having arrived at this dignity.

cially from Nicolaus Præpositus; the names of the medicines are often very much corrupted, and the author now and then falls into great mistakes from ignorance of the language of the writers whom he quotes. It was translated from the Greek by Leonhardus Fuchsius, and first published, Basil, fol. 1549; it is inserted in the second volume of the 'Medicæ Artis Principes,' Paris, ap. H. Stephanum, fol. 1567; the best edition is that published, Norimb. 1658, 8vo.

NICOLAÛS PRÆPOSITUS, called also *Salernitanus*, was at the head of the famous medical school at Salerno about the beginning of the twelfth century, and has left behind him a treatise on the composition of medicines under the title of 'Antidotarium.' This has very often been confounded with a work on the same subject by Nicolaus Myrepsus, who indeed must either have copied a great portion of his book from Nicolaus Præpositus, or else they both drew their materials from some common source. It may be useful to mention the marks by which the two works may be distinguished. The treatise of Nicolaus Præpositus is much shorter than that of Nicolaus Myrepsus, and contains only about 140 or 150 formulæ, in alphabetical order, whereas the other consists of more than a thousand, and is divided into forty-eight sections. Nicolaus Præpositus has prefixed a short preface to his work; in Nicolaus Myrepsus there is none. Nicolaus Myrepsus often quotes several prescriptions for the same remedy; Nicolaus Præpositus never more than one. Both works begin with the 'Aurea Alexandrina,' but the formulæ are often very different. This work is of very little value, and contains many absurdities, though, with the exception of Mesue, perhaps no work of the kind enjoyed a higher reputation during the middle ages. It has been several times reprinted; the first edition was published, Venet. 1471, fol., in the editio princeps of Mesue, to whose works it has generally been appended.

NICOLAÛS DAMASCE'NUS, or Nicolas of Damascus (Νικόλαος ὁ Δαμασκηνός), a native of Damascus [DAMASCENUS, NICOLAUS], wrote a general history in Greek, including the reign of Herod the Great, of which Josephus gives the following character:—'For living in his kingdom and with him (Herod), he composed his history in such a way as to gratify and serve him, touching on those things only which made for his glory, and even glossing over many of his actions which were plainly unjust, and concealing them with all zeal. And wishing to make a specious excuse for the murder of Mariamne and her children, so cruelly perpetrated by the king, he tells falsehoods respecting her incontinence and the plots of the young men. And throughout his whole history he eulogises extravagantly all the king's just actions, while he zealously apologises for his crimes.' (*Antiq.*, xvi. 7, 1.) This history extended to 144 books; for Josephus refers to the 123rd and 124th. (*Antiq.*, xii. 3, 2.) The fragments of this history have been published several times. There is an appendix to the edition of Orelli, Leipzig, 1811, 8vo. Nicolaus wrote other works. A fragment of his 'Life of Augustus' is extant, and an autobiography is attributed to him, but it is probably not genuine.

On two occasions Nicolaus appears as the advocate before Agrippa of certain Jews who were molested in the practise of their peculiar customs by the Greeks among whom they lived. (Josephus, *Antiq.*, xii. 3, 2; xvi. 2, 2.) In the year 6 B.C. he was sent by Herod on an embassy to Augustus, who had taken offence against Herod, because he had led an army into Arabia to enforce certain claims which he had upon Syllæus, the prime minister of the king of Arabia, and the real governor of the country. (Josephus, *Antiq.*, xvi. 9.) Nicolaus, having obtained an audience of the emperor, accused Syllæus and defended Herod in a skilful speech, which is given by Josephus. (*Antiq.*, xvi. 10, 8.) Syllæus was sentenced to be put to death as soon as he should have given satisfaction to Herod for the claims he had upon him. This is the account of Josephus, taken probably from the history of Nicolaus himself, who appears to have exaggerated the success of his embassy, for Syllæus neither gave any satisfaction to Herod, nor was the sentence of death executed upon him. (Josephus, *Antiq.*, xvii. 3, 2.) We find him afterwards acting as the accuser of Herod's son Antipater, when he was tried before Varus for plotting against his father's life, B.C. 4 (Josephus, *Antiq.*, xvi. 5, 4-6; *Jewish War*, i. 32, 4), and again as the advocate of Archelaus before Augustus in the dispute for the succession to Herod's kingdom, B.C. 3. (Josephus, *Antiq.*, xvii. 9, 5; xi. 3; *Jewish War*, ii. 2, 6.)

NICOLAY, BARON LUDWIG HEINRICH, born at Strasburg, December 29th, 1737, was, though not of first-rate talent, one of the most pleasing among the minor poets of Germany. His style is easy and natural, his versification flowing, and his narrative interesting. All these qualities display themselves in his 'Romantic Tales,' which, although their subjects are chiefly derived from Ariosto and Bojardo, are remodelled and treated with great originality, and manifest considerable fancy, skill in the management of the story, and truth of expression, both in the comic and serious parts. Of his abilities, both as a didactic and satiric writer, proof is afforded by his 'Poetical Epistles,' which have much of the spirit and gracefulness of Wieland, with not a little of his manner. His Fables, too, and minor Tales, though not always of his own invention, show genuine talent, and frequently no small power of humour.

Nicolay resided for the greater part of his life at St. Petersburg, where he was invited, in 1769, to undertake the office of preceptor to the grand-duke (afterwards emperor) Paul. Besides being honoured with several Russian orders, he was made director of the Imperial Academy of Sciences in 1798, which office however he afterwards resigned; and in 1801 was raised to the rank of imperial privy-counsellor. He died in 1820.

NICOMACHUS, a physician of Stagira in Macedonia, and one of the family of the Asclepiadæ, flourished about 400 B.C., Ol. xcv. 1. He was the friend and physician of Amyntas, king of Macedonia, but is now only known as the father of Aristotle. (Ammonius, and Diogenes Laertius, in *Vita Aristot.*; Suidas, in voce *Nicomachus*.)

NICOMEDES (*Νικομήδης*), the name of several kings of Bithynia.

1. **NICOMEDES I.** succeeded his father Zibætes, B.C. 278. His succession was disputed by his brother Zibætes; and he called in the Gauls to support his claims, B.C. 277. With their assistance he was successful; but his allies became his masters, and the whole of Asia Minor was for a long time overrun by these barbarians. [GALATIA.] He probably died about B.C. 250, and was succeeded by his eldest son Zielas.

2. **NICOMEDES II.**, surnamed Epiphanes, succeeded his father Prusias II., B.C. 149. He accompanied his father to Rome, B.C. 167, where he appears to have been brought up under the care of the senate. (Liv., xlv. 44.) Prusias becoming jealous of the popularity of his son, and anxious to secure the succession to his younger children, formed a plan for his assassination; but Nicomedes, having gained intelligence of his purpose, deprived his father of the throne, and subsequently put him to death.

Nicomedes remained during the whole of his long reign a faithful ally, or rather obedient subject, of the Romans. He assisted the Romans in their war with Aristonicus, brother of Attalus, king of Pergamus, B.C. 131; and he was applied to by Marius for assistance during the Cimbrian war, about B.C. 103. During the latter part of his reign, he was involved in a war with Mithridates, of which an account is given in the life of that monarch. [MITHRIDATES VI., vol. xv., p. 289.]

Coin of Nicomedes II.

British Museum. Actual Size. Silver

3. **NICOMEDES III.**, surnamed Philopator, succeeded his father Nicomedes II., B.C. 91. During the first year of his reign, he was expelled from his kingdom by Mithridates, who placed upon the throne Socrates, the younger brother of Nicomedes. He was restored however to his kingdom in the following year by the Romans, who sent an army under Aquilius to support him. At the breaking out of the Mithridatic war, B.C. 88, Nicomedes took part with the Romans, but his army was completely defeated by the generals of

Mithridates, near the river Anmas, in Paphlagonia (Strabo, xii., p. 562); and he himself was again expelled from his kingdom, and obliged to take refuge in Italy. At the conclusion of the Mithridatic war, B.C. 84, Bithynia was restored to Nicomedes. He died B.C. 74, without children, and left his kingdom to the Romans.

(Memnon, as quoted by Photius; Livy; Justin; Appian's *Mithridatic War*; Strabo; Clinton's *Fasti Hellenici*, vol. iii., Appendix 7, 'Kings of Bithynia'.)

NICOMEDES. [CONCHOID.]

NICOMEDIA (*Νικομήδεια*), a city of Bithynia, at the head of the gulf Astacenus, in the Propontis, was founded by Nicomedes I., B.C. 264. According to Pausanias, this city was originally called Astacus (v. 12, § 5); but Strabo informs us that Astacus was another city on the same gulf, which was founded by the Megarians and Athenians, and afterwards destroyed by Lysimachus; on which occasion its inhabitants were removed to Nicomedia (xii., p. 563. Casaub.).

Under the Roman emperors Nicomedia became one of the chief cities of the empire. Pausanias speaks of it as the principal city in Bithynia (v. 12, § 5); but under Diocletian, who chiefly resided there, it increased greatly in extent and populousness, and became inferior only to Rome, Alexandria, and Antioch. (Liban., *Orat.* viii., p. 203; Lactant., *De Morta Persec.*, c. 17.) It was almost entirely destroyed by an earthquake during the reign of the emperor Julian, but it was again rebuilt with great splendour and magnificence, and recovered nearly its former greatness. (Amian. Marcell., xxii. 9; xxii. 13; xvii. 7.) It is called at the present day Ismid, and is still a town of considerable importance; but it contains few remains of antiquity.

NICOSIA. [CYPRUS.]

NICOTIANA TABACUM, an annual plant, of which the leaves are used in a variety of forms and ways, and also in medicine. The dried leaves are large, long, entire, smooth, somewhat glutinous, and of a brown colour, with a peculiar stupefying odour, and an acrid, nauseous, bitter taste. The processes of maceration and partial fermentation, and admixture of different substances, render it more agreeable in the dried than in the fresh state. The analysis of tobacco shows its chief ingredients to be:—1st, a tobacco-campher, called nicotian, or nicotianin, which crystallizes, and is solid at the ordinary temperature of the air; has a faint odour of tobacco, with a warm, bitterish, aromatic, but not acrid taste, and is not possessed of any narcotic power; if applied to the nostrils, it causes sneezing; and if a grain be taken into the stomach, it creates uneasiness and giddiness. It is called by some the acid principle of tobacco, and if such be its nature, it is most probably combined in the herb with, 2nd, nicotina, an alkaloid, which, like conia, does not exist at ordinary temperatures in a solid form, but in a fluid and volatile state, having an oily appearance.

The empyreumatic oil of tobacco appears to be formed during the destructive combustion, and does not exist naturally in the leaf, but is probably formed at the expense of the nicotina. It does not therefore exist in the infusion of tobacco, the mode of action of which differs in several respects from the other forms in which it is employed. The active part of the oil can be removed from it by washing with weak acetic acid. The products of tobacco when burnt, as in smoking, are:—carbonate of ammonia, nicotianin, empyreumatic oil, soot, and some gases.

Nicotina seems to be the formidable principle of tobacco when used in the solid form, or as an infusion; and the empyreumatic oil, when it is smoked, or when obtained by destructive distillation. The action of nicotina is highly poisonous; a quarter of a drop will kill a rabbit; one drop can destroy a dog. It is distinguished from the other alkaloids obtained from the tribe of the Solanaceæ by not causing dilatation of the pupil; the external application of it to the eye produces other very alarming narcotic symptoms. The tenth part of a grain put into the eye of a cat causes strong convulsions, with foaming at the mouth, quick respiration, accompanied with rattling in the throat, and rapid palpitations of the heart, which can be heard at a considerable distance, staggering, and paralysis of the hinder extremities, which symptoms disappear in an hour.

The empyreumatic oil, in the quantity even of a single drop placed on the tongue, excites convulsions and coma, without affecting the heart. It may prove fatal in two minutes.

Tobacco is a very powerful agent, the active principles

of which are extracted by water, either in the form of infusion or decoction. The local effects of tobacco-leaves, or any preparation of them, are those of an acrid substance; hence when taken internally they cause vomiting and purging, pain of the stomach and intestines, followed by inflammation and ulceration. The external application occasions irritation of the part, and, if kept long in contact with it, inflammation: snuffing the prepared powder induces sneezing and increased secretion of mucus; chewing or smoking it causes increased secretion of saliva, with diminished appetite in those unaccustomed to its use.

Besides these local effects it has a secondary action, which results from the absorption of the active principles. It is immaterial by what channel they are introduced into the circulation: the same consequences follow, and affect on the one hand the intestinal canal, the lungs, and the heart; and on the other, the nervous centres of the brain and spinal chord. The former show themselves by nausea, vomiting, purging, pain and inflammation of the stomach, and here and there of the intestines; on the lungs, by the slower, painful, and irregular respiration; and after death the tissue of the lungs is found to be thicker, more injected with blood, and accumulations or extravasation of it. The action on the heart, or probably the nerves of the heart, manifests itself by irregular, generally slower pulsations, and by the heart losing its irritability sooner than after natural death; but the chief secondary action is on the brain and spinal chord, and this succeeds the external as well as internal application of it, but most so after injection into the rectum. Giddiness, weight, and pain of the head; deafness, a feeling like intoxication, staggering, trembling, general weariness of the muscles, with convulsive contractions of them, or cramps, general insensibility, sleepiness, and death are the consequences.

Tobacco must therefore be considered as a narcotic acrid poison. Habit reconciles the system to its action when used moderately, but nothing can secure the body from its irritative property and its ultimate absorption when employed in excess or incautiously. Uncontrollable fits of sneezing have produced death, and smoking a number of pipes or cigars has also caused death. The use of an infusion as a wash to the head in ringworm, or against the itch, has produced death by absorption through the abraded surface. The greater number of fatal cases have resulted from the employment of it as an injection into the rectum, either against worms, or, by a most singular practice, in the form of smoke in the case of persons drowned, a custom which ought to be strongly censured and relinquished.

The few cases which can justify the use of so formidable an agent are those in which great relaxation of the muscles is wished, such as to reduce dislocations or hernias, or to remove obstructions in the intestines, in ileus, and similar diseases. But the utmost caution is here requisite; and an injection of uniform strength, as ordered in the 'Pharmacopœia,' is to be prepared, and thrown up in divided portions, under the direction and in the presence of the medical attendant. In case of over-dose, vital stimulants, such as brandy or ammonia, must be resorted to. The infusion of tobacco has been recommended as a diuretic in some cases of dropsy; but it is a dangerous remedy, and seldom employed.

Against the common use of tobacco for snuffing or smoking it is perhaps useless to declaim. Chewing it is limited in a great measure to sailors, and it were to be wished that the practice of smoking were similarly restricted. The evils which follow indulgence in these customs are not very obvious, but that injury results is in most cases certain. [ANTIDOTES; ERRHINES.]

NICOTIANIN, the principle which gives the characteristic odour to tobacco. It is a concrete oil, and may be obtained by the following process:—distil six pounds of tobacco-leaves with twice their weight of water, till half has come over. To the distilled liquor add twice its weight of water, and again distil; and this operation is to be repeated. A fatty substance will be found floating on the surface of the distilled liquid in very small quantity, and this is nicotianin.

Its properties are, that it has the smell of tobacco, and a bitterish taste. It is insoluble in water, but readily dissolves in alcohol and in æther; dilute acids do not dissolve it, but potash takes it up. By heat it is of course volatilized, and if water be present, without change. It does not appear to have been analyzed.

NICOTINA, an alkali which exists in the different species of tobacco. It is procured by the action of sulphuric acid upon tobacco-leaves, and subsequent treatment with alcohol, and afterwards with lime or magnesia, and various complicated operations. Other processes have also been adopted.

Its properties are, that it crystallizes in small plates, which, by exposure to the air, absorb moisture sufficient to become a transparent colourless liquid. When cold it is nearly inodorous, but when heated it yields a vapour, the smell of which resembles that of tobacco, and is disagreeable and acrid; its taste is also disagreeable, and somewhat caustic, and remains long in the mouth; even when cooled down to 21° it retains its fluidity. Its alkaline properties are evinced by its action upon test-papers; and when heated to 212° its vapour renders turmeric paper brown. It boils at 375°, is soluble in water, æther, and almond oil; its specific gravity is 1.048. The salts which it forms with alkalis are colourless, and are usually soluble in water and alcohol, but not in æther. Virginia tobacco yields about one-tenth of its weight of nicotina, and there is no one kind which gives much more. It has not been analyzed.

NICTITATING MEMBRANE. [BIRDS.]

NIEBUHR, CARSTEN, a celebrated modern traveller, and a native of the duchy of Lauchburg, on the southern confines of Holstein, was born in the year 1733. His family had been farmers in easy circumstances, but he lost his parents early; and, through some mismanagement in the division of their property, he was so utterly deprived for a time of the means of continuing his education, that he passed several years of his youth in the condition of a mere peasant, and was even prevented from cultivating a taste for music, which had given him hopes of obtaining the situation of organist. But, in his twenty-first year, an occasion arose which elicited his natural energy of spirit, and decided the direction of his fortunes. Some legal proceedings rendering it necessary to employ a land-surveyor in his native district, he resolved to qualify himself for the office, and for this purpose applied zealously to the study of geometry. With the thirst of knowledge thus excited, being now of age to dispose of the wreck of his little patrimony, he was led to employ a portion of it in acquiring higher instruction in the mathematics, first at Hamburg, and subsequently in the university of Göttingen. Here, as his views enlarged and his pecuniary resources diminished, he gladly embraced an opportunity, in his twenty-fourth year, of entering the corps of Hanoverian engineers: but he was soon diverted from that service by an offer from the Danish government of employment in a scientific expedition to Arabia.

The idea of this enterprise, which forms the most honourable event in the reign of Frederic V. of Denmark, was suggested to his minister Count von Bernstorff, by the learned Michaëlis, for the purpose of illustrating some passages in the Old Testament; and the original project, which contemplated the mission only of a single Arabic scholar, was liberally extended by the Count to include a mathematician for purposes of astronomical and geographical observation, a naturalist, a draughtsman, and a physician. When the first of these appointments was offered to Niebuhr, he showed his conscientious character by stipulating for a delay of eighteen months, in order to improve his scientific qualifications. This period of preparation he employed chiefly in gaining practice as an astronomical observer, and also in studying Arabic for a time with Michaëlis; though, under that instructor, he made but small progress in overcoming the difficulties of a language which he afterwards learned to speak fluently in the country. He modestly declined the title of professor, not considering that his acquirements were sufficient for that distinction; and he accompanied the expedition therefore only as a lieutenant of engineers, in the capacity of mathematician or geographer, to which the Danish minister, who had received some proofs of his disinterestedness in pecuniary affairs, added the responsible office of treasurer to the mission. Its other members were Frederic Christiern von Haven, as professor of the Oriental languages, Peter Forsskål as naturalist, Christiern Charles Cramer as physician, and George William Baurenfeind as painter or draughtsman. By the royal instructions for the expedition, a perfect equality was established among the five members; and they were enjoined to decide every difference of opinion regarding their course by plurality of voices, or, if votes should be equal, by lot.

The expedition sailed from Copenhagen, in January, 1761,

in a frigate of the Danish royal navy, and arrived, not without some accidents, at Constantinople; from whence, after a short residence, the travellers proceeded in a merchant vessel to Alexandria, ascended the Nile, and reached Cairo in November, 1761. Having carefully explored the pyramids and other antiquities of Lower Egypt, they crossed the desert to Mount Sinai and Suez, embarked at that port in an Arab vessel, and landed at Loheia, in Arabia Felix, the destined seat of their mission, in December, 1762. They crossed the country, mounted on asses, the usual conveyance of Mussulmans as well as Christians in Yemen, and after visiting several places of interest, finally arrived at Mocha, where the philologist Von Haven unfortunately died, in May, 1763. The surviving travellers proceeding from thence to Sana, the capital of Yemen, were favourably received by the Imaum; but they had meanwhile lost another of their number, the naturalist Forskäl, who died on the road. His companions returning to Mocha, there embarked in an English vessel for Bombay, on the voyage to which place the painter Baurenfeind expired; and at Bombay, Niebuhr had the affliction to bury the last of his fellow-travellers, the physician Cramer. The fact is admitted by Niebuhr, that his ill-fated friends persisted in living after the European manner under the burning sun of Arabia; and it may be surmised that they lost their lives through that disregard to necessary habits of abstinence for which the Danes in their tropical colonies are remarkable, even above all other northern people. Niebuhr himself, who had suffered severely from illness with the rest of his party, after their decease adopted the same diet as the natives of the countries in which he was travelling, and thenceforth enjoyed excellent health. Sailing from Bombay, he visited Persia, including the ruins of Persepolis; ascended the Euphrates; proceeded by way of Bagdad and Aleppo to the Syrian coast; embarked for Cyprus, returned from that island to the continent; saw Jerusalem and Damascus; passed through Aleppo, and over Asia Minor to Constantinople; and finally returned to Copenhagen, in November, 1767. The whole of the travels of the mission, which occupied six years, and extended over so many countries, is said, by the good management and conscientious economy of Niebuhr, who indeed defrayed every expense that could be considered personal to himself out of his own narrow income, to have cost the Danish government only the incredibly small sum of about four thousand pounds.

Niebuhr was welcomed in Denmark as he deserved. The government undertook at its charge the engraving of all the plates of his travels, which were to be presented to him as a free gift; and he was left to publish the result of his labours at his own cost and for his own profit. Resolving to commence with the 'Description of Arabia,' he printed, in the year 1772, his volume under this title, which has become the text-book of every writer, from the historian Gibbon down to the present time, who has had occasion to treat of the antient and modern aspect of that country. The depth of research, the fidelity of delineation, and the accuracy of detail which it exhibits on the geography of Arabia, and the enduring character and condition of its inhabitants, have rendered this work of Niebuhr perfectly classical. He has sometimes been compared, and the comparison is just and appropriate, with the historian of Halicarnassus: both travellers were characterised by accuracy of observation, strict veracity, and a simplicity of narrative which art alone can never attain. [Herodotus.] The appearance of this work was followed, in 1774-1778, by two volumes of equal merit and interest, narrating his 'Travels in Arabia and adjacent Countries.' To these volumes it was his intention to add a third, enriched with the result of his inquiries into the state of the Mohammedan religion and Turkish empire, and containing his astronomical observations: but some causes, not sufficiently explained, delayed this publication, until a fire, which, in 1796, destroyed the king's palace at Copenhagen, and with it the original plates both of his published and unedited works, put an end to his design. This third volume was however published in 1827, owing to the liberality of the bookseller Perthes of Hamburg, and the affection of Niebuhr's family, particularly of his daughter, under the title of 'Reisebeschreibung nach Arabien und andern umliegenden Ländern.' It contains his remarks on Aleppo, his voyage to Cyprus, and his visit to Jaffa and Jerusalem, his return to Aleppo, and journey thence through Kóniyeh to Constantinople, and an abridged account of his route through Bulgaria, Wallachia, Poland,

and Germany, to Denmark. (*London Geog. Journal*, vol. viii.) After the publication of the first two volumes of his travels, he contributed to a German periodical journal, among other papers, two on the 'Interior of Africa' and the 'Political and Military State of the Turkish Empire.' His principal works, which were published in German at Copenhagen, have been translated into French and Dutch, and reprinted at Amsterdam and Utrecht. Niebuhr himself likewise edited and published, in his usual generous spirit, at his own cost, the contributions to natural history (*Descriptiones Animalium* and *Flora Egyptiaco-Arabica*) of his deceased friend Forskäl, which were also among the fruits of the mission to Arabia.

Niebuhr, whose life was prolonged to a great age, survived his return from his Oriental travels for nearly half a century. He had, about 1772, some thoughts of undertaking another journey of discovery, at the instance of the Tripoline ambassador at Copenhagen, into the interior of Africa: but a happy marriage induced him to abandon this project; and, tired of military service and a residence at Copenhagen, he obtained, in 1778, a civil situation under the government at Meldorf in Holstein, to which he withdrew, and where he passed the long remainder of his existence. He did not however suffer his mind to be idle in retirement; for he maintained an extensive correspondence with the learned in several countries of Europe, and continued so active a public officer, that, at the age of seventy-two years, notwithstanding the failure of his eye-sight, he assisted in a new territorial survey ordered by the Danish government. His long services were rewarded with the cross of Danebrog and the title of counsellor of state; and when he became quite blind, the government liberally refused to accept his resignation, and appointed a friend to assist him in his duties until the end of his life, which terminated in April, 1815. A brief memoir of him in the German language, published by his son at Kiel, two years after his death, furnished the materials for an article in the 'Biographie Universelle,' from which and his works the present account has chiefly been compiled.

NIEBUHR, BARTHOLD GEORGE, was born at Copenhagen, on the 27th August, 1776. His father, Carsten Niebuhr, had returned from the East about nine years before that time, and was residing at Copenhagen as a captain of engineers; however, two years after Barthold's birth, he received the appointment of land-surveyor, which made him remove to Meldorf, a town of Dithmarsh, in Holstein, the native province of the Niebuhrs. It was here that B. G. Niebuhr spent the whole of his infancy and boyhood, living in great retirement, and necessarily contracting studious habits, as well from the absence of all outward interruptions, as because a weakly constitution, produced by a marsh-fever, had incapacitated him for the boisterous amusements of more robust children. He derived great advantages from the society of Bojes, then well known in the literary world, who came to settle at Meldorf as landvogt in the year 1781. The wife of Bojes taught him French, his father instructed him in geography, in the English language, in the elements of mathematics, and in the Latin accidence. He began to learn music in 1783, but never made any great progress in it. In other branches of knowledge so great was his proficiency that Bojes describes him as a juvenile prodigy in 1783, when Niebuhr was only seven years old, and when he was sent to the public school of the place, in 1789, he was placed at once in the first class. He also gave considerable assistance to his father about the same time in making some long calculations connected with his office of surveyor. After having been at school from Easter, 1789, to Michaelmas, 1790, he became the private pupil of the head-master, Dr. Jäger, with whom he read for an hour every day till Easter, 1794, with the exception of three months which he spent at Hamburg, in 1792, at a kind of commercial school kept by his father's friend Professor Büsch. He also received some advice with regard to the prosecution of his classical studies from the celebrated J. H. Voss, who paid occasional visits to his father, and he acknowledges with gratitude the benefit which he had derived, in common with all Germans, from Voss's excellent translations.

Carsten Niebuhr's wish was that his son should engage in some active business; he even entertained the hope for some time that his son might follow in his own footsteps, and become celebrated as an Eastern traveller. But Barthold's tendencies were from the first in favour of a studious life, and his father was unwilling to oppose his inclinations. It was resolved then that after spending two years at Kiel,

he should go to Göttingen, and study under Heyne. He had already had communication with the last-named scholar, and had collated for him some MSS. after his return from Hatzburg, in 1792.

He studied at Kiel from Easter, 1794, to the spring of 1796. Here he formed an intimacy with the family of Dr. Hensler, professor of medicine, which had the greatest influence on his subsequent career. The widow of Dr. Hensler's son, a lady from Dithmarsch, was residing in his house, and Niebuhr's acquaintance with her ripened into a friendship which lasted till his death. By far the greater part of his numerous letters are addressed to her. In August, 1794, Dr. Hensler was visited by the mother and sisters of his daughter-in-law, and Niebuhr soon formed an attachment to one of the latter, Amalie Behrens, who subsequently became his first wife.

In January, 1796, Count Schimmelmann, the Danish minister of finance, proposed to Niebuhr to become his private secretary. His father accepted the offer for him, and thus Niebuhr was introduced into the best circles of his native city. His bashfulness and studious habits however rendered him unhappy in this situation, and he soon exchanged it for that of supernumerary secretary to the Royal Library, which he entered upon in May, 1797, and held till April, 1798, when he paid a visit of two months to his family in Holstein, and then sailed for England. He resided in London and Edinburgh for about a year and a half, and returned to Holstein towards the end of 1799. About the middle of April, 1800, he went to Copenhagen, and, after a stay of a few weeks, obtained the appointment of assessor in the college of commerce for the East Indian department, and of secretary and accountant to the African consulate. The income arising from this appointment enabled him to marry Amalie Behrens, in May, 1800, and he resided with her at Copenhagen till the year 1806, performing his duties with the greatest punctuality and diligence, and to the entire satisfaction of his employers. He did not however altogether neglect his literary pursuits; they formed his evening amusement, and he found time in the midst of his business avocations to give lessons to the nephew of his friend Count Schimmelmann, and to translate part of an Arabic history of the conquest of Asia. In the spring of 1803 he had to make a journey into Germany on public business connected with the administration of the Danish finances. An offer was made to Niebuhr, at the end of 1805, to enter into the service of the Prussian government, and his dissatisfaction at the prospect of having some one appointed over his head, and the advantages held out by the situation proposed to him, induced him to accept the situation of joint-director of the first bank at Berlin, with the promise of further promotion.

He arrived at the Prussian capital on the 5th October, 1806, shortly before the battle of Jena. A few days after that event he was obliged to take flight with all the other officials. He resided till April, 1807, at Memel and Königsberg, and then became one of the secretaries of the prime-minister Hardenberg, having chiefly to attend to the supply of the army then in the field. This office kept him with the head-quarters of the army till the battle of Friedland, after which he went to Riga. The provisions of the peace of Tilsit having exacted the dismissal of Hardenberg, his office was put into commission, which consisted of Von Altenstein, Von Schön, Stägemann, Von Klewitz, and Niebuhr. Upon the accession of Stein to the administration, Niebuhr was despatched to Amsterdam to negotiate a loan, and he resided there till April, 1809. In December, 1809, he was nominated privy-counsellor, and received a high appointment in the administration of the funds. This brought him to Berlin, where, and at Königsberg, he resided through the winter of 1809-10. The opposition to a financial plan of his made him however more anxious than ever to retire from public life; and after some fruitless attempts on the part of the government to retain him in office, he exchanged his public situation for the post of historiographer to the king, vacant by the death of J. Von Müller. About the same time he was elected member of the Royal Academy of Sciences.

The opening of the university of Berlin, at Michaelmas, 1810, brought forward Niebuhr as a lecturer on Roman history; and the lectures which he delivered in this and the following year were published in 1811, and contain the germs of those new combinations and discoveries for which Niebuhr will be best known to posterity. The time which he

spent at Berlin, from 1810 to 1813, seems to have been one of the happiest periods of his life. He formed a small philological society, consisting of Spalding, Buttmann, Heindorf, Schleiermacher, Ancillon, Süvern, Savigny, Schmedding, and Nicolovius, and with these distinguished scholars he spent all his spare hours. He felt very acutely the loss which this society sustained in the death of Spalding (on the 7th June, 1811). How greatly Niebuhr valued his intercourse with these highly-gifted men, may be presumed from the way in which he speaks of them at the end of the preface to his History; and there can be no doubt that many valuable hints in that work were suggested to him by his friend Savigny in particular.

Niebuhr's studious life was interrupted by the war of liberation, as it was called, in 1813-14. He took an active part in these events. He was chiefly with the head-quarters of the allied army till February, 1814, when he was again sent to Holland on public business. He returned to Berlin in the October of that year, and resided there till the summer of 1816, when he proceeded as ambassador to the court of Rome. During this residence at the capital he wrote, besides some political tracts, a biography of his father, who died in April, 1815, and some essays for the Royal Academy of Sciences, and resumed his intercourse with his philological friends. He also instructed the crown-prince of Prussia in the principles of political economy.

His wife died on the 20th June, 1815, shortly before he received his appointment as ambassador. His first intention was to take with him to Rome her sister, his friend the widow Hensler; in fact she came to Berlin for that purpose, in April, 1816, accompanied by her niece and adopted child Margaret Hensler, the orphan daughter of Christian Hensler, who had been professor of theology at Kiel, and the young lady was also to have accompanied Niebuhr to Rome. During their residence with him however he found reason to change his mind; he married Margaret Hensler before he started for Rome, and the widow returned to Holstein.

Niebuhr did not receive his final instructions till after he had been four years in Rome. By his interest however with the pope and his secretary, the Cardinal Consalvi, he contrived to bring the negotiations to a close in seven months after the arrival of his instructions: the Prussian minister, Hardenberg, went to Rome himself in February, 1821, and Niebuhr gave him the credit of completing the concordat, though his own services in the matter were fully acknowledged by his court, and he received from the king of Prussia, as a mark of his satisfaction and approbation, the order of the Red Eagle of the second class, to which the emperor of Austria added the first class decoration of the Leopold order of knighthood.

The climate of Rome had always disagreed with his wife, and as the business which had brought him to the papal court was now finished, he wrote for his recal. This was after the birth of his third daughter, in February, 1822. He was advised in the first instance to apply for leave of absence for a year, which left his return open to him. He spent part of the autumn of 1822 at Albano, and also made a journey to Tivoli. In March, 1823, he went to Naples, in order to visit his friend De Serre, who was French ambassador in that city; and after staying there till the beginning of May, set out for Berlin.

In consequence of some slight difference with the leading men in the capital, Niebuhr retired to Bonn, where a university had been recently established, and where his friend and former secretary, Brandis, was a professor. Here he was attached to the university as an adjunct professor, and gave lectures on Roman antiquities and various subjects. At the same time he availed himself of every opportunity of promoting and encouraging the labours of other scholars. It was partly with this view that he set on foot the 'Rheinisches Museum,' a philological repository, in which the shorter essays and scattered thoughts of learned men might be given to the world. The first volume of this periodical appeared in 1827, under the joint editorship of Böckh, Niebuhr, and Brandis. The new edition of the Byzantine historians, which was commenced under his direction, was intended only as a diversion, taken up to relieve his mind from the severer studies required by the revision and correction of his 'History of Rome.' He brought out the first volume of the new edition of this history early in 1827; the alterations in this edition are so numerous that it may almost be considered as a new work. The publication of the

second volume was delayed by a fire, which burned his house to the ground and consumed all the manuscript with the exception of a leaf that he happened to have lent to a friend, and it did not appear till the end of 1830. Niebuhr's sensitive mind was much affected by the Revolution which took place in Paris in the July of that year, and by the subsequent revolt of Belgium: he looked forward with the deepest anxiety to the probable consequences of those events: he expected the renewal of that devastating war which had been the result of the first French revolution; and feared that his own happy dwelling-place, by the Rhine, would be the first to suffer from the invaders. These considerations preyed upon his spirits, and he sunk under the continued agitation of mind produced by them. He died on the 2nd of January, 1831, leaving behind him several children. His family, we understand, is now settled at Kiel; one of his sons is an officer in the Prussian army.

It is difficult to conceive a more excellent and delightful person than Barthold Niebuhr appears to have been; there is no one, of whom we have read, who has combined so blameless a character and so amiable a disposition with such boundless acquirements and such brilliant intellectual qualities. His 'History of Rome' is perhaps the most original work that this age has produced. To understand what he has done in this work, we should keep in mind the state of knowledge on the subject before his time. The disjointed ruins had lain for ages in a confused heap, though there was hardly a child in Europe who was not familiar with their rude outlines, and though many a skilful and laborious workman had endeavoured to reduce them to symmetry and order. Niebuhr, by a series of combinations which will appear most surprising to those who are most capable of appreciating works of genius, succeeded in reconstructing from the scattered fragments a stately fabric, which, if it is not identical with the original structure, is at least almost perfect and complete in itself. There cannot be a greater mistake than to suppose, as some have done, that Niebuhr was a sceptic whose sole delight was to render insecure the basis of historical evidence. He has actually done more than any one that ever lived towards extracting truth and certainty from the misty and mystical legends of early tradition, and toward substituting rational conviction for irrational credulity. The great object which he proposed to himself, in all his philological speculations, was to reproduce a true image of the past by getting rid of the deceitful influence of the present. This view he often expresses in very plain terms. Thus, he says in his introductory lecture on Roman history (*Kleine Schriften*, p. 93), 'As there is nothing which Eastern nations find more difficult to conceive than the idea of a republican constitution, as the people of Hindustan cannot be induced to regard the East India Company as an association of proprietors, or in any other light than as a princess, just so is it with even the acutest of the moderns when they study ancient history, unless they have contrived, by critical and philological studies, to shake off the influence of their habitual associations.' And in a letter to Count Adam Moltke, he exclaims (*Lebensnachrichten*, ii., p. 91), 'O, how people would cherish philology did they but know how delightfully it enables us to recal to life the fairest periods of antiquity. Reading is the most trifling part of it; the chief business is to domesticate ourself in Greece and Rome at the most different periods. Would that I could write history so vividly, that I could so discriminate what is fluctuating and uncertain, and so develop what is confused and intricate, that every one, when he heard the name of a Greek of the age of Thucydides or Polybius, or a Roman of the days of Cato or Tacitus, might be able to form a clear and adequate idea of what he was.' The very existence of such a general design presumes a lively fancy and active imagination: though these are qualities often possessed by shallow and superficial persons, they are very rarely combined with that extensive and minute learning for which Niebuhr was so distinguished. The range of his acquisitions was really wonderful. He had got together a mass of statistical information relative to the modern states of Europe, which would have sufficed of itself to gain a reputation for any man; there was hardly a stray hint in the whole series of classical writers which had escaped his searching eye, and the whole of his knowledge lay before him so as to be comprehended at one glance. In the words of one of his most ardent admirers, 'While his horizon was ever widening before him, it never sunk out of sight behind him.'

what he possessed he always retained; what he once knew became a part of his mind, and the means and instrument of acquiring more knowledge; and he is one of the very few examples of men gifted with a memory so tenacious as to seem incapable of forgetting any thing, who at the same time have had an intellect so vigorous as in no degree to be oppressed or enfeebled by the weight of their learning, but who, on the contrary, have kept it in orderly array, and made it minister continually to the plastic energy of thought.' (*Philol. Mus.*, i., p. 271.)

Some deductions must however be made from this general eulogy. While Niebuhr's great work has been neglected or censured, with equal injustice, by persons who have been too indolent to encounter the labour of studying it or incapable of appreciating the method of critical investigation which the author has adopted, it may be doubted, on the other hand, whether many scholars, both in Germany and England, have not been too willing to acquiesce in all Niebuhr's results, to adopt whatever he has written, and sometimes even to receive as established truths assertions unsupported by evidence or directly opposed by express testimonies. Some recent German writers have indeed taken a middle course; they adopt the general views and critical method of the historian, but they find much in the details that is defective or erroneous. This appears to us to be the true spirit in which Niebuhr's work should be studied. The young students of Roman history should be told that they will prove themselves worthy disciples of Niebuhr rather by following his method than by assuming his results; it must be impressed upon them that the original authorities should in all cases be carefully sifted and compared, and that they cannot rely implicitly on the authority of their master in cases where the theory depends on philological interpretation. It cannot be denied that the ardent imagination of Niebuhr, and his power of combining and constructing, sometimes led him to form a complete theory before he had examined all the evidence; one consequence of which is, that, under the influence of his own creations, he will sometimes extract a meaning from a passage which the words do not contain, and at other times arbitrarily reject evidence when it interferes with his own hypothesis. It is true that this same power and his intuitive sagacity have sometimes enabled him to supply a link in a chain when all direct evidence is wanting, and the certainty of his conjectures in such cases is at once felt by the symmetry and consistency which they impart to the whole fabric of the theory. The writings of Savigny, the illustrious friend of the historian, also furnish examples of the certainty which historical conjecture may attain when it is founded on complete knowledge and directed by a matured judgment. It must also be remarked that Niebuhr's style is very faulty. It is generally deficient in perspicuity, and though eloquent passages and striking descriptions are found here and there, it wants that sustained dignity which we remark in the writings of J. von Müller and other distinguished historians.

Considering the long time which Niebuhr spent in public life, it is somewhat strange that he should not have been better acquainted than he seems to have been with the modern science of political economy; and he occasionally betrays very crude and ill-formed opinions on the internal polity of other countries; witness his remarks on the relative position of England and Ireland. But with all the drawbacks which the most rigorous criticism can exact, the feeling with which we contemplate his character and attainments is one of almost unmixed admiration. He was in fact a rare combination of the man of business, the scholar, and the man of genius. If he had had no other claim to celebrity, he would have deserved to be mentioned among the general linguists whose attainments have from time to time astonished the world. His father, writing in December, 1807, states that he was then acquainted with twenty languages (*Lebensnachrichten*, i., p. 30), and there is no doubt that he subsequently added to the list. No man has ever borne his faculties more meekly than Niebuhr. Though he had been trusted and honoured by a powerful sovereign, and rewarded for public services in a situation of dignity and importance, and though he was recognised as the chief of philologists in the most learned country of Europe, his habits were to the last those of a retired student, and his manners those of an unassuming domestic man. A very pleasing picture of his mode of living has been given by the late Professor Sandford, who

visited him at Bonn, in 1829 (see *Blackwood's Magazine*, for January, 1838, p. 90, &c.); a warm testimony to the benevolence of his character and the goodness of his heart is furnished by Lieber, in his 'Reminiscences of Niebuhr'; and we see the whole man, in all his relations, social, literary, and political, in the highly-interesting collection of his letters now in the course of publication (*Lebensnachrichten über Barthold Georg Niebuhr, aus Briefen desselben*, &c., Hamburg, 1838, vols. 1 and 2).

The following is a list of Niebuhr's philological works:

1. 'Römische Geschichte,' 2 vols. 8vo., Berlin, 1811. This edition was translated into English, by Mr. Walter, Lond. 1827.

2. 'Frontonis Reliquiæ, ab A. Maio primum editæ, notis variorum edidit B. G. Niebuhrius; accedunt C. Aurel. Symmachi octo Orationum Fragmenta.' Berol., 1816.

3. 'Cicero pro Fonteio et Rabirio,' 8vo., Romæ, 1820.

4. 'Flavii Merobaudis Carmina,' St. Galli, 1823, 2nd edition, Bonnæ, 1824.

5. 'Römische Geschichte,' Erster Theil, Berlin, 1827; Zweiter Theil, Berlin, 1830; Dritter Theil (posthumous), 1832. The two first volumes have been translated into English by J. C. Hare and Connop Thirlwall: 1st vol. Lond. 1828; 2nd edition, 1831; 2nd vol. 1832. The third volume is still untranslated. Of this translation Niebuhr himself has expressed his opinion in dedicating his 'Byzantine Historians' to the translators,—'quorum ope Historia mea Romana à Britannis prorsus ita ut eam animo concepi patrioque sermone conscripsi legitur.'

6. 'Corpus Scriptorum Historiæ Byzantinæ, editio emendatior et copiosior, consilio B. G. Niebuhrii, C. F. instituta,' &c., Bonnæ, 1828. Of this edition Niebuhr published the 'Agathias,' and joined with Bekker in publishing 'Dexippus,' 'Eunapius,' and other shorter histories, which appeared together in one volume.

7. 'Kleine Historische und Philologische Schriften, Erste Sammlung,' Bonn, 1828. This was the first volume of a collection of his shorter essays, which had appeared in the 'Transactions of the Berlin Academy' or in the 'Rheinisches Museum'; it also contained his biography of his father and his introductory lecture on Roman history. Many of these treatises have been translated into English, some of them in the 'Classical Journal' and the 'Philological Museum.' The essays 'On the Geography of Herodotus' and 'On the Scythians' have appeared in a separate form at Oxford.

Besides these works, which he published in his own name, Niebuhr has conferred a most important benefit on Roman jurisprudence by his discovery of the fragments of Gaius. [GAIUS.] He was unable to stay at Verona long enough to copy the MS. himself, and, as he says in a letter to the widow Hensler (*Lebensnachr.*, ii., p. 240), was obliged to content himself with the merit, which would soon be forgotten, of having made the discovery, not by accident, but after a diligent search. Niebuhr interested himself very much in the restoration of passages from lost writings contained in palimpsests, and in consequence became involved in a controversy with his rival discoverer, Mai, with regard to some emendations which he had proposed in certain fragments discovered by Mai, which emendations were subsequently confirmed by a MS. at Turin. Mai charged Niebuhr with having borrowed his emendations from the MS., and it was not without difficulty that Niebuhr prevailed upon the authorities at Rome to grant an *imprimatur* to his justification.

NIEMCEWICZ, JULIAN URSYN, a modern Polish writer, to whom the literature of his country is under considerable obligations for his exertions in its behalf, and for the nationality he infused into it. Neither was it as an author alone that he distinguished himself, for he took an active part in public affairs, and gave indisputable proof of his patriotism. As nuntius of Lithuania, he displayed his political talents in the diet, 1788-92; and in 1794 became not only the military companion, but the attached friend of Kosciusko, with whom he was taken prisoner and sent to St. Petersburg, where they remained till they were liberated by the emperor Paul on his accession. He afterwards accompanied Kosciusko to the United States, where he became personally acquainted with Washington, respecting whose personal character and domestic habits he has furnished many minute particulars in his 'Krotka Wladomosc o Zyciu Gen. Washingtona.' His poetical works are rather numerous, and consist of six books of Fables; narratives,

and miscellaneous pieces (among which are translations of Milton's 'Allegro' and 'Penseroso'); and 'Spiewy Historyczne,' a series of thirty-three historical songs, wherein the poet-patriot chants the heroic deeds of his countrymen. Of these historic hymns, which first appeared in 1816, and have since gone through several editions, a German version, not however including all of them, was published in 1783, by Baron F. Gaudy. His dramatic productions consist of several comedies and tragedies, some in verse and others in prose; among which may be mentioned 'Wladyslaw,' a tragedy, in five acts; 'Casimir the Great,' a prose drama, in three acts; 'Jadwiga, Queen of Poland,' an historical opera; also a translation of Racine's 'Athalie.' His prose works consist of 'Oriental Tales,' a 'History of the Reign of Sigismund III.' 2 vols., 1819; 'Memoirs relative to the earlier History of Poland,' 3 vols., 1822; 'Lejbe i Siora' (Levi and Sarah), or Letters of two Jewish Lovers, 1825; and 'Janj Teczyrna' (John of Teczyn), an historical romance, the scene of which is laid in the court of Sigismund Augustus (sixteenth century). In the course of it many of the personages of that period are introduced, and the national manners and costume of the time are described with great minuteness.

NIEMEN is the Polish name of a river, which by the Germans is called *Memel*, and by the Lithuanians *Niemona*. It rises in the swampy region which, between 51° and 56° N. lat., forms the watershed between the rivers which run into the Baltic and Black seas. It originates between 53° and 54° N. lat. and near 27° E. long., and runs in its upper course about 180 miles westward. At the town of Grodno it suddenly turns to the north, and continues in that direction about 100 miles. It then turns again to the west, and soon afterwards is joined, at Kowno, by the Wilia, the largest of its affluents, which flows about 180 miles in a western direction. The remainder of its course is to the west. From Grodno to its entrance into Prussia it forms the boundary-line between Russia and Poland. Its course through Prussia amounts to about fifty miles. About eight miles below Tilsit the river divides into two arms, which branch off respectively to the north-west and south-west. The northern arm, called Rusa, divides again, about two miles from its mouth, into two arms, the Atmat and Skirwieck. The southern arm is called the Ghilgha. Both arms empty themselves into the Curisches Haff, a lake of fresh water separated from the Baltic by a narrow strip of land which is formed by a continual line of sand-hills. The delta included between the Rusa and Ghilgha, called the island of Kaukehnen, is alluvial and of great fertility, but it is swampy towards the lake. Though impeded by shoals at several places, the river is of great importance for the exportation of the produce of the adjacent countries. Large though clumsily-made river-barges called *witlinnes* bring the produce of Lithuania (governments of Wilna and Grodno) and of a portion of Poland to Königsberg and Memel. These barges go up the Niemen to Grodno, and up the Wilia to Wilna. They bring down all kinds of corn, hemp, flax, hides, bacon, and some minor articles. All the timber exported from Memel is floated down from the interior of Russia. As the *witlinnes* were formerly frequently lost owing to the westerly and north-westerly gales, which prevail on the Curisches Haff, two canals have been made along the shores of the lake, by which the Ghilgha is united to the Dniepr, and thus to the Prægel river, on which the commercial town of Königsberg is built. These canals, which were made in the beginning of the last century at the expense and under the auspices of the countess of Trochasz, then proprietor of the county of Rautenburg, are called the Little and the Great Frederick's Canal (Grosse und Kleine Friederichs Graben). The former is also known by the Lithuanian name of *Grotuska* (the rapid river); on account of its more rapid course, and is about three miles long. The Great Frederick Canal is about 12 miles long and terminates in the Dniepr near Labiau. The Dniepr itself is chiefly an artificial canal, which was made 400 years ago, when Prussia was governed by the Knights of the Order of St. John. This canal, which extends from Labiau to Tapiau, unites the Haff to the river Prægel. In the middle of the last century an attempt was made to establish a water-communication between the Niemen and the Prypoc, an affluent of the Dnieper, which runs into the Black Sea. The noble Polish family of Oginski caused a canal to be dug in the swampy region between the Dniepr, a cr-

butary of the Upper Niemen, and the Yasiolda, an affluent of the Prypec. This canal of Oginsky is more than 30 miles long, but as its dimensions are small, and both the rivers which are united by this canal are only navigable for small craft, it is not much used.

There is perhaps no river in Europe whose floods rise to such a height and whose inundations are so destructive as the Niemen. Many circumstances unite to produce this effect. Snow to the depth of from four to six feet falls every winter on the country which is drained by it; and as the course of the river in general lies from east to west, this immense quantity of snow, being dissolved in so short a time as ten or fourteen days, causes the river to rise 20 or 30 feet above its general level; and as the fall of the river is in all its extent very inconsiderable, and its current slow, the water can only be carried off in a much longer time, and hence it accumulates in its bed and inundates the adjacent lands to a distance of several miles in many places, and causes great damage.

NIEUENTYT, BERNARD, was born 10th of August, 1654, at Westgraafdyk, a village of North Holland. There are short notices of his life in Nicéron (*Mémoires des Hommes Illustres*, tom. xiii., p. 356), and in the periodical entitled 'L'Europe Savante,' for April, 1719, tom. viii., p. 297, from which the following particulars are taken. His education was conducted with a view to his entering the church, of which his father was a minister; but evincing an early indifference to an ecclesiastical life, he was left by his parent to the free choice of a profession. He accordingly commenced the study both of law and physic, having previously applied himself to the study of logic, in order the more effectually 'to restrain and fix his imagination, and acquire the habit of reasoning correctly.' He appears to have excelled as a public speaker, to which circumstance, and the general amiability of his character, may be attributed his influence in the provincial states, as also in the government of the town of Purmerend, wherein he resided, and of which he was burgomaster. As a physician he is said to have been celebrated; and able and equitable as a magistrate. He was a zealous but not very able supporter of the doctrines of Descartes, and his mathematical writings, though now valueless, obtained a temporary popularity in consequence of their author being one of the first opponents of the infinitesimal calculus. His objections, which Montucla designates 'a mere tissue of absurdities,' were replied to, first by Leibnitz (*Leipzig Acta*, 1694), and afterwards by MM. Bernoulli and Herman, the latter of whom showed, to the satisfaction of mathematicians, that their adversary knew little or nothing of the calculus against which he had written so freely. A work of much greater merit was published by him at Amsterdam in 1715, in one volume 4to., entitled 'The right use of Contemplating the Works of the Creator;' the object of the author is first to convince atheists of the existence of a supreme and benevolent Creator, by contemplating the mechanism of the heavens, the structure of animals, &c.; and secondly, to remove the doubts of Deists concerning revealed religion. It was originally published in Dutch, but has passed through several editions in German, French, and English. The English editions, translated by Chamberlayne, under the title of the 'Religious Philosopher,' appeared at London in 1718-19, and 1730, in 3 vols. 8vo.

Nieuentyt died May 30, 1718, not in 1730, as stated in Hutton's Dictionary. The following are the titles of his mathematical works: 'Considerationes circa Analysin & Quantitates infinitè parvas applicatas Principia, et Calculi Differentialis Usus in resolvendis Problematibus Geometricis,' Amst., 1694, 8vo.; 'Analysis Infinitorum, seu Curvilinearum Proprietatis ex Polygonorum Natura deductæ,' Amst., 1695, 4to.; 'Considerationes Secundæ circa Differentialis Principia, et Responsio ad Virum Nobilissimum G. G. Leibnitium,' Amst., 1696, 4to.; 'A Treatise upon a New Application of Tables of Sines and Tangents,' 1714 (printed in the 'Journal Littéraire de la Haye').

NIEUPORT, a fortified town in West Flanders, six miles north-west from Furnes, and eighteen miles west-south-west from Bruges, in 51° 8' N. lat. and 2° 44' E. long. The town stands about a mile from the sea, on the Yporlée. The port, which is only a fishing-place, consists of a narrow creek, in which vessels are left aground at low-water; this creek forms a quay about 600 feet in length outside the walls of the fort. Nieuport has water communication with Furnes, Ostende, and Bruges, by means of the Yporlée, the

Yser, and the Ostand and Bruges canal. The town is regularly fortified and capable of sustaining a long siege; a great part of the surrounding district may be laid under water by means of sluices. There are upwards of 500 houses, a fine church, a chapel, a town-hall, and several hospitals. The population in 1836 amounted to 2847.

NIEUWELANDT, WILLEM VAN DEN, a Dutch author and artist, born at Antwerp in 1684, at first followed the manner of Paul Bril, whom he accompanied to Italy, but after his return, when he fixed himself at Amsterdam, he chiefly painted architectural compositions—ruins, baths, mausoleums, triumphal arches, and other subjects of that class. These works of his pencil, in which he showed how diligently he had studied the ancient monuments of Rome, were eagerly sought after, and many of them were engraved. He himself also possessed considerable skill in engraving and etching.

His literary works consist of six tragedies, namely, 'Saul,' 'Claudius Domitius,' 'Nero,' 'Livia,' 'Cleopatra,' and 'Sophonisba;' all of which display talent. The 'Nero,' which was brought out at Antwerp in 1618, at the expense of the city, met with extraordinary success. He also wrote a poem entitled 'Von den Mensch' (Man, or the Vanity of the World), wherein he expatiates on the emptiness of all human pursuits. He died at Amsterdam in 1635.

NIEUWLAND, PIETER, who has already been mentioned in the account of the literature of the Netherlands (p. 161), was one of the most extraordinary men among his contemporaries and countrymen. Like Bellamy, between whom and himself there were only a very few years' difference as to the time of their deaths, as well as that of their births, he raised himself from an obscure station to literary eminence as a poet, and not as a poet alone, but also by his acquirements and labours in philosophy and science. He was born in 1764, at Diemermeer, where his father was a carpenter, and a man of some information for one in his class of life. From him he acquired some insight into arithmetic and geometry; read all the books which the house contained, and at the age of seven began to display a turn for making verses. His verses were considered by others, besides his father, as very extraordinary productions for such a mere child, and caused him to be greatly noticed by many, and especially by Bernardus De Bosch,* who was a lover of poetry, and who had himself some pretensions to be a poet. By him the boy was taken into his own house and placed under the tuition of his brother, the celebrated Jeronimo De Bosch, by whom he was instructed in Greek and Latin, in both which he soon made great proficiency, as well as in other studies. He was then sent to the Athenæum at Amsterdam, where he had Tollius and Wyttenbach for his instructors, and where, in 1780, he gave proofs of his learning and acquirements, by a dissertation on Terence, and another on the Stoic philosopher Musonius. After attending Reinkenius's lectures at Leyden, he became 'candidate' of philosophy, and so distinguished himself, that in 1787 the post of rector-master at the school of Utrecht was offered him. In the following year he increased his fame by the publication of some of his poetical pieces, including that entitled 'Orion,' one of his noblest productions. In these, and his subsequent poems, there are abundant marks of real genius and originality, striking thoughts and ideas expressed with great power of language. Their chief defect is, that many of them possess little interest of subject, being of the class denominated 'occasional poems,' and therefore charm only by their beauties of execution. But as his translations from Anacreon are unrivalled for their sprightliness and elegance, so is his elegy on the death of his wife for its simple and touching pathos: and if their mere beauties of style can reconcile us to the insipidity and tediousness of Petrarch's amatory strains, that poem may be allowed to charm, though written not by an Italian, but a Dutchman, and though inspired, not by a fanciful platonic passion, but by so homely and old-fashioned a feeling as sincere conjugal affection. His poems, and those of Bellamy, produced a wholesome change in that species of writing: full of feeling and thought, they showed themselves eminently superior to the correct but mechanical and spiritless productions then generally received as poetry.

* He was born 1746, died 1803. He made himself first known by his poem 'De Eigenhaat' (Interest), and he began a selection from Lavater's writings, and an edition of Vondel's works, but neither of them was completed. Jeronimo, the other brother, and by far the more celebrated of the two, was also the scholar, being born at Amsterdam in 1740. As a classical scholar, as a writer of Latin poetry, and as an original critic, he stood high in the learned world. He died in 1811.

Nieuwland's high poetical talent was the more remarkable because combined with other talents which have generally been considered incompatible with an ardent imagination. In conjunction with Van Swinden he published a nautical almanac; and also wrote a treatise (1787) on the means of ascertaining the longitude at sea, which has been frequently reprinted. Besides this he had begun a work on navigation, of which only the first volume appeared (1792), his death preventing him from completing it. An account of his other scientific and philosophical writings may be found in his Elogé by Van Swinden. It is related of him that he possessed such quickness of apprehension as to be able to make himself master of the contents of any work by merely running over its pages. That he possessed very extraordinary mental powers and rapidity of apprehension admits of no doubt, when the extent of his studies and attainments is compared with the shortness of his life and the variety of his avocations. In 1789 he was lecturer in navigation and natural philosophy at Amsterdam; in 1792 he became head teacher at Leyden, in the mathematical and physical sciences; and in 1793 professor of mathematics, physics, architecture, hydraulics, and astronomy. He died on the 14th of November, 1794, about eight months after the death of his wife and child.

NIEVRE, a department of central France, bounded on the north and north-east by that of Yonne, on the east by that of Côte d'Or, on the south-east by that of Saône et Loire, on the south by that of Allier, on the west by that of Cher, and at the north-west extremity, for a short distance, by that of Loiret. The greatest length of this department is from the north-west, on the bank of the Loire below Neuvy, to south-east, near the banks of the Tannay, 73 miles; the greatest breadth, at right angles to the length, is from the bank of the Allier, near St. Pierre-le-Moutier, to the village of St. Agnant, near Saulieu (Côte d'Or), 65 miles. The area is calculated at 2637 square miles: the population, in 1831, was 282,521; in 1836, 297,550, showing an increase in five years of 15,029 persons, or more than 5 per cent., and giving rather more than 113 inhabitants to a square mile. In size it is above the average of the French departments; but in amount and density of population, considerably below the average. It may be compared in area with the English county of Devon, which however it rather exceeds: in amount of population it falls very far below Devonshire, and scarcely equals the much smaller county of Suffolk. In density of population it falls below any English county except Cumberland and Westmoreland. Nevers, the capital, is in 47° 0' N. lat. and 3° 10' E. long., 133 miles in a direct line south by east of Paris, or 140 miles by the road through Fontainebleau, Montargis, and Cosne.

The heights which separate the basin of the Loire from that of the Seine traverse the department from north-west to south-east: in the south-east part they are called the mountains of Morvan, being included in the district of that name, which comprehends the eastern side of the department. [MORVAN.] This eastern portion of the department is the more rugged portion, and consists chiefly or wholly of primitive rocks, granitic or schistose; the western part is covered by beds of the secondary strata, which intervene between the red marl and the chalk: the valleys of the Allier and the Loire, in the southern extremity of the department, and the valley of the Loire, in the north-western extremity, are occupied by the supracretaceous formations.

There are quarries of granite and marble, and of sandstone suitable for grindstones: yellow-ochre and potters' clay are also procured, but the chief mineral treasures of the department are iron and coal. The department is the seventh in the order of productiveness in coal, the quantity of which raised in 1834 was 27,055 tons, and, in 1835, 30,162 tons. This quantity was raised from one pit, in connexion with which (in 1834) 400 labourers were employed, viz. 292 in the pit, and 108 without it. There were in the same year 84 iron-works, in which were 26 furnaces for making pig-iron, 153 forges for producing wrought-iron, and 71 forges for producing steel. Charcoal was the fuel chiefly used, but coal was also employed.

The principal rivers are the Loire, the Allier, and the Yonne. The Loire enters the department on the south side, and flows about 34 miles north-west by Décise and Nevers to the junction of the Allier, on the western border, a little below Nevers, and from thence along the border of the department 44 miles to below Neuvy; in all 78 miles.

The Allier has no part of its course within the department, but flows for about 24 miles along the south-western and western borders, until its junction with the Loire. These two rivers are navigable throughout that part of their course which appertains to this department. The Yonne (a feeder of the Seine) rises in the mountains of Morvan, near Château Chinon, and flows north-north-west by Château Chinon, Corbigny, Tannay, and Clamécy, into the department of Yonne. Its course in this department may be estimated at 56 or 58 miles: it is not navigable.

The other rivers are all small, and are tributaries of the more important streams above mentioned. The Tannay (15 miles long), the Avron (about 40 miles long), the Accolin (32 miles long), the Nièvre (25 miles long), and the Nohain (25 miles long), join the Loire; the Bayes, the Tannay, the Vandouësse, the Halene, the Canne, and the Landrage, join the Avron. The Cure (which has a course of 50 miles, but only part of it in this department), the Oussière, the Angnison, and the Beuvron (20 miles long), flow into the Yonne; the Chalaux flows into the Cure, and the Soray into the Beuvron.

There are several lakes or pools, but none are very large. The principal are that of Entrains, near the head of the Nohain (5 miles long, 1 or 2 miles broad), and those at the heads of the Avron and the Bayes, in the centre of the department.

The canals are, the canal lateral to the Loire from Digoin (Saône et Loire) to Briare (Loiret), of which about 36 miles are in this department; and the Nivernais Canal, extending from the Loire, at the junction of the Avron, to the Yonne below Corbigny, and thence by the channel of the Yonne to Auxerre. It is carried from the valley of the Avron to that of the Yonne by a tunnel through the intervening mountain-ridge. About 77 miles of this canal are in the department of Nièvre.

There were, in 1836, eight government roads in the department, having an aggregate length of 257 miles, namely, 214 in good repair, 17 out of repair, and 26 unfinished. The principal road is that from Paris to Lyon, which passes by Neuvy, Cosne, Pouilly, Meves, La Charité, and Nevers, all on the right bank of the Loire: from Nevers the road follows the valley of the Allier by St. Pierre le Moutier to Moulins, in the department of Allier. The road from Bourges (Cher) to Auxerre (Yonne), which crosses the Loire by the bridge at La Charité, passes through La Charité, Varzy, and Clamécy, from whence another road branches to Avallon. The road from Nevers to Auxerre passes through Premery and Montenoison, to Clamécy, where it unites with the road from Bourges. Other roads from Nevers pass, one by Château Chinon to Autun and Châlons-sur-Saône, both in the department of Saône et Loire; and the other along the valley of the Loire by Décise to Charolles and Mâcon, also in the department of Saône et Loire. The departmental roads had an aggregate length of 305 miles, of which 181 were in good repair, 2 out of repair, and 122 unfinished. The aggregate length of the bye-roads, paths, &c., amounted to 2400 miles.

The surface of the department is estimated at nearly 1,700,000 acres, of which nearly 730,000 acres are under the plough. The produce in grain is considerably below the average of France, but, from the smallness of the population, it is (combined with the growth of potatoes) sufficient for the supply of the inhabitants. The corn-land is chiefly in the western part of the department, in the valley of the Loire. The principal crop is wheat, then follow rye, with maslin or mixed corn, then oats, then barley; all these are grown to a considerable extent. The quantity of buckwheat and maize grown is but trifling, especially of buckwheat. The quantity of potatoes is considerably above the average of France, and some hemp is raised. The extent of grass-land is considerable: the meadows and other grass enclosures amount to between 160,000 and 170,000 acres, and the commons and open pasture-grounds to about 38,000 acres. The number of oxen is nearly twice the average of the French departments; they are bred here for the supply of the Paris market. The number of cows is rather below the average of the departments, unless regarded with reference to the population, when it rises considerably above the average. The number of heifers is above the average however estimated. The elevated plains of Morvan constitute the chief grazing-land. Sheep are not numerous; neither are they of good breed, though daily improvements are introduced. The long-wooled English sheep have been

naturalised in the department. The number of horses is below the average of France, even when estimated relatively to the population. Oxen are employed in the labours of the field. There is a government establishment of stallions at Corbigny. Game is abundant in the department, the streams and lakes abound in fish, and a few truffles are found.

The vineyards occupy about 24,000 acres, little more than half the average extent of the vineyards of the French departments; they are however very productive, but the wine is only of ordinary quality, except the white wine of Pouilly on the Loire, which is in good estimation. The woodlands occupy above a third of the department, chiefly in the district of Morvan. The timber is excellent, and consists chiefly of oak, hornbeam, and beech. There are abundance of wild cherry-trees, the fruit of which might be made to yield an excellent Kirschwasser. A considerable portion of the supply of firewood for Paris comes from this district: the wood is made up into large bundles or 'trains,' by twisting the branches without rope or other fastening. In this way it is floated down the Yonne, the affluents of which are pent up or opened so as to furnish just the supply of water requisite for the transit of these floating bundles, which as they descend the Yonne and the stream becomes wider are augmented by fresh accessions.

The department is divided into four arrondissements, as follows:—

		Area in sq. Miles.	Population in 1831.	Population in 1836.	No. of Communes.
Nevers,	S.W.	875	86,847	94,382	99
Château Chinon, E.		650	58,443	61,837	58
Clamécy,	N.	570	70,381	72,334	95
Cosne,	N.W.	542	66,850	68,997	65
		2637	282,521	297,550	317

It is divided into 25 cantons or districts, each under a justice of the peace.

In the arrondissement of Nevers are—the towns of Nevers (population in 1836, 16,967) [NEVERS], Décise or Décize (pop. 2154 town, 3068 whole commune), and Pougues, all on the Loire; St. Saulge, near the head of the Canne; St. Pierre le Moutier (pop. 1545 town, 2110 whole commune) and Dorne, between the Loire and the Allier; and La Ferté Langeron, on the Allier. At La Machine near Décise are the great coal-works of the department already noticed. There are also glass-works in this neighbourhood. Pougues is a neat little place of 500 or 600 inhabitants, situated in a pleasant valley. About half a mile from the town is a mineral spring, the waters of which are of good repute in the district, and are said to resemble those of Spa in Germany. They were at one time more famous, and are said to have been visited by Henri III. of France (A.D. 1586). St. Pierre le Moutier owes its origin to the Cluniac monks, who had a monastery here up to the time of the Revolution. There is a large piece of water in the town, which contributes to its embellishment, but is considered to diminish the salubrity of the air. Guerigny, a village on the Nièvre, 7 or 8 miles north of Nevers, has large iron-works, noticed elsewhere. [NEVERS.] At the village of Fourchambault on the Loire are large iron-works, which, with their branch establishments in this and the neighbouring departments, furnish employment to more than 2000 men. Steam-power is employed, and the iron is wrought by cylinders or rollers, not hammers. (Dupin, *Forces Productives, &c., de la France*.) Wood and coal (partly converted into coke) are used at these works. There are other iron-works scarcely less important at Imphy, another village on the Loire, 5 or 6 miles above Nevers; at the village of Pont St. Ours on the Nièvre, 2 or 3 miles from Nevers; and at Raveau near La Charité on the Loire. At Pont St. Ours women are employed in some part of the work. There are other iron-works at Bezes and Uxloup in this arrondissement.

In the arrondissement of Château Chinon are—Château Chinon (pop. in 1831, 2466 for the town, or 3865 for the whole commune; in 1836, 2775 for the commune), on the Yonne; Moulins-en-Gilbert, on a branch of the Avron; Luzy, on the Halene; and La Roche Millay, on a small foeder of the Halene. Château Chinon is the chief town of the district of Morvan: it is situated on a hill, commanded by wooded hills of greater elevation in the immediate neighbourhood. The principal trade carried on is in wood, charcoal, and cattle. The other towns of the arrondissement are unimportant. At the village of Vandeleuse

are considerable iron-works, which in 1827 gave employment to about 60 workmen.

In the arrondissement of Clamécy are—Clamécy (pop. in 1831, 4926 town, 5539 whole commune; in 1836, 5539 for the commune) [CLAMÉCY], Tannay, and Morecaux, on the Yonne; Corbigny (pop. 1692 town, 2077 whole commune), on the Angnison; Corval and Varzy (pop. 1751 town, 2909 whole commune), on branches of the Soray; Entrains, near the head of the Nohain; St. Reverien, near the head of the Beuvron; and Lormes (pop. 1634 town, 2750 whole commune), between the Yonne and the Cure. At Corbigny is a government stud: at Corval, or Corvolle, is a paper-mill on the most approved principles, and at Varzy a considerable manufacture of linen. The other towns are unimportant.

In the arrondissement of Cosne are—Cosne, or Cône (pop. in 1831, 5123 town, 5987 whole commune; in 1836, 6212 commune) [COSNE], Neuvy, Pouilly (pop. 1821 town, 3071 whole commune), Meves, and La Charité (pop. 4480 town, 5086 whole commune) [CHARITÉ, LA], on the Loire; St. Amand, on the Vrille; St. Vrain, on a small stream flowing into the Vrille; Donzy (pop. 1879 town, 3566 whole commune), on the Nohain; Champlemy, near the head of one branch of the Nièvre; and Montenoison and Prémery, on the other branch of the Nièvre. Some geographers have considered Neuvy to be the Noviodunum of Cæsar's 'Commentaries,' a position which we have followed D'Anville in fixing at Nevers. Pouilly is a handsome town in a district which produces a heady wine, compared, but without reason, with Chablis. There are iron-works at Meves on the Loire, at Prémery, at Donzy, and at two or three villages round La Charité. Round St. Amand are a number of potteries, at which a coarse ware is made from sandstone, and exported to Nantes and Paris.

The population, when not otherwise distinguished, is that of the whole commune: we have followed the census of 1831.

The department of Nièvre is under the jurisdiction of the Cour Royale of Bourges, and in the circuit of the Académie Universitaire of the same city. In respect of education it is one of the most backward of the French departments; the number of those who could read and write, of the young men enrolled in the military census of 1828-29, was only 20 in every 100; little more than half the average number in France. The department constitutes the diocese of Nevers, the bishop of which is a suffragan of the archbishop of Sens and Auxerre: it is included in the fifteenth military division, the head-quarters of which are at Bourges; and sends four deputies to the chamber.

In the earliest period of the history of France the department was occupied by the Ædui, except a small portion in the north-west and north, which was included in the dominions of the Senones. These were both Celtic nations. The tract between the Ligeris (Loire) and the Elaver (Allier) was allotted to the Boii, when the latter settled in the territories of the Ædui. (Cæs. *De Bel. Gal.*, lib. i.) The Yonne was known to the Romans by the name Icauna. There were several Celtic or Roman towns within the limits of the department: Noviodunum, or Nivernum, or Nevirnum, now Nevers; Massava, now Meves, formerly written Mesves; Condate, now Cosne; and Decetia, now Decise, all on the Loire; and Alisincum, now Anizi, a village near Moulins-en-Gilbert. Massava and Condate belonged to the Senones, the other towns to the Ædui. The territories of the Ædui were included in the Roman province of Lugdunensis Prima; those of the Senones in Lugdunensis Quarta. On the downfall of the Roman empire, the department fell successively into the hands of the Burgundians and the Franks. In the middle ages it constituted for the most part the county, afterwards duchy, of Nevers; and previous to the French revolution formed the province or military government of Le Nivernois or Nivernais.

NIGER, or rather NIGIR, a name which has been given till lately to a large river mentioned by ancient as well as modern geographers as flowing through the interior of Libya or Central Africa. Herodotus (ii. 32) gives an interesting account of five young men of the Libyan tribe of Nasamones, which dwelt on the coast of the Greater Syrtis, who proceeded on a journey of discovery into the interior. After traversing in a southern direction the inhabited region, and next to it the country of the wild beasts, they crossed the great sandy desert in a western direction for many days, until they arrived at a country inhabited by men of low

stature, who conducted them through extensive marshes to a city built on a great river which contained crocodiles and flowed towards the rising sun. This information Herodotus derived from the Greeks of Cyrene, who had it from Etearchus, king of the Ammonii, who said that the river in question was a branch of the Egyptian Nile, an opinion in which the historian acquiesced.

Strabo seems to have known little of the interior of Africa and its rivers: he cites the opposite testimonies of Posidonius and Artemidorus, the former of whom said that the rivers of Libya were few and small, while the latter stated that they were large and numerous (p. 830).

Pliny (*Hist. Nat.*, v. 1) gives an account of the expedition into Mauritania of the Roman commander Suetonius Paulinus, who (A.D. 41) led a Roman army across the Atlas, and, after passing a desert of black sand and burnt rocks, arrived at a river called Ger, in some MSS. Niger, near which lived the Canarii, next to whom were the Perorsi, an Ethiopian tribe; and farther inland were the Pharusii, as Pliny states above in the same chapter. The Canarii inhabited the country now called Sus, in the southern part of the empire of Morocco, near Cape Nun, and opposite the Fortunate or Canary Islands; and the Perorsi dwelt to the south of them along the sea-coast. The Ger, or Niger, of Suetonius Paulinus, which he met after crossing the Atlas, must have been one of the streams which flow from the southern side of the great Atlas through the country of Taflelt, and which lose themselves in the southern desert. One of these streams is still called Ghir, and runs through Sejelmesa. (Grüberg's *Marocco*.) Ger or Gir seems to be an old generic African appellation for river. As for the desert which Suetonius crossed before he arrived at the Ger, it could evidently not be the great desert, which spread far to the south of the Canarii, but one of the desert tracts which lay immediately south of the Atlas. Caillié describes the inhabited parts of Draha, Taflelt, and Sejelmesa as consisting of valleys and small plains, enclosed by sterile and rocky tracts of desert country.

But besides the Ger, or Niger, of Suetonius, Pliny in several places (v. 8, 9, and viii. 21) speaks of another apparently distinct river, the Nigris of Ethiopia, which he compares with the Nile, 'swelling at the same seasons, having similar animals living in its waters, and, like the Nile, producing the calamus and the papyrus.' In his extremely confused account, which he derived from the authority of king Juba II. of Mauritania, he mixes up the Nigris and the Nile together with other rivers, as if all the waters of Central Africa formed but one water-course, which seems to have been a very prevalent notion of old. He says (v. 9) that the Nile had its origin in a mountain of Lower Mauritania, not far from the ocean; that it flowed through sandy deserts, in which it was concealed for several days; that it reappeared in a great lake in Mauritania Cæsariensis, was again hidden for twenty days in deserts, and then rose again in the sources of the Nigris, which river, separating Africa (meaning Northern Africa) from Ethiopia, flowed through the middle of Ethiopia, and became the branch of the Nile called Astapus. The same story, though without any mention of the Nigris, is alluded to by Vitruvius, Strabo, and others, and Mela (iii. 9) adds that the river at its source was called Daras, which is still the name of a river that flows along the eastern side of the southern chain of the Atlas of Morocco and through the province of the same name which lies west of Taflelt, and is nominally subject to Morocco. The Dara or Draha has a southern course towards the desert, but its termination is unknown. There is another river, the Akassa, called also Wadi Nun, on the west side of the Adrar ridge or southern Atlas, which flows through the country of Sus in a western direction, enters the sea south of Cape Nun, and seems to correspond to the Daras or Daratus of Ptolemy. It has been supposed that the Dara and the Akassa were one river, but the Adrar ridge seems to lie between the two.

Throughout all these confused notions of the hydrography of interior Africa entertained by the ancients, one constant report or tradition is apparent, namely, that of the existence of a large river south of the great desert, and flowing towards the east. It is true that Herodotus, Strabo, Pliny, and their respective authorities thought that this river flowed into the Nile, but Mela seems to have doubted this, for he says that when the river reached the middle of the continent, it was not known what became of it.

Ptolemy, who wrote later than the preceding geographers,

and seems to have had better information concerning the interior of Africa, after stating that 'Libya Interior is bounded on the north by the two Mauritanias, and by Africa and Cyrenais; on the east by Marmarica and by the Ethiopia which lies south of Egypt; on the south by Interior Ethiopia, in which is the country of Agisymba, and on the west by the Western Ocean from the Hesperian gulf to the frontier of Mauritania Tingitana,' proceeds to enumerate various positions on the coast of the ocean, after which he mentions the chief mountains of Libya and the streams which flow from them to the sea. He then adds, 'In the interior the two greatest rivers are the Geir and the Nigeir; the Geir unites Mount Usargula (which he places in 20° 20' N. lat. and 33° E. long.) with the Garamantic pharax (the name of a mountain which he has stated above to be in 10° N. lat. and 50° E. long.). A river diverges from it at 42° E. long. and 16° N. lat., and makes the lake Chelonides, of which the middle is in 49° E. long. and 20° N. lat. This river is said to be lost under ground and to reappear, forming another river, of which the western end is at 46° E. long. and 16° N. lat. The eastern part of the river forms the lake Nuba, the site of which is 50° E. long. and 15° N. lat.' The positions here assigned to the Geir and the direction of its main stream, from the Garamantic mountain to Mount Usargula, being south-east and north-west, seem to point out for its representative either the Shary of Bornou and its supposed affluent the Bahr Kulla of Browne, or perhaps the Bahr Misselad of the same traveller, called Om Teymam by Burckhardt, who says that an indigenous appellation is Gir, a large stream coming from about 10° N. lat., and flowing north-west through Wadai, west of the borders of Dar-Fur. The Misselad is supposed to flow into lake Fittre; we do not know whether any communication exists between lake Fittre and the Tschad. In fact it appears that several streams, besides the Bahr Kulla and the Bahr Misselad, all coming from the great southern range, or Mountains of the Moon, flow in a north-west direction through the countries lying between Bornou and Dar-Fur, and the Geir of Ptolemy may have been the representative of any or all of them. Liguant was informed by some Takrousi pilgrims from Dar-Sille that they travelled two months on the Bahr al Abiad before they arrived at Sennaar; and that before arriving at the Abiad they followed the course of another river upwards; and that the Abiad had its rise in a country called Bahr el Losse, from which some of the waters flow towards Marok, that is to say, to the north-west.

We now come to Ptolemy's Nigeir, a name which, having been mistaken for the Latin word Niger, has added to the confusion on the subject. Nigeir is a compound of the general appellation of Geir or Gir, which is found applied to several rivers in various parts of Africa, and the prefix Ni or N', which is found in several names of the same region reported by Denham and Caillié. Ptolemy makes the Nigeir quite a distinct river from the Geir, and places it to the westward. He says that it joins the mountain Mandrus, 19° N. lat. and 14° E. long., with the mountain Thala, 10° N. lat. and 38° E. long. Its course is thereby defined as much longer and in a less oblique line to the equator than the Geir. In fact it would correspond tolerably well—allowing for the imperfection of the means of observation in ancient times—with the actual direction of the course of the Joliba and that of the river of Sakkatoo, supposing that river to form a communication with lake Tschad, as Ptolemy says that the Nigeir has a divergent to the lake Libye, which he places in 16° 30' N. lat. and 35° E. long., and the words of the text seem to express that the water ran into the lake, so that the course of the Nigeir, according to Ptolemy, as well as his predecessors, was easterly, as the Joliba or Quorra actually runs for a great part of its course. 'The lake Libye,' observes a distinguished geographer, 'to which there was an easterly divergent, I strongly suspect to have been the lake Tschad, notwithstanding that the position of Libye falls 300 geographical miles north-westward of this lake, for the name of Libye favours the presumption that it was the principal lake in the interior of Libya; it was very natural that Ptolemy, like many of the moderns, should have been misinformed as to the communication of the river with that lake, and that he should have mistaken two rivers flowing from the same ridge in opposite directions, one to the Quorra and the other to the Tschad (I allude to the Sakkatoo and the You rivers), for a single communication from the Quorra

to the lake.' (Leake's paper 'On the Quorra and Niger,' in the second volume of the *Journal of the Royal Geographical Society of London*, 1832, with map at the end of the volume illustrating the subject.)

But Ptolemy, after all, may not have been so much misinformed with respect to a communication existing between the lake and his Nigeir, if, as is now strongly suspected, the communication really exists, though in an inverse direction from that which Ptolemy appears to have understood. It is surmised that the river Tschadda, which, at its junction with the Quorra, just above the beginning of the delta, is larger than the Quorra itself, receives an outlet from the lake somewhere about the town of Jacobah. (Captain W. Allen, R.N., *On a New Construction of a Map of a Portion of Western Africa, showing the possibility of the Rivers Yeu and Chadda being the Outlet of the Lake Chad*, in vol. viii. of the *Journal of the Geographical Society of London*, 1838; and also the *Map of West Africa*, No. 11, published by the Society for the Diffusion of Useful Knowledge.) If this surmise prove true, it would explain the statement of the Arabian geographers of the middle ages, Edrisi, Abulfeda, and Leo Africanus, who state that the Nil el Abid, or river of the negroes, flowed from east to west. The Tschadda then would be the river of the Arabian, and the Joliba, or Upper Quorra, that of the Greek and Roman geographers. Both were ignorant of the real termination of their respective streams. It is nevertheless remarkable that the distance laid by Ptolemy between his source of the river and the western coast is the same as that given by modern observations; that Thamoudocana, one of the towns on the Nigeir, is exactly coincident with Timbuktu, as recently laid down by M. Jomard from the itinerary of M. Caillié; that the length of the course resulting from Ptolemy's positions is nearly equal to that of the Quorra as far as the mountains of Kong, with the addition of the Tschadda or Shary of Funda, and that his position of Mount Thala, at the south-east extremity of the Nigeir, is very near that in which we may suppose the Tschadda to have its origin; so that it would seem as if Ptolemy, like Sultan Bello and other modern Africans, had considered the Tschadda as a continuation of the main river, though he knew the Egyptian Nile too well to fall into the modern error of supposing the Nigeir to be a branch of the Nile. The mountains of Kong, and the passage of the river through them at right angles to their direction, formed a natural termination to the extent of the geographer's knowledge, in like manner as among ourselves the presumed, and at length the ascertained existence of those mountains, has been the chief obstacle to a belief that the river terminated in the Atlantic.' (Leake's Paper already quoted.)

The opinions established by the Arabian geographers of the middle ages of the Niger flowing westward, led Europeans to look for its estuary in the Senegal, Gambia, and Rio Grande; but upon examination of those rivers the mistake was ascertained; and D'Anville and other geographers separated the course of the Senegal from that of the Niger, and of the latter from that of the Nile. Mungo Park was the first European who saw the great internal river of Soudan flowing towards the east, and called Joliba. He traced it in two different journeys, from Bamnakoo, about ten days from its source, to Boussa, where he was unfortunately killed in 1806. Clapperton crossed the river at Boussa, on his second journey to Sakkatoe in 1826; and after his death his faithful servant Richard Lander undertook to navigate the river from Boussa to its mouth. In 1827 he proceeded from Badagry, on the coast, to Boussa, and there embarked on the river; found that it flowed in a southern direction, receiving several large rivers from the east; among others the noble Tschadda, after which the united stream passed through an opening in the Kong chain, and that after issuing from the mountains it sent off several branches both east and west towards the coast, while he himself reached the sea by the branch known till then by the name of Rio Nun.

A fuller description of the river and its banks is given under QUORRA, the object of the present article being only to elucidate the historical question whether the great river of the Libya of Herodotus, the Nigrit of Ptolemy, the Nigeir of Ptolemy, and the Niger of modern geographers, be one and the same river with the Quorra. M. Walckenaer (*Recherches Géographiques sur l'Intérieur de l'Afrique Septentrionale*) has maintained the negative side of the question, asserting that the ancients had no

knowledge of Soudan, and that the Nigeir of Ptolemy was one of the rivers flowing from the Atlas. But Col. Leake has ably answered him and supported the affirmative in the paper above quoted.

NIGER, CAIUS PESCE'NNIUS, appears to have been of humble origin; but his great military talents recommended him successively to the notice of Marcus Aurelius, Commodus, and Pertinax, by whom he was employed in offices of trust and honour. He was consul together with Septimius Severus, and obtained the government of Syria.

On the murder of Pertinax, A.D. 193, the empire was exposed for sale by the Prætorian guards, and was purchased by Didius Julianus, whom the senate was compelled to acknowledge as emperor. The people however did not tamely submit to this indignity; and three generals, at the head of their respective legions, Septimius Severus, who commanded in Pannonia, Clodius Albinus, in Britain, and Pescennius Niger, in Syria, refused to acknowledge the nomination of the Prætorians, and each claimed the empire. Of these, Niger was the most popular, and his cause was warmly espoused by all the provinces of the East. But he did not possess the energy and activity of his rival Severus. Instead of hastening to Italy, where his presence was indispensable, he quietly remained at Antioch, while Severus marched to Rome, dethroned Didius, and made active preparations for prosecuting the war against him in Asia. Roused at length from his inactivity, Niger crossed over to Europe and established his head-quarters at Byzantium; but he had scarcely arrived at this place, before his troops in Asia were defeated near Cyzicus by the generals of Severus. He was soon however able to collect another army, which he commanded in person; but being defeated successively near Nicæa and at Issus, he abandoned his troops, and fled towards the Euphrates with the intention of seeking refuge among the Parthians. But before he could reach the Euphrates, he was overtaken by a detachment of the enemy, and put to death on the spot.

(Herodian, b. ii.; Spartianus; *Life of Pescennius Niger*; Aurelius Victor, *De Cæsaribus*, c. 20; Eutropius, viii. 10; Dion, *Epitome*, b. 73, 74.)

Coin of Niger.

NIGHT-JARS, the English name of those Night-Swallows vernacularly termed Goat-suckers; whence the name *Caprimulgus*, by which the family is generally known among ornithologists. Mr. Reunie changes the name of the European Night-Jar to *Nyctichelidon* (Night-Swallow), objecting that the name *Goat-sucker*, which it has received in all languages, and which, he thinks, has been most absurdly continued by systematic naturalists in the term *Caprimulgus*, shows the opinion of it entertained by the vulgar. Now we cannot admit this great absurdity though we entirely agree with Mr. Reunie that 'it is as impossible for the Night-Jar to suck the teats of cattle (though most birds are fond of milk), as it is for cats to suck the breath from sleeping infants, of which they are popularly accused.' If every zoological name that has not a sure foundation were to be changed, there would be no small alteration in nomenclature and not a little confusion; as it is, the perpetual change of names is quite sufficiently perplexing. Nor are we at all sure that such names as *Caprimulgus* are not of some value as showing, in connexion with a true history of the habits of the bird, how the errors and superstitions of old times have vanished before the light of modern investigation. Thus much as an apology for not changing the family name *Caprimulgus*.

Mr. Vigors remarks that when we search among the *Perchers* for that point where they approximate the *Oiols*, we at once light upon a group, the *Caprimulgus* of Linnæus, whose general appearance and habits point out the affinity. 'The nocturnal and predatory manners of this genus,' says Mr. Vigors, 'the hawking flight, the legs feathered to the talons, the large ears and eyes, the very disk that surrounds the face, and the pectination of the external quill-feathers, observable in some of the species, the general softness of the plumage, together with its peculiarly striking colour and

markings, produce a similarity between it and the *Strix* that has attracted the eye of the common observer no less than the naturalist. The provincial names of this genus have generally a reference to this resemblance; while the earlier scientific describers of the different species have for the most part ranked them with the owls. I know not whether the singular character observable in some of the species of this family, the serrated nail of the middle toe, may not be cited as an additional proof of their approach to the *Birds of Prey*. The strong toes of the latter are lost in *Caprimulgus*: but a construction of similar import (for the serration of the nail appears capable of being applied to the purposes of seizure only), preserves, though faintly, the resemblance. May we not almost venture to affirm that this apparently trivial appendage is an instance of that beautiful shading by which nature softens down the extremes of her neighbouring groups—one of those minute and delicate touches by which she marks at once an affinity and a deviation? But while we may discern at a glance the general approximation of these two families, we must at the same time acknowledge that they stand in need of an intermediate link to give them a closer connection. The weakness of the bill and of the legs and feet of the *Caprimulgus* still keeps it at some distance from the *Owls*, in which the same members are comparatively strong; while the wide gape of its mouth serves to divide the families still further. A connecting link has been however supplied by an Australian group, the *Podargus* of M. Cuvier, which harmonises these discrepant characters. We have an opportunity of observing among the specimens in the collection of the Linnean Society, how far the bill of this extraordinary genus combines the different forms of that of the two genera, and how far the legs, still maintaining the characteristics of *Caprimulgus*, such as the unequal length of the toes, are related to those of *Strix* by their superior robustness. Here indeed there is a beautiful gradation of affinities. All the front toes of *Caprimulgus* are united by a connecting membrane as far as to the first joint; those of *Strix* are divided to the origin; while those of *Podargus* partake of the characters of both, in having the middle toe connected with the outer, but divided from the inner. Again, as I have already remarked, *Caprimulgus* has the nail of the middle toe dilated and serrated: *Strix* has it, generally speaking, undilated and entire at the margin; but in *Podargus* the same part displays the singular dilatation of the one and the marginal integrity of the other. It is difficult to say to which of these groups it comes nearest, until further and more accurate accounts than we at present possess of its food and economy may determine its actual situation. At present it remains osculant between the two families, and may decidedly be pronounced the immediate passage from the *Birds of Prey* to the *Perchers*. Mr. Vigors adds in a note that he had latterly obtained accounts from actual observers of some of these *Podargi* in New Holland, stating their manners to be generally conformable to those of the *Caprimulgi*.

Mr. Vigors further observes that the union between the two families of *Caprimulgidae* and *Hirundinidae* in the most essential particulars, in the habits, economy, and general conformation, is too evident to the common observer, and too universally acknowledged by scientific writers, to need any further illustration. But he remarks that it is gratifying to observe, how, even in minute particulars, a gradual succession of affinities imperceptibly smooths the passage between conterminous groups; nor does he pass over without remark the circumstance of the hind toe of *Caprimulgus* being usually retractile, which enables it to place all its toes in front, in a similar position to that which they maintain in *Cypselus*, where the family of the *Hirundinidae* terminates. He notices also the conformation of the tail in the two families as showing a similar affinity, observing that some species of *Caprimulgus*, then lately arrived from Brazil, exhibit the forked tail of *Hirundo*, one of which, indeed, the *C. psalurus* of Temminck, has this character developed to an almost disproportionate degree. 'Leaving those typical families,' continues Mr. Vigors, 'with the short bill, and taking a general survey of the tribe, we may perceive that the *Caprimulgidae* unite themselves to the longer-billed families, by means of the Linnean *Todi*, which preserve the broad base of the bill of the latter, but lead on, by comparative length of that member, to the succeeding family of *Halcyonidae*. If we compare the bill of the type of the last-mentioned genus, the *Todus viridis*, Linn.

[*MUSCICAPIDÆ*, ante, p. 14], with those of *Caprimulgus* and *Halcyon* [*KINGFISHERS*, vol. xiii., p. 228], we shall perceive that it stands exactly midway between them in the relative proportions of strength and breadth which it bears to each. In the length also of the tail, an important character in the groups that feed on the wing, it maintains a middle station between them.' For the group which forms the immediate connection between the present family of *Todidae* and the preceding *Caprimulgidae*, Mr. Vigors observes that we are indebted to Dr. Horsfield, since in the depressed and broad-based bill and wide gape of *Eurylaimus* we recognise the characters which unite those families [*MUSCICAPIDÆ*, ante, pp. 15, 16], and Mr. Vigors refers to the valuable plates of the *Zoological Researches in Java*, as exhibiting the intimate approach of the bill of this latter genus to that of *Podargus Javanensis*. Near to *Eurylaimus*, which in the opinion of Mr. Vigors is united to *Todus* by some species now referred to the former genus, but which were originally included in the latter, he would place the genus *Eurystomus* of Vieillot [*MEROPIDÆ*, vol. xv., p. 118], which in the essential characters of the bill, and from all Mr. Vigors could ascertain of its general habits and economy, seems to him to bear a striking affinity to the present group. Here also the same considerations would incline him to arrange the *Calypomena* of Sir Stamford Raffles, which differs chiefly from the groups now mentioned in its comparatively shorter bill and the singular covering of plumes that project over the upper mandible. All these and some other corresponding genera will be found, Mr. Vigors makes no doubt, on more accurate knowledge of their economy, to belong either to the present family, which is placed at the extremity of the *Fissirostres*, or to that of *Pipridæ*, which forms, in the system of Mr. Vigors, one of the aberrant groups also of the neighbouring circle of *Dentirostres*, and thus comes in contact with the *Todidae*. Mr. Vigors admits that more extensive knowledge respecting these birds will determine the line of demarcation between them; but the general affinity by which they approach each other, at least, in continuous families, may at once, in his opinion, be decided without hesitation. ('On the Natural Affinities that connect the orders and families of Birds,' *Linn. Trans.*, vol. xv.)

Mr. Swainson (*Classification of Birds*) considers the order of *Fissirostres* to be best represented by the *Swallows* and *Goat-suckers*; observing at the same time, that the former are the most isolated; whilst the latter, above all other birds, show the nearest affinity to the owls. 'No species, indeed,' says Mr. Swainson, 'has been yet discovered which would perplex a naturalist to decide to which of these families it belonged, but that is not material; we do not uphold the injudicious theory that every one of nature's links is so perfect, or rather so well known, as to leave no unequal intervals in the series; on the contrary, we maintain that such interruptions are frequently found, and in this manner are the *Goat-suckers* detached by a slight interval from the *Owls*.' The same author remarks, that the *fissirostral* birds, as a whole, are peculiarly distinguished by having the powers of flight developed in the highest degree; all the energies of their nature, he observes, seem concentrated in this one perfection; for their feet are always very short, weak, and generally so imperfect as to be of use only to rest the body after flight; their food being exclusively insects captured upon the wing. 'To accomplish this,' proceeds Mr. Swainson, 'nature has given to their mouth an enormous width, by which, superadded to their amazing flight, and rapidity of movement, they are almost sure to capture their prey. Who that has watched the swallow or the goat-sucker, has failed to recognise these peculiar perfections? As the nocturnal goat-suckers frequently prey upon beetles and large moths, the mouth, in such species, is defended by stiff bristles; but these appendages are rendered unnecessary to the swallows; their game consisting entirely of those little soft insects seen in the air on a summer's evening or sporting on the flowers of a sunny field. The goat-suckers choose the twilight, and catch their food precisely in the same way, excepting, indeed, that their little short feet are sometimes used for the same purpose, a most singular part of their economy, first noticed by our countryman White. Some of these nocturnal birds (*Pogardus*,* Cuv.) have a bill nearly as strong as an owl's; others are furnished with forked tails of excessive length; and one species, discovered during our researches in Brazil (*Caprimulgus diurnus*, Temm.) quits the nocturnal habits of its

* *Podargus* must be meant.

congeners, and in cloudy days may be seen, in troops of fifteen or twenty, skimming over the surface of ponds, precisely in the manner of swallows. Mr. Swainson then remarks that the *Swallows* and the *Goat-suckers* are, in fact, connected by certain *Swifts*, for the *Balassian Swift* is described as a nocturnal bird, appearing at sunset and going to rest at sunrise; and thus he enters the family *Hirundinidae*. [SWALLOWS.]

The *Caprimulgidae*, according to Mr. Swainson's classification, consist of the following genera and subgenera. But it should be remembered that he states that he has thought it best not to attempt a natural arrangement, until the family is better understood.

Character of the Family.—Plumage lax, soft. Bill exceedingly small; gape enormous. Feet very short, weak; the hallux directed forwards. (Sw.)

Genus *Podargus*, Cuv.

Size large. The middle claw not serrated. The hallux not directed forward.

Subgenera, *Podargus* proper. Bill large, very strong; the tip and margins of the upper mandible folding over those of the lower. Culmen elevated and arched. True rictal bristles none. Tongue very thin, entire. Tarsus short. (Swainson.)

Several species of this subgenus have been found in New Holland; and we select as an example of these *Podargus humeralis*.

Description.—Variegated above with ashy brown and dirty yellow; head and sides of the back conspicuously striped with black; forehead and dorsal plumage lightly dotted and banded with white. Tessellated beneath with black stripes and approximating dirty yellow bands. Length of the body 20 inches, and of the tail 8½.

Mr. Vigors and Dr. Horsfield observe that the birds of this genus in the collection of the Linnean Society bear such a general resemblance to each other, that they felt some hesitation in describing them as different species. The careful examination of many individuals in their own country will, in the opinion of these zoologists, alone determine with certainty whether they are distinct or merely varieties of the same species from age or sex. They state however that Dr. Latham, as well as themselves, distinguished this as a species, under the name of the *Cold River Goat-sucker*, from the *Wedge-tailed Goat-sucker* (*Podargus Stanleyanus*). Mr. Swainson also cites it as a species.

Podargus humeralis.

Here we must notice an Asiatic example of P. C., No. 1095.

Podargus Javanensis of Horsfield, the *Chabba-wonna* of the Javanese.

Description.—General colour ferruginous or rufous, with a tint of isabella varied by undulated transverse bands of dark brown. A collar of pale whitish isabella, variegated with two very narrow bands of deep brown, passes round the lower part of the neck, and from this collar several large, irregular, white marks are disposed in an interrupted series from the axilla to the middle of the back; on the breast and belly several white feathers are scattered. The transverse bands are strongest on the rounded tail. Feet rufous; claws blackish; bill obscure yellow and rather shining; middle toe not dentated. Length 9 inches.

Habits.—Not known. It is nocturnal and conceals itself in large forests.

Podargus Javanensis.

The other two subgenera arranged by Mr. Swainson under the genus *Podargus* are *Aegothales*, Horsf. and Vigors, and *Nyctibius*, Vieill.

Mr. Allis has stated that the sclerotic ring of the great *Podargus* does not present the slightest appearance of distinct plates, being simply a bony ring.

M. Lesson is of opinion that *Steatornis* [GUACHARO BIRD] forms the passage between the *Caprimulgi* and the *Crows*.

Caprimulgus. (Linn.)

Bill remarkably small and weak; the sides inflexed and sometimes gaping. Tarsus short. All the toes directed forwards; the inner and outer toes equal; the middle claw pectinated. (Sw.)

Head and Foot of Goat-sucker (*Caprimulgus Europeanus*)
VOL. XVI.—21

Mr. Swainson subdivides the genus into the following Subgenera, *Caprimulgus*. Gape strongly bristled. Tail lengthened, rounded. Lateral toes equal. (Sw.)

We select as an example *Caprimulgus Europæus*.

Description: Male.—Plumage above and that of the throat ash-grey, thickly streaked and spotted with brown mostly of a yellowish tinge; head and neck with longitudinal blackish streaks; a white stripe beneath the base of the lower mandible extends along each side of the lower part of the head, and there is a central patch of white upon the throat; quills with the outer webs blotched with reddish-brown, and the three exterior feathers with a large white patch near the tips of the inner webs; tail irregularly marked and indistinctly barred with blackish-grey and yellowish-brown; the two external feathers on each side white at their termination. Plumage of the under parts yellowish-brown, with transverse blackish bars. Bill and irides dark brown; tarsi paler.

Female with the plumage of the male generally; but she wants the white spots on the quills and tail-feathers.

This is most probably the *αἰγοθήλας* (*Ægothēlas*, or Goat-sucker) of Aristotle and the Greeks, and the *Caprimulgus* of Pliny and the ancient Italians. There is indeed, as we shall presently see, another European species, but it is very rare. The *Caprimulgus Europæus* is the *Culcabotto Piataglione*, *Porta quaglie*, *Roccaccio*, and *Cova-terru* of the modern Italians; *Chotacubras* of the Spaniards; *Tettechevre*, *Engoulevent ordinaire*, and *Crapaud volant* of the French; *Milchsauger*, *Geissmilcher*, *Nacht Rabe*, *Nacht Schwalbe*, and *Tug-Schlüfer* of the Germans; *Natkrassu*, *Natskarra*, and *Quallknarren* of the 'Fauna Suecica'; *Nat-Ravn*, *Nat-Skade*, and *Aften-bakke* of Brunnich; *Muckenstecker* and *Nachtrabb* of Kramer; *Aderyn y droell*, *Rhodion* of the ancient British; and *Goat-sucker*, *Night-Jar*, *Jur-Owl*, *Churn-Owl*, *Fern-Owl*, *Dor-Hawk*, *Night-Hawk*, and *Wheet-Bird* of the modern British.

Caprimulgus Europæus.

The absurd story of the goat-sucking habits of this bird may be traced back as far as the time of Aristotle, and is probably of much older date. It has all the appearance of a deep-rooted popular prejudice, which was so extensively believed when that zoologist wrote, as to demand, in his opinion, insertion in his 'History of Animals.' In the ninth book of that history (c. xxx.), Aristotle says, 'The bird called *Ægothēlas* is a mountain-bird, a little larger than the blackbird (*κωρρίβου*) and a little less than the cuckoo. It lays eggs to the number of two or three at most, and is of a slothful nature (*βλαβερή*). Flying upon the goats, it sucks them (*θηλάζει δὲ τὰς αἰγὰς προσπετόμενος*), whence it has its name. They say that when it has sucked the teat it becomes dry, and that the goat becomes blind. It is not sharp-sighted by day: but it sees by night.' *Ælian's*

version of the effect of the bird's sucking is confined to the part sucked. He says that the operation makes the teat dry or blind (*τιμολοῖ μαθόν*), and so the flow of the milk is stopped. He speaks of the great audacity of the bird, observing that it is fearless of the vengeance of the goatherds (iii. 39). *Ælian* also refers to its goat-sucking propensity in c. 22 of book xvi. *Pliny* (*Nat. Hist.*, ix. 40) states that the '*Caprimulgi* are nocturnal thieves; for they cannot see by day (*interdiu enim visu carent*). They enter the folds (*stabula*), and fly to the udders of the goats in order to suck the milk, from which injury the udder dies away, and blindness falls upon the goats which have been so sucked.' Nor is the charge of goat-sucking the only false accusation made against the Night-Jar. *White* (*Selborne*) informs us that the country-people have a notion that the fern-owl, or churn-owl, or eve-jarr, which they also call a puckeridge, is very injurious to weanling calves, by inflicting, as it strikes at them, the fatal distemper known to cow-leeches by the name of puckeridge. 'Thus,' says *White*, 'does this harmless ill-fated bird fall under a double imputation, which it by no means deserves; in Italy, of sucking the teats of goats, whence it is called the *Caprimulgus*, and with us, of communicating a deadly disorder to the cattle. But the truth of the matter is, the malady is occasioned by the *æstrus bovis*, a dipterous insect, which lays its eggs along the chines of kine, where the maggots, when hatched, eat their way through the hide of the beast into the flesh, and grow to a very large size.' (*White's Selborne*.) *Belon*, in his folio edition (1555), gives no figure of this species, but appears to confound it with an Owl, '*L'Effraye* or *Fresaye*.' In the small 4to. '*Portraits d'Oyseaux*,' &c. (1557), a figure is given at the end of the Owls, which, though bad, cannot be mistaken for anything but the *Goat-sucker*, with the titles of '*Αἰγοθήλας*, *Strix Caprimulgus*, *Fur nocturnus*, *Effraye*, *Frezaye*,' with the following old quatrain:

'Le hideux cry de la Fresaye effraye
Celuy qui l'oit: elle vole de nuit,
Et à tetter les chevies prend deduit.
L'esbahis-tu s'elle se nomme Effraye ?'

Food, Habits, Reproduction, &c.—The food of the European Goat-sucker consists chiefly of night-flying and evening-flying moths and beetles, *Phalæna*, *Melolonthæ*, &c. In the stomach of one which *Willughby* opened were seeds as well as beetles. The Fern-chafar, *Melolontha solstitialis*, seems to be a favourite food, and hence the bird is frequently found in those neighbourhoods where fern abounds. It spends the summer in the temperate countries of Europe, but on the approach of winter retires to the south of the Mediterranean sea. Its arrival in these islands may be looked for from the middle of May to the end of that month, and its departure takes place towards the end of September or beginning of October. The earliest appearance of the bird in *White's Calendar* is dated on the 1st of May, and the latest on the 26th of that month. The last-named naturalist paid particular attention to the habits of this species. 'There is no bird, I believe,' writes that delightful observer, in a letter to *Pennant*, 'whose manners I have studied more than that of the *Caprimulgus* (the goat-sucker), as it is a wonderful and curious creature; but I have always found that though sometimes it may chatter as it flies, as I know it does, yet in general it utters its jarring note sitting on a bough; and I have for many an half-hour watched it as it sat with its under mandible quivering, and particularly this summer. It perches usually on a bare twig, with its head lower than its tail, in an attitude well expressed by your draughtsman in the folio *British Zoology*. This bird is most punctual in beginning its song exactly at the close of day; so exactly that I have known it strike up more than once or twice just at the report of the Portsmouth evening gun, which we can hear when the weather is still. It appears to me past all doubt that its notes are formed by organic impulse, by the powers of the parts of its windpipe, formed for sound, just as cats purr. You will credit me, I hope, when I assure you that, as my neighbours were assembled in an hermitage on the side of a steep hill, where we drink tea, one of these churn-owls came and settled on the cross of that little straw edifice and began to chatter, and continued his note for many minutes; and we were all struck with wonder to find that the organs of that little animal when put in motion gave a sensible vibration to the whole building! This bird also sometimes makes a small squeak, repeated four or five times; and I have observed that to happen when the cock has been pur-

swing the hen in a toying way through the boughs of a tree. Again—'On the twelfth of July I had a fair opportunity of contemplating the motions of the *Caprimulgus*, or Fern-owl, as it was playing round a large oak that swarmed with *scarabæi solstitiales*, or fern-chafers. The powers of its wing were wonderful, exceeding, if possible, the various evolutions and quick turns of the swallow genus. But the circumstance that pleased me most was, that I saw it distinctly, more than once, put out its short leg, while on the wing, and by a bend of the head deliver somewhat into its mouth. If it takes any part of its prey with its foot, as I have now great reason to suppose it does these chafers, I no longer wonder at the use of its middle toe, which is curiously furnished with a serrated claw.' Mr. Vigors (*loc. cit.*) remarks that the common Barn Owl (*Strix flammea*) possesses the same character of serrated *unguis*: and that some other species of the *Strigidae* exhibit somewhat of the rudiments of it; thus establishing more closely the affinity of the Owls and the *Caprimulgi*. Mr. Vigors adds that his conjecture as to the use of the serrated claw—that is, its being devoted to the purposes of seizure—is considerably corroborated by the passage from White above quoted. At the same time he refers to Wilson, who in his account of the *Caprimulgus Carolinensis* (*Antrostomus Carolinensis* of Bonaparte) assigns a different use to this serrated claw. Of this species Wilson says, 'Reposing much during the heat of the day, they are much infested with vermin, particularly about the head, and are provided with a comb on the inner edge of the middle claw, with which they are often employed in ridding themselves of these pests, at least when in a state of captivity.' Upon this Mr. Vigors observes that such can be at best but an accidental use to which the serration can be applied. There are many other groups of birds, he adds, possessing the same character, to which the same application of it can never be assigned—for instance, the greater part of the genus *Pelecanus* of Linnæus. Many of these birds, whose feet, Mr. Vigors observes, are naturally ill adapted by their webbed structure for laying hold of any object, are yet found to incubate among trees, where the serrated claw may give them a further power of prehension; they are also, he remarks, asserted to seize their prey occasionally with the foot; in which acts the structure of the nail, as in the case cited by White respecting the *Caprimulgus*, may be peculiarly useful. 'The family of the *Ardeidae* among the wading birds equally exhibit,' says Mr. Vigors, in conclusion, 'an analogous construction in the middle nail. Here again this character seems adapted to their mode of life in enabling them to hold their prey more firmly in those slimy and muddy situations where it might otherwise elude them; while, at the same time, it may assist their feet (which, like those of the *Pelecanidae*, are naturally ill suited for grasping) in their hold among the trees, where, like some also of the latter family, they build their nests.' Mr. Dillon is of opinion that the chief use of the serrated claw is simply to comb out or dress the *vibrissæ* which surround the gape. Mr. Swainson opposes this view, observing that there is an American group of this family which have no bristles round the bill, and yet have the serrated claws; and another group in Australia which have bristles round the bill, and yet with the claw smooth and simple. He also observes that the Heron tribe have the gape smooth, but the claw serrated. Mr. Rennie remarks that the passage in Wilson 'appears to settle the question;' but he gives no satisfactory reason why.

The Goat-sucker is sometimes to be seen abroad in gloomy days; we have seen it on such days, and generally on the ground. On a tree it is observed to perch not across a branch, but on its longitudinal direction. These birds affect the neighbourhood of oaks, where in May they find the *Melolontha vulgaris*, and at Midsummer the *Melolontha solstitialis*. White graphically describes the evolutions of one round his 'great spreading oak,' where it was hawking after a brood of some particular *Phalæna* belonging to that tree. On this occasion he says it exhibited a command of wing superior to the swallow itself. The same author states that when a person approaches the haunts of this species in an evening they continue flying round the head of the obtruder; and by striking their wings together above their backs, in the manner that the pigeons called smiters are known to do, make a short snap; perhaps at that time, he adds, they are jealous of their young, and their noise and gestures are intended by way of menace. The eggs, two in

number, oblong, white or dusky, and streaked somewhat like the plumage of the bird, are equal in size at each end, and are laid on the bare ground, generally among fern, heath, or long grass, sometimes in furze-brakes or woods, but always near the latter. Montagu describes the noise made by the male during incubation when perched, and with his head downwards, as not unlike that of a spinning-wheel, and notices its uttering a sharp squeak as it flies.

The other European species, *Caprimulgus ruficollis*, which is very rare, has been shot in the oak-woods some miles distant from Algeiras, and also in the valley of the Rio del Mel, near that city. The Spanish name for it is *Sainalu*. Mr. Gould has no doubt that its natural habitat is Northern Africa. The Prince of Musignano notes it as occurring in south-western Europe during the summer.

Mr. Gould has established a new genus for some of the American *Caprimulgi*, under the name of *Antrostomus*. [WHIP-POOR-WILL.]

Psaturus (Sw.). Gape strongly bristled. Tail excessively long, and very deeply forked.

Example, *Psaturus macropterus*.—A bright ruddy demi-collar ornaments the back part of the neck, and the two external tail-feathers in the male are much longer than the others. The tail of the female is much shorter.

Locality.—Paraguay and Brazil.

Psaturus macropterus (old male).

Chordeiles (Sw.). Gape perfectly smooth. Wings very long, equal to the tail, which is slightly forked.

Example, *Chordeiles Americanus*. Ground of plumage above, sides of the head and front of the neck, dark liver-

brown glossed with greenish. Head, neck, and upper rows of lesser wing-coverts spotted with yellowish brown; back, scapulars, and tertiaries mottled with brownish white, and a little wood brown, the pale colour forming speckled bars on the tail and its coverts; intermediate wing-coverts more thickly mottled with a purer white; greater coverts spotted with brown on the margin; band on middle of quills beginning on the inner web of the first and ending with the fifth, and a broad arrow-shaped mark on the throat pure white. A white dotted superciliary band reaches to the nape. Lateral tail-feathers banded with white. Plumage below and inner wing-coverts barred alternately with brownish-white and liver-brown. Bill blackish. Legs pale. Tail forked. Middle toe, which is longest, with a serrated claw.

This is the *Caprimulgus Americanus* of Wilson, and the *Caprimulgus Virginianus* of the Prince of Musignano, who notices the bird, in his *Geographical and Comparative List*, as *Chordeiles Virginianus* (Bonap.), and *Caprimulgus Popetus* (Vieill.). It is the *Peesquaw* of the Cree Indians.

Chordeiles Americanus.

Upper figure, Male. Lower figure, Female, with an egg.

Habits, Food, Reproduction, &c.—Dr. Richardson informs us that few birds are better known in the Fur Countries than this, which ranges in summer even to the most remote arctic islands. Captain (now Major) Sabine notices it, in the appendix to Captain (now Sir Edward) Parry's 'First Voyage,' as the *Musqueto Hawk*, and states that a female was found on Melville Island, lying dead on the ground about a quarter of a mile from the sea. He adds, that these birds are known to breed and inhabit as far north as Hudson's Bay; but as they live principally in woods, and feed on mosquitoes and other winged insects, which are very rare in the North Georgian Islands, it is more than probable that

the individual found dead was an accidental visitor, and had perished for want of food. It was extremely thin, but the plumage was in good preservation. Fabricius does not mention it; he observes in conclusion, as known in Greenland. Dr. Richardson states that its very peculiar noise is most frequently heard in the evening, and often seems to be made close to the listener, though the bird that produces it is so high in the air as to be nearly imperceptible. He describes this sound as resembling that produced by the vibration of a tense thick chord in a violent gust of wind, and says that the *Pisk* (the common name for the bird) considerably resembles some of the *Falconidae* in its evolutions in the air. It often remains stationary, fluttering its wings rapidly, and then suddenly shoots off a long way, by a gliding motion: at that moment the loud vibratory noise is heard. 'It also traverses the air backwards and forwards, quartering the sky as regularly as the Hen Harrier surveys a piece of ground. The female deposits her eggs on the ground without making any nest, generally selecting the border of a cultivated field or an open glade in the forest, and, during incubation, sits so close, that she may be almost trodden down. When any person approaches her, the male sallies from the adjacent thicket and stoops at the intruder, passing within a foot or two of his head, then rising again and wheeling round to repeat the same manœuvre. In the meanwhile, his mate flutters from the nest along the ground as if disabled, and hides herself at a short distance among the grey grass, from which she can hardly be distinguished. The *Pisk* makes its first appearance at Great Bear Lake generally about the last day of May, and was observed hatching on the Saskatchewan on the 8th of June. Its eggs are narrower than those of *Caprimulgus vociferus*, but of the same colours, rather differently distributed; they measure nearly 14 lines in length.' (*Fauna Boreali-Americana.*)

Geographical Distribution.—See above. In Dr. Richardson's table, the extreme northern range of this bird is stated as 68° N. lat. (east of the Rocky Mountains, migratory), and he notices it as observed in the summer, when it is common, on the Saskatchewan, lat. 53° to 54° north, and from 600 to 1000 miles distant from the sea-coast; as very common in the vicinity of Philadelphia, lat. 40° N. (Bonaparte), but as not having its winter-quarters in the United States. It also appears in the doctor's list of species which summer or breed in the Fur Countries and in Pennsylvania, but winter farther to the southward. In the Prince's *Geographical and Comparative List*, the southern and central parts of North America are recorded as the localities of the species.

Scotornis* (Sw.).

General structure of *Caprimulgus*; but the outer toe is shorter than the inner.

Subgenera—*Scotornis*. Rictus strongly bristled. Tail lengthened, graduated, or rounded. (Sw.)

Example, *Scotornis climaturus*, African Long-tailed Night-Jar.

Description.—Size rather smaller than that of *Macrodipteryx*, although, from the development of its tail, it is much longer. The bristles considerably exceed the length of the bill; the third quill is longest; the first is rather shorter than the fourth, while the fifth is $\frac{1}{4}$ ths of an inch shorter than the fourth. The tail is very long, measuring from the base 9 inches, of which $3\frac{1}{2}$ inches are occasioned by the two middle tail-feathers exceeding the others; the outer lateral toe is shorter than the inner. The ground colour of the plumage is light ferruginous brown varied with dark freckles. The chin and rictal stripe white; the lesser wing-coverts have at their tips a broad band of white, and the greater have a terminal spot of cream-colour, much smaller than the former. The ground colour of the five primary quills is entirely black, without any rufous, their tips only being freckled with grey; but they are crossed in the middle by a snowy-white broad band beginning in the inner web of the first and terminating on the outer web of the sixth quill: the remaining quills are varied with black and rufous and tipped with white. The tail is variegated in the usual manner, the middle pair of feathers having about 20 very slender transverse bars, but much

* In the *Classification of Birds*, Mr. Swinson prints *Scotornis*; but we apprehend *Scotornis* (Bird of Darkness) is meant; and so the word is printed in his *Birds of Western Africa*.

undulated, while the outer margin of the exterior feather, and the tips of that and of the next, are pure white. No grey in the plumage. Total length, including tail, 13 inches. (Sw.)

Locality.—Africa. Common in Senegal.

Scotorus clinaturus. (*Caprimulgus clinaturus*, Vieill.)

Macrodipteryx (Sw). Rictus strongly bristled. Wings long, equal to the tail, and with a lengthened reniform feather in each. Tail even.

Example, *Macrodipteryx Africanus*, Pennant-winged Night-Jar, or Long-shafted Goat-sucker.

Description.—Wings, for the small size of the bird, very long, rather exceeding, or at least equalling, the tip of the tail, which is quite even and consists of ten feathers. Of the three first quills, which are much the longest, the first is shorter than the third, which is slightly succeeded by the second. The long-shafted feathers are inserted immediately between the primary and secondary quills. The bristles of the mouth are strong and equal to the length of the bill, which is weak. The middle toe is lengthened, and the lateral toes are equal. Colour of the plumage mixed, as in others of the family. Upon each web of each of the primary quills is a row of nine rufous and nine black spots: the rufous bars become very small towards the tips, where the black predominates. The lesser quills are black, with four rufous bands, the tips black. The middle tail-feathers are grey, speckled with black points, and crossed by six black bars, all of which are irregular, excepting the last, which, as on all the other feathers, is regular, well defined, and placed just behind the tips; the outer web of the exterior feather is fulvous white, with about ten black spots, at equal distances from each other. Some of the scapulars have a broad cream-coloured stripe, which forms a connected series when the feathers lay over each other, but those which are conspicuous on the supposed female can scarcely be discerned in the male; this latter however has a few obscure white mottles on the chin, throat, and round the ears. Total length about 8 inches.

Mr. Swainson, from whose 'Birds of Western Africa' the above description is taken, observes that the female is entirely destitute of the long-shafted or supplementary feathers. 'Now this,' says Mr. Swainson, 'is a very important fact, for it goes far to prove that they are not essential to the economy of the species; for if otherwise, both sexes would possess them, unless it be contended, a supposition highly improbable, that the male feeds in one manner and the female in another. In the absence of all information upon this point, we are led to conclude that they are more ornamental than useful, given to the male sex as attractive decorations to the female, in a similar manner as the flowing feathers of the Paradise Bird are known to distinguish the male sex.

Whether or no these ornamental plumes are lost after the season of incubation is a subject for future inquiry; but they are certainly of very unequal lengths in different individuals. We have seen them in one bird only seven inches long, while in that now before us they measure in extreme length seventeen inches; the webs occupy exactly six, while all the rest of the shaft is naked, the rudimentary hairs on each side merely indicating the position of the laminae, had they been developed. We cannot subscribe to an opinion we have heard expressed, that these latter have been rubbed or worn off. Another specimen, which we suppose is the female, is perfect in all its plumage, but has no indication, as already observed, of these feathers. In their texture they are remarkably flexible, moving about with the least breath of wind. The inner web is so broad, that the laminae in the middle measure $2\frac{1}{4}$ inches; the outer web, on the contrary, is very narrow, and the longest laminae are hardly half an inch.'

This is the *Caprimulgus Macrodipterus* of Afzelius, and the *Caprimulgus longipennis* of Shaw.

Locality.—Africa, Sierra Leone.

Macrodipteryx Africanus. Male.

Proïthera (Sw). Rictus almost smooth. Wings very long, equal to the tail, which is short and even. Tarsus very naked.

Example, *Proïthera diurna* (*Caprimulgus diurnus*, Wied., *Nacunda*, Tomm.).

Description: Female.—Plumage above a mixture of grey-brown, yellowish-red, and brownish-black, marked with great spots of blackish-brown, with wide borders of yellowish-red; chin pale yellow, striped with grey-brown; tail marbled with brownish-black and bright yellow, with nine or ten transverse bands speckled with brownish-black. Plumage beneath white lineated with grey-brown; middle of the belly white, spotless. Length rather more than 10 inches.

Habits.—See ante, pp. 224, 225.

Locality.—Brazil and Paraguay.

Troilothera diurna.

NIGHT HERON. [NYCTICORAX.]

NIGHTINGALE, the English name for the most celebrated of the song birds of the Old World. This well known species is the *ἀνθός* (*Anthos*) of the ancient Greeks; *Luscinia* of the ancient Italians; *Rossignuolo*, *Rusignuolo*, and *Usignuolo* of the modern Italians; *Rossignol* of the French; *Ruiseñor* of the Spanish; *Nachtigall* of the Germans; *Nachtergahl* of the 'Fauna Suecica'; *Nattergale* of Brunnich; and *Eos* of the ancient British.

It is the *Luscinia* of Gesner, Aldrovandus, Willughby, Ray, and Brehm; *Motacilla Luscinia* of Linnæus; *Sylvia Luscinia* of Latham and others; *Curruca Luscinia* of Fleming; and *Philomela Luscinia* of Selby, Gould, and Swainson.

The Nightingale, or night singer, is a migratory bird visiting us early in the spring (about the middle of April), and leaving us about August or September. The male birds arrive first, and are instantly sought after by the bird-catchers, who generally make the most of the interval of ten days or a fortnight that elapses before the arrival of the females, well knowing that those males which are taken after they have paired seldom survive. The bird-fanciers have a notion that a Surrey Nightingale possesses the finest quality of tone. To dwell upon the richness and variety of its song, a subject which has employed the pens of poets of all ages, and of all countries where the bird is known, would be superfluous here; but there are points connected with the habits and geographical distribution of the bird which require notice.

M. Temminck states that the Nightingale haunts woods, thickets, and gardens; that it is common in nearly all the parts of Europe to Sweden inclusive; and that it migrates in winter into Egypt and Syria. Hasselquist saw it among the willows of Jordan and the olive-trees of Judea. Mr. Strickland saw it at Smyrna on the 5th of April. The Prince of Musignano notes it (*Specchio Comparativo*) as common in the neighbourhood of Rome, which it leaves in winter only. In his *Geographical and Comparative List*, the Prince records it as found in Europe generally.

Pennant (*Arctic Zoology*) says that it visits the temperate parts of Russia, and even some parts of Siberia. The same author (*British Zoology*) remarks that the Nightingale is a species that does not spread itself over our island. 'It is not,' says Pennant, 'found in North Wales, or in any of the English counties north of it, except Yorkshire, where it is met with in great plenty about Doncaster. It has also been heard, but rarely, near Shrewsbury. It is also remarkable that this bird does not migrate so far west as Devonshire and Cornwall, counties where the seasons are so very mild, that myrtles flourish in the open air during the whole year; neither is it found in Ireland. Sibbald places Nightingales in his list of Scotch birds; but they certainly are unknown in that part of Great Britain, probably from the scarcity and the recent introduction of hedges there; yet they visit Sweden, a much more severe climate.' The editor of the last edition of the 'British Zoology' states that in 1808 a Nightingale was several times heard in the gardens

of the earl of Lonsdale, in Fisher Street, Carlisle. M. Nilsson notes its arrival in Sweden by the 1st of May. Montagu informs us that it is said to be found only as far north as Yorkshire (his observations being confined to Britain), and certainly not farther west than the eastern borders of Devonshire; although they are plentiful both in Somersetshire and Dorsetshire. 'Why,' adds Montagu, 'they should not be found in all the wooded parts of Devonshire and Cornwall, which appear equally calculated for their residence, both from the mildness of the air and variety of ground, is beyond the naturalist's penetration. The bounds prescribed to all animals, and even plants, is a curious and important fact in the great works of nature. It has been observed, that the Nightingale may possibly not be found in any part but where cowslips grow plentifully; certainly with respect to Devonshire and Cornwall this coincidence is just.'

Mr. Blyth (*Analyst*, and *Note to an edition of White's Selborne*) enters fully into the inquiry as to the distribution of the Nightingale in Britain. Among other highly interesting observations, Mr. Blyth remarks that he thinks this bird appears to migrate almost due north and south, deviating but a very little indeed either to the right or left. He states that there are none in Brittany nor in the Channel Islands, Jersey, Guernsey, &c. Mr. Blyth is of opinion that the most westward of them probably cross the Channel at Cape La Hogue, arriving on the coast of Dorsetshire, and thence apparently proceeding northward rather than dispersing towards the west; so that they are only known as accidental stragglers beyond, at most, the third degree of west longitude—a line which cuts off the counties of Devonshire and Cornwall, together with Wales and Ireland. Mr. Gould (*Birds of Europe*), after referring to Mr. Blyth's papers in the 'Analyst,' states that the Nightingale appears to be confined to particular districts: it is, he remarks, plentiful in the southern and eastern counties, while Devonshire appears to be its limit westward, and Doncaster in Yorkshire in a northern direction, few if any authenticated instances being on record of its occurrence beyond that town, which is the more singular, as Nightingales are common in Sweden and other countries situated farther north than England. 'Our own observation,' continues Mr. Gould, 'respecting the migrations of the Nightingale is, that after leaving our island it proceeds to the opposite shores of the Continent, and gradually makes its way southwards, until it arrives in Africa, which is its ultimate resting-place during our winter months. We have ourselves received specimens killed in the northern districts of Africa, but have never obtained any from the central or southern parts of that portion of the globe; it would appear therefore that its distribution over that vast continent is comparatively limited. In no part of Europe is it more abundant than in Spain and Italy; from whence, however, equally as from our own, it regularly migrates on the approach of winter.' The islands of the Greek Archipelago are among the favoured localities visited by this delightful bird. Mr. Yarrell (*History of British Birds*, now in the course of publication) says, 'When we consider that this bird extends its visits during the summer as far north as Russia and Sweden, its very limited range in this country is unaccountable. It is found in Sussex, Hampshire, Dorsetshire, and the eastern part only of Devonshire, along the line of our south coast. It has been heard about Teignmouth and Exmouth, but no farther west in that direction. In North Devon it has been heard near Barnstaple, but not in Cornwall or Wales. A gentleman of Gower, which is the peninsula beyond Swansea, procured from Norfolk and Surrey, some few years back, some scores of young Nightingales, hoping that an acquaintance with his beautiful woods and their mild climate would induce a second visit; but the law of nature was too strong for him, and not a single bird returned. Dyer, in his "Grospar Hill," makes the Nightingale a companion of his Muse in the vale of Towey or Caermarthen; but this is a poetical licence, as the bird is not heard there.'

It is singular, that concurring, as all the more modern authors do, that the Nightingale is not now to be found in Wales, a Welsh name for the bird should exist; yet Pennant gives this name in his list, and it will be found at the head of this article. Pennant, be it remembered, only excludes it from North Wales.

In Ireland the Nightingale seems never to have been heard.

Mr Yarrell, who remarks that it is not included by Mr. Rylands in his 'Catalogue of the Birds of Lancashire,' though it has been heard as high up as Carlisle, but no farther, goes on to state, that on the eastern side of our island the bird frequents Essex, Suffolk, Norfolk, some of the more wooded parts of Lincolnshire, and several parts of Yorkshire; but not higher than five miles north of the city of York, as he learned from his friend and correspondent Mr. Thomas Allis. Mr. Yarrell states his belief that it has not been heard in Scotland or in the Scottish islands, which, he adds, considering that it visits Denmark, is extraordinary. He then quotes from a note to an edition of White's 'Selborne,' published in Edinburgh, the following record of an attempt to establish the Nightingale in Scotland:—'It has been generally believed that the migratory songsters, both old and young, return to their native haunts in the breeding season. . . . Impressed with this belief, Sir John Sinclair, Bart., long known for his patriotism, commissioned the late Mr. Dickson, of Covent Garden, to purchase for him as many Nightingales' eggs as he could procure at a shilling each. This was accordingly done, the eggs carefully packed in wool, and transmitted to Sir John by the mail. Sir John employed several men to find and take care of the nests of several Robins, in places where the eggs might be deposited and hatched in security. The Robins' eggs were removed, and replaced by those of the Nightingale, which were all sat upon, hatched in due time, and the young brought up by the foster parents. The songsters flew when fully fledged, and were observed for some time afterwards near the places where they were incubated. In September, the usual migratory period, they disappeared, and never returned to the place of their birth.'

Description.—Rich brown above; rump and tail with a reddish tinge; throat and middle part of belly dirty or greyish white; lateral parts of the neck, breast, and flanks grey; bill and legs light brown. Sexes alike.

Habits: Food: Reproduction.—The Nightingale shuns observation, abiding in the thickest covert, and in these the nest is sometimes placed on a low fork, but generally on the ground. Withered leaves, particularly those of the oak, very loosely conjoined with dried bents and rushes, and lined internally with fine root-fibres, form the structure. The eggs, of an olive-brown, are four or five in number. After the young are hatched, generally in June, the melodious song of the male ceases, and is succeeded by a low croak, varied occasionally with a snapping noise; the first is considered to be meant for a warning, and the last as a defiance. The food consists of insects, such as flies and spiders, moths and earwigs. Green caterpillars were the food brought by the parent birds to the nest of young Nightingales taken by Colonel Montagu. It is not improbable that the bird's choice of localities is in some measure determined by the absence or presence of some favourite insect food.

Luscinia Philomela (Bonaparte). The Nightingale.

There is another European Nightingale (*The Thrush*

Nightingale, Philomela Turdoides of Blyth, *Luscinia major* of Brisson, *Sylvia Philomela* of Boeckstein), inhabiting central Europe. The song of this species is loud, but far inferior to that of the true Nightingale. It is said to be common in Egypt.

Mr. Swainson makes the *Philomelinae* the second sub-family of his *Sylviadae*. [SYLVIADÆ.]

NIGRIN, oxide of titanium, containing about fourteen per cent. of iron. It resembles menaccanite in colour, lustre, and appearance of the fractured surfaces. It occurs in Ceylon and in Transylvania.

NIKA, a name given by M. Risso to a genus of *Macrurous Crustaceans*, placed by M. Milne Edwards between the genera *Caridina* and *Athanas* in the tribe of *Alpheans*, to which the latter zoologist also refers the genus *Autonomea*. [SALICOQUES.]

NIKON, a celebrated personage in the annals of Russia, and the sixth patriarch in the Russian church, was born in May, 1605, in a village near Nischnei-Novgorod, where his father was a husbandman. A natural inclination for study led him to become the pupil of a monk in the convent of St. Makarius. The taste which he there acquired for monastic life and discipline was so strong, that although he married, in compliance with the pressing instances of his family, he separated from his wife after ten years' union, and prevailed upon her to enter the convent of St. Alexis at Moscow, while he himself retired to a small island in the White Sea, not far from Solowetz, where there was a brotherhood of hermits living in detached cells. The desolation of the place and the severity of the discipline served rather to increase than to abate the ardour of the new recluse; but the zeal of the brethren led to dissensions that terminated in his expulsion, or at least his flight. Being desirous of replacing their wooden church by a stone edifice, Nikon, and Elizar, the founder and head of the community, proceeded to Moscow, where they collected contributions for the purpose; but on their return, Elizar took the money into his own keeping, and manifested no intention of applying it to the intended purpose. This led to remonstrances and altercations; and to such persecution on the part of Elizar, that Nikon pushed off from the island in a small boat; and after incurring great danger, was driven to the island KJ, at the mouth of the Onega, where he set up a wooden cross. At the same time he made a vow to erect a monastery on that spot, in fulfilment of which may now be seen the magnificent cloister of the Holy Cross. Associating himself with a community called the Koscheoser hermits, he so distinguished himself by his superior sanctity and severity of life, that on the death of their abbot, or principal, he was elected in his place, in 1645. Being compelled three years afterwards to take a journey to Moscow, to arrange some affairs of their community, he there became known to the Czar Alexis Mikailovitch, who was so struck with his eloquence and understanding, that he caused him to be appointed archimandrit of the Novospasky Convent. A new career was thus suddenly opened to him: his influence with the sovereign increased daily, and he employed it in behalf of the distressed. On being appointed metropolitan of Novgorod, in 1648, he attached the people of that city to him no less strongly: his eloquence drew crowds to hear his discourses in the cathedral, and his bounty maintained numbers during a severe famine. Besides this he appeased a violent popular insurrection at Novgorod in 1650, at very imminent peril to his own person. In the mean while he continued in high favour with the Czar, who frequently corresponded with him, and who, on the death of the patriarch Joseph, in 1652, appointed him his successor. It was about this time that he commenced his reforms in the books, as he had previously done in the liturgy, of the church; and held several councils relative to the translations of the Scriptures. But herein his zeal led to his disgrace: his reforms were regarded as dangerous innovations; and notwithstanding the Czar had shown such friendly confidence in him as to place his own family under his care during the pestilence at Moscow in 1653-4, and had attended at the consecration of the Voskresensky monastery (erected by Nikon) in 1657, the patriarch's enemies contrived to prejudice him in the good opinion of his sovereign, and in 1658 he retired to the monastery just mentioned, situated about forty versts from the capital, whence he refused to return. How this unfortunate quarrel and misunderstanding originated is not precisely known; and it will be sufficient here to remark that it increased, till at length, in 1667, a

council was held at Moscow, at which the Czar himself presided, and which was attended by the patriarchs of Alexandria and Antioch, those of Constantinople and Jerusalem having excused themselves. The result was that Nikon was deposed from his dignity, and was banished to the Bieloozersky monastery, with the rank of a simple monk. There he remained until after the death of Alois, whose successor, Pheodor Alexievitch, granted him permission to return to the Voskresensky monastery; but he died on his journey thither, at Yaroslav, August 17th, 1681, at the age of seventy-five.

Nikon compiled a collection of ancient Russian chronicles to the year 1630, which were printed by the Academy of Sciences of St. Petersburg, in eight volumes, quarto, 1767-1792. He also wrote several dogmatical and theological pieces, which were printed in his lifetime.

NILE (*Nilus*, in Latin), the name of the great river of Eastern Africa, the various branches of which have their rise in the high lands north of the equator, and, flowing through Abyssinia and other regions to the westward of it, meet in the country of Sennaar. The united stream flows northwards through Nubia and Egypt, and after a course of more than eighteen hundred miles from the farthest explored point of its principal branch, enters the Mediterranean by several mouths, which form the delta of Egypt. The word Nil seems to be an old indigenous appellation, meaning river, like that of Gir in Soudan and other countries south of the Atlas. The modern Egyptians call the river Bahr-Nil, or simply Bahr; in Nubia it is called by various names; in Sennaar the central branch, or Blue River, is called Adit; and in Abyssinia, Abawi. The three principal branches of the Nile are—1, the Bahr el Abiad, or White River, to the west, which is now ascertained to be the largest and longest; 2, the Bahr el Azrek, or Blue River, in the centre; 3, the Tacazze, or Atbara, which is the eastern branch. These three branches were known to Ptolemy, who seems to have considered the western as the true Nile, and to have called the others respectively Astapus and Astaboras. He fixed the sources of the western river in numerous lakes at the foot of the Mountains of the Moon, which he placed in 10° S. lat. Strabo (p. 821) speaks of the island of Meroe as bounded on the south by the confluence of the Astaboras, Astapus, and Astasobas. In another place (p. 786) he says that the Nile receives the Astaboras and the Astapus; which latter 'some call the Astasobas, and say that the Astapus is another river which flows from some lakes in the south, and makes pretty nearly the direct course of the Nile, and is swollen by the summer rains.' While these passages certainly prove that the ancient geographers knew that there were three main streams, they also prove that their notions about them were confused. The numerous reports of the natives, who call this ridge or group of Mountains by the Arabic version of the same name, Jibalu 'l Kumari, though generally pronounced Jibali 'l Kumri, which would mean 'blue mountains,' seem to agree in placing the sources of the Abiad several degrees north of the equator, at nearly an equal distance between the eastern and western coasts of Africa. But we have no positive information either as to the true position of the sources or of the mountains. According to the report of Antonio Fernandez given by Tellez, the high land of Abyssinia extends to the south into the kingdom of Narea, the northern part of which is about 8° N. lat., and it probably extends thence to the westward through central Africa. The Bahr el Abiad was traced upwards by Linant, in 1827, as far as Aleis, a direct distance of 132 geographical miles south of Khartum, which is in $15^{\circ} 34'$ N. lat. and about $32^{\circ} 30'$ E. long., and at the confluence of the Blue and White Rivers. Since that time a party of Turco-Egyptians, headed by Ibrahim Kashef, an officer of the viceroy of Egypt, marched upwards from Khartum for thirty-five days along the banks of the river. On the twelfth day they reached the first island of the Shilluka, and after traversing the territory of that people they entered on the twenty-ninth the country of the Denka, probably the Donga of Browne, through which they continued to ascend along the banks for six days more, when they began to retrace their steps. At this point the river was shallow, full of islands, and six hours in breadth; and there were no mountains in sight. The latter part of the march appears from the description of Ibrahim to have been in a direction nearly west, and as the first island of the Shilluka, which they reached on the twelfth day, is not

far from Aleis, according to Linant's statement, the extreme point attained by Ibrahim was probably about 10° N. lat. and 29° E. long. The result of this expedition agrees with Browne's report from hearsay, in giving an easterly course to that part of the river which is south of Dar-Fur, and placing its sources full to the south-westward of that kingdom. (Col. Leake's paper 'On the Quorra,' in the 2nd vol. of the *Journal of the Royal Geographical Society of London*, and Linant's *Journal of a Voyage up the Bahr el Abiad*, with some general notes on that river and illustrative maps, in the same volume.) The enormous breadth attributed to the Abiad by the Turkish party, although it may be exaggerated, leaves little doubt that the river at the extreme point of their journey was much broader than at its junction with the Blue River, and indicates that it has a peculiar character, its origin being perhaps in a lake or lakes which may be supplied by streams flowing from a distant range of mountains. The existence of lakes which have communication with the river only in time of high water is rendered highly probable by a passage in Linant's 'Journal,' which states that at the time of the inundation of the White River a prodigious quantity of fish is brought down towards Khartum by the current.

Mr. Holroyd, in his 'Notes on a Journey to Kordofan in 1836-7,' in the ninth volume of the 'Journal of the London Geographical Society,' states that Khurshid Pasha told him that he had been twenty-one days above Aleis, on the Bahr Abiad, in the boats of the country with soldiers, and had reached Denka. He mentioned that the river divided a considerable distance above Khartum, but was not prepared to say which was the direction of the White Nile properly so called. In the country of the Shilluks it seems that several rivers join the Bahr Abiad from the west, the names of which are mentioned by Linant in his Notes. One of these may be the Bahr el Adda mentioned by Browne as the last western tributary of the Bahr Abiad.

The Bahr Abiad, which at its confluence with the Blue River is only about 1800 feet wide, is described by Linant as being, just above it, in many places a mile and a half wide in the month of April, and even then far within its regular banks, which sometimes appeared four miles distant from one another, and were distinctly marked beyond these limits by a wide sandy beach without any appearance of verdure. But even this is not the full width at the greatest height, as the river then overflows the adjoining country, and the waters extend in some places above twenty miles from side to side. The shores of the river are very flat, especially on the western side, and the water is deep only towards the middle of the stream, where Linant found it to be from three to four fathoms. The rise of the Bahr Abiad is not perceptible till some time after that of the Bahr Azrek, according to Linant; but an American who accompanied Ismael Pasha to Sennaar in 1821 says that 'the Abiad commenced its rise this year about twenty days sooner than the Adit (the name of the Blue River in Sennaar), and that the difference of colour of their waters proves that they flow through very different soils. The white colour of the Abiad is occasioned by a very fine white clay with which its waters are impregnated, whilst the Adit is almost black during the season of its increase.'

At the confluence the contrast between the two streams, says Linant, is very great, the waters of the Abiad being always white, and as it were soapy, even in the dry season, when the Azrek is of a greenish hue. The Abiad remains of the same colour during the inundations, when the Bahr Azrek becomes reddish owing to the alluvium brought down by its affluent the Bahr Toumet, which comes from the highlands of Narea and falls into the Azrek in the province of Fazuolo, above Sennaar.

The Bahr el Azrek, or Blue River, which was long supposed to be the main branch of the Nile, has three sources in the high land of Gojam, near the village of Geesh, south-west of lake Dembea, in $16^{\circ} 59' 25''$ N. lat. and $36^{\circ} 55' 30''$ E. long., according to Bruce's observations. The Agows, who inhabit that district, worship the river. [ABYSSINIA; BRUCE.] The sources of the Azrek appear to have been visited by Father Paetz, and perhaps by other missionaries, long before Bruce. The vast importance attached to that discovery has become much diminished since the information which we have acquired of the Abiad, whose sources are still unexplored, and still involved in that mystery which the ancients represent as hovering about the fountains of the Nile. After a north and north-west course of about seventy miles, the Azrek, or Abawi, as the Abye-

synians call it, enters the lake Dembea or Tzana on its south-western side. This fine lake is sixty-five miles in length from south-east to north-west, according to Bruce's map, and above thirty in its greatest breadth; its surface is more than twice that of the lake of Geneva. It occupies the centre of an elevated table-land, surrounded by hills and mountain ranges, from which numerous streams fall into the lake. The Blue River, issuing from the lake at its south-east extremity, runs first to the south-east, forming a large cascade at Alata; after which it flows nearly due south, and then turns to the south-west, encompassing the provinces of Gojam and Damot, and leaving Amhara Proper on its right or eastern bank. After receiving several affluents from the high lands of Shoa and Efat, it turns to the north-west, forming a curve which twice intersects the tenth degree of north latitude, being nearly the same parallel as that of the farthest explored point of the Abiad, which is six degrees of longitude farther west. The vast tract between the two rivers is yet unexplored; it is nominally dependant on Sennaar, and is inhabited by the Denka, the Shilluks, the Bokki, and other Negro tribes, who are pagans.

On the 1st of January, 1822, Ismael Pasha, son of the viceroy of Egypt, with 1600 men, started from Fazoclo, which is about 11° 20' N. lat., on the left bank of the Blue River, and marched southwards into the interior in search of the gold-mines of Quâmâmyl. After crossing the Bahr Tounet, an affluent of the Azrek, in about 10° 50' N. lat., they discovered on the 18th the first appearance of gold mixed with the sand in the beds or borders of rivulets. Cailliaud, who accompanied the expedition, found that the washing of the sands produced very little, only four grains of gold in a hundred weight of sand. A negro chief told Ismael that after the rainy season there were sometimes found bits of gold of the size of beans. After seventeen days passed among golden sands, Ismael became convinced of their barrenness; and on the 5th of February gave orders to proceed farther south, and in two days arrived at Singue, south-west of Quâmâmyl, and in about 10° 30' N. lat. and 34° 30' E. long. But the negro inhabitants of the neighbouring mountains became so troublesome and daring, that Ismael was obliged on the 11th of February to order a retreat towards Fazoclo. (Cailliaud, *Voyage à Meroc, au delà du Fazogl, &c.*, 1826-7.)

Continuing its course in a north-north-west direction, towards the low country of Sennaar, the Azrek, or Adit, as it is here called, after crossing the province of Fazoclo, a dependency of Sennaar, passes by the town of Sennaar, which is on its left bank, in about 13° 30' N. lat. and 33° 45' E. long. Continuing to flow nearly in the same direction, it receives on its right bank the Dandar, Rahat, and other streams which flow from the outer or western side of the highlands which enclose the basin of lake Dembea. The country on its left bank, and between it and the Abiad, constitutes the kingdom of Sennaar proper, which is also called Al Jezira, or the island [SENNAAR], and is divided by the Azrek from Halfay, a Nubian province, forming part of the country of Atbara, or island of Meroe. [NUBIA.] At Khurtûm the White and Blue rivers unite, the former being the wider; and the two streams flow for several miles in a common bed without mixing their waters, like the Rhône and the Arve below their junction near Geneva. After passing Halfay the united stream of the Nile bends towards the north-east, passes by Shendy and the ruins of Meroe, and on entering the country of Berber, it receives on its eastern bank the Tacazze or Atbara, the third great confluent of the Nile.

The following is a description of the appearance of the Nile in its course through Upper Nubia. The Nile below the point of junction of the Abiad and Azrek presents a truly magnificent spectacle. Between Halfay and Shendy the river is straightened, and traverses a deep and gloomy defile formed by high rocky hills, between which the Nile runs dark, deep, and rapidly for about twelve or fifteen miles. On emerging from this defile the river again spreads itself majestically and flows between immense plains of herbage bounded only by the horizon. About thirty miles above Nourseddin, the head village of Berber, we passed the mouth of the Bahr el Jarwood (the Tacazze) on the eastern shore; it is the last river that empties itself into the Nile. I estimated it at about two-thirds of a mile at its embouchure. The Nile below the point of junction of this river is more than two miles broad from bank to bank. (*Narrative of an Expedition to Dongola and Sennaar under Ismayl Pacha*, by an American, London, 1822.)

gola and Sennaar under Ismayl Pacha, by an American, London, 1822.)

The Tacazze, perhaps the Astaboras of the ancients, rises in the high mountains of Lasta, in about 11° 40' N. lat. and 39° 40' E. long. Its sources were known to the Jesuit missionaries in Abyssinia, and have been visited of late years by Pearce. It flows for a considerable distance in a northern direction between the range of the Samen mountains on the west, and those of Lasta, Salowa, and Bora on the east. It receives on its right bank the Arequa from Antalo. On arriving at 13° 15' N. lat. the Tacazze turns to the north-west, forming the boundary between the kingdom of Amhara, on its left, and Tigre on its right bank. The river has numerous rapids, which render it fordable at most seasons of the year. Salt saw in it enormous crocodiles of a greenish colour and large hippopotami. Proceeding north-west the Tacazze flows through the lowlands of Waldhuba and Walkayt, which are dependencies of Tigre; and about 14° 50' N. lat. and 36° 40' E. long. it receives on its left bank the Angrab, which rises on the north slope of the high land of Dembea. It afterwards receives several other streams which come from the same direction and pass through the country of Ras el Feel, which was visited by Poncet and Bruce. It then inclines more to the north; and between the parallels of 16° and 17° N. lat., in the country of the Taka, it is supposed to receive on its eastern bank the Mareb, a considerable stream which comes from Tigre, and the course of which has been traced north-west to within a short distance from the Tacazze. [BEJA, or BOJA.] The Tacazze then passes Gous Radjib, visited by Burkhardt on his journey to Suakim in 1814, and inclines again to the north-west, forming the boundary of the so-called island of Meroe and the Berber country [BARABRA]; and at last enters the Nile at 17° 45' N. lat. and about 34° 5' E. long. A short distance before its confluence the Tacazze receives on its right bank the Mogren from the north-east, which rises in the Langay ridge near the Red Sea, in the country of the Bishareens. At the season of the inundation the Bahr Mogren brings down from the interior a quantity of black earth, which is said to affect the colour of the Nile. (Linant's *Notes on the Bahr el Abiad*.)

The Nile, from the confluence of the Tacazze down to its entrance into the Mediterranean, a distance of 1200 geographical miles measured along the course of the river, receives no permanent streams; but in the season of rains it receives wadys, or torrents, from the mountains which lie between it and the Red Sea. After flowing through Berber in a north-north-western direction, a populous and fertile district, and full of villages, the Nile enters a barren and dreary country, where the desert sands come close to the river's edge. The rocks and stones of the desert are generally of black granite. No verdure is to be seen, except on the margin of the river. On arriving at about 19° N. lat. the Nile turns nearly direct west, and forms the large island of Mogrât. This district is called El Raba Tab; and its malek, or chieftain, is said to rule over eighty-five large and fertile islands formed by the Nile, besides the adjacent banks. The Nile below Mogrât turns abruptly to the south-west. This is known as the great bend of the Nile. Continuing in the same direction, it passes through the country of the Sheygia Arabs. [BARKAL.] Arriving at the village of Korti, 18° N. lat. and 31° 50' E. long., the river turns to the west; and after a course of about thirty miles in that direction, it resumes a northern course, flowing through the province of Dongola. The breadth of the cultivable land on each bank through the Dongola country, which is above 100 miles in length, varies from one to three miles, beyond which is the desert. The left or western bank is the more fertile, the eastern bank being in many places sandy and barren. Some of the islands, such as that of Argo, are very fertile. (Waddington and Hanbury's *Travels*; Rüppel's *Travels in Nubia and Kordofan*.) North of Argo, in 19° 40' N. lat., the Nile enters the province of Dar Mahass, in Lower Nubia, where it forms a cataract, or rapid, commonly called the third cataract by those who ascend the river. After several windings the river inclines to the north-east; and near 22° N. lat. forms the second cataract, called Wady Halfa, after which it passes the splendid temple of Ipsambul. [ABUSAMBOUL.] Continuing its north-east course, the Nile passes by Derr, Dandour, and Kalabshah; and at about 24° N. lat. forms the last cataract between granite rocks which cross the river near Essouan, or Assouan. Along this tract of Lower Nubia the valley of

the Nile is very narrow, 'the rocks of the eastern and western mountains often coming close to the river, and leaving little space for the deposit of alluvium: in other places, on the Libyan side, the sand covers the whole level space between the hills and the bank; and the character of the country between Wady Halfa and Assouan is totally different from that of Egypt. The river about Kalabshah rises between 30 and 40 feet perpendicularly during the inundation; and after it has subsided, in February, the stream runs at a rate of two or three nautical miles an hour.' (Sir J. Gardner Wilkinson, *On the Nile and Former Levels of Egypt*, in *London Geog. Journal*, vol. 9.)

After entering the boundaries of Egypt the Nile flows through the whole length of that country, which it waters and fertilises. Egypt owes to the Nile its very existence as a productive and habitable region, and accordingly, in olden times, the people worshiped the beneficent river as their tutelary god. A full account of the Nile in its progress through Egypt, of its periodical rise, and its delta and various mouths, is given under EGYPT.

The rich alluvial deposit which the Nile spreads over the lands of Nubia and Egypt is mainly derived through the Blue River and its affluents the Toumet, Tacazze, Mareb, &c., from the high lands of Abyssinia: the White River brings no such alluvial deposit; but its stream, rising about the same time as the Blue River, assists in raising their combined waters over the lands, which they fertilise in their northward course. Owing to the yearly deposit of alluvial matter, both the bed of the Nile and the land of Egypt are gradually raised, the elevation varying in different places, and always lessening in proportion as the river approaches the sea. According to an approximate calculation, the land about the first or lowest cataract has been raised nine feet in 1700 years, at Thebes about seven feet, and at Cairo about five feet ten inches; whilst at Rosetta and the mouths of the Nile, where the perpendicular thickness of the deposit is much less than in the valley of Central and Upper Egypt, owing to the great extent east and west over which the inundation spreads, the rise of the soil has been comparatively imperceptible. (Wilkinson.) As the bed of the Nile always keeps pace with the elevation of the soil, and the proportion of water brought down by the river continues to be the same, it follows that the Nile now overflows a greater extent of land, both east and west, than in former times; and that the superficies of cultivable land in the plains of Thebes and of Central Egypt continues to increase. All fears therefore about the stoppage of the overflowing of the Nile are unfounded. In the valley of the Nile the banks are much more elevated than the land at a distance from the river, and they are seldom quite covered with water, even during the highest floods. The difference between the height of the banks and the land near the edge of the desert is often as much as 12 and 15 feet. The dykes which form a communication between the villages during the inundation commence on a level with the banks of the river, and as they extend into the interior rise to so great a height above the fields as to leave room for the construction of arches for the passage of the water. This appearance of an elevated strip of land along the banks of a river, sloping towards the interior, is common to other river valleys which are subject to periodical inundations.

NILEUS, a surgeon of the Alexandrian school, celebrated for the invention of a machine called the 'plinthium,' which was employed with success in reducing luxations of the femur. (Cels., *De Med.*, lib. viii., cap. 20; Oribas., *De Machinam*, cap. 8, p. 617.) Some of his medicines are quoted by Galen, Aëtius, Celsus, Paulus Aegineta, Cælius Aurelianus, and Oribasius. The exact time when he lived is not known; but as he is mentioned by Celsus, we may perhaps safely place him a little before the beginning of the Christian era.

NILGHERRY MOUNTAINS. [HINDUSTAN, vol. xii., p. 207.]

NIMES or NISMES, a town in the south of France, capital of the department of Gard, in 43° 50' N. lat. and 4° 23' E. long.; 358 miles from Paris in a direct line south by east, 450 miles by the road through Auxerre, Lyon, St. Etienne, Valence, and Font St. Esprit, or 417 miles by the road through Nevers, Moulins, Clermont, and Mende.

Nîmes, antiently Nemausus (*Nemausus*), is a town of great antiquity. Strabo (p. 186. Casaub.) notices it as the capital of the Celtic nation, the Volca Arcomisci, or Aricomisci

(*Ὀβωλακαὶ Ἀρικουμισκοί*), and states that though inferior to Narbonne in the number of strangers and others resorting to it for the purposes of trade, it was superior in the number of citizens; the town exercised authority over twenty-four populous villages, and enjoyed the 'Jus Latii,' by virtue of which those elected to the ædileship or quæstorship in Nemausus acquired the rights of Roman citizens. Nemausus was situated on the high road from Italy into Spain, which, though in excellent condition in summer, was in spring and winter impeded by mud or by floods caused by the mountain torrents. It was fortified with walls and gates by the emperor Augustus, about fourteen years before the Christian era. In the downfall of the Roman empire Nîmes suffered much. It fell into the hands of the Visigoths, and was comprehended in the kingdom established by them in the south-west of France and in Spain; it was besieged by Wamba, king of the Visigoths (about A.D. 673), against whom it had rebelled, and was subsequently taken by the Saracens, from whom it was wrested by Charles Martel, at whose hands the town suffered much. In the tenth century it became the capital of an hereditary viscounty, and after some changes was united to the crown of France, in the reign of St. Louis, A.D. 1258. In the religious wars of the sixteenth century it was one of the strongholds of the Calvinists: it submitted to Louis XIII., who dismantled the fortifications. In the earlier periods of the French revolution (A.D. 1791) and on the second restoration of the Bourbons (A.D. 1815) it was the scene of serious intestine troubles, political or religious.

Of all the towns in France, Nîmes preserves the most striking memorials of its antient grandeur. It has been styled 'a second Rome.' The antient building known as La Maison Carrée (the square house), is not square, as its name would imply, but a parallelogram. It is surrounded by thirty fluted Corinthian columns, so arranged as to present eleven on each side, six in the front, and as many at the back: the columns at the angles being in this computation counted twice. The columns on the back-front and eight of those on each side are half encased in the wall of the building which fills up the intermediate spaces; the remaining three columns on each side and those of the front belong to the portico, which is of considerable depth in proportion to its width, and is open on three sides. The pillars are nearly 30 feet in height, and nearly 3 feet in diameter; but M. Millin, from whom we borrow these dimensions (*Voyage dans les Dép. du Midi de la France*), does not say whether the first of them includes the base and capital, or is that of the shaft alone. The intercolumnar spaces are less than two diameters in breadth. The total length of the building is given by M. Millin at 72 French (or 77 English) feet, including, we presume, the depth of the portico; the breadth is 36 French (or 38½ English) feet: our authorities do not state whether these are exterior or interior measurements; they are probably exterior. The cornice and frieze run all round the building, and, as well as the capitals of the columns, are regarded as models of architectural beauty: indeed the building is so enriched as to require a large and accurate drawing to do it justice. The very corona is fretted. The only entrance to the building is by a door in the front under the portico; and there were originally no windows; it is conjectured that light was obtained by openings in the roof. The Maison Carrée, like most of the temples of antiquity, was enclosed. The recent excavations, made about three years ago, render it probable that another similar building faced the temple, at some little distance from it. Séguier, a French antiquary, conjectured that it was dedicated to Caius Cæsar and Lucius Cæsar, the grandchildren of Augustus; but it has recently been shown by M. Auguste Pelet to have been erected to M. Aurelius and L. Verus. Probably there were two temples within the same enclosure, one dedicated to Aurelius, the other to Verus. In the middle ages it served as a town-hall, was afterwards part of the offices of a private house, and in the time of Louis XIV. the canons of St. Austin fitted it up as a church. When visited by M. Millin, in the reign of Napoleon, it was defiled by filth and exposed to the mischievous pranks of children. The Maison Carrée is now used as a museum for objects of antiquity. The State House at Richmond, in Virginia, which stands on a commanding elevation, is a copy of the Maison Carrée. The plan and drawings were sent to Virginia by Mr. Jefferson, when he was minister of the United States at Paris.

The amphitheatre, which is near La Maison Carrée, is in

better preservation than the Coliseum at Rome, and of greater extent than the amphitheatre of Verona. It is a perfect oval. The greater diameter, including the thickness of the wall, is estimated at 405 French, or 434 English feet; the smaller diameter, 317 French, or 340 English feet. The exterior wall, which is nearly perfect, consists of a ground story and an upper story, each pierced with sixty arches, and is surmounted by an attic. Its height from the level of the ground is above 70 English feet. The lower or ground story is adorned with pilasters, and the upper with Tuscan or Doric columns. The attic shows the holes destined to receive the posts on which was stretched the awning that covered the amphitheatre. The rows of seats are computed to have been originally thirty-two in number. There were four principal entrances. The amphitheatre has been computed to hold 17,000 persons: it was built with great solidity without cement: the stones were quarried in the neighbourhood, and some of them are of immense size. When the Visigoths possessed Nîmes, they converted this building into a fortress, to defend the place against Clovis and his Franks. They built the square towers which yet remain near the eastern door. It was defended by the Saracens against Charles Martel, who assailed it with fire, of which it still exhibits the traces. Under the viscounts of Nîmes it was still kept as a fortress. The arena was encumbered till of late years with a parcel of wretched hovels, now removed.

There is an antient edifice which antiquaries have designated the temple of Diana; it is of moderate dimensions, and is built of large stones without cement; but the violence which has been offered to it at different times has reduced it to a mere ruin. The interior still exhibits some remains of a fine vaulted roof and of the niches and columns which once adorned it. A number of inscriptions, capitals, and other fragments of columns, or of different parts of the building, statues, and other antiquities, are confusedly reaped together in this building. The adjacent baths of

Diana, and the fountain which supplied them, have disappeared or lost their antique character under the more modern works which have been added to them. The waters of the fountain are conveyed by a canal round one of the public gardens of the modern town, and the place of the baths is occupied by statues and groups in marble, of modern date and inferior execution.

Near the temple of Diana is a singular edifice called La Tour-magne, *Turris Magna*; 'the great tower.' It consists of a lower story of heptagonal form, 245 French, or 262 English feet in circumference; and of an upper story, an octagon, of 107 French, or 115 English feet in circumference. It is 117 French, or 125 English feet high; but the ruins which surround it much diminish its apparent height. It is built of small square stones, and each front was originally adorned by two pilasters of freestone, Tuscan or Doric. It stands on an elevation, and joined the antient walls of the town; but its origin and use are both entirely unknown.

There are two Roman gates; one is called the gate of Cæsar, and was discovered A.D. 1791, on the demolition of some antient ramparts erected in the twelfth century. This gate is built of large blocks of freestone, and has two large arches in the middle, and two smaller arches, one on each side. It bears an inscription, showing that the gates and walls were the gift of Augustus Cæsar to the colony. The inscription is *IMP. CAESAR DIVI. F. AVGVSTVS . COS XII. TRIBV. POTEST. VIII.*; and in smaller letters, *PORTAS. MVROS. COL. DAT*; from which we learn that at this date Nîmes was a Colonia: indeed, Augustus is considered as the founder of the colony. The other Roman gate is far inferior.

Besides these more important remains Nîmes has a vast number of inscriptions, monumental and other, and one or two fine mosaic pavements: in the neighbourhood there is a Roman bridge.

Nîmes is situated in a delightful plain at the foot of hills

A bird's-eye view of the Corinthian Temple at Nîmes, called the *Maison Carrée*, with the remains of the Colonnade which once surrounded it.—From the beautiful model by M. Pelet of Nîmes, made during the recent excavations from the year 1822 to the year 1838. N.B. The columns and fragments have not been re-erected, but lie round the area. (Drawn by W. B. Clarke, Nov. 1838.)

covered with vineyards and olive-gardens. The city, properly so called, has narrow, crooked, and ill-built streets; it is surrounded by boulevards, which occupy the site of the antient ramparts, and separate the city from its suburbs, which at least equal it in extent, and have straight, wide, and long streets, but the houses are ill built. The boulevards are receiving continual accessions of embellishment from the erection of new and handsome buildings. Of the public edifices the most remarkable are Le Palais de Justice (the court-house), the hospital, the theatre, the cathedral, the college church, and le Dépôt de Mendicité, or poor-house. Le Palais de Justice fronts the boulevard of the esplanade, and is a handsome specimen of Grecian Doric. The hospital fronts another of the boulevards, and is remarkable for the tedious uniformity of its extended front; the theatre is on the same boulevard as the hospital. The cathedral is a Gothic building, and contains some interesting monuments, among them that of Flechter. Some of

the additions to this building are remarkable for their incongruity, being of Greek architecture. The college church is a handsome building of modern date. The Dépôt de Mendicité is established in a fortress, built by Louis XIV., on the ruins of a Huguenot church.

Nîmes has long been an important manufacturing town. Before the Revolution it had a population of 50,000, but the troubles of that period, and the injury to trade which resulted from the long wars that followed, considerably affected it. In 1826 it had 40,000 inhabitants; in 1831 there were 39,639 inhabitants in the town, or 41,266 in the whole commune; in 1836 there were 43,036 in the commune. The principal manufacture is that of fancy silk goods, silk stockings and caps, and other articles, which are made in great abundance and at low price. In quality the goods are not considered equal to the fabrics of Lyon or the silk stockings of Ganges. A considerable quantity of printed cottons, shawls, Madras handkerchiefs, chintzes,

and sewing and embroidering silk, is also manufactured. There are several dye-houses and tan-yards, and the town is the great market for the raw silks of the surrounding district. Brandy is distilled and vinegar manufactured. The surrounding hills produce the vine, the fig, the olive, the pomegranate, the almond, and a great number of aromatic herbs; the plains yield pasturage, corn, and vegetables. The town carries on considerable trade in these various productions; in wine, spices, drugs, essences, silks raw and wrought; also in the oleaginous seeds, medicinal plants, and those used in dyeing. The merchants have connections with most of the great towns of Europe, but especially with Amsterdam, Hamburg, Lübeck, and other places in the north. There are two fairs in the year, but they are of short duration and little importance.

Nîmes is the seat of a bishopric: the diocese comprehends the department; and the bishop is a suffragan of the archbishop of Avignon. It has a Cour Royale, the jurisdiction of which extends over the departments of Gard, Ardèche, Lozère, and Vaucluse; and there are subordinate judicial courts and several fiscal or administrative government offices. It has an Académie Universitaire, a Collège Royale or high school, an Académie Royale for the department, a cabinet of natural history, a course of instruction on chemistry as applied to the arts, a public library of 10,000 (or, according to M. Millin, 30,000) volumes, an agricultural society, a society of medicine, a commission of antiquities, and a Bible society. Elementary instruction is considerably diffused. There are several cabinets of antiquities, of which the principal is that belonging to the high school, which contains more than 8000 medals.

Nîmes has been the birth-place of several men of eminence; among them are the Greek scholar Cotelier (Cotelierus); the learned Petit and Seguier; Saurin, an eminent preacher among the Huguenots; and Rabaut de St. Etienne, one of the victims of the Revolution.

The arrondissement of Nîmes comprehends an area of 650 square miles, and contains 72 communes. It is divided into eleven cantons or districts, each under a justice of the peace. The population in 1831 was 128,461; in 1836, 131,712.

Bronze Coin of Nîmes, from the Museum of Avignon. (Drawn by W. B. Clarke.)

This coin is the celebrated 'Pied de Niche,' which is very rare. There is a similar coin which is so common that it is often found current with the copper money of France. The two heads are said to be those of Agrippa and the Emperor Augustus; that on the right hand is Augustus, and that on the left is Agrippa. The inscription is read, 'Imperator Divi Filius Pater Patriae.' The crocodile chained to a palm tree, surmounted by a streamer, is said to commemorate the victory of Actium and the subsequent reduction of Egypt, of which the crocodile is the symbol. The words Col. Nem. (Colonia Nemausus) refer to the founding of the colony by Augustus. (Rasche, *Lexicon Rei Numariae*.)

NIMWEGEN, or NYMEGEN, is a strongly fortified town in the province of Guelderland, in the kingdom of the Netherlands, in $51^{\circ} 51'$ N. lat. and $5^{\circ} 52'$ E. long. It is on the left bank of the Waal, and is built partly on some hills, and partly on the level ground between the hills and the river, over which there is a flying bridge. It is not ill built, yet the streets being narrow, and the houses rising above and overlooking each other, owing to the steep ascent of the hills, the town has an irregular appearance. The inhabitants amount to 17,300. Their chief occupations are tanning, bleaching, glue-making, and especially brewing a peculiar kind of pale beer called Moll, large quantities of which are exported. They manufacture common brass snuff-boxes, and have a good commission trade. They show an old edifice, now forming part of the fortifications, which is supposed to be of Roman origin; and in the town-hall (which is a handsome building) there is a

large collection of Roman antiquities. Nimwegen is supposed to be on the site of the Roman Noviomagus. Of the nine Calvinist, Lutheran, and Roman Catholic churches, some are worthy of notice. On an eminence near the river stand the ruins of an ancient castle called the Falkenhof, which is said to have been built by Charlemagne, and was the residence of the kings of the Franks. Two public promenades, the Katverbosch and the Belvedere, are much frequented on account of the extensive views which they command of the course of the river and of the surrounding country.

Nimwegen, having joined in 1579 the union of the northern provinces, was besieged and taken by the Spaniards in 1585, but recovered in 1590 by prince Maurice of Nassau. In 1672 the French obtained possession of it without resistance; and in 1678 the treaty of peace was concluded here between France, Spain, and the United Provinces, by which it was restored to the Dutch. In 1702 the French made an unsuccessful attempt to surprise it. During the war of the Revolution it was taken by the French, on the 8th of September, 1794, after a severe action, in which the allies were defeated.

NINEVEH (נִינְוֵה), LXX., *Ninevé, Nivevî*), called by the Greeks and Romans Ninus (*Nῆνος*), the capital of the Assyrian empire, was situate in the plain of Aturia, on the Tigris (Strabo, xvi. 737; Herod., i. 193; ii. 150; Ptolem., vi. 1) and not on the Euphrates, as Diodorus states on the authority of Ctesias (ii. 3, 7).

The Hebrew and Greek writers concur in describing Nineveh as a very large and populous city. Jonah speaks of it as 'an exceeding great city of three days' journey' (*Jon.*, iii. 3), and states that there were more than 120,000 persons in it that knew not their right hand from their left (iv. 11). Rosenmüller and other commentators suppose this to be a proverbial expression to denote children under the age of three or five years, and accordingly estimate the entire population at two millions; but the expression in Jonah is too vague to warrant us in making such a conclusion. Strabo says that it was larger than Babylon (xvi. 737); but if any dependence is to be placed on the account of Diodorus (ii. 3), who states that it was 480 stadia in circumference, it must have been about the same size as Babylon (Herod., i. 178.) The walls of Nineveh are described by Diodorus as 100 feet high, and so broad that three chariots might be driven on them abreast. Upon the wall stood 1500 towers, each 200 feet in height, and the whole was so strong as to be deemed impregnable. (Diod., ii. 3; *Nahum*, chap. ii.)

According to the Greek writers, Ninus was founded by a king of the same name; but in the book of *Genesis* it is only stated to have been built by the Assyrians, which appears to be the meaning of the passage in *Gen.*, x. 11. It was the residence of the Assyrian kings (2 *Kings*, xix. 36; *Isaiah*, xxxvii. 37; compare Strabo, ii., p. 84; xvi., p. 737), and is mentioned as a place of great commercial importance; whence Nahum speaks of its merchants as more than the stars of heaven (iii. 16). But as in the case of most large and wealthy cities, the greatest corruption and licentiousness prevailed, on account of which Nahum and Zephaniah (ii. 13) foretold its destruction.

On the dissolution of the great Assyrian monarchy, in the eighth century B.C., Nineveh was taken by the Medes under Arbaces, in consequence of the river demolishing part of the wall; when it is said to have been destroyed. (Diod., ii. 26-28.) [ASSYRIA.] But it appears to have still existed as the capital of an Assyrian kingdom till B.C. 625, when it was taken by the Medes under Cyaxares. (Herod., i. 106.) The prophecy of its destruction by Zephaniah must refer to its capture by the Medes. Strabo also says that it fell into decay immediately after the dissolution of the Assyrian monarchy by the Medes (xvi., p. 737); and this account is confirmed by the fact that in the history of Alexander the Great the town is not mentioned, although in his march along the banks of the Tigris, previous to the battle of Gaugamela, he must have been very near the spot where it is supposed to have stood. Under the Roman emperors however we read of a town Ninus (*Tac., Ann.*, xii. 13), or Ninive (*Ammian. Mar.*, xviii. 7); and Abulfaraj in the thirteenth century mentions a castle Ninivi.

According to Abulfaraj and the general testimony of Oriental tradition, most modern writers suppose Nineveh to have been situated on the left or east bank of the Tigris, opposite Mosul [Mosul] and partly on the site of the mo-

dern village of Nunia, or Nebbi Yunus, which contains about 300 houses. (Rich.) From the account of Niebuhr, and more especially of Rich, it appears evident that there must have been formerly a large city on this spot; though it is difficult to determine whether the ruins described by these travellers are the remains of ancient Nineveh or of a city built in after-ages. At first sight the ruins of Nineveh present the appearance of a range of hills; but from all these hills large stones, frequently with bitumen adhering to them, are constantly dug out in great numbers. The bridge over the Tigris is said by Rich to have been entirely built of stones dug out of the ruins of Nineveh, which, he adds, is an inexhaustible resource. On the largest of these hills or mounds there is a celebrated mosque, which is supposed to cover the tomb of Jonah. The walls and ditches which surrounded part of the city may still be traced very clearly in many parts. Rich calculated the area enclosed by these walls at from one and a half to two miles broad, and four miles long, extending a little way south of Nebbi Yunus; and he observes that on the river or west side there are only remains of one wall, as well as on the north and south extremities, but that on the east side there are remains of three walls. It is also his opinion that the part enclosed by these walls formed only a part of a great city, probably either the citadel or royal precincts, or perhaps both, as the practice of fortifying the residence of the sovereign is of very ancient origin. In the East to this day the dwelling of the prince, and indeed of many governors, consists of a number of buildings enclosed in quite a separate quarter; and from what we are told of the Babylonian palaces, and see of that of the Siffiviyahs and of the sultan of Constantinople, this extent would not be too much to assign for the residence of the Assyrian kings. There are very few traces of ruins outside these walls; but they may probably exist to a greater extent than has yet been supposed, since Rich relates that some people who been digging for stones in a place outside the enclosure, where it would have been impossible to have known from the appearance of the surface of the ground that there had been buildings beneath, found many huge stones laid in layers of bitumen and lime mortar.

Fragments of bricks, whole bricks, and pieces of gypsum, covered with inscriptions in the cuneiform character similar to the inscriptions at Babylon, are frequently found.

(Winer's *Biblisches Realwörterbuch*; Rosenmüller's *Handbuch der Biblischen Alterthumskunde*; Niebuhr's *Travels*; Rich's *Narrative of a Residence in Koordistan, and on the Site of ancient Nineveh*; and the authorities cited in this article.)

NINTH, an interval in music, a discord retarding the 8th, but may be resolved into either the 6th or the 3rd; and though this is the octave of the 2nd, yet it is essentially different in harmony, both as to treatment and effect. [CHORD; THOROUGH-BASE.]

Of this interval there are two kinds; the major 9th, composed of six tones and two semitones—

and the minor 9th, composed of five tones and three semitones—

NINUS. [NINEVEH.]

NIO, IOS, one of the Cyclades, situated five miles south by west of Naxos, and ten miles north by west of Thera or Santorini. Nio is about nine miles in length and five in its greatest breadth, which is towards the middle of the island. The surface is hilly, but not so rocky or barren as most of the smaller Cyclades. The chief produce is corn, which is of good quality, but the island is deficient in fruit and other trees. The present population, according to Thiersch, is about 2200. The town, called also Nio, is built on a hill on the western coast, above a bay in which there is good anchorage and a fine spring of water issuing out close to the shore. On the eastern coast is another good harbour, called Manganuri. The pilots of Nio are reckoned among the best in the Archipelago. Whilst under the

Turks, the harbours of this island were a favourite place of resort for the pirates who infested the seas of the Levant.

Nio was called Ios by the ancient Greeks, in consequence, it is said, of having been colonised by the Ionians, before which, according to Pliny (iv. 12) and Stephanus of Byzantium, it was called Phœnicia, from the palm-trees which grew on the island, but which have long since disappeared in the same manner as at Delos and other places, where the palm-tree was also found in ancient times. (Spon; Tavernier.)

Strabo, Pliny, and Pausanias speak of the tomb of Homer being at Ios; and the author of the Life of Homer, attributed to Herodotus, reports the epitaph of the poet. The story is that Homer, coming from Samos to Athens, stopped at Ios, which was the native country of his mother, and was there taken ill and died; and the author of the Life above mentioned says that some of the inhabitants of the town, which was built on a mountain, used to come down every day to the sea-coast to attend on the poet during his illness. Tavernier found no ancient monuments on the island, but he mentions a medal of Nio in the French king's cabinet, with the head of Jupiter on one side, and on the other that of Pallas with a palm-tree, bearing the legend *HTON*.

During the middle ages Nio formed part of the duchy of Naxos, founded by the Venetians, but John Crispus, the twelfth duke, detached it from the duchy, and gave it as a separate principality to his brother Marcus, who built a castle on the summit of the hill, round which the modern town of Nio has grown. Marcus also called in many Albanian families to cultivate the soil. His only daughter Adriana Sanudo having married Louis Pisano, a Venetian noble, the dominion of the island passed into and remained with the latter family, until the island was taken by the Ottomans. (Dapper; Tavernier.) It now forms part of the kingdom of Greece.

NIOBE, the daughter of Tantalus, king of Lydia, was married to Amphion, by whom she had, according to Ovid and other ancient writers, seven sons and seven daughters. This is the most commonly received opinion, though Homer (*Il.*, xxiv. 602, &c.) and others give the numbers variously. The pride of Niobe at having this numerous progeny was so great that she is said in ancient story to have insulted Latona, the mother of Apollo and Diana, by refusing to offer at the altars raised in her honour, declaring that she had a better claim to worship and sacrifices than one who was the mother of only two children. Latona, indignant at this insolence and presumption, called upon her children to revenge her, and punish the arrogance of Niobe. Apollo and Diana heard the prayer, and obeyed the entreaty of their outraged parent. All the sons of Niobe fell under the arrows of Apollo, while the daughters in like manner met their death from the hands of Diana. Chloris alone escaped the common fate. She was the wife of Neleus, king of Pylos. This terrible judgment of the gods so affected the now heart-stricken and humiliated Niobe, that she was changed by her excessive grief into stone on Mount Sipylus in Lydia. Pausanias says (i. 21, 3) that the rock on Sipylus, which went by the name of Niobe, and which he had visited, 'was merely a rock and precipice when one came close up to it, and bore no resemblance at all to a woman; but at a distance you might imagine it to be a woman weeping with downcast countenance.'

The fable of Niobe and her children has afforded a subject for art, which has been finely treated by one of the greatest ancient masters of sculpture. It consists of a series, rather than a group, of figures of both sexes, in all the disorder and agony of expected or present suffering; while one, the mother, the hapless Niobe, in the most affecting attitude of supplication, and with an expression of deep grief, her eyes turned upwards, implores the justly offended gods to moderate their anger and spare her offspring, one of whom, the youngest girl, she strains fondly to her bosom. It is difficult by description to do justice to the various excellence exhibited in this admirable work. Its great merit is independent of fine execution, in which it is inferior as a whole to many other well-known productions of the Greeks. Its excellence consists in the finer qualities of sentiment, as expression, grace, propriety, and variety of action, with that unity of effect by which the scene is brought dramatically and at the same time truly before the spectator, and a story of the most affecting interest told in language that cannot be mistaken. The arrangement of the composition is supposed to have been adapted to a tympanum or pedi-

mont. The figure of Niobe, of colossal dimensions compared with the other figures, which are life size, forms, with her youngest daughter pressed to her, the centre; while the rest of the sons and daughters are ranged in various ways on each side, some exhibiting expression of fear, others agonised with pain, others in grief, while one of the sons lies dead or dying, and stretched upon the ground. All are graceful, and some of the figures possess also great beauty, and the action and expression of many of the heads offer admirable examples for study to the artist. The whole attitude and expression of Niobe herself may truly be called sublime. An eminent professor has observed of this figure, 'The character of the head, though indicative of a more matured age and less delicate than the daughters, still presents an image of the most attractive beauty; while grace, sentiment, and dignified simplicity reign throughout the figure.'

The colossal scale of the principal figure has justly been objected to as a fault. The artist doubtless had two purposes in view when he ventured on this deviation from truth. The first was the necessity which he felt of giving a superior height and volume to the apex and key, as it were, of his composition; and next perhaps the desire he had to concentrate the interest in his chief figure by forcing it thus upon the attention. But although we should hesitate before taking any exception to the practice of the great leaders and masters of art, yet, generally speaking, any departure from the truth of nature—the real canon of excellence when rightly studied—is so far from being commendable or admissible, that, where it has been indulged in by the artists with the view of gaining greater effect and energy, it may usually be considered rather as evidence of their inability to work out their idea with the authorised means, than as a practice to be admired or imitated; and it may always be argued that they would have been so much the more entitled to our admiration if they had produced their works within those limitations which nature dictates. The productions which exhibit these faults, for they must be accounted so, will be found to be worthy of the high estimation in which they are held for other properties, and rather in spite of than because of the licence which their authors have allowed themselves.

The execution of this interesting monument of Greek art is attributed by some to Scopas, a native of Paros, who lived about 300 years before the Christian era; while others think it is the production of Praxiteles. Pliny says it was a question which of the two was the author of it. The group was in the temple of Apollo Sosianus at Rome. (Plin., *Hist. Nat.*, xxxvi.; Sillig., *Cat. Artificum*, in verb.)

Flaminio Vacca says the group of Niobe and her children was found at Rome, but *outside* the walls, near S. Giovanni; but the learned antiquary Fea denies this, and says it was found near the Villa Altieri. The well known statues of the 'Boxers' were discovered at the same place, and it has been supposed by some that they formed part of the group; the fable being that some of the children of Niobe were slain while thus exercising. (Winckelman, *Sur l'Allegorie*, pref.)

All the above statues are in marble, and are now at Florence in the gallery of the grand-duke of Tuscany; but many of them are thought to be copies only, from originals now lost. There is in England a head of Niobe, which is engraved in the 'Select Specimens of Sculpture,' published by the Society of Dilettanti (vol. i.), similar in action and expression, but preferable, for its style and execution, to that of the Florence statue; and as there are known repetitions of some of the other figures, it is not improbable that the principal and most interesting of the series may also have been frequently copied, and that the figure in the grand-ducal collection, though an ancient work, may come under this class.

The subject of Niobe and her children was a favourite one also with the poets of antiquity. Besides the beautiful story in Ovid (*Metam.*, vi. 146), there are numerous epigrams in the Greek Anthology, several of which have great merit, and appear to be descriptive either of the group of figures which still exists, or of some similar group. See particularly that beginning—

Ἰαυτάδ' καὶ Νιόβη, κλέ' ἑμὴν φάτιν ἄγγελον δρας.

For further information and references as to the group of Niobe, see Thiersch, 'Ueber die Epochen der Bildenden Kunst,' &c., pp. 368, &c.

NION, or NYON. [WAADT.]

NIONS, or NYONS. [DRÔME.]

NIORT, a city in the west of France, capital of the department of Deux Sèvres, situated on the bank of the Sèvre Niortaise, in 46° 13' N. lat. and 29' W. long.; 218 miles from Paris in a direct line south-west, or 260 miles by the road through Versailles, Chartres, Tours, and Poitiers.
