Manufacturers and dealers avoid following a definite system of grades to keep others from knowing their grades and to safeguard private blends. Private blends are established by careful experiment with different types and qualities of tobacco, and the several qualities of each type used in a blend are then set up as the grades for that blend. These grades are usually designated by letters or numbers or by a combination of letters and numbers. For instance, a new grade may take the initials of one of the company's directors or a certain letter in the name of the blend may be selected. Although the grade is kept as constant as possible, sometimes the grade symbol is changed to keep competitive buyers from learning the grades. Apparently there is no written description, of any private grade, and a word picture of a private grade has heretofore been considered not only impracticable but undesirable.

The large manufacturer ordinarily buys from 20 to 40 grades for his private blends; no manufacturer covers the entire range of the market, but some of the larger dealers who have orders from several domestic and foreign manufacturers cover the full range of the market on which they operate. Usually the buyers of commercial concerns are the graders. The buyer examines the tobacco for which he is negotiating and determines the grade or grades it will make in his private system. This, in turn, fixes the price he is able to pay for the lot.

The Commercial Grading School

Each firm requires a large number of men to receive, handle, work, pack, and condition the tobacco after it has been graded and bought. This series of operations constitutes the commercial grading school for

Aspen, the species most commonly used, is usually the first tree crop that comes in at the higher elevations following fires, and its lighter foliage permits the conifers to reseed and reproduce on the burned area. Aspen also sprouts readily, so that poles can be cut from old burns that have restocked to coniferous stands or from stands of aspen which will then reproduce a new crop by sprouting. Pine poles can be obtained from thinnings, and the suppressed and defective trees removed, leaving the young stands in better silvicultural condition.

Assistant Regional Forester, Forest Service.

TOBACCO Graders Trained to Apply New System of Clearly Defined Grades Men are now being taught to grade tobacco in a new way. Instead of following the old methods that have been in vogue since early colonial days, the Department of Agriculture is training its graders to work with a definite system of clearly defined grades. The men to be trained have so far been drawn chiefly from two commercial sources—buyers who have been employed by tobacco firms or who have operated as independent speculators.

Each independent buying firm, whether manufacturer or dealer, has always had a more or less stable system of private grades, but there is no definite correlation between the grades of the various manufacturers and dealers. The manufacturers' grades are built around their private blends and the grades of the larger dealers usually reflect the blends of the domestic or foreign manufacturers for whom they buy.

Manufacturers and dealers avoid following a definite system of grades to keep others from knowing their grades and to safeguard private blends. Private blends are established by careful experiment with different types and qualities of tobacco, and the several qualities of each type used in a blend are then set up as the grades for that blend. These grades are usually designated by letters or numbers or by a combination of letters and numbers. For instance, a new grade may take the initials of one of the company's directors or a certain letter in the name of the blend may be selected. Although the grade is kept as constant as possible, sometimes the grade symbol is changed to keep competitive buyers from learning the grades. Apparently there is no written description, of any private grade, and a word picture of a private grade has heretofore been considered not only impracticable but undesirable.

The large manufacturer ordinarily buys from 20 to 40 grades for his private blends; no manufacturer covers the entire range of the market, but some of the larger dealers who have orders from several domestic and foreign manufacturers cover the full range of the market on which they operate. Usually the buyers of commercial concerns are the graders. The buyer examines the tobacco for which he is negotiating and determines the grade or grades it will make in his private system. This, in turn, fixes the price he is able to pay for the lot.

The Commercial Grading School

Each firm requires a large number of men to receive, handle, work, pack, and condition the tobacco after it has been graded and bought. This series of operations constitutes the commercial grading school for its young men. They are employed as receiving clerks, warehouse managers, and in other capacities in which they come into daily contact with the firm's purchases. It becomes an important part of each such employee's duty to acquire a knowledge of grades and to keep a careful watch for any irregularities in the grades as the tobacco passes through his hands.

A receiving clerk or warehouse manager is not ordinarily authorized to change the grade assigned by the buyer, but it is his duty to set aside doubtful lots to be reviewed by the buyers. This gives him an opportunity to observe the grading of the buyer, and to check his judgment with the buyer's on doubtful lots. In such cases the buyer usually explains his reason for placing each lot in a certain grade. Gradually these young men acquire sufficient knowledge to qualify them as substitute buyers on small stations. Later, if they develop sufficient skill they may be assigned to a small market or made an assistant buyer on a large market.

FIGURE 172.—Studying tobacco grades at a grading school held at the North Carolina State College in cooperation with the Department of Agriculture

Another kind of so-called training school is composed of a large number of young men who are unable to obtain positions with the companies. They follow the tobacco markets throughout the season studying tobacco and speculating on a number of lots, buying from the producers and reselling to manufacturers or large dealers. Ordinarily, these small speculators have no system of grades of their own, but they learn all they can about the grades and special quality preferences of the well-organized companies, so that they can resell to them. It is is difficult to learn the companies' private grades, but in the course of years, by careful observation and study, they can become familiar with them and develop a high degree of skill in judging the different qualities, colors, and lengths of the tobacco.

Contrasted with the private grades of the trade, the department has established for the leading types a uniform system of grades worked out on a definite plan and has formulated a written description of each grade. Since these standardized grades are intended to serve all interests who may care to use them, including producers, dealers, and manufacturers, they are not based upon the blends of any company, but upon four definite grade factors—group, quality, color, and length. The same system is used for each of the 26 important types produced in the United States, and a uniform symbol is used to designate each corresponding grade factor in all types.

Full Range of Characteristics Covered

The standardized grades cover the full range of quality, color, and length in each type, whereas the private grades of a manufacturer cover only such quality, colors, and length as are called for by his particular blends. There are from 50 to 75 standardized grades in each type; they divide the tobacco into uniform steps, from the highest to the lowest quality, from the lightest to the darkest color, and from the longest to the shortest lengths.

When inaugurating the Federal-State tobacco grading service, in 1929, the department required a number of graders. Men drawn from commercial sources, who were already good judges of tobacco, were employed and trained to grade according to Government standards. Each new grader was given a grade book with a list of the grades for the type he was to grade. This book gave a full explanation of the standard grading system, clear definitions of all indefinite tobacco terms, certain grading rules, and a complete description of each grade. It was demonstrated that, with sufficient background of experience, a person with the aid of a grade book and a few representative tobacco samples, in a very short time can familiarize himself with the standardized grades and can proceed to grade tobacco according to Government standards.

Plans are now being developed to establish tobacco grading schools in cooperation with some of the leading agricultural colleges. Three short courses of this nature have been held with encouraging results. (Fig. 172.)

TOBACCO Plants Spaced Close Yield More and Better Flue-Cured Leaf

The increasing demand for flue-cured tobacco during the past decade has been for the cigarette leaf or cutter grade, which is bright lemon to orange in color and is thinner than the wrapper. In order to produce a leaf of such characteristics it was found necessary to plant more tobacco on the land. A thinner leaf with brighter color can be produced by topping (pinching out the bud) higher or spacing the plants closer in the row. The former method did not prove to be as satisfactory as the close spacing, as the result was so often adversely affected by unfavorable seasons. During a period of eight years the closer spacing with only a few exceptions produced a larger yield of tobacco with a larger percentage of cigarette leaf and a greater total acre value than the ordinary distance of planting. By close spacing of

TOBACCO Plants Spaced Close Yield More and Better Flue-Cured Leaf

The increasing demand for flue-cured tobacco during the past decade has been for the cigarette leaf or cutter grade, which is bright lemon to orange in color and is thinner than the wrapper. In order to produce a leaf of such characteristics it was found necessary to plant more tobacco on the land. A thinner leaf with brighter color can be produced by topping (pinching out the bud) higher or spacing the plants closer in the row. The former method did not prove to be as satisfactory as the close spacing, as the result was so often adversely affected by unfavorable seasons. During a period of eight years the closer spacing with only a few exceptions produced a larger yield of tobacco with a larger percentage of cigarette leaf and a greater total acre value than the ordinary distance of planting. By close spacing of the plants in the row a heavier application of fertilizer produced larger yield and net value of crop per acre and thus accentuated the gain over the usual methods.

With an application of 1,100 pounds per acre of a fertilizer mixture containing 5 per cent ammonia, 8 per cent phosphoric acid, and 10 per cent potash, tobacco planted 36 inches apart in rows 3 feet and 9 inches wide had an average value for eight years of $168.50 per acre. When the plants were spaced 30, 24, and 18 inches apart, respectively, the corresponding values of the crop were $187.50, $198.30, and $239.80. Where only 500 and 800 pounds per acre of the same fertilizer mixture were used the differences in favor of close spacing were not so great, being $22.70 and $37.20 per acre, respectively. These differences, however, were more than enough to pay for the total fertilizer cost.

In addition to the increased yield and value obtained by close spacing of tobacco, some of the common leaf-spot diseases are more easily controlled by close spacing than when the plants are spaced farther apart. It is easy to conclude, therefore, that liberal fertilization combined with close spacing in the flue-cured tobacco belt will produce a leaf of better quality and one that is in greater demand at the present time.

TOMATO Ripening After Frost Requires Proper Handling and Storage

The ripening of tomatoes on a commercial scale after frost has killed the vines is a subject of considerable interest in many parts of the country. It is a more or less common custom for home growers and market gardeners to gather a limited quantity of green tomatoes after the first killing frost and to store them after a fashion under chaff in a mow or shed, or uncovered in a basement. To some extent these methods suffice to supply a certain quantity of ripe tomatoes after frost, but usually they result in considerable loss from decay and much of the fruit that ripens is of poor color and quality.

Proper handling and storage methods are necessary if attractive tomatoes of good quality are to be had. The local gardener who attempts to supply ripe tomatoes for the market after frost has killed the vines, and who wishes to compete in any degree with the shipped tomatoes that are usually commencing to come on the market at this time, must display an equally attractive product.

Investigations to determine the best conditions for the ripening of locally grown green tomatoes have been carried on for several years by the United States Department of Agriculture.

Tomatoes from plants that have passed their period of maximum productivity and are more or less spent are inclined to be soft and watery and will not ripen or keep as well as the firmer-fleshed fruits from plants in full vigor. Therefore to ripen marketable quantities of high-class tomatoes after frost it is advisable to set the plants in the field late enough so that they will come into full bearing at about the average time of the first frost. In the vicinity of Washington, D. C., where the experiments were carried on, the plants were set in the field the plants in the row a heavier application of fertilizer produced larger yield and net value of crop per acre and thus accentuated the gain over the usual methods.

With an application of 1,100 pounds per acre of a fertilizer mixture containing 5 per cent ammonia, 8 per cent phosphoric acid, and 10 per cent potash, tobacco planted 36 inches apart in rows 3 feet and 9 inches wide had an average value for eight years of $168.50 per acre. TOMATO Ripening After Frost Requires Proper Handling and Storage

The ripening of tomatoes on a commercial scale after frost has killed the vines is a subject of considerable interest in many parts of the country. It is a more or less common custom for home growers and market gardeners to gather a limited quantity of green tomatoes after the first killing frost and to store them after a fashion under chaff in a mow or shed, or uncovered in a basement. To some extent these methods suffice to supply a certain quantity of ripe tomatoes after frost, but usually they result in considerable loss from decay and much of the fruit that ripens is of poor color and quality.

Proper handling and storage methods are necessary if attractive tomatoes of good quality are to be had. The local gardener who attempts to supply ripe tomatoes for the market after frost has killed the vines, and who wishes to compete in any degree with the shipped tomatoes that are usually commencing to come on the market at this time, must display an equally attractive product.

Investigations to determine the best conditions for the ripening of locally grown green tomatoes have been carried on for several years by the United States Department of Agriculture.

Tomatoes from plants that have passed their period of maximum productivity and are more or less spent are inclined to be soft and watery and will not ripen or keep as well as the firmer-fleshed fruits from plants in full vigor. Therefore to ripen marketable quantities of high-class tomatoes after frost it is advisable to set the plants in the field late enough so that they will come into full bearing at about the average time of the first frost. In the vicinity of Washington, D. C., where the experiments were carried on, the plants were set in the field the first or second week in July. The plants were at their best and were loaded with a good crop of mature and almost mature green and some ripe fruit by the middle of October, when the first frost can be expected. However, the writer does not wish to discourage the utilization of all available tomatoes of good quality left in the field even if they do represent the leavings of a midseason crop. These can be ripened and good use made of them.

It is doubtful whether tomatoes should be left on the plants after the first frost, even though part of the leaves are still uninjured. There is some indication that fruit so left loses its keeping quality. Furthermore, there is danger of a second and heavier frost following soon which may seriously injure the fruit.

Necessary Conditions for Ripening

For ripening purposes, only sound tomatoes that are mature or nearly so should be selected. These should be carefully handled to avoid bruising or other mechanical injury. Tomatoes in the proper stage for ripening can be sorted out by selecting only those showing a yellowish-white color or whitening about the blossom ends or sides, in contrast to the immature ones of solid dark green. The size of tomatoes is not necessarily an indication of maturity; medium-sized specimens may be more mature and may color up sooner than certain large ones.

When rapid ripening is desired a temperature around 70° F. with a relative humidity of 75 to 80 per cent is best. Although tomatoes will ripen rather rapidly at this temperature, or even a few degrees higher, they quickly break down after ripening. Moderately rapid ripening with a comparatively slow development of decay may be secured at a temperature of 60°.

Rapid ripening is not always desirable. Where a large quantity of tomatoes is to be ripened and marketed, a part should be held back and the rate of ripening adjusted so as to prolong the marketing period. The results of the investigations by the department show that a temperature of 55° F. is about the lowest at which satisfactory ripening will take place. Tomatoes held at this temperature will ripen slowly but with good color and quality and will keep in good sound condition longer than at temperatures above or below this point.

Cellars as Ripening Places

Usually a well-ventilated cellar, provided it is not damp, makes a good ripening or storage space, because the temperature is uniform and the humidity sufficiently high to prevent undue shriveling or wilting. The usual type of outside shed has a fluctuating temperature, being probably too cold at night and too warm on many days. Often such buildings can be remodeled so as to make a tight double-walled structure in which the desired temperature and humidity can be maintained. Shelves can be provided, although shallow trays on which to ripen the fruit are preferable. The tray should be supported in tiers a few inches apart on racks from which they can be readily removed independently for convenience in grading out the ripe or decayed fruits. The trays should be deep enough to hold only one layer of fruit and not too large when loaded for one person to carry. The ripening room should be kept dark so that the tomatoes will ripen more uniformly.

Good ventilation should be provided. Too high a humidity should be avoided, as this will promote undue decay.

An ideal arrangement for the ripening of tomatoes would be to have two rooms, one to be kept uniformly cool but not lower than 55° F. and the other at about 70°. The cool room would be considered a storage space from which tomatoes could be transferred to the warm room for rapid ripening in quantities as needed. With such an arrangement it should be possible to extend the marketing season a month or six weeks after frost.

Grading and Packing Important

At about the time frost has destroyed most of the local field crop, shipped tomatoes, carefully and attractively wrapped and packed, begin to appear on the market. To compete with these the local grower should uniformly grade his stock as to quality and size and pack it carefully in 4-quart baskets, rather than offer ungraded stock in hampers or other unsuitable containers. A very attractive pack can be made by wrapping alternate tomatoes with green tissue paper.

R. C. Wright,
Physiologist, Bureau of Plant Industry.

TREES of Four Kinds Are Becoming Important in Planting on Farms

Two kinds of pines and two of hardwoods are assuming an important rôle in our forest tree planting. They are red pine, slash pine, black locust, and black walnut. Red, or Norway pine (fig. 173), is a member

TREES of Four Kinds Are Becoming Important in Planting on Farms

Two kinds of pines and two of hardwoods are assuming an important rôle in our forest tree planting. They are red pine, slash pine, black locust, and black walnut. Red, or Norway pine (fig. 173), is a member

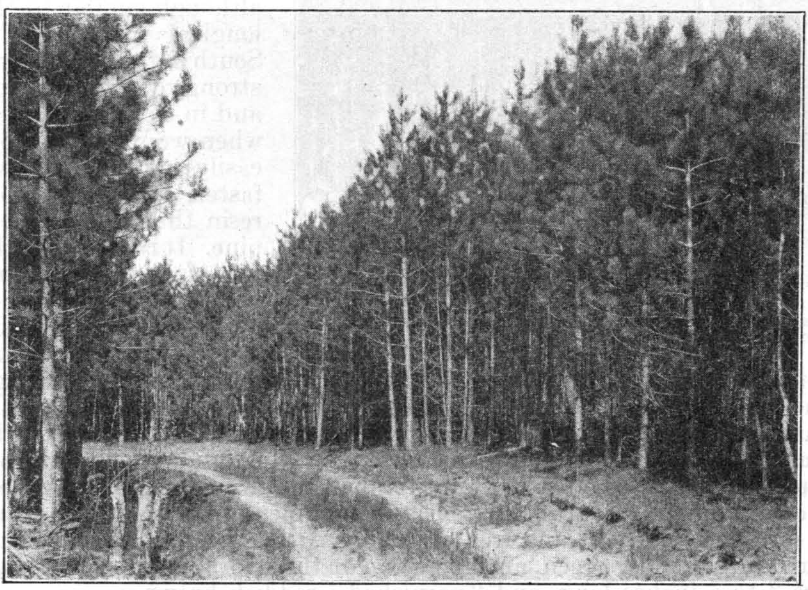

FIGURE 173.—Red, or Norway pine, important in forest planting in the Northeastern and Lake States

of the yellow-pine group. It ranks as one of the most popular pines for forest planting from Maine to Minnesota and south to the Mason and Dixon's line. In the same region the white pine is extensively planted. The trunks of red pine trees growing in close stands become smooth and relatively free of limbs. The growth is comparatively rapid and the wood is of good quality with a wide range of uses. Red pine's home range is about the same as that of eastern white pine, except that it does not extend south in the Appalachians. It enjoys a freedom from blister rust, an enemy of white pine, but is subject to the white-pine weevil.

FIGURE 174.—Slash pine is our most vigorous growing pine. Its home is the coastal plain in the Southeastern States where it is being extensively planted

The red pine may be distinguished by its short, rather thick needle leaves, two in a bundle, its small cones with very small seeds, the orange and red tinged branchlets, the straightness of the trunk, and the sturdy appearance of the tree. The name "Norway" pine is unfortunate since it suggests the country of Norway as its original home, whereas the name came from the town of Norway, Me.

Slash pine (fig. 174), although similar to the longleaf pine of the South in the hard, heavy, strong yellow-pine wood and in the flow of resin when wounded, is more easily propagated, grows faster, and yields more resin than the longleaf pine. It ranks, up to the age of about 20 years, as the fastest growing of all our native pines. Its geographic range extends over much of the coastal plain from South Carolina through the lower parts of Georgia, Florida, Alabama, Mississippi, and southeastern Louisiana. Within this range and a little farther north the slash pine is being extensively planted for the production of timber and resin. The wood is used for lumber, pulpwood, crossties, veneer blocks, and the tree trunks extensively for poles and piling. The trunk is unusually straight and free of branches; the needles or leaves are long, bright shiny green, and grow two or three in a bundle; the cones are 3 to 5 inches long, and "varnished" reddish brown.

In southern Georgia many farmers and larger timberland owners are planting areas of fire-devastated and worn-out cotton lands with 1-season-old slash pine seedlings, either dug up in the woods or, more generally, grown in private or State-managed nurseries. The same is true on a smaller scale in South Carolina and Florida. Probably the most extensive pine planting by a lumber company in the United States is that of the Great Southern Lumber Co. of Bogalusa, La. Of a total of about 30,000 acres of young planted forest, over 20,000 acres are slash pines.

At 5 years of age slash pines are commonly from 5 to 10 feet in height, at 15 years the stand is usually in good condition for turpentining and may be "worked" almost continuously thereafter for periods up to 40 years of age. Considering the abundance and relative cheapness of lands in portions of the South, and the rapidity of growth of slash pine and the products it yields, growing it as a crop is regarded as most profitable.

FIGURE 175.—Black locust combines several outstanding qualities for forest planting on farms. Before planting it, however, the landowner should seek the advice of the local forestry agencies, as in some localities an insect pest is serious

Black locust (fig. 175) has been widely distributed by man because of its high intrinsic value. It is favorably regarded in most sections, but unfavorably in some. Its good points are the cheapness and ease of propagation, rapid growth, ability to grow on well-drained banks, hillsides, and eroded lands, and the high value of the wood for stakes, posts, and poles. Black locust wood used in the ground lasts from 15 to 40 years. No other wood except osage-orange lasts longer in the ground without preservative treatment, and few trees grow faster or mature earlier than black locust. In some regions like the brown loams of the Mississippi Valley black-locust stands are mature in 15 years, and elsewhere in not over 20 years.

Small trees dug up in locust thickets or grown from seed are easily set out. The trees grow from 1 to 3 feet a year, and do well on many kinds of soil, although they do not thrive on very sandy or poorly drained sites. As the root system spreads rapidly just beneath the surface, the tree is of value as a soil binder. No tree in the United States ranks so high as black locust for planting to prevent or check erosion.

The chief drawback to successful growing of black locust is the locust borer, an insect which almost everywhere is doing some damage to the tree trunks. In some regions it is so serious as to make the locust growing impracticable. This appears to be the case in much of Ohio and Indiana and portions of West Virginia and northern Kentucky along the Ohio River. In poor soil where growth is slow, the borer may seriously injure or even destroy plantations, but in favorable regions of growth the damage is not so severe.

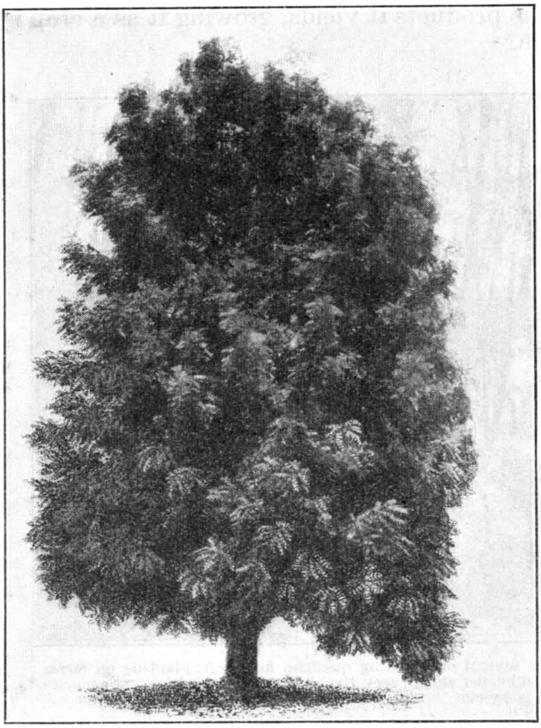

FIGURE 176.—The tree aristocrat, the black walnut, is recommended for planting singly or widely spaced in small groups about the farm

Favorable regions for planting and growing black locust as a crop are found from central New York south through Maryland and the upland hilly or piedmont section and the Appalachian Mountain region to middle Georgia and Alabama, and generally throughout the central Mississippi Valley region. Particularly favorable are limestone soils and others that are nonacid in character. In Idaho and other parts of the western United States the growing of black locust under irrigation is eminently successful and profitable.

Before attempting to establish a plantation, except on a small experimental scale, the landowner would do well to consult the State forester, the extension forester located at the State college of agriculture, the local agricultural county agent, or the Forest Service of the United States Department of Agriculture.

Black walnut (fig. 176), a native American tree, has many and varied uses, ranging all the way from the finest cabinets and furniture to gunstocks and gimlet handles. If a farmer wants wood for a special gate lock or other use where the weather must have little effect upon it he may well select black walnut. The nuts of this dual-purpose tree bring good prices in an increasing market.

Young trees may be started by planting the nuts 2 inches deep in the ground where squirrels or hogs can not dig them up, or by planting year-old nursery-grown seedlings. A few hundred seedlings can be grown in the garden, and set out successfully the next spring.

Black walnut should not be planted closely to form a stand—it does not grow that way in nature—but rather it should be planted as individual trees about the farm, always, however, in good soil. Planting black walnut in small patches in corners or along fence rows, or in stony but good soil, should be a good investment. Often in such out-of-the-way places inferior kinds of trees are now growing. For example, sycamores are trees of low value that might well be replaced by black walnut.

A deep, good soil, well supplied with moisture and well drained, is required for growing walnut successfully. Limestone soils are very favorable, as well as deep rich alluvial soils along streams not subject to heavy overflow.

On many farms active effort should be made to restock them with black walnut, as this choice forest tree is easy to grow and profitable to handle.

W. R. Mattoon,
Extension Forester, Forest Service.

TUBERCULOSIS of Cattle Practically Eradicated from State of Michigan

When the nation-wide bovine-tuberculosis-eradication project was launched in 1917, supporters had no tangible basis for their predictions of success. The project at that time was but a plan on paper. Yet this plan had received much serious thought by veterinary officials and representatives of the livestock industry. Now that this disease has been brought under complete control in three States—North Carolina, Maine, and Michigan—and under partial control in more than a thousand counties elsewhere, a successful termination of the project can not be questioned. The conduct of the work in Michigan illustrates some of the problems that are encountered in such an undertaking, as well as the manner in which they are met.

Testing Individual Herds Was First Step

When the eradication campaign started in 1917 it was found that Michigan, like nearly all other States, had no suitable laws for carrying out a project of this nature. Nearly four years were required to obtain necessary legislation. During that time State and Federal officials cooperated with owners of purebred herds, under what was known as the accredited-herd plan. This was a method of freeing individual herds from tuberculosis, on a voluntary basis.

This procedure led to benefits that stimulated a demand for accreditation work on a large scale. In 1920 accredited-herd owners in Livingston County requested the board of supervisors to appropriate funds for a cooperative arrangement with the State and Federal Governments in a county-wide campaign against bovine tuberculosis. When put into effect, this county-area plan was so favorably accepted that before the end of 1921 eight counties had appropriated funds and work was under way in seven of the counties. Within eight years every county board of supervisors in the State had made similar appropriations for participation in county-wide testing.

Black walnut should not be planted closely to form a stand—it does not grow that way in nature—but rather it should be planted as individual trees about the farm, always, however, in good soil. Planting black walnut in small patches in corners or along fence rows, or in stony but good soil, should be a good investment. On many farms active effort should be made to restock them with black walnut, as this choice forest tree is easy to grow and profitable to handle.

W. R. MATTOON,
Extension Forester, Forest Service.

TUBERCULOSIS of Cattle Practically Eradicated from State of Michigan When the nation-wide bovine-tuberculosis-eradication project was launched in 1917, supporters had no tangible basis for their predictions of success. The project at that time was but a plan on paper. Yet this plan had received much serious thought by veterinary officials and representatives of the livestock industry. Now that this disease has been brought under complete control in three States—North Carolina, Maine, and Michigan—and under partial control in more than a thousand counties elsewhere, a successful termination of the project can not be questioned. The conduct of the work in Michigan illustrates some of the problems that are encountered in such an undertaking, as well as the manner in which they are met.

Testing Individual Herds Was First Step

When the eradication campaign started in 1917 it was found that Michigan, like nearly all other States, had no suitable laws for carrying out a project of this nature. Nearly four years were required to obtain necessary legislation. During that time State and Federal officials cooperated with owners of purebred herds, under what was known as the accredited-herd plan. This was a method of freeing individual herds from tuberculosis, on a voluntary basis.

This procedure led to benefits that stimulated a demand for accreditation work on a large scale. In 1920 accredited-herd owners in Livingston County requested the board of supervisors to appropriate funds for a cooperative arrangement with the State and Federal Governments in a county-wide campaign against bovine tuberculosis. When put into effect, this county-area plan was so favorably accepted that before the end of 1921 eight counties had appropriated funds and work was under way in seven of the counties. Within eight years every county board of supervisors in the State had made similar appropriations for participation in county-wide testing.

Procedure for County-Wide Testing

Before the county-area plan was put into effect, officials in charge agreed that cooperation be confined to State, Federal, and county authorities, excluding any outside organizations. It was agreed also that no support be solicited by either State or Federal officials and that the plan be placed before no board of supervisors except upon invitation from that board. These arrangements proved to be wise. When pressure was brought upon any board of supervisors to make an appropriation, it came from the taxpayers in that county.

The county-area plan was brought before the State legislature, and resulted finally in a State law which empowered any board of supervisors to make county appropriations for cooperating with the Federal Government in the eradication of tuberculosis. The law also made it compulsory for every herd owner in a county where the project had been adopted to have his herd tuberculin tested. However, no owner was compelled to accept State and Federal supervision but

FIGURE 177.—A tuberculosis-free herd, one of approximately 150,000 that were tested during the state-wide campaign in Michigan

could employ an accredited veterinarian to apply the test, if he so desired. Though having legal features, the entire plan, as carried out, was essentially one of voluntary cooperation between the Federal, State, and county Governments and herd owners. Cases in which owners did not desire to cooperate voluntarily were left to State authorities for law enforcement, an arrangement which did not directly involve the cooperating organization.

At the beginning of the campaign the State had a cattle population of over 1,500,000 head distributed among more than 150,000 farms. (Fig. 177.) A careful estimate showed an average of about 4 per cent infection. The "drive" plan of operating appeared to be the most efficient and economical and was therefore followed throughout the campaign.

Hillsdale County, the second to make appropriations for the work, was chosen as the area in which to make the first drive. An aggressive campaign was begun October 24, 1921 with 33 veterinarians, 15 of whom were Federal veterinarians sent in from other States, not only to assist in the actual work but also to study the methods and observe the results. The entire county was covered in 12 days, 95 per cent of the herd owners voluntarily cooperating.

Test Reveals Many Generalized Cases

It took nine years and four months to reduce the percentage of bovine tuberculosis infection from approximately 4 per cent to less than one-half of 1 per cent, which is the requirement for accreditation. In carrying out this work the tuberculin test was applied 3,236,376 times and 58,324 reactors were removed.

Several interesting points were noted during the campaign. One was that countries having the heaviest infection were accredited with the smallest number of county-wide tests. Macomb County, for instance, with the highest degree of infection, 14.4 per cent, was accredited after two complete tuberculin tests of all the cattle. Ontonagon, an upper peninsula county, having only 1.2 per cent of tuberculosis on the first test, required three complete tests to reach the point of accreditation. This is explained by the manner of handling the cattle in the different localities. In Macomb County the cattle owners were largely in the dairy business and the herds were kept on individual farms, making control methods comparatively easy. In Ontonagon County the conditions were reversed. The cattle were owned by miners and were kept mostly in community herds, which made it difficult to control the spread of infection.

The general impression that a large percentage of extensively diseased cattle do not react to the tuberculin test was disproved in the Macomb County work where the post-mortem reports showed that of the 4,063 reactors, 547 were generalized cases. Furthermore, 509 of the 547, or 93 per cent, reacted to the first test, leaving but 38 head to be found by subsequent testing.

There is ample evidence to support the belief that bovine tuberculosis, once eradicated, can be kept suppressed. In Michigan 42 counties have been retested three years from the date of first accreditation. All of these counties have been reaccredited, showing that the disease has been kept from reappearing. Furthermore, in the last two years 23,266 cattle from various parts of Michigan were tuberculin tested to meet the requirements for shipment to other States. Of this large number only 10 were reactors, representing 0.04 per cent of infection.

The result of the Michigan campaign should be sufficient to convince the most skeptical person that bovine tuberculosis can eventually be entirely eradicated.

THEODORE S. RICH,
Senior Veterinarian, Bureau of Animal Industry.

TURKEY Grading by U. S. Grades Extended to Many Country Points Government grading of turkeys was confined practically to terminal markets until the holiday season of 1929–30. But as receivers, favorable to Government grading, insisted that the place to do the grading is at the shipping point where the turkeys are packed, and as requests for grading were received from many of the State departments of agriculture, State agricultural colleges, turkey pools, and the results. The entire county was covered in 12 days, 95 per cent of the herd owners voluntarily cooperating.

TURKEY Grading by U. S. Grades Extended to Many Country Points Government grading of turkeys was confined practically to terminal markets until the holiday season of 1929–30. But as receivers, favorable to Government grading, insisted that the place to do the grading is at the shipping point where the turkeys are packed, and as requests for grading were received from many of the State departments of agriculture, State agricultural colleges, turkey pools, and associations, the Bureau of Agricultural Economics extended its grading service to the country points.

Before the grading work was started it was decided to hold a turkey-grading school at a convenient central point where instructions could be given in the interpretation, application, and use of the Government grades for turkeys to all who cared to attend. As the requests for the grading work came chiefly from the Northwestern States the first school was held at Salt Lake City in October, 1929. Representatives from 10 States attended. Of a total attendance of 125 persons, 86 registered for examination.

In response to an urgent demand for more aid, 14 schools were later held in California, Oregon, Wyoming, Colorado, Nevada, and Minnesota. In addition, certain State colleges and State agricultural workers held local schools in their States. The attendance at all these schools is estimated at 2,500 persons.

FIGURE 178.—Packing Government-graded turkeys at a country-receiving station

At each school some time was devoted to the problems of producers because in the Pacific Northwest States the producers do the dressing. Demonstrations included the grading of live turkeys, the methods of ascertaining whether a turkey is ready for market, and desirable methods of sticking, bleeding, and picking. Precooling and packing also received attention. In fact, the whole series of operations that occur from the time the turkey leaves the roost until it is packed and loaded into the car on its way to market were covered.

Six Hundred Students Take Examination

More than 600 students took the examinations for grading that were given at the various Federal schools; 286 of these were licensed as Federal-State turkey graders, and 32 were licensed as supervising graders. (Fig. 178.)

During the 1929–30 holiday season, including the Thanksgiving and Christmas markets, the graded turkeys, at shipping points and markets combined, totaled nearly 8,000,000 pounds. Much of this work was done through Federal-State cooperative grading services. The turkeys were classed as young turkeys, old turkeys, hens, and toms, and there were four grades of each class—U. S. Prime, U. S. Choice, U. S. Medium, and U. S. Common. Less than half of the total number of pounds graded were of U. S. Prime.

Of the 400 cars graded, only one car was subjected to regrading, and in that case the original grading was sustained except on a small part of the car. In general, satisfaction was expressed by producers, packers, and receivers.

The fees charged for the grading work, which accrue to the State cooperating agency and to the United States Treasury, amounted to $4,071.26, or less than one-half of a cent a bird.

Requests received for the grading services for the 1930–31 turkey crop indicated that there will be considerable expansion of the bureau's turkey-grading program; in fact, the indications are that Government grading of turkeys will eventually become an important factor in the marketing of the country's turkey crop.

TURKEY Raising Is Being Stabilized by Modern Methods

Turkey raising, an industry which a few years ago had been almost wiped out in the Eastern and Middle Western States by the ravages of the blackhead disease, appears to be staging a comeback. This is not because of the discovery of anything unusual or actually new in turkey management but is mainly the result of modern methods of sanitation.

Turkeys raised in accordance with the new system obtain their feed only from clean, waste-proof feeders, never from the ground. They drink only from clean dishes. In order that they may obtain water only from this source, puddles are not allowed to stand in the yard. Yards are kept clean by graveling them, using them in rotation, moving buildings to a clean location from time to time, disposing of manure properly, and keeping chickens and turkeys separate. The young turkeys are raised on land that has not been used by poultry of any kind for at least one year. Modern methods of sanitation, therefore, may be summed up in these words: Clean feed, clean water, and clean environment.

Any system of feeding that has been found to be successful with chickens gives promise of being satisfactory with turkeys, though there is some evidence that turkeys require a more careful compounding of rations for maximum growth, low mortality, and straight breastbones. Their basic ration is usually a dry mash. During the first two months of the poult's life the composition and physical character of this mash are especially important. A mash very finely ground or one that contains much coarse material, such as oat hulls, is unsatisfactory. The mash usually is supplemented by milk, grit, and green feed, and by cod-liver oil in the absence of abundant direct sunlight. Six or eight weeks before marketing, the turkeys are given liberal feedings of scratch grain containing a large percentage of corn.

This is not because of the discovery of anything unusual or actually new in turkey management but is mainly the result of modern methods of sanitation.

Turkeys raised in accordance with the new system obtain their feed only from clean, waste-proof feeders, never from the ground. They drink only from clean dishes. In order that they may obtain water only from this source, puddles are not allowed to stand in the yard. Yards are kept clean by graveling them, using them in rotation, moving buildings to a clean location from time to time, disposing of manure properly, and keeping chickens and turkeys separate. The young turkeys are raised on land that has not been used by poultry of any kind for at least one year. Modern methods of sanitation, therefore, may be summed up in these words: Clean feed, clean water, and clean environment.

Any system of feeding that has been found to be successful with chickens gives promise of being satisfactory with turkeys, though there is some evidence that turkeys require a more careful compounding of rations for maximum growth, low mortality, and straight breastbones. Their basic ration is usually a dry mash. During the first two months of the poult's life the composition and physical character of this mash are especially important. A mash very finely ground or one that contains much coarse material, such as oat hulls, is unsatisfactory. The mash usually is supplemented by milk, grit, and green feed, and by cod-liver oil in the absence of abundant direct sunlight. Six or eight weeks before marketing, the turkeys are given liberal feedings of scratch grain containing a large percentage of corn.

TABLE 22.—*Average weights of male and female large-type Bronze turkeys raised at the United States Range Livestock Experiment Station, Miles City, Mont., 1929*

Age (weeks)	Average weight of 161 males	Average weight of 172 females	Age (weeks)	Average weight of 161 males	Average weight of 172 females
	Pounds	*Pounds*		*Pounds*	*Pounds*
4	0.71	0.61	16	9.56	6.99
8	2.58	2.04	20	13.90	9.59
12	5.48	4.16	24	17.96	11.48

Other factors essential to successful turkey raising are plenty of heat for the baby turkeys with temperatures beginning at 95° F. in the brooder and 80° in the room, the elimination of corners in the brooders where the poults can pile up, and protection from enemies such as coyotes and dogs. The turkeys usually are kept within a fenced inclosure, although some poultry men allow their turkeys to range at will. Turkeys develop well in confinement, at all ages, but must not be overcrowded at any age. It is difficult to rear the young birds successfully in groups of more than 150. Turkeys are naturally quiet and easily handled. If given the opportunity, they will range far and wide, but if they are confined to a limited range they appear to be contented as long as they are well fed.

FIGURE 179.—Bronze turkeys at the United States Range Livestock Experiment Station, Miles City, Mont.

Turkeys Are Economical Feeders

Turkeys are economical feeders and fast growers. Growth-rate and feed-consumption data are available for several hundred birds grown in 1929 at the United States Range Livestock Experiment Station, Miles City, Mont. That year 3.1 pounds of dry mash and 1.34 pounds of scratch grain were required, on the average, to produce 1 pound of live turkey for market at the age of about 25 weeks. An average young turkey tom weighing 18 pounds, therefore, required about 80 pounds of these feeds, and a young turkey hen weighing 11½ pounds required 51 pounds. Table 22 shows the average weights of males and females of large-type Bronze turkeys at the station mentioned. (Fig. 179.)

The last few years have brought great advances in the science of poultry husbandry. Blackhead, formerly the chief limiting factor in turkey production, is being controlled to a large extent, as described, by sanitation. Some of the most important problems that face the turkey grower at present are the elimination of crooked breastbones, feeding methods that will promote growth and reduce mortality in large flocks, greater hatchability of eggs, successful methods of artificial incubation, progressive methods of breeding, and more effective control of diseases.

Bureau of Animal Industry.

TYPES of Farming on Larger Farms Shown by a Special Survey

Advantages and disadvantages of the large farm have been the subject of much discussion during the past few years. Some people have advocated the application of "big business" methods to farming, whereas others have expressed serious doubts as to the desirability of the decrease in the number of family sized farms which would probably accompany any marked increase in the operation of farms as large business enterprises.

It is common knowledge that there are a number of well-organized farms that should be classed as large businesses, but there is little information as to the number and size of units included in the class. One measure of size is area of land in the farm. This measure alone, of course, will not give a complete picture, but since it has been used as a basis of classification in the census reports on agriculture beginning in 1880, there is an opportunity to note the changes in the number of farms in the different size classes.

The group 1,000 acres or more in size is of especial interest because it includes many large-scale businesses and because the total area of land in farms of that size increased from 1920 to 1925, while every other size group decreased in total area. The total area in farms 1,000 acres or more in size was approximately 2,000,000 acres greater in 1925 than in 1920, although the number was 4,000 less. During the 25-year period 1900 to 1925 there was an increase of approximately 12,500 farms 1,000 acres or more in size in the West North Central, Mountain, and Pacific Coast States, and only an increase of 3,500 for the remainder of the country.

TABLE 23.—*Farms 1,000 acres or more in size and all other farms, number and total acres, 1900–1925*

Year	Farms of 1,000 acres or more		Farms of less than 1,000 acres	
	Number	*Acres*	*Number*	*Acres*
1900	47, 276	200, 324, 045	5, 692, 381	640, 877, 501
1910	50, 135	167, 082, 047	6, 311, 367	711, 716, 278
1920	67, 405	220, 635, 519	6, 380, 938	735, 248, 196
1925	63, 328	222, 548, 890	6, 308, 312	701, 770, 463

young turkey tom weighing 18 pounds, therefore, required about 80 pounds of these feeds, and a young turkey hen weighing 11½ pounds required 51 pounds. Table 22 shows the average weights of males and females of large-type Bronze turkeys at the station mentioned. (Fig. 179.)

TYPES of Farming on Larger Farms Shown by a Special Survey Advantages and disadvantages of the large farm have been the subject of much discussion during the past few years. Some people have advocated the application of "big business" methods to farming, whereas others have expressed serious doubts as to the desirability of the decrease in the number of family sized farms which would probably accompany any marked increase in the operation of farms as large business enterprises.

It is common knowledge that there are a number of well-organized farms that should be classed as large businesses, but there is little information as to the number and size of units included in the class. One measure of size is area of land in the farm. This measure alone, of course, will not give a complete picture, but since it has been used as a basis of classification in the census reports on agriculture beginning in 1880, there is an opportunity to note the changes in the number of farms in the different size classes.

The group 1,000 acres or more in size is of especial interest because it includes many large-scale businesses and because the total area of land in farms of that size increased from 1920 to 1925, while every other size group decreased in total area. The total area in farms 1,000 acres or more in size was approximately 2,000,000 acres greater in 1925 than in 1920, although the number was 4,000 less. During the 25-year period 1900 to 1925 there was an increase of approximately 12,500 farms 1,000 acres or more in size in the West North Central, Mountain, and Pacific Coast States, and only an increase of 3,500 for the remainder of the country.

Table 23.—*Farms 1,000 acres or more in size and all other farms, number and total acres, 1900–1925*

Year	Farms of 1,000 acres or more		Farms of less than 1,000 acres	
	Number	*Acres*	*Number*	*Acres*
1900	47, 276	200, 324, 045	5, 692, 381	640, 877, 501
1910	50, 135	167, 082, 047	6, 311, 367	711, 716, 278
1920	67, 405	220, 635, 519	6, 380, 938	735, 248, 196
1925	63, 328	222, 548, 890	6, 308, 312	701, 770, 463

The fact that many of these farms of 1,000 acres or more are large businesses is shown by the average value of real estate per farm, which was $49,020 in 1925, while for the next lower group (500 to 999 acres in size) the average real estate value was only $23,120.

Kinds of Farming on Large Farms

What kind of farming is done on large farms? To answer this question in part, a special study was made of 55,000 of the 63,328 farms of 1,000 acres or more enumerated by the 1925 Census of Agriculture. States [14] having large numbers of plantations were not included in the study because of the fact that each cropper or tenant was considered to be operating a separate farm. If all plantations had been included, the total number of large farms would have been greater.

TABLE 24.—*Farms 1,000 acres or more in size, classified according to type of farming*[1]

Type of farming	Number of farms	Type of farming	Number of farms
Cattle, including dairying	22,677	Wheat [2]	11,791
Sheep	5,312	Miscellaneous, fruits, vegetables, sugar beets, etc.	727
Cattle and sheep	2,378		
General	12,721		
Cotton	2,231		57,837

[1] Eight Southeastern States omitted.
[2] Includes 500 farms upon which small grains other than wheat are principal products.

Half Were Livestock Farms

About one-half of the farms studied were classified as livestock farms. Cattle production, including dairying, accounted for almost 23,000 farms, sheep for 5,000, and those about evenly balanced as to cattle and sheep for 2,000 more. The livestock industry is also important on many of the 13,000 general farms.

Of the 11,000 farms that are devoted principally to wheat production, 9,500 are in the group 1,000 to 2,000 acres in size and another 1,000 in the 2,000 to 3,000 acre group. There were some 600 farms classed as grain farms, including barley, oats, and wheat in various combinations. There were no farms classified as corn farms. Small grain, principally wheat, is much more likely than other crops to be found on large farms.

In the group of 5,000 acres or more the number of general farms is small, only 4 per cent of the 7,000 included in the special tabulation, while in the group 1,000 to 5,000 acres in size about 25 per cent of the farms were general farms upon which no one product was outstanding.

Of the 3,163 farms 10,000 acres or more in size, all except 132 are devoted to some form of livestock production.

Farms were classified as to the principal source of income in 1900, at which time approximately 57 per cent of the group 1,000 acres or more in size were livestock farms. In 1925 the tabulation shows a little over 52 per cent mainly devoted to livestock production.

Grain farms in both 1900 and 1925 were approximately 20 per cent of all farms 1,000 acres or more in size.

Senior Agricultural Economist,
Bureau of Agricultural Economics.

[14] North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, and Arkansas omitted.

VAT Dyes Play Big Part in Broadening Cotton Goods Market

In order to appreciate better the rôle that vat dyes have played in bringing cotton goods into fashion and popularity, it is necessary to examine the characteristics of such dyestuffs. Vat dyes as a class are the fastest and most complex of synthetic colors. They are not attacked by weak acids, and alkalies, and only faintly by bleach or perspiration. In fact, they are so stable and resistant that their general use on a large scale awaited only the development of convenient and economical means of applying them to the yarn or cloth.

Unlike most other types of dyes, vat colors as a class possess excellent fastness to light and severe washing. In fact these dyestuffs depend on an oxidizing atmosphere to bring out their color and brightness to the fullest extent.

In order to apply these dyes they must be in solution. At first a hydrosulphite vat was used, hence the name vat dyes. Hydrosulphite is a very strong reducing compound which converts the dyestuff to what is known as a soluble leuco compound. Oftentimes these leuco compounds possess no color, but when material impregnated with the leuco compound is exposed to the air, an oxidation process sets in and the original insoluble dyestuff is regenerated. More recently other compounds have been discovered which make it possible to apply vat colors directly on the cloth by a printing process. Indeed, the procedure is very similar to the printing of the colored supplements of the Sunday papers. The dyeing process is of course distinctly more complicated and must be subjected to a very refined control in order that the printed vat colors may be developed to their maximum fastness and brightness.

Printing Methods for Applying Colors

The utilization of printing methods for applying vat colors on lustrous cotton goods has made possible the manufacture of fabrics which are at once serviceable and attractive. Even the casual male observer has discerned the colorful house dresses which adorn milady in her daily tasks. This vogue for fast-colored cotton materials has been chiefly responsible for the tremendous growth in the production of vat dyes, which growth not only reflects the appreciation of color, but reveals the innate desire to combine the esthetic with the practical.

The combination of permanent colors of many hues on a lustrous cotton will always be in demand. The printing of artistic and novel designs makes possible dyed creations which are destined to remain popular and continue in fashion.

The cotton grower must realize that the popularity of cotton depends on a number of factors. To obtain the best results in the printing of cotton fabrics with vat dyes it is necessary that the raw cotton going into the cloth be uniformly bright and lustrous. By mechanical and chemical processes nature's product will then be improved so that the dyer may apply his vat colors to the best advantage.

P. H. Groggins,
Senior Chemist, Bureau of Chemistry and Soils.

VEGETABLE Weevil, a New Invader, Spreading in South and California In the spring of 1922 the vegetable weevil, *Listroderes obliquus* Gyll., a pest known to attack a considerable variety of vegetable crops, was found in Stone County, Miss. This constituted the first record of the occurrence of this weevil in the United States. For several years after its discovery it was injurious only locally, but is now known to be distributed over 55 counties in Mississippi, 40 parishes in Louisiana, 19 counties in Alabama, and 3 counties in Florida, ranging from Beauregard Parish in Louisiana on the west, northward to Yalobusha and Monroe Counties in Mississippi, and eastward to Coffee and Geneva Counties in Alabama and Holmes County in Florida. In 1926 it was discovered in the vicinity of San Jose, Calif. During the past season in the Gulf States, dispersal northward was retarded by the severe winter of 1929–30, although the spread to the east and west has maintained a normal rate.

The vegetable weevil is a small, grayish-brown snout beetle, about one-third of an inch long, and when newly emerged it bears a gray V-shaped mark on the wing covers. The beetle gradually darkens and the V-mark merges with the surrounding color, so in older individuals it may be entirely lacking.

While the adult beetles feed on the host plants, the most serious injury is done by the larvae, which, like the adults, feed principally at night. The larvae or grubs are about one-half inch in length when full grown, and pale to dark green in color. They feed principally on the leaves, spending the day down in the crowns of the plants and dropping to the ground if disturbed. As indicating their probable origin in the Southern Hemisphere, the adult vegetable weevils become active and begin to deposit eggs in the fall, the larvae live and feed throughout the winter and early spring, and the resting period occurs during the summer. The eggs are laid on the leaves and stems and in the crowns of the host plant, and pupation takes place in the soil, usually at depths of from one-half to 4 inches, although during dry weather the larvae may penetrate to a depth of 9 inches before pupating. There is a single generation annually, although, since the adults continue to deposit eggs throughout the winter, partially grown larvae may be found in late spring, and all are not mature before June. The time required for the completion of the various stages varies greatly with the temperature conditions encountered. The male is unknown, although many individuals have been examined as to sex.

A Strong Flier at Times

When the weevil was first discovered in this country it was believed to be distributed largely through traffic. It has since become evident that the species is a strong flier at times and hence can not be readily restrained. The long list of plants upon which it is able to subsist, including turnip, cabbage, collard, carrot, mustard, spinach, beet, chard, radish, potato, tomato, lettuce, onion, parsley, parsnip, chickweed, mallow, pigweed, dock, and milk thistle, will insure distribution as well as persistence of attack.

The vegetable weevil may be controlled by spraying or dusting with such standard stomach poisons as lead arsenate and calcium arsenate. Either of these may be expected to give satisfactory control of both adults and larvae.

When the crop attacked is one in which the leaves constitute the edible portion, the use of arsenicals becomes dangerous. Contact insecticides are not practical. It has been found that the adult weevils at the time of their emergence in May and June may be controlled by a poisoned bran mash such as is used for cutworm bait, flavored with cull vegetables and scattered along the rows. At best, however, this is only a supplementary remedy.

Associate Entomologist, Bureau of Entomology.

WALNUT Burl, a New Forest Product, Wanted for Cabinet Making In the Southwest, a new forest product is being sold from the national forests and from private lands. It has been found that some specimens of nogal (*Juglans rupestris major*) and little walnut (*J. rupestris*) have wood in burls at and below the root collar that is valuable for the production of fancy veneers for cabinet purposes. These trees occur along the banks of streams in the canyons of central and southern New Mexico and Arizona. They do not form continuous stands, but are found as single individuals or clumps of trees in favorable localities.

Not all trees form valuable burls, so that it is necessary for the burl hunter to visit each tree and at times dig down beside the trunk to determine if valuable wood is present. Burl is indicated by a distinct swelling of the tree; a chip on this swelling indicates the grain of the burl.

The weight of burls varies greatly; occasionally a good one weighs up to 2 tons. The average in this region would be 700 to 900 pounds. The cost of locating, preparing, and hauling this material to the railroad from the rather inaccessible locations where it is found is considerable.

Walnut trees occupy what would otherwise be waste land. They grow relatively fast. Why some trees have burl and others do not is unknown. It if were possible to grow trees with burl, a good business could be developed in growing these trees.

QUINCY RANDLES,
Assistant Regional Forester, Forest Service.

WATERMELONS Prove Valuable Source of Vitamins A and C According to Government reports, during the year 1929 some 67,000,000 watermelons were produced and presumably consumed in the United States. In this age when we are continually faced with the problem of evaluation of all kinds of foodstuffs it was only natural that a fruit as plentiful as the watermelon should become the subject of investigation. Seemingly, it had occurred to no one that such a watery fruit would possess any value other than cool refreshment on a hot summer's day. Vitamins have been shown in abundance in many fruits and vegetables possessing a high water content, but no similar study had been made of the watermelon. For this reason, the Bureau of Home Economics conducted a series of experiments to test its vitamin content.

WATERMELONS Prove Valuable Source of Vitamins A and C

According to Government reports, during the year 1929 some 67,000,000 watermelons were produced and presumably consumed in the United States. In this age when we are continually faced with the problem of evaluation of all kinds of foodstuffs it was only natural that a fruit as plentiful as the watermelon should become the subject of investigation. Seemingly, it had occurred to no one that such a watery fruit would possess any value other than cool refreshment on a hot summer's day. Vitamins have been shown in abundance in many fruits and vegetables possessing a high water content, but no similar study had been made of the watermelon. For this reason, the Bureau of Home Economics conducted a series of experiments to test its vitamin content.

It is possible to determine the relative amounts of the vitamins present in a foodstuff by feeding the food in question to laboratory animals such as the rat and the guinea pig, and observing the rate of growth made by these animals. The melons used were of the Tom Watson variety and they were fed so as to determine the vitamin A, B, C, and G content. Vitamin G is one of the newer vitamins, and is essential for normal growth. Some investigators consider this vitamin to be identical with the pellagra-preventing factor.

In making the tests 125 rats and about 24 guinea pigs were fed daily, weighed portions of watermelon. The experiments were carried on from July through October, until it was no longer possible to obtain fresh melons on the Washington market. Only the edible portion was given to the test animals although other experiments indicated that guinea pigs preferred the green rind to the red flesh. The speed with which the portions of melon were consumed, even when fed in rather large quantities, left no doubt as to the extent the animals relished this test food.

In the case of the vitamin A and C tests the animals grew well and appeared healthy. However, when the watermelon was fed as a source of vitamin B or G, growth was not very pronounced and the animals appeared subnormal. The final summary of the data showed watermelons to be a good source of vitamins A and C and to contain small but detectable amounts of vitamins B and G.

WHEATS from Many Countries Compared in Milling, Baking Tests

World production of wheat in 1928, excluding Russia and China, was 3,900,000,000 bushels. Grown as it is under a wide range of soil, climatic, and topographical conditions, this wheat necessarily varies considerably in its adaptability to milling and baking purposes.

Recognizing the need for information as to the milling and baking properties of the wheat grown throughout the world as essential to economical marketing and utilization of the wheat grown in the United States, studies were made to compare the milling and baking properties of the wheat grown in other parts of the world with that grown in the United States.

In the United States five commercial classes of wheat are recognized: The hard red winter wheats grown largely in the South Central States; the soft red winter wheats grown mostly in the more humid Central and Eastern States; the hard red spring wheats grown extensively in the North Central region; the durum (spring) wheats grown in practically the same region as the hard red spring wheats; and the white wheats, both spring and winter, grown largely in the Pacific Western States, although some are found in New York and Michigan.

From the study made, it was apparent that wheats of the world are of the common type (*Triticum vulgare*) with very minor acreages devoted to other types. Wheat similar in character to the hard red spring wheats produced in the United States is grown in Australia, Bulgaria, Canada, Czechoslovakia, England, Estonia, Germany, Hungary, India, Japan, Latvia, Manchuria, Norway, Russia, Sweden, Switzerland, the Netherlands, the Union of South Africa, and Uruguay. The greatest quantity of hard red spring wheat is produced in Canada, It is possible to determine the relative amounts of the vitamins present in a foodstuff by feeding the food in question to laboratory animals such as the rat and the guinea pig, and observing the rate of growth made by these animals. The melons used were of the Tom Watson variety and they were fed so as to determine the vitamin A, B, C, and G content. Vitamin G is one of the newer vitamins, and is essential for normal growth. WHEATS from Many Countries Compared in Milling, Baking Tests

World production of wheat in 1928, excluding Russia and China, was 3,900,000,000 bushels. Grown as it is under a wide range of soil, climatic, and topographical conditions, this wheat necessarily varies considerably in its adaptability to milling and baking purposes.

Recognizing the need for information as to the milling and baking properties of the wheat grown throughout the world as essential to economical marketing and utilization of the wheat grown in the United States, studies were made to compare the milling and baking properties of the wheat grown in other parts of the world with that grown in the United States.

In the United States five commercial classes of wheat are recognized: The hard red winter wheats grown largely in the South Central States; the soft red winter wheats grown mostly in the more humid Central and Eastern States; the hard red spring wheats grown extensively in the North Central region; the durum (spring) wheats grown in practically the same region as the hard red spring wheats; and the white wheats, both spring and winter, grown largely in the Pacific Western States, although some are found in New York and Michigan.

From the study made, it was apparent that wheats of the world are of the common type (*Triticum vulgare*) with very minor acreages devoted to other types. Wheat similar in character to the hard red spring wheats produced in the United States is grown in Australia, Bulgaria, Canada, Czechoslovakia, England, Estonia, Germany, Hungary, India, Japan, Latvia, Manchuria, Norway, Russia, Sweden, Switzerland, the Netherlands, the Union of South Africa, and Uruguay. The greatest quantity of hard red spring wheat is produced in Canada, with Russia and the United States ranking next in order. While hard red spring wheats are grown in Australia, England, India, Switzerland, the Netherlands, and Uruguay, their production is relatively unimportant.

Considerable acreages in Algeria, Bulgaria, Canada, Greece, Iraq, Italy, Morocco, Palestine, Russia, and Tunis are devoted to the production of durum wheat. Although durum wheat is raised in Argentina, Australia, India, Latvia, Rumania, Uruguay, and Yugoslavia, it is relatively unimportant.

Russia produces probably the greatest quantity of hard red winter wheat, with the United States and Argentina following in volume of production. Smaller quantities are also grown in Canada, Czechoslovakia, and Hungary, and negligible quantities in Australia, Bulgaria, and India.

Soft red winter wheats are grown in Argentina, Australia, Belgium, Bulgaria, Chile, Denmark, England, France, Germany, Hungary, India, Ireland, Italy, Japan, Latvia, Lithuania, Mexico, Portugal, Russia, Scotland, Spain, Sweden, Switzerland, the Netherlands, Union of South Africa, and the United States. They are outstandingly important commercially in Belgium, the lower Danube countries of Rumania, Yugoslavia, and Bulgaria, Denmark, England, France, Germany, Hungary, Ireland, Italy, Japan, Latvia, Portugal, Russia, Scotland, Spain, Switzerland, the Union of South Africa, and the United States.

Countries in which white wheat is of importance commercially are Australia, Belgium, China, Chile, Egypt, England, Estonia, India, Iraq, Japan, Lithuania, Mexico, Morocco, New Zealand, Poland, Scotland, Spain, the Netherlands, Union of South Africa, Tunis, and the United States. White wheat is also produced in small amounts in Algeria, Argentina, Bulgaria, Canada, Greece, Ireland, and Italy. The greatest production of white wheat is in India, with Australia second and the United States third. With the exception of Spain and China, for which statistics on class production are not available, all the other countries produce annually less than 25,000,000 bushels of white wheat.

Milling and Baking Factors

A study of the facts pertaining to milling and baking, compiled from the analysis of the world's wheat, shows that while milling quality, i. e., capability of producing a large quantity of high-grade flour from a minimum amount of wheat, is a factor in determining the relative standing of quality of wheat, it is the baking quality of the flours milled for light bread that sharply differentiates between the wheats.

Of the hard red spring wheats, the higher grades of Canadian wheat rank first in milling value. From a baking standpoint, however, the flours milled from the hard red spring wheats grown in the United States are equally as good. Russian spring wheats appear to be somewhat deficient in baking strength compared with those grown in North and South America.

Spring wheats grown in northern Europe, i. e., Norway, Sweden, Germany, Latvia, and Poland, while in most instances of good milling value, are somewhat deficient in baking strength. This is also true of the spring wheats grown in the Union of South Africa. Uruguay, on the other hand, produces spring wheat of very good baking strength.

Russia, Canada, and the United States produce the best quality of durum wheat. All other countries producing durum wheat, with but minor exceptions, have a product very noticeably deficient in baking strength.

From both a milling and a baking standpoint, the best quality of hard red winter wheat is produced in the United States. Hard red winter wheat grown in Argentina appears to be of lesser milling value than that grown in the United States. The baking quality of the flour milled from Argentine wheat, while not the equal of that milled from the hard red winter wheats of the United States, is fair. Flour milled from the Russian hard red winter wheats appears to be lacking in baking strength. The hard red winter wheats of Bulgaria and Hungary do not appear to be quite as strong as the Argentine wheats of similar classification.

Soft red winter wheats grown in the United States, while failing to meet the milling quality values of some of the wheats of the same class grown in other parts of the world, excelled in baking quality in every instance. Those produced in the United Kingdom, as well as in the greater part of continental Europe, are of average to above average milling quality, but are decidedly deficient in baking quality. Only in European Russia, Hungary and the lower Danube countries are soft red winter wheats to be found that have fair to average baking quality as well as average milling quality.

Quality of White Wheats

The milling quality of the white wheats grown in India, Australia, and the United States rank in the order named. From a baking standpoint, the flours milled from the white wheats produced in the United States and Australia are approximately of the same strength, while the baking strength of the flours milled from the white wheats of India is noticeably of lesser quality. Mexico, Russia, Poland, Chile, Morocco, and the Union of South Africa also produce white wheat of good baking strength. Those grown in all other parts of the world are much below average in this respect.

In the warm and dry areas of southern Europe and Asia and northern Africa, Poulard wheat (*Triticum turgidum*) is popular. Milling and baking tests made on this class of wheat on samples submitted from Egypt, Italy, Palestine, Portugal, and India gave results that were always below the average of any of the other classes of wheat studied.

WILD-FOWL Conservation Furthered by Regulation and Educational Methods

In one of the larger cities of Oklahoma last October, the guests at a "duck dinner," all of them prominent conservationists and sportsmen, ate heartily, conversed pleasantly the while on the relative gustatory merits of wild fowl, and yielded to the temptation to ask for second helpings. As one of the diners put it:

> After every plate had been cleaned and coffee had appeared, the stunning truth was told: the meat course of this "duck" dinner had been mud hen—nothing else, and the Department of Agriculture had been gloriously vindicated in its official announcement that the despised coot, properly prepared, is fit to eat.

minor exceptions, have a product very noticeably deficient in baking strength.

From both a milling and a baking standpoint, the best quality of hard red winter wheat is produced in the United States. Hard red winter wheat grown in Argentina appears to be of lesser milling value than that grown in the United States. The baking quality of the flour milled from Argentine wheat, while not the equal of that milled from the hard red winter wheats of the United States, is fair. Flour milled from the Russian hard red winter wheats appears to be lacking in baking strength. The hard red winter wheats of Bulgaria and Hungary do not appear to be quite as strong as the Argentine wheats of similar classification.

Soft red winter wheats grown in the United States, while failing to meet the milling quality values of some of the wheats of the same class grown in other parts of the world, excelled in baking quality in every instance. Those produced in the United Kingdom, as well as in the greater part of continental Europe, are of average to above average milling quality, but are decidedly deficient in baking quality. Only in European Russia, Hungary and the lower Danube countries are soft red winter wheats to be found that have fair to average baking quality as well as average milling quality.

Quality of White Wheats

The milling quality of the white wheats grown in India, Australia, and the United States rank in the order named. From a baking standpoint, the flours milled from the white wheats produced in the United States and Australia are approximately of the same strength, while the baking strength of the flours milled from the white wheats of India is noticeably of lesser quality. Mexico, Russia, Poland, Chile, Morocco, and the Union of South Africa also produce white wheat of good baking strength. Those grown in all other parts of the world are much below average in this respect.

In the warm and dry areas of southern Europe and Asia and northern Africa, Poulard wheat (*Triticum turgidum*) is popular. WILD-FOWL Conservation Furthered by Regulation and Educational Methods

In one of the larger cities of Oklahoma last October, the guests at a "duck dinner," all of them prominent conservationists and sportsmen, ate heartily, conversed pleasantly the while on the relative gustatory merits of wild fowl, and yielded to the temptation to ask for second helpings. As one of the diners put it:

> After every plate had been cleaned and coffee had appeared, the stunning truth was told: the meat course of this "duck" dinner had been mud hen—nothing else, and the Department of Agriculture had been gloriously vindicated in its official announcement that the despised coot, properly prepared, is fit to eat.

None of the guests had suspected that they were being experimented upon in the interests of science. When informed that they had been the victims of a "coot" dinner they decided that they were not victims at all, but converts to a delicious new viand.

Complaints from rice growers of the West that coots were damaging their fields had resulted in requests for permission to use extraordinary measures to reduce the numbers of these birds. Sportsmen also had charged that coots compete with wild ducks for food in some localities. Shooting coots out of season, removing protection entirely, and wholesale destroying by various methods, including poisoning, were suggested, many persons overlooking the fact that the coot is a game bird protected by the migratory-bird treaty, but that during open seasons it can be legitimately reduced in numbers by the hunters themselves. (Fig. 180.)

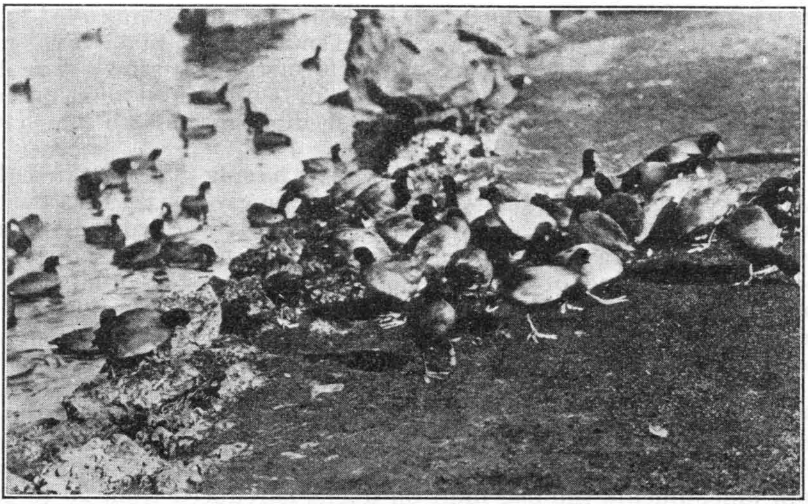

FIGURE 180.—Coots in Golden Gate Park, San Francisco, Calif. These birds are excellent eating, in spite of their name "mud hen." They are protected under the migratory-bird treaty act, and during the open season allowed for hunting, the bag limit is 25 a day

These grievances coming to the department led the Bureau of Biological Survey to issue a statement, showing that coots skinned and broiled are excellent eating, and that skinning is not difficult. It was pointed out also that in many localities where wild ducks are plentiful and are hunted by strangers, the lowly coot is prized for home consumption, and that visiting hunters with mistaken ideas on the edibility of game birds, and wanting only canvasbacks and the like, are precluded by their own prejudices from experiencing the delicious taste of coot. The coot was described as feeding more upon the green foliage of aquatic plants than do any of the wild ducks, and as consuming in addition such delicacies as the tubers of wildcelery and sago pondweed and the grain of wildrice; it was described as being in fact a cleaner feeder than many other birds prized as game. Sportsmen were urged to experiment and take the legal limit of coots a few times in the season, with the assurance that they would have something worth while from a gastronomic viewpoint, and at the same time would aid in reducing to proper proportions the numbers of this species, thus tending to eliminate complaints of damage. The experimental "duck" dinner in Oklahoma was one of the first to demonstrate that coot is as delectable as is claimed by the Biological Survey. The Federal open seasons on coots conform with those on ducks, geese, and brant for the various parts of the country, and the bag limit is 25 a day.

Methods of Conservation

Educational methods of conservation, including such experiments as the foregoing, which by encouraging the utilization of the abundant coot indirectly tend to spare some of the less numerous wild ducks, must naturally be supplemented by effective regulation, particularly in view of the increasingly adverse conditions confronting the wild fowl. Water regions frequented by the birds have been reduced by drought and drainage. The number of hunters is constantly on the increase. Modern transportation facilities, including improved highways, fast motor cars and boats, and even airplanes, make it easy for gunners to reach the regions where formerly waterfowl were unmolested. Furthermore the extension of agricultural development inevitably curtails the breeding and feeding grounds to which the birds have been accustomed to flock.

Recent studies by the Biological Survey having demonstrated that additional legal protection would have to be given wild fowl if they were to hold their own, all available safeguards were considered and recognized as three in number. Two of these could only be operative over a long period of years, namely, to increase the production of birds and to provide refuges for their use in resting and feeding during migration. The third, and the only one that would have immediately beneficial results, would be to restrict the annual kill by hunters.

Accordingly, at the end of December, 1929, the Bureau of Biological Survey recommended that a reduction be made in the bag limits allowed hunters, and the regulations were thereupon amended to take effect at the beginning of the fall hunting season of 1930. Under the new amendments the bag limit on ducks is reduced from 25 to 15 a day and on geese from 8 to 4 a day, and a possession limit of two days' bag is prescribed.

These changes may have little effect on the average hunter, but should lessen the aggregate kill on important winter concentration areas of the birds. In the event the measures already taken prove inadequate for the conservation of the wild fowl, the department is authorized to impose still further restraint upon hunting, possibly shortening the seasons, establishing rest days, restricting further the use of devices now allowed in taking the birds, and limiting the artificial methods employed to lure the birds within gunshot.

It is evident that if hunting as a sport is to continue, certain restrictions must be imposed on gunners. To effect the most satisfactory degree of conservation, the hunters should be good sportsmen and be willing to exercise personal restraint in shooting. Finally, conservationists generally must bring into play all possible educational measures, that the people of the country may be in possession of the facts on which conservation measures are based and in sympathy with efforts being made.

WILLIAM H. CHEESMAN,
Editor, Bureau of Biological Survey.

WILD-LIFE Protection Aided by Cooperation of U. S. Forest Service

Public interest in the country's wild life is growing with the recognition that in the present stage of our social, economic, and industrial development wild life can not shift for itself. The so-called balance of nature will no longer serve the needs of wild life. Public-resource aspects are receiving more and more thought.

Wild life, therefore, has become subject to human guidance and definite administration. There must be coordination of effort and meeting of minds, with emphasis on the premise that there is a definite, important, and permanent place in our American life and institutions for the wild-life resource. Conflicts in jurisdiction, where they tend to hinder progress, should give way to cooperation. Political considerations should have no place in the ultimate management of wild-life resources.

Any program of administration must consider and provide for the protection and development of existing wild life, the best methods of handling it, and the most efficient cooperation possible between Federal, State, and other agencies. Research is fundamental as in other forms of natural resource management. Its importance can not be overstressed in any practical development of wild-life programs.

Game Law Enforcement Necessary

Game laws, international, Federal, and State, constitute one of the important present factors in protection. Law enforcement must be stressed until public appreciation and cooperation, brought about through information and education, gradually reduce the necessity for special vigilance. The most important of Federal or international laws so far enacted are those to give effect to the migratory-bird treaty of August 16, 1916, between Great Britain and the United States. These laws, both of which are administered by the Bureau of Biological Survey, are the migratory-bird treaty act of 1918 and the migratory-bird conservation act of 1929. The former makes provision for hunting regulations and the latter provides for the establishment of refuges for waterfowl and other migratory game birds. Both Federal and State laws make provision for open and close seasons by species, for licenses, bag limits, interstate transportation, and for wild-life refuges. These laws become more specific as to species and localities as life history, distribution, economic status, and other studies are made and local conditions analyzed. (Fig. 181.)

The Forest Service personnel, through its opportunities for close observation and direct field contacts, and its interest in wild life as a forest resource, extends cooperation to States and other agencies in many ways. Forest officers hold appointments as nonsalaried wardens, record and report annually their first-hand observations, and make systematic and comprehensive game estimates. Progressive stock-taking is important and the information is widely used. Forest officers thus constitute a large auxiliary force of field men engaged in the study and protection of wild life. They are so recognized by the States and by the general public, and exert influence in building up respect for game laws and emphasizing the importance of wild life to the public. Some 30,000 hunting and fishing licenses were examined by forest officers in 1929. This activity is important in preventing possible game-law violations. In remote localities, where the public can not be satisfactorily served by other agencies, licenses are sold by the Forest Service for the States. Assistance is given in some localities in handling fur trapping on a sustained yield basis. Long-time fish-planting plans have been developed and assistance given

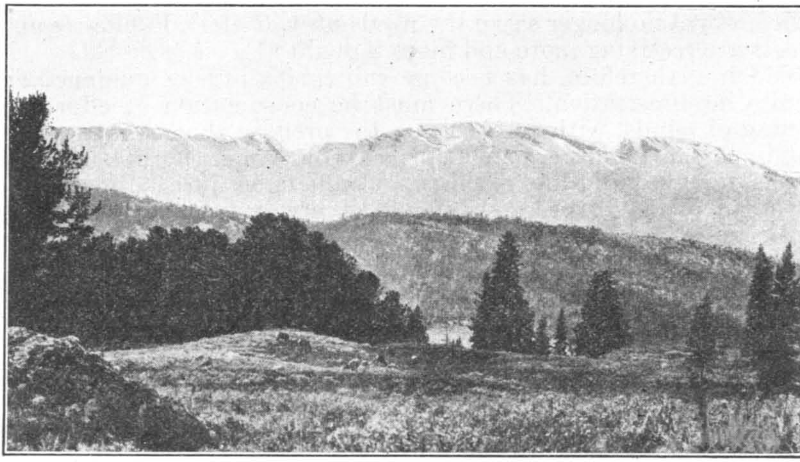

FIGURE 181.—Band of elk grazing on their native range, Wyoming National Forest, Wyo.

to State and Federal hatcheries in fish planting. Forest officers on the Colorado national forests planted 3,532,500 fish from Federal and State hatcheries in 1929.

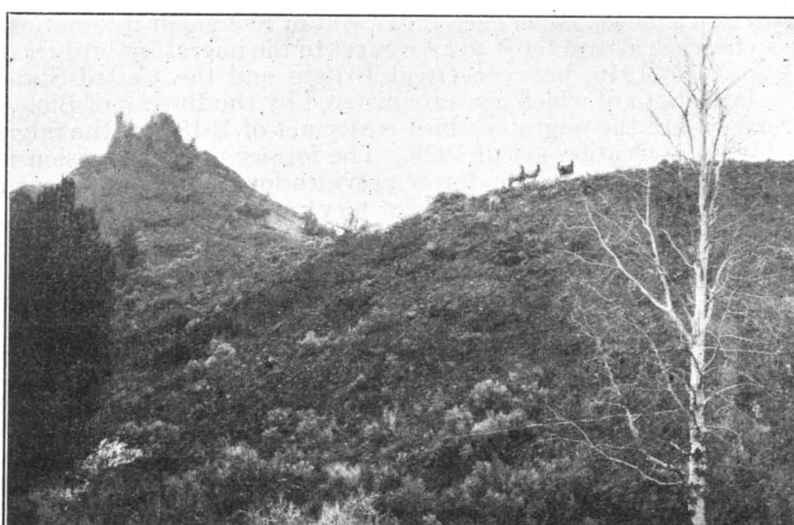

FIGURE 182.—Mountain sheep ranges, Shoshone National Forest, Wyo.

Wild-Life Sanctuaries Provided

State game refuges, totaling 19,652,580 acres, and Federal refuges, involving 1,386,955 acres, administered by the Forest Service, lie wholly within the national-forest boundaries. (Fig. 182.) In addition, 1,740,272 acreas at strategic places are under administrative restrictions for the protection of game. Such refuges provide special sanctuaries and protected breeding grounds. The national-forest areas furnish most of the remaining natural habitats of big-game animals in the western country during the summer months, though they comprise a comparatively small part of their winter range.

Satisfactory increases on the national forests are recorded in deer, elk, black and brown bears, beavers, and certain other fur bearers. Between the years 1924 and 1928, deer on the national forests showed an estimated increase of 25 per cent, elk about 69 per cent, and brown and black bears, 15 per cent. A considerable part of the elk increase has been due to transplants from surplus to depleted or "shot-out" areas. An important percentage of the present elk in Colorado, for instance, is the result of importations of 328 animals from 1913 to 1917, in which forest officers took an active part. Twenty-three hundred and eighty elk were estimated as a result of these plants at the close of 1928, and provision must now be made through hunting or other means to take care of the numbers represented by further natural increases.

Problems of Winter Range

Moose, mountain goats, and mountain sheep showed slight increases on the national forests in 1928 over 1924, but in the last two years there has been some falling off in the estimated number of mountain goats and a sharp decline in Colorado of mountain sheep. Special studies looking to the further protection and increase of mountain sheep are indicated.

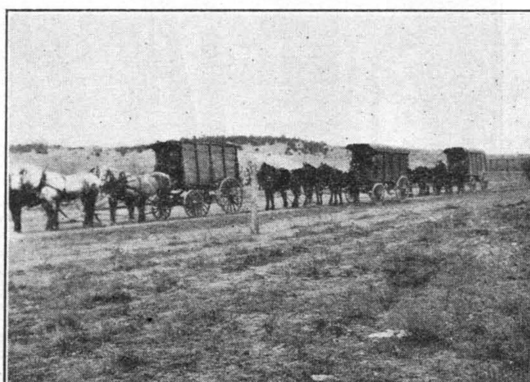

FIGURE 183.—Elk from Gardiner, Mont., being hauled from railroad station in ice wagons and transplanted on San Isabel National Forest, Colo., January 27, 1916

Protected winter ranges are of special importance to herbivorous game species, if material increases are to be expected. Such areas lie mostly outside the present national-forest boundaries. Most of the western country winter ranges are beginning to limit the numbers of forage-eating game animals that may be accommodated the yearlong. The balance between winter and summer ranges is becoming more and more a determining factor in the proper maintenance of big game. Summer capacities, except for local congested areas like the Kaibab National Forest in Arizona, will accommodate more than the present numbers without conflict with domestic livestock and other uses of the mountain pastures. Of first importance, therefore, is the segregation and protection of winter game ranges in proper locations to supplement present summer ranges. (Fig. 183.)

The Forest Service encourages the maintenance of proper feed and game balances by provisions for hunting the surplus or transplanting it to appropriate unstocked or understocked areas.

To achieve adequate protection of wild life and to provide for its maintenance and increase is a large task, because of the number of animals and vast areas of range involved. The responsibility for a constructive program must be shared alike by National, State, and other interested agencies.

JOHN H. HATTON,
Assistant Regional Forester, Forest Service.

WOODS on Farms Must Not Be Grazed If Good Timber Crop Is Wanted The farm woods, in order to serve in their highest capacity in supplying fuel wood, fence posts, and rough timbers for farm needs, should be given adequate protection. The use of the woodland as a dual-purpose area for timber production and grazing will prove a failure. With grazing animals excluded from the farm woods a first-class crop of timber may be developed which will well repay the owner.

FIGURE 184.—A grazed woods damaged by livestock. The soil is being packed and the roots trampled. No young seedling trees are coming in to renew the stand

Unrestricted grazing of farm woodlands in the hardwood regions of the Central and Eastern States has caused much damage to timber and soil. Comparatively little attention has been given to the effects of this practice, partly because of the almost unnoticeable damage to the woods over a short period of a year. Hence there is a tendency among woodland owners to consider the damage as a negligible factor. The cumulative effect, however, over a period of years is that the woods develop a degenerate condition. With continued pasturing there is a gradual changing over from the forest to open or prairie condition. In some cases this process brings poor land into pasture of low value. In other instances on good soils it causes the

To achieve adequate protection of wild life and to provide for its maintenance and increase is a large task, because of the number of animals and vast areas of range involved. The responsibility for a constructive program must be shared alike by National, State, and other interested agencies.

John H. Hatton,
Assistant Regional Forester, Forest Service.

WOODS on Farms Must Not Be Grazed If Good Timber Crop Is Wanted The farm woods, in order to serve in their highest capacity in supplying fuel wood, fence posts, and rough timbers for farm needs, should be given adequate protection. The use of the woodland as a dual-purpose area for timber production and grazing will prove a failure. With grazing animals excluded from the farm woods a first-class crop of timber may be developed which will well repay the owner.

FIGURE 184.—A grazed woods damaged by livestock. The soil is being packed and the roots trampled. No young seedling trees are coming in to renew the stand

Unrestricted grazing of farm woodlands in the hardwood regions of the Central and Eastern States has caused much damage to timber and soil. Comparatively little attention has been given to the effects of this practice, partly because of the almost unnoticeable damage to the woods over a short period of a year. Hence there is a tendency among woodland owners to consider the damage as a negligible factor. The cumulative effect, however, over a period of years is that the woods develop a degenerate condition. With continued pasturing there is a gradual changing over from the forest to open or prairie condition. In some cases this process brings poor land into pasture of low value. In other instances on good soils it causes the demolition of the farm woods even though they may be needed as a part of the farm and may be considered as an asset to the place.

Comparatively little attention has been given to this practice, but what has been done, together with extended observation, shows that farm woods grazed continually hold little promise for profitable timber growing. One of the most noticeable factors in a grazed woods is the absence of young seedling and sapling trees. There is little chance for the woodland to perpetuate itself with young trees, as they are either browsed off, defoliated, or trampled down. Studies conducted by the Forest Service show that some of the more valuable species of trees are palatable to livestock, especially when they are either seedlings or very young trees. Such trees as white ash, sugar maple, tulip poplar, elm, basswood, white oak, red oak, and shellbark

FIGURE 185.—A rapidly growing farm woods protected from grazing animals. Valuable young growth is filling in the openings

hickory appear to be relished under most conditions. With somewhat less frequency, the following species are browsed: Butternut, honey locust, black gum, black oak, shagbark hickory, scarlet oak, sycamore, and chestnut. In contrast to these species browsed under most conditions are a number of trees which are seldom eaten even during heavy grazing. Among these are blackjack oak, hawthorn, black cherry, dogwood, ironwood, red gum, pawpaw, and persimmon. Consequently grazing encourages the growth of the "weed trees" in the last group and leaves them to fill in the openings that should be occupied by the species in the former group that have a higher commercial value.

Soil Compacted by Trampling

Another damage resulting from grazing is the compacting of the soil by constant trampling of livestock in going through the woods. Forest soil in a natural state is loose and well covered with a leaf mold or mulch which is an essential factor for growth and for retaining moisture in the soil. When this covering is disturbed by trampling and the soil exposed through animals devouring a large portion of the young growth, the soil becomes sun-baked, packed, dry, and unfavorable to natural restocking. Constant trampling and rubbing exposes and injures tree roots, and allows them to dry out. This process is reflected in the poorer quality of timber and wood products and eventually brings on a weakened condition in the older trees, accompanied in some cases with stag-headedness and subsequent death. It is obvious that if grazing is permitted to the point of destruction of the young trees, with some loss among the larger ones, the resulting stand becomes unattractive from a timber buyer's point of view. A farm woods dwindling in timber value is a direct loss to the owner. Timber, like a corn or potato crop, needs some attention, and both are similar in that they need protection from livestock. In the case of timber the returns are deferred because of a longer period required to reach merchantable size, but if managed properly, the woods can be made to produce an income besides meeting, in a large measure, the timber requirements for home needs.

The exclusion of livestock by fencing off the farm woods is necessary for best timber production. If the woods are now a part of the pasture, a good plan for developing both phases would be to fence off the heavier timbered areas, leaving the lightly wooded portion in the pasture. This would provide shade and protection for livestock during the hot summer months and insure better and more profitable timber-growing conditions.

WOOL Growth Increased by Supplemental Feeding of Sheep on the Range An experiment conducted for the last three years at the United States Sheep Experiment Station, Dubois, Idaho, has resulted in valuable information on the effects of supplemental feeding on the growth of wool. Two groups each consisting of 10 Corriedale ewes were selected, the ewes being as nearly uniform as possible in every respect. Extreme care was exercised in the selection of the ewes assigned to each group to be certain that they were strictly representative and to be assured that the results obtained would be reliable. The ewes were inspected individually in detail, and pedigrees were carefully studied to be certain that ewes in each group would be as much alike as possible in inheritance as well as in individual characteristics.

The ewes in one of these groups were handled under strictly range conditions and received only such feed and care as are ordinarily furnished to range ewes by practical wool growers. During periods of extreme cold they received a limited amount of concentrated feed to supplement range forage; and when the depth of the snow became too great to permit them to graze, they were fed slightly more than a maintenance ration of alfalfa hay. The ewes of the other group received additional feed from November 1 to March 15 and were purposely maintained in better condition during this period than the ewes which were handled entirely in accordance with common range practices. The procedure mentioned was carried out for three successive years.

ture in the soil. WOOL Growth Increased by Supplemental Feeding of Sheep on the Range

An experiment conducted for the last three years at the United States Sheep Experiment Station, Dubois, Idaho, has resulted in valuable information on the effects of supplemental feeding on the growth of wool. Two groups each consisting of 10 Corriedale ewes were selected, the ewes being as nearly uniform as possible in every respect. Extreme care was exercised in the selection of the ewes assigned to each group to be certain that they were strictly representative and to be assured that the results obtained would be reliable. The ewes were inspected individually in detail, and pedigrees were carefully studied to be certain that ewes in each group would be as much alike as possible in inheritance as well as in individual characteristics.

The ewes in one of these groups were handled under strictly range conditions and received only such feed and care as are ordinarily furnished to range ewes by practical wool growers. During periods of extreme cold they received a limited amount of concentrated feed to supplement range forage; and when the depth of the snow became too great to permit them to graze, they were fed slightly more than a maintenance ration of alfalfa hay. The ewes of the other group received additional feed from November 1 to March 15 and were purposely maintained in better condition during this period than the ewes which were handled entirely in accordance with common range practices. The procedure mentioned was carried out for three successive years.

Individual body weights were obtained for all the ewes at 56-day intervals. The ewes which received additional feed were about 7 per cent heavier on an average than the ewes which were handled under ordinary range conditions.

Measurements at 56-Day Intervals

Representative wool samples were taken for length measurements at 56-day intervals. These samples were obtained from every sheep in both groups on the same day. The technic and all the methods used were uniformly followed during the entire 3-year period. Although relatively small numbers of sheep were used in this test, the results are considered reasonably reliable owing to the very careful manner in which the work was performed.

The rate of wool growth was slower during the winter and early spring than in the summer when the sheep had access to abundant palatable and nutritious range forage in the mountains. Measurements of wool growth taken on both lots of ewes in September indicated that they had been producing wool at the rate of about one-half inch a month. In this 3-year experiment, the wool from the group of sheep which received additional feed in the winter was from 9 to 14 per cent longer during the periods of the least wool growth than was that of the other group.

These results indicate that the condition in which sheep are maintained has an important bearing on the rate of wool growth. The wool made its greatest growth during the summer months when these sheep had access to abundant feed and were gaining rapidly. The sheep which received additional feed during the winter were maintained in better condition and produced wool of greater length than the sheep handled under ordinary range conditions.

WOOL-PRICE Trend Reflects World-Wide Business Depression Wool producers of the United States have been confronted with falling prices for their product throughout most of the past two years. From the high point reached in the summer of 1928 domestic wool prices have fallen about 40 per cent. Present low wool prices constitute a very serious problem for wool growers. If sheep and wool prices are to remain low there are undoubtedly many producers who will want to go out of the wool-growing business. On the other hand, if it could be determined that wool prices would improve in the reasonably near future, many, who otherwise would become discouraged and liquidate while prices remain low, would manage to continue in the business. The key to the future trend of wool prices is to be seen in the fundamental conditions which brought about the low prices.

Conditions underlying the important trends in wool prices are world wide. The United States is now the second largest wool-producing country, but it produces considerably less than half as much wool as Australia, and only a little over one-tenth of the total world production. The United States consumes about one-fifth of the world's wool

WOOL-PRICE Trend Reflects World-Wide Business Depression

Wool producers of the United States have been confronted with falling prices for their product throughout most of the past two years. From the high point reached in the summer of 1928 domestic wool prices have fallen about 40 per cent. Present low wool prices constitute a very serious problem for wool growers. If sheep and wool prices are to remain low there are undoubtedly many producers who will want to go out of the wool-growing business. On the other hand, if it could be determined that wool prices would improve in the reasonably near future, many, who otherwise would become discouraged and liquidate while prices remain low, would manage to continue in the business. The key to the future trend of wool prices is to be seen in the fundamental conditions which brought about the low prices.

Conditions underlying the important trends in wool prices are world wide. The United States is now the second largest wool-producing country, but it produces considerably less than half as much wool as Australia, and only a little over one-tenth of the total world production. The United States consumes about one-fifth of the world's wool clip. It is, therefore, one of several countries that greatly influences world wool supply, demand and price conditions, but that individually does not dominate the world wool situation. On the other hand, this country can, and does, separate itself to some extent from the world level of wool prices by a tariff on wool. The United States has never produced enough wool to satisfy its own consumption requirements. On the whole, this country consumes about twice as much wool as it produces. It is necessary, however, to distinguish between carpet wools, all of which are imported, and combing and clothing wools. This country produces slightly over three-fourths of the combing and clothing wools that it consumes. Domestic production more nearly satisfies the domestic requirements for fine than for medium grades of combing and clothing wools, but some fine wools as well as medium wools are imported. These import requirements serve to make the

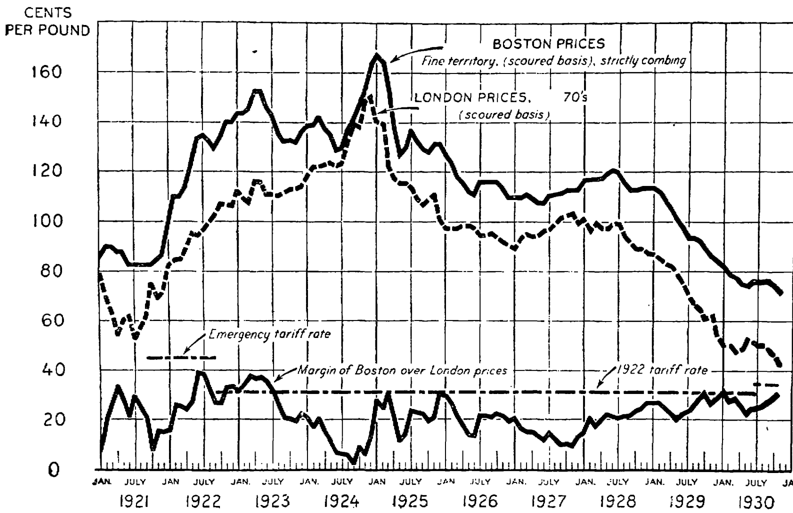

FIGURE 186.—Increased production caused world wool prices to trend downward for several years. In 1929 and 1930 a falling off in demand, due to the world business depression, caused further price declines. The major trends in wool prices in the United States are similar to those abroad, but the margin of domestic over foreign prices depends upon the supply of wool available in the United States and the strength of domestic demand. This country produces nearly all the fine wool it requires, so that prices on these grades follow very closely the trends abroad

tariff on wool effective. The tariff tends to hold domestic wool prices farther above foreign prices than they would be without the tariff. Differences between foreign and domestic wool prices are not uniform. They vary with the domestic supply and demand situations and the short-time trends of prices. At times domestic prices fall nearly to the world level, at other times they rise above the world level sufficiently to attract large imports. One effect of the tariff seems to be to retard the influence that changes in foreign prices have on domestic prices. Nevertheless, the major trends in both domestic and foreign wool prices are similar, although the domestic prices are higher.

Rapid Rise After Postwar Slump

Following the postwar deflation of 1920 and 1921 and its accompanying depression, wool prices rose rapidly and attained a high level in 1923. (Figs. 186 and 187.) Foreign prices continued gradually upward until the middle of 1924 and then rose sharply to a peak in the latter part of the year. Business conditions became unfavorable in the United States in 1924 and had an adverse effect on the demand for wool. This caused domestic prices to decline somewhat in the first part of the year and the sharp rise abroad the latter part of the year was only slowly reflected in the American market. As demand improved, however, the margin of domestic over foreign prices increased.

Wool prices were unusually high in 1923 and 1924, and, although they had a downward trend after 1924, they were still comparatively high through 1928. It was after 1928 that the purchasing power of wool became unusually low. The generally high level of prices from 1923 to 1928 caused production to increase. The wool clip of the United States rose from 222,000,000 pounds in 1922 to 304,000,000 pounds in 1928 and to 328,000,000 pounds in 1930. The total world production, excluding that of Russia and China, rose from 2,566,000,000 pounds in

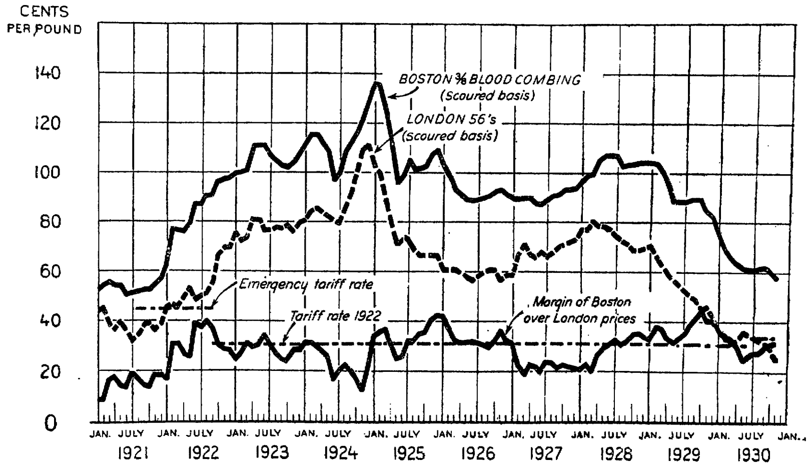

FIGURE 187.—Relatively small supplies of medium grades of wool caused prices on these grades to hold steady in the United States during most of 1929 despite declines abroad. Much of this firmness was subsequently lost. In the present depression, wool prices in the United States have been maintained at a wider margin above the world level than in previous periods of low consumer demand

1923 to the record of 3,232,000,000 pounds in 1928. Since 1928 world production has held at only a little below the record level. The trends of prices and production for the period since 1922 correspond to the trends for earlier periods of somewhat similar length. In the earlier periods, as in the present one, high prices first caused production to increase, then increased production caused prices to decline, and subsequently low prices checked the expansion in production. Finally, in the earlier periods, very low prices necessitated liquidations and restricted expenditures and made alternative enterprises relatively more profitable. As sheep numbers were reduced and the downward phase of the wool production cycle got under way, prices tended to improve gradually. So far in the present cycle, wool production has not been materially reduced, but there can be no doubt that present prices will cause producers in many parts of the world to liquidate their sheep enterprises, and practically all producers will be forced to restrict expenditures. Many producers will market breeding stock where they can do so at acceptable prices.

Influence of World Depression

The fall in wool prices that has taken place in the last two years was caused only in part by production. In large part it was caused by the world business depression and reduced consumer buying power and the accompanying decline in general commodity prices. A smaller world wool clip in 1927 and favorable demand conditions abroad had caused foreign prices to rise in 1927, but they started down early in 1928. In 1927 demand in the United States was rather weak and domestic prices were slow to reflect the rise abroad, but as domestic demand improved domestic prices strengthened. Except for a few short periods wool prices abroad have been falling steadily since the early part of 1928. Domestic prices fell more slowly and the margin of domestic over foreign prices became very wide. This wide margin reflected the strong demand in the United States until the fall of 1929 when the depression got under way in the United States. Supplies of medium wools in this country were short and prices on them were comparatively strong. With the development of the depression the American market weakened, and consumption and imports declined. It is worthy of note, however, that the margin of domestic over foreign prices has been maintained at as high a level as it has been despite severe depression in the United States and large supplies of the domestic clip coming rapidly on the market. In comparable earlier periods the margin was very small. Quite clearly this new development reflects the price stabilizing activities that have been conducted.

The first series of the 1931 London wool sales opened in January with further sharp declines in prices. Continued declines in general commodity price levels in important countries throughout 1930 reflected the generally unsatisfactory business conditions, and the declines in wool prices reflected the difficulty that world markets had in taking another large wool clip in the face of continued low consumer demand. With foreign wool prices materially lower than American prices, however, foreign producers who have costs at all comparable with those in the United States fare even worse than do American producers. In the past, low returns have ultimately brought a reduction in world sheep numbers. On the other hand, world business recovery, when it comes, can be expected to br ng a considerable improvement in the demand for wool.

CROP AND LIVESTOCK PRODUCTION TRENDS

Charts of production statistics for important products, covering 40 years, as far as available

Prepared under the direction of the Statistical Committee: J. A. Becker, chairman, Lewis B. Flohr, secretary, C. A. Burmeister, L. M. Davis, S. W. Mendum, and E. J. Working

This series of charts traces the growth of production of some of the more important agricultural commodities over a period of 40 years. Uniform treatment has not been possible at this time because of lack of comparable figures for the full period. Crop reporting developed earlier than livestock reporting except for numbers on farms on January 1, and, in general, is now more complete in detail.

The figures used in the charts are for the most part those given in the several related tables in the statistical section of this Yearbook.

In addition to the charts for the United States as a whole, a few charts depicting the variations in States or regions are given, and others showing the relation of production in the United States to production in other parts of the world.

Increase in production prior to 1900 was rapid with the opening of new producing territory west of the Mississippi River; since then the increase has come mainly from shifts in farming. During the early years of this period of expanding production the Nation's export trade furnished an outlet for much of the increase, and this outlet was further expanded during the war period; but in the last few years the export outlet has been considerably curtailed, thus forcing a larger proportion of the Nation's production on the domestic market.

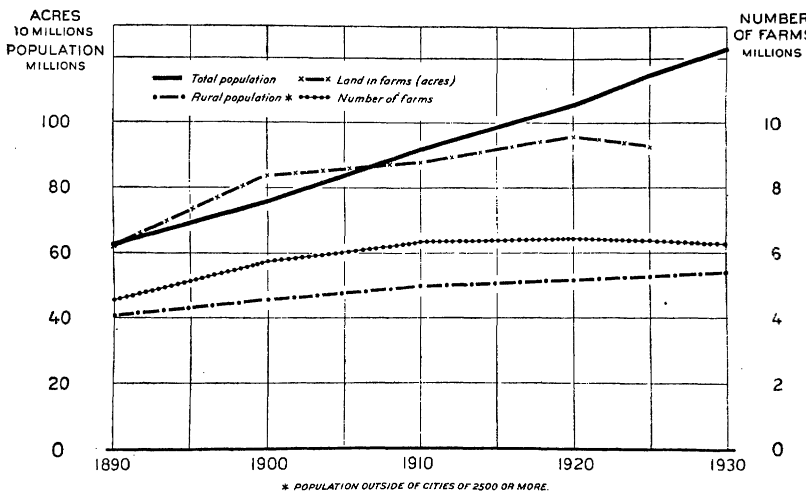

FIGURE 1.—POPULATION, NUMBER OF FARMS, AND LAND IN FARMS, CENSUS YEARS, 1890–1930

In the last 40 years the population of the continental United States has doubled. The number of persons to be provided for has increased steadily and relatively uniformly, and continued growth of population even at a slower rate has been counted upon to absorb the increasing quantities of farm products brought forth by expansion in area and by improvements in technic. The increase in domestic demand for farm products has, however, not increased as fast as the producing power of farms and farmers. Land in farms has declined from the maximum reached in 1920, and number of farms has changed very little since 1900. Rural population, which now includes nearly 20,000,000 people not on farms, has dropped from two-thirds of the population in 1900 to less than one-half.

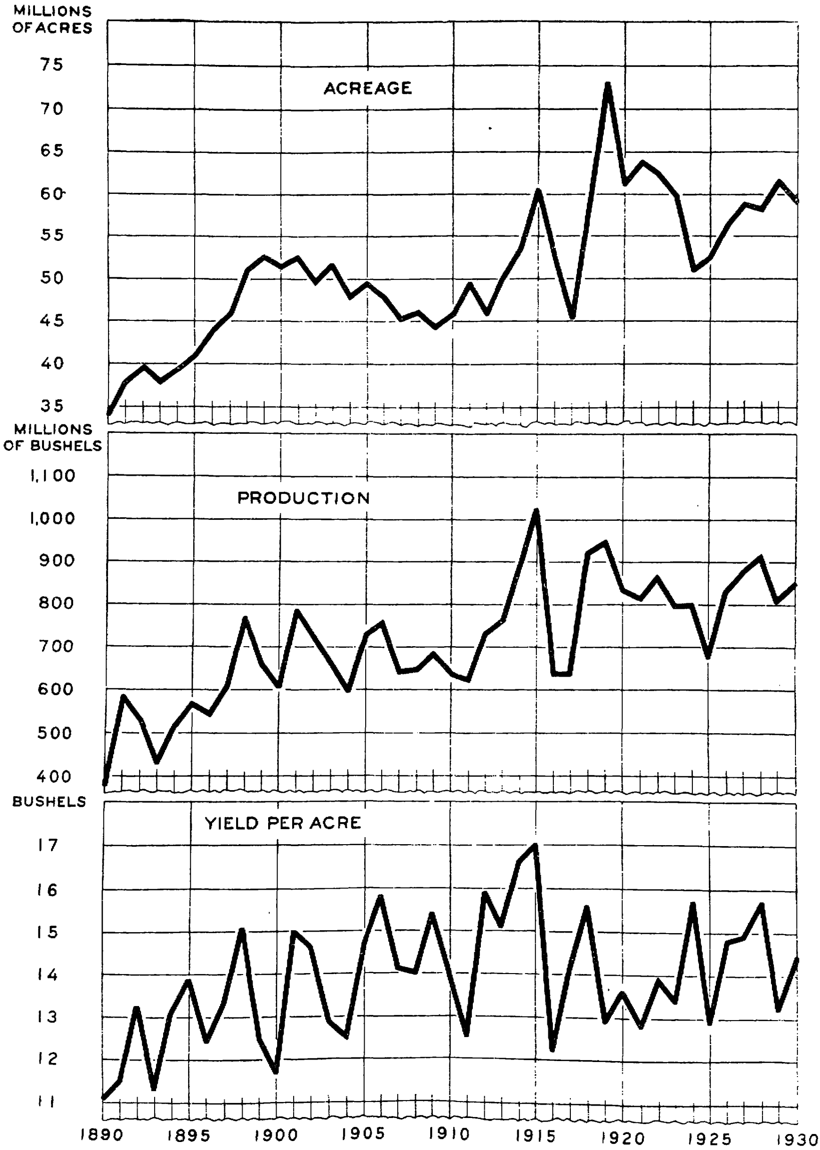

FIGURE 2.—WHEAT: ACREAGE, PRODUCTION, AND YIELD PER ACRE IN THE UNITED STATES, 1890–1930

Wheat acreage has not quite doubled in 40 years, but yield per acre has increased so that production has fallen below 800,000,000 bushels in only 1 of the last 13 years. Domestic consumption per capita is less than it was 30 years ago. Exports have not been so large as they were and carry-overs in recent years have been large. Yields as low as 13 bushels per acre have been exceptional. For the next few years, unless acreage is reduced below 50,000,000 acres any yield per acre above 13 bushels will supply probable domestic demand.

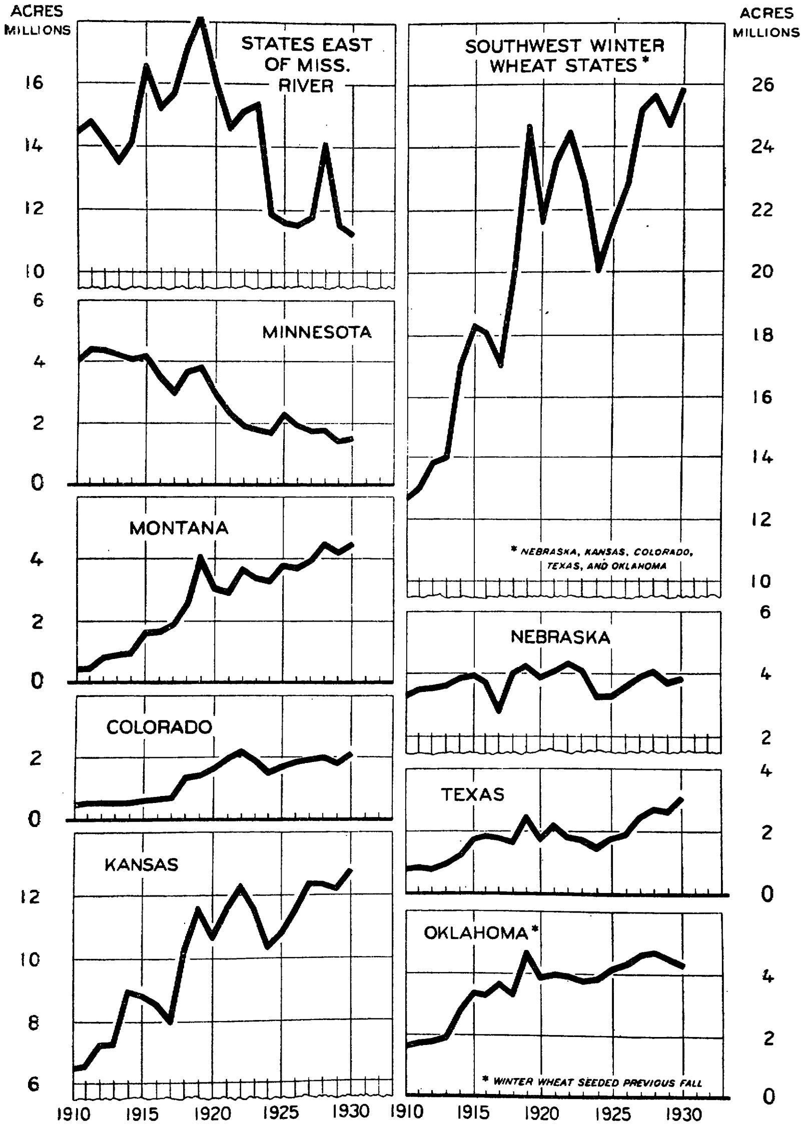

FIGURE 3.—WHEAT ACREAGE, BY REGIONS (WINTER WHEAT SEEDED PRECEDING FALL AND SPRING WHEAT), 1910–1930

Increase in wheat acreage since 1910 has been large in five southwestern winter-wheat States. States east of the Mississippi River increased acreage during the war period, but since then appear to have reduced acreage to below pre-war levels. Acreage decreases in Minnesota in the last 10 years have about offset the increases in Montana. These are the most striking changes in acreages since 1910. Elsewhere production (acreage times yield per acre) has varied without showing positive evidence of marked increase or marked decrease not associated with climatic factors affecting acreage seeded or yield per acre.

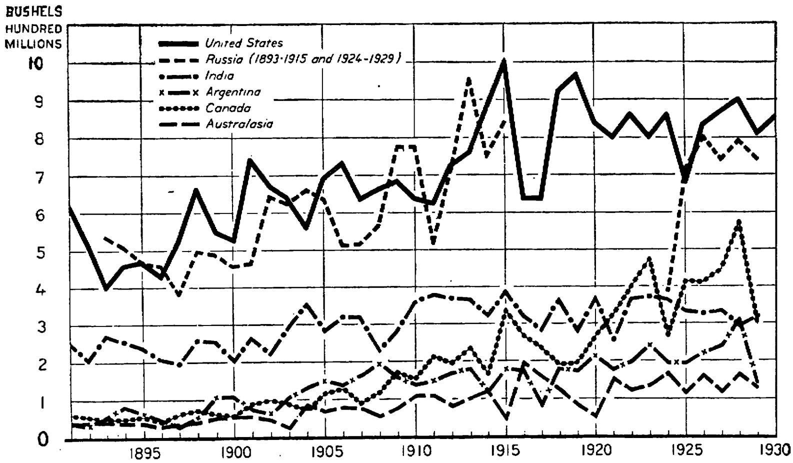

FIGURE 4.—WHEAT PRODUCTION: LEADING COUNTRIES, 1891–1930

World wheat production in the last 10 years, outside of Russia and China, has not gone below the maximum pre-war figure, and in 1928, the record year, was 21 per cent greater than the previous maximum of 1913. The large world acreage of wheat is so widely distributed that conditions making for decreased production in any part tend to be offset by conditions in other parts making for increased production. Russian production is now near pre-war levels and may be much increased in the near future. Wheat production in China has little effect on the world trade in wheat.

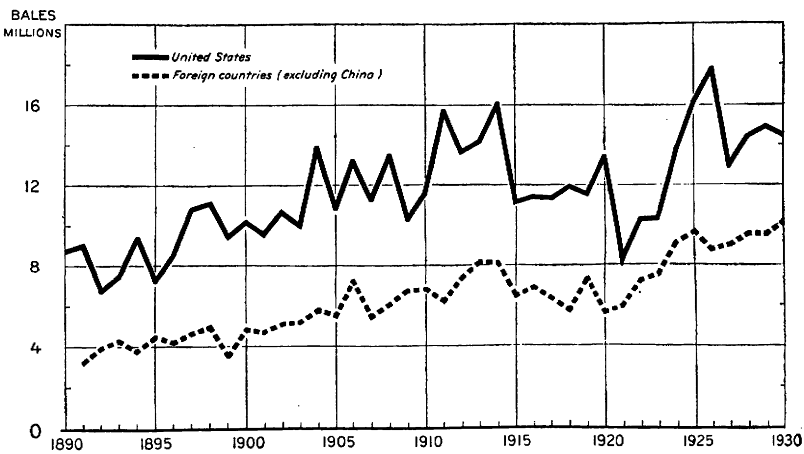

FIGURE 5.—COTTON PRODUCTION IN THE UNITED STATES AND FOREIGN COUNTRIES, 1890–1930

World cotton production (excluding China) in recent years has been only a few million bales larger than it was just before the war. Production in foreign countries has definitely increased; for seven years it has been above the previous maximum. The relative importance of American cotton in consumption in foreign countries has decreased. Breaks in the upward trend of production in the United States in 1915 and again in 1921 are associated with extension of serious boll-weevil infestation in new territory. The peak of production, in 1926, resulted from a record acreage and the highest yield per acre since 1914.

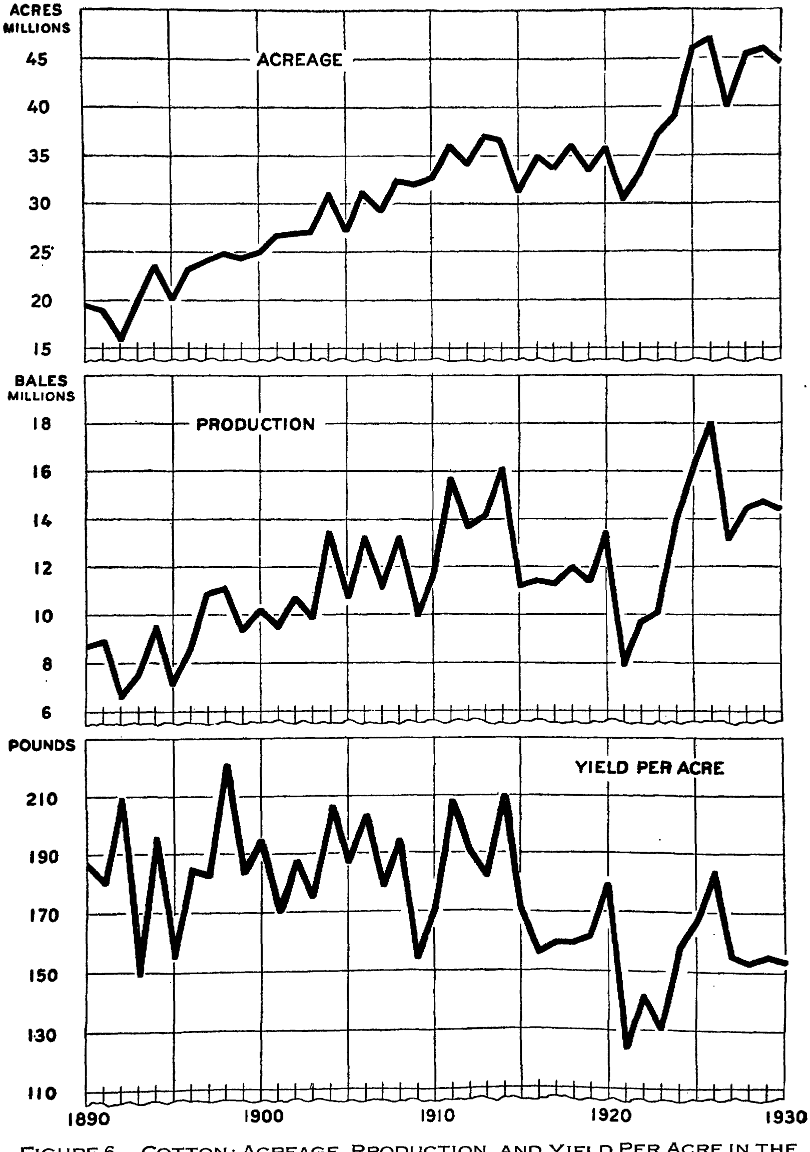

FIGURE 6.—COTTON: ACREAGE, PRODUCTION, AND YIELD PER ACRE IN THE UNITED STATES, 1890–1930

The upward trend in acreage of cotton, halted during the war period, was resumed in 1923 by extensions in most of the States, but chiefly in Texas and Oklahoma. Production on the larger total area has been held down by the lower average yields. Average yields on the 45,000,000 acres of recent years mean crops large enough to make marketing difficult, in view of the increasing competition from foreign cottons and other fibers, and the heavy carry-overs.

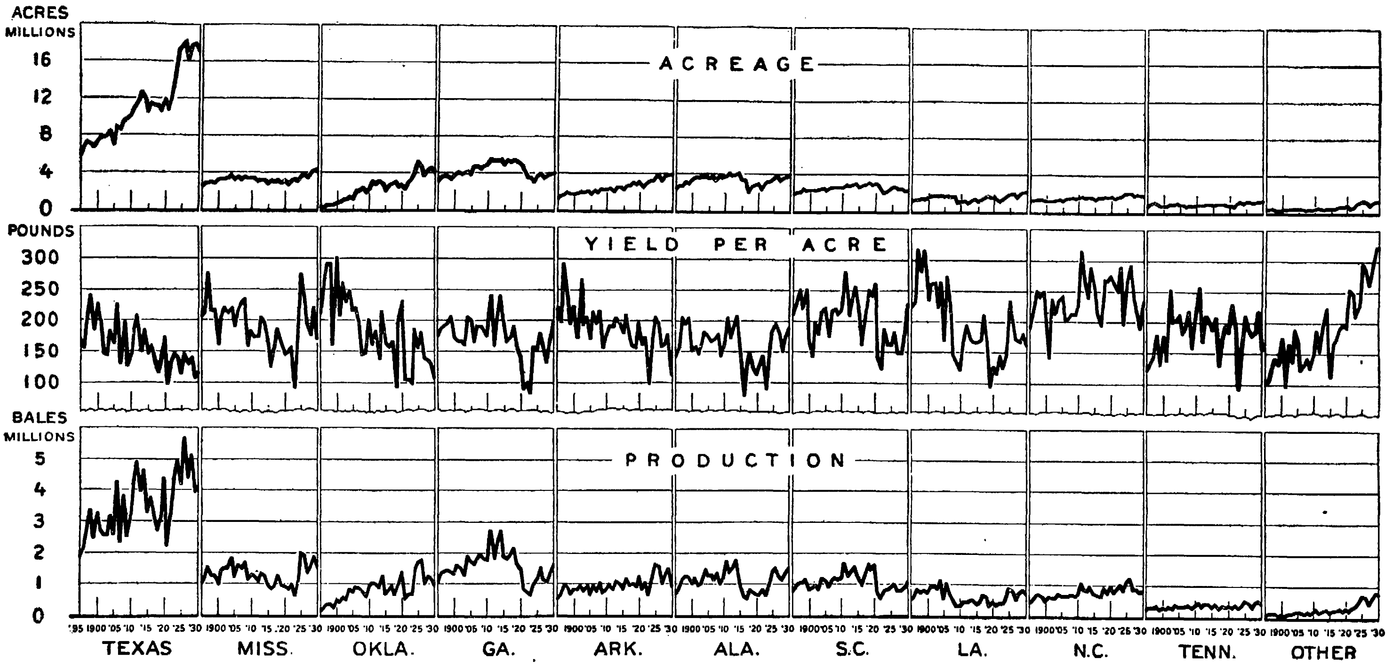

FIGURE 7.—COTTON: ACREAGE, YIELD PER ACRE, AND PRODUCTION, BY STATES, 1895–1930

The outstanding features of cotton production in the last 40 years are the extension of cotton acreage in Texas and Oklahoma, with increased production in spite of declining yields per acre, and the moderate changes in the remainder of the South. Reductions in acreage and production were largely caused by boll-weevil damage in Louisiana in 1908, in Alabama in 1915, in Georgia in 1920, and in South Carolina in 1921, but were followed by gradual recovery. Yield per acre has been highly variable.

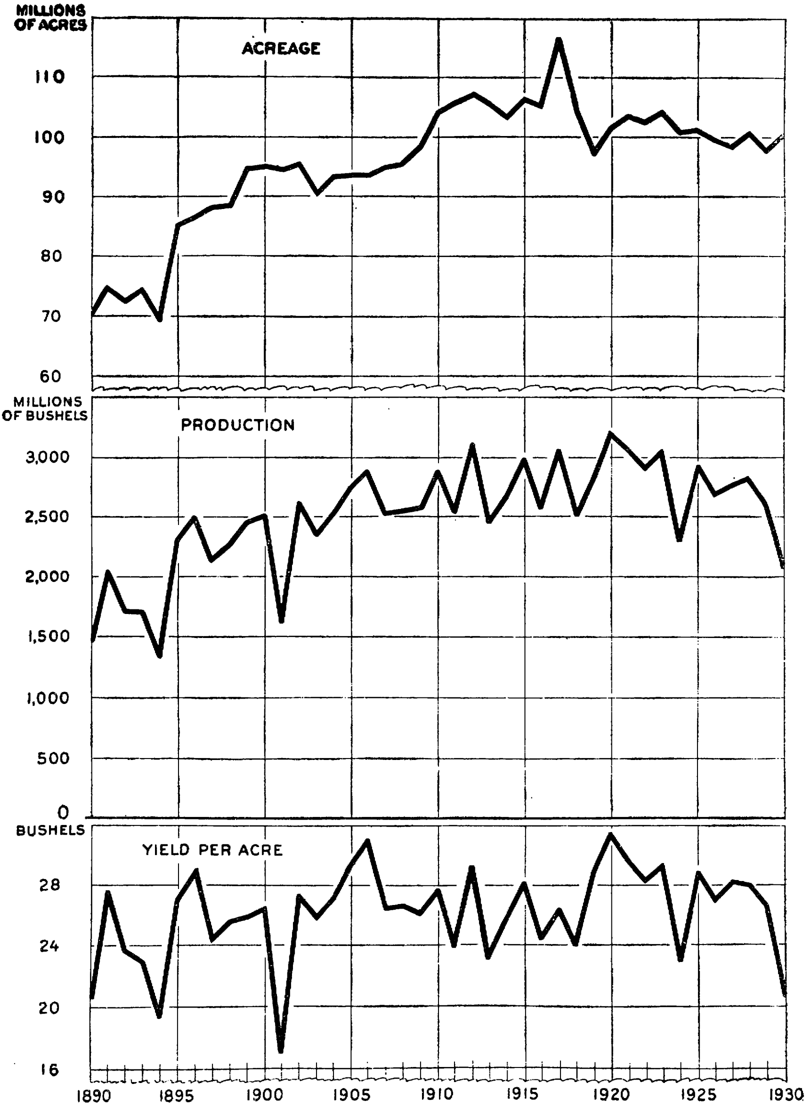

FIGURE 8.—CORN: ACREAGE, PRODUCTION, AND YIELD PER ACRE IN THE UNITED STATES, 1890–1930

Corn acreage increased steadily from 1890 to 1912, receded slightly thereafter except for the record acreage of 1917 (116,700,000 acres), and since 1918 has remained close to 100,000,000 acres. Production has been below 2,000,000,000 bushels only once since 1894—in 1901, when yield per acre dropped to 17 bushels. Five 3,000,000,000-bushel crops have been produced, resulting from high yields rather than from high acreage. Production figures include the corn used as silage, as forage, or hogged down and grazed. About 90 per cent of the corn produced is used as feed for livestock.

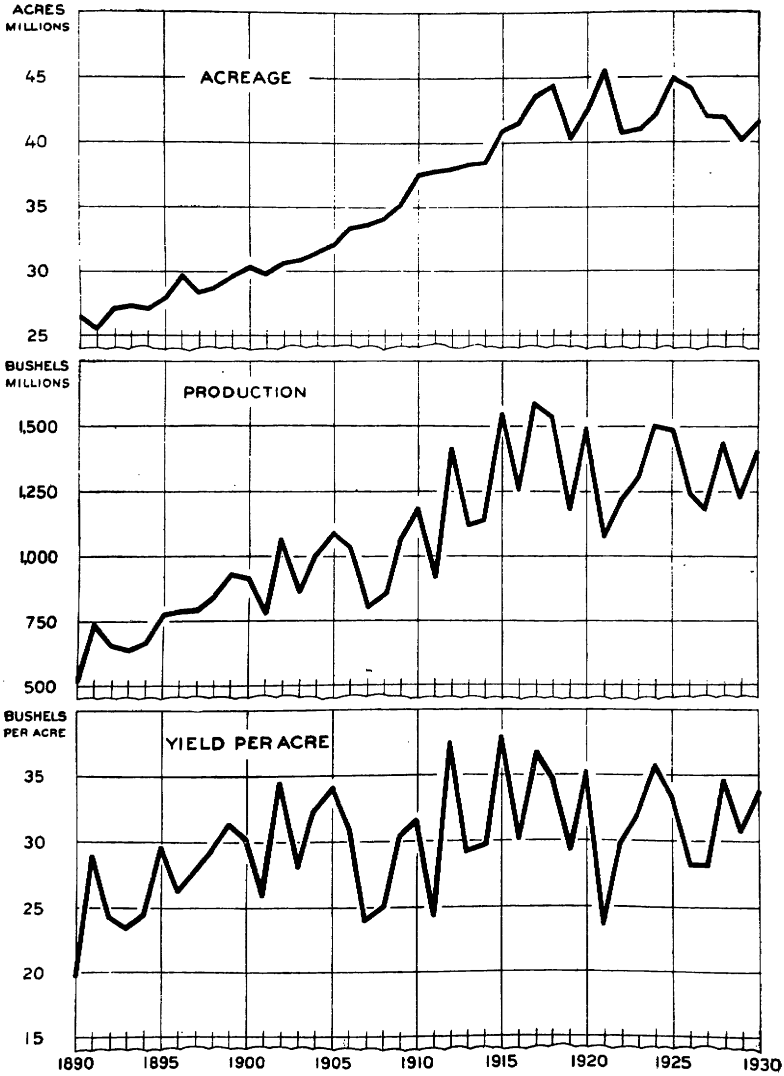

FIGURE 9.—OATS: ACREAGE, PRODUCTION, AND YIELD PER ACRE IN THE UNITED STATES, 1890–1930

Production of oats has just about doubled in 40 years, though there has been a tendency toward reduction during the last 10 years, during which numbers of horses and mules have declined greatly. One reason why a large acreage of oats is still grown is that the crop fits well in the rotation between corn and grass.

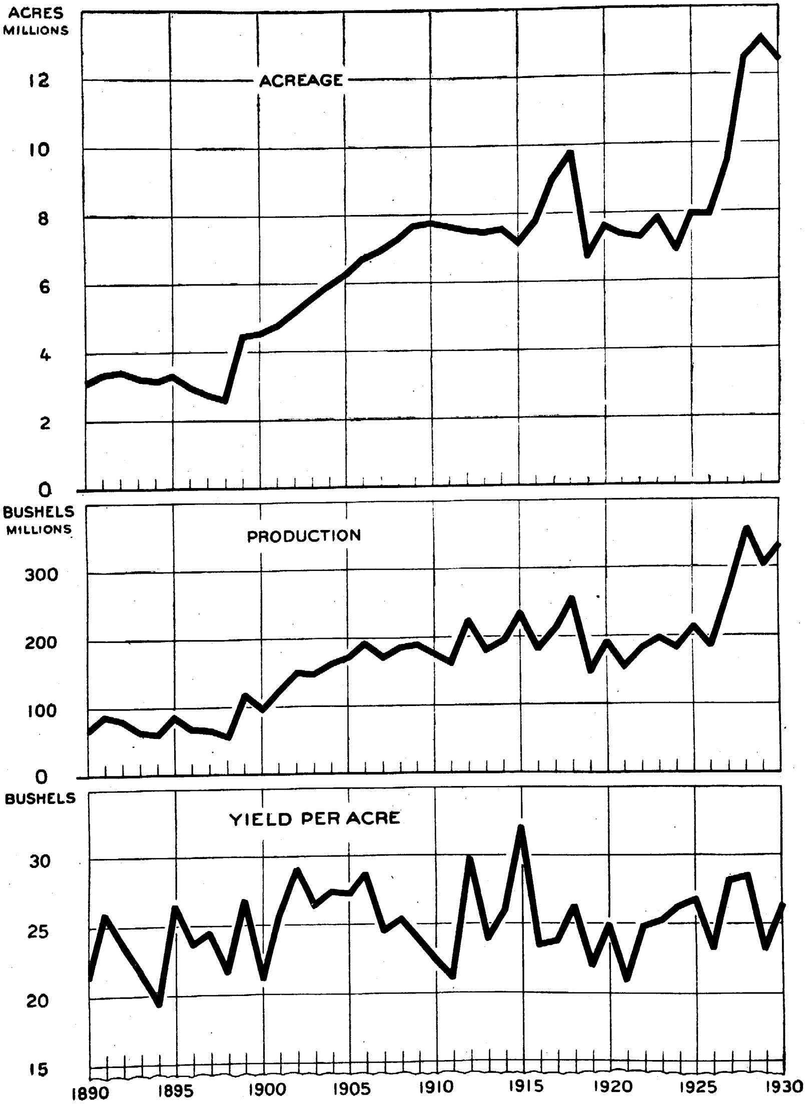

FIGURE 10.—BARLEY: ACREAGE, PRODUCTION, AND YIELD PER ACRE IN THE UNITED STATES, 1890–1930

Increase in barley production has been three-fold during the 40-year period, with little change in average yields. The marked increase in acreage and production since 1925 represents an extension of barley into the region to the north and west of the Corn Belt for use in feeding livestock, where corn is not so sure a crop; elsewhere barley sometimes takes the place of part of the oats.

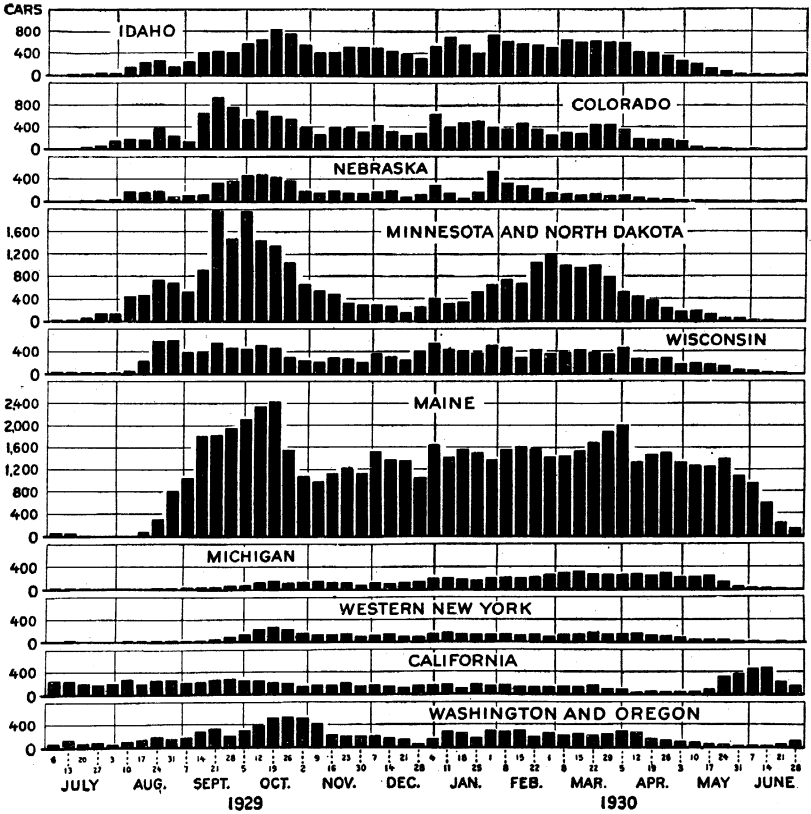

FIGURE 11.—LATE POTATOES: WEEKLY CAR-LOT SHIPMENTS, 1929–30

Though first shipments of main-crop or late potatoes begin to move from the farms in July, the heavy movement to market gets under way in September and continues through the following April. The size and distribution of the crop in the several States varies somewhat from year to year. Large quantities of late potatoes are sold locally or in markets within easy reach by motor truck and these are not reflected in this chart.

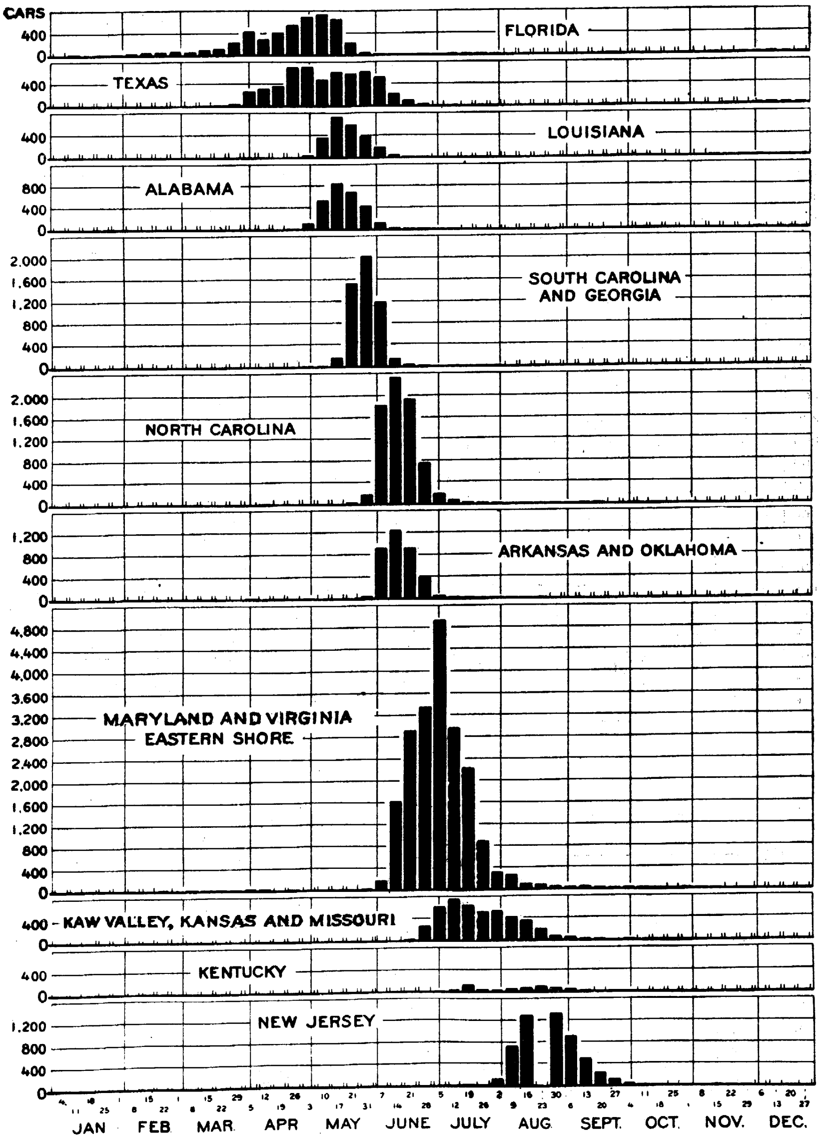

FIGURE 12.—EARLY POTATOES: WEEKLY CAR-LOT SHIPMENTS, 1930

Potatoes begin to move from Florida early in January, and movement from Texas begins before Florida shipments reach their peak. Early in May keen competition between areas begins. The outlet for early potatoes is affected by the supply and price of late potatoes still available, but as the season progresses the extent of the market for the early crop of a district is definitely limited by the appearance in volume of the early crop in districts closer to the consuming markets. The Eastern Shore of Maryland and Virginia is the principal source of early potatoes for city markets.

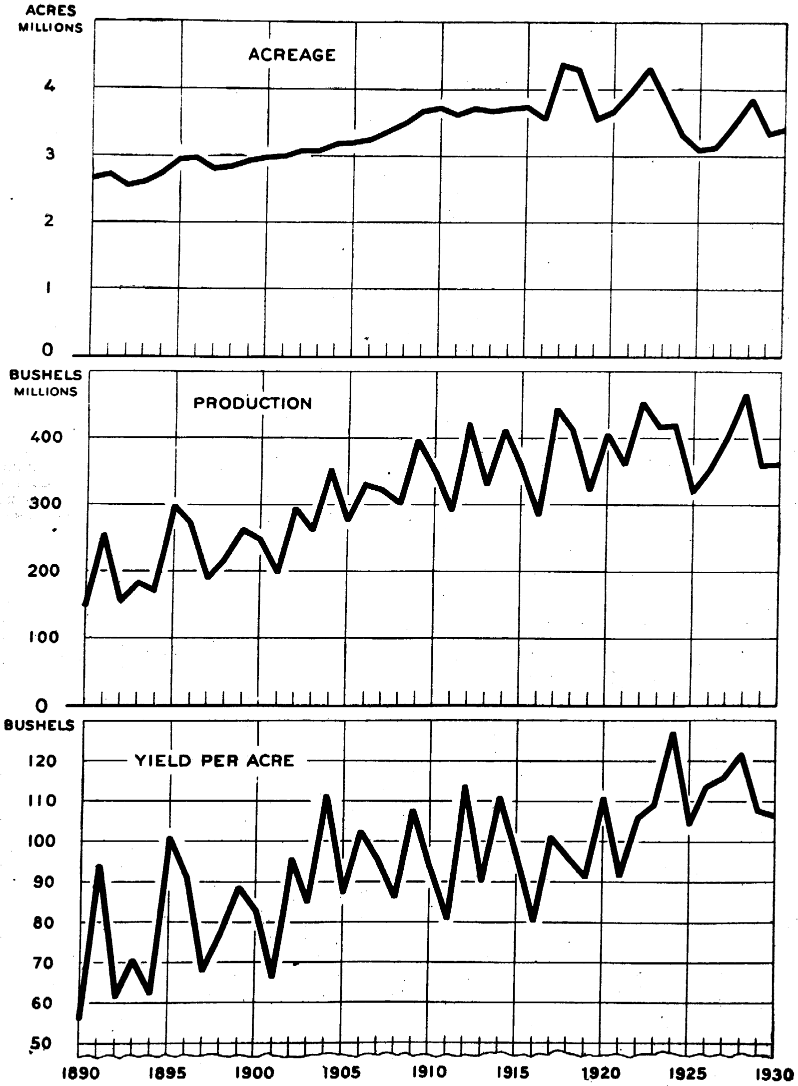

FIGURE 13.—POTATOES: ACREAGE, PRODUCTION, AND YIELD PER ACRE IN UNITED STATES, 1890–1930

Potato production has in general increased with population growth. Average yields per acre have increased about 50 per cent in the 40-year period with improvements in production methods and concentration in the more favored districts. In the last 15 years producer response to price has been promptly reflected in acreage change, and shifts in acreage from year to year have been greater than they were previously. Effectiveness of acreage changes has been reduced by the rather wide variations in yield resulting from a combination of factors in which weather is important.

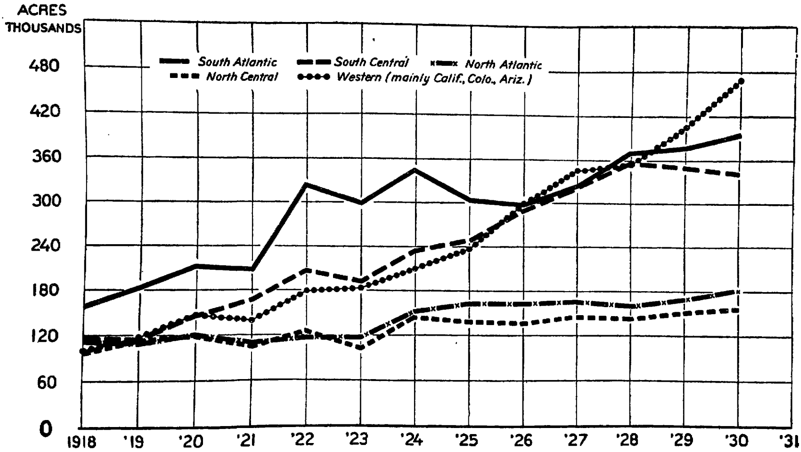

FIGURE 14.—ACREAGE OF COMMERCIAL TRUCK CROPS, 1918–1930 [1]

Acreage of truck crops has shown a steady expansion in recent years, especially in the 11 Western States. In the South Atlantic States the expansion came earlier and has been moderate since 1924. The term "commercial" covers those acreages grown for shipment to market or for canning and manufacture, but not market gardens or home gardens, and in this case early potatoes are not included. Figures for years prior to 1918 are available for only a few crops, and census figures relate to total acreage rather than to the commercial acreage.

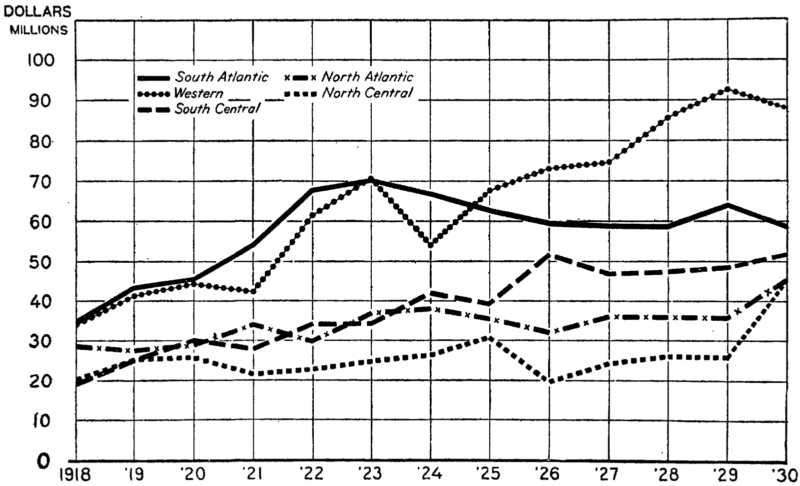

FIGURE 15.—VALUE OF COMMERCIAL TRUCK CROPS, 1918–1930 [1]

Value of commercial truck crops as defined in the legend of Figure 14 has increased markedly in the 11 Western States, but not to the same extent as the acreage. Values at the farm are sensitive to variations in supply and distribution. City markets are now so well supplied with fresh and processed goods the year around that competition between producing areas is keen, and results to growers are increasingly dependent on high quality, wide distribution, and the avoidance of market supplies in excess of the consumer demand at the time and place of marketing the crop. The market situation in recent years suggests that further increases in demand are likely to be moderate.

[1] Excluding early potatoes, but including strawberries, cantaloupes, and watermelons.

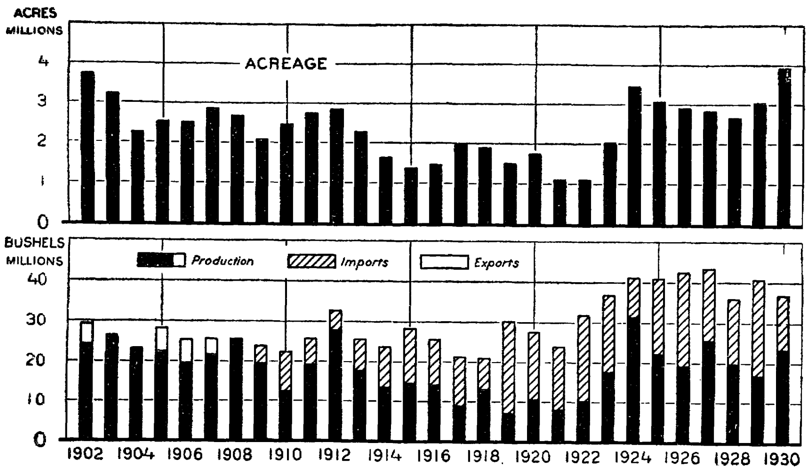

FIGURE 16.—FLAXSEED: ACREAGE, PRODUCTION, IMPORTS, AND EXPORTS, 1902–1930

Acreage and production of flaxseed in the United States have been highly variable during the last 40 years. The record acreage of 1930 was only slightly larger than that of 1902, the first year of annual acreage figures, and for 9 years (1914–1922) acreage was lower than it was in 1889. In 1924 a combination of high yield per acre on an acreage only once before exceeded gave a record crop of 31,547,000 bushels. Yields have varied between 4.6 and 11.2 bushels per acre. Since 1907 there have been no net exports. A high yield on an acreage equal to that of 1930 would reduce the imports to a very small quantity.

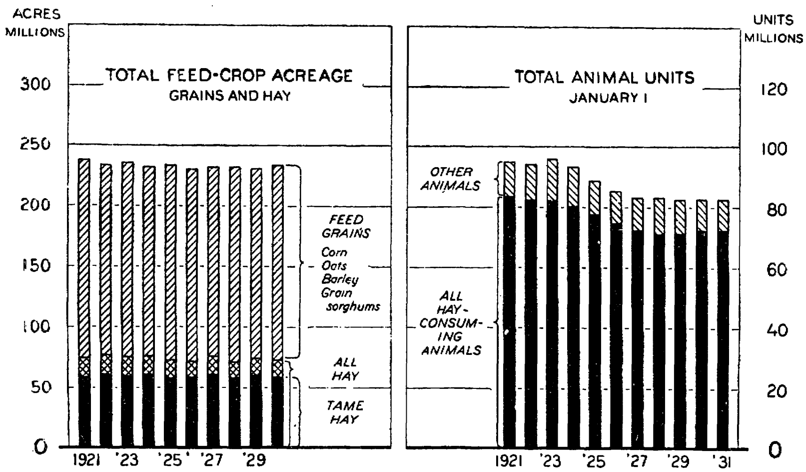

FIGURE 17.—FEED-CROP ACREAGE, HAY ACREAGE, AND LIVESTOCK NUMBERS, UNITED STATES, 1921–1931

In the last 10 years the acreage of feed grains and hay has remained practically stationary, but the numbers of animal units were less at the end of the decade than they were at the beginning. The "animal unit" is based on the feed consumption of the mature horse or mule; 8 sheep, or 5 hogs, or 1.2 cattle and calves are considered as 1 animal unit. Hay and feed consumption depends to some extent on the pasture available and the feeding practice. In recent years the ratio of production of livestock and livestock products to numbers on hand on January 1 has been somewhat larger than it was 20 years and more ago.

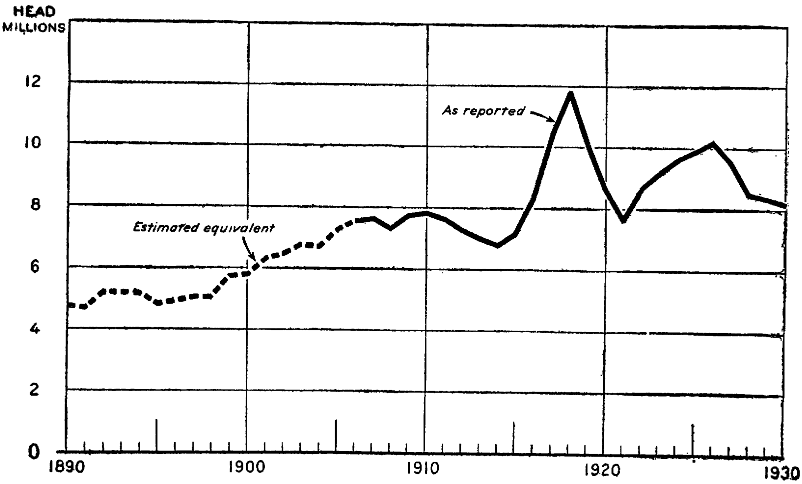

FIGURE 18.—CATTLE: ESTIMATED EQUIVALENT FEDERALLY INSPECTED SLAUGHTER, 1890–1906, AND SLAUGHTER UNDER FEDERAL INSPECTION, 1907–1930

The general trend of cattle slaughter has been upward in the last 40 years. The years of largest slaughter were during the war period, when production was stimulated by the war demands for beef. During the last 30 years there have been two cycles of cattle production of 14 to 16 years in length. These production cycles were reflected in similar cycles of cattle slaughter which began about 2 years later. The slaughter cycle which began about 1914 was distorted somewhat by the war and the abnormal economic conditions which followed.

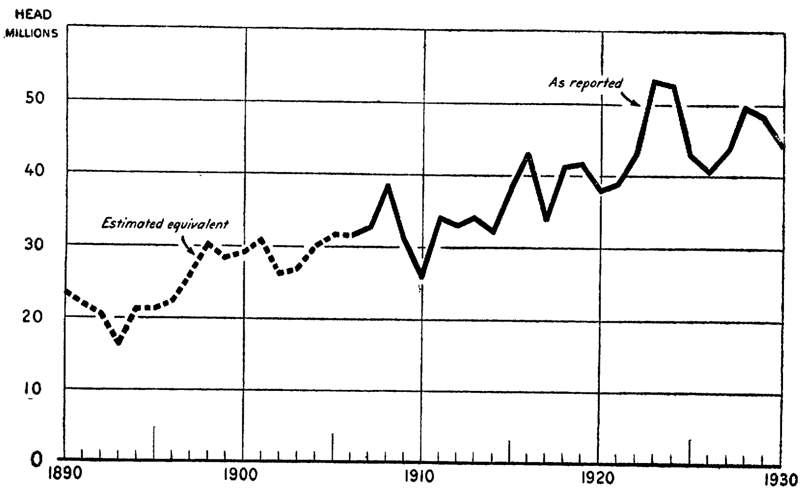

FIGURE 19.—HOGS: ESTIMATED EQUIVALENT FEDERALLY INSPECTED SLAUGHTER, 1890–1906, AND SLAUGHTER UNDER FEDERAL INSPECTION, 1907–1930

Annual hog slaughter tends to fluctuate in cycles of 3 to 5 years in length, but the general trend has been sharply upward during the past 40 years. Hog production is influenced to a large extent by variations in the relationship of corn prices to hog prices. These variations account largely for the cyclical variations in slaughter.

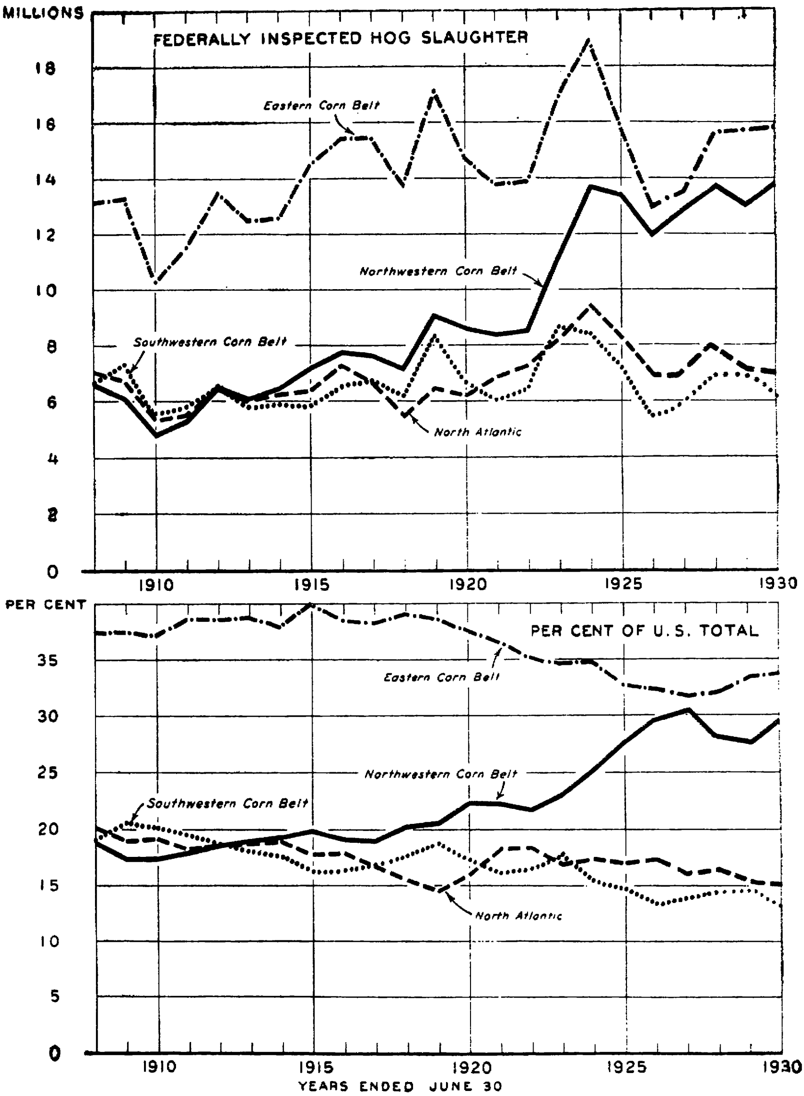

FIGURE 20.—FEDERALLY INSPECTED HOG SLAUGHTER BY AREAS, 1908–1930

Changes in both production and slaughter of hogs in the United States have accompanied the shifts in corn production. For several years there has been an upward trend in corn acreage in the northwestern Corn Belt (Iowa, Nebraska, Minnesota, North Dakota, and South Dakota), whereas the acreages in other areas of the Corn Belt have remained about stationary or have decreased. Similar changes have taken place in hog production and hog slaughter. Most of the increase in total hog slaughter during the last 15 years has been due to the increase that has taken place in the northwestern Corn Belt.

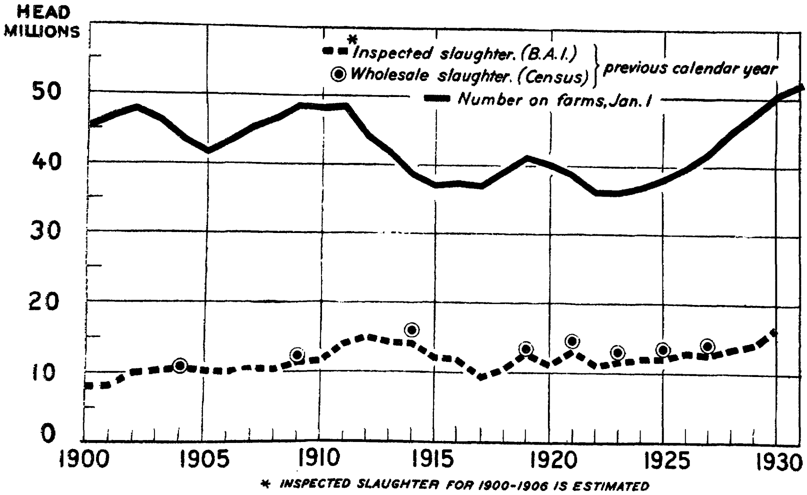

FIGURE 21.—SHEEP AND LAMBS: NUMBER ON FARMS JANUARY 1 AND INSPECTED AND WHOLESALE SLAUGHTER, 1900–1931

Sheep numbers in the United States reached the highest level on record in 1931, and a new slaughter record was established in 1930. In the last 30 years both numbers and slaughter have tended to move in cycles which have varied somewhat in length, with the slaughter cycle lagging behind the production cycle. The increase in numbers since 1922 has been more marked than that of slaughter, due to the holding back of a large proportion of the lamb crop each year for flock expansion purposes.

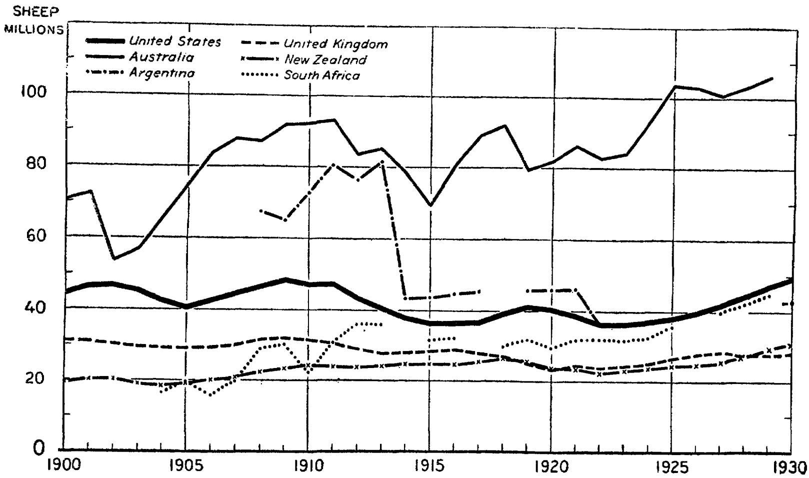

FIGURE 22.—NUMBER OF SHEEP IN IMPORTANT COUNTRIES, 1900–1930

Sheep and wool production in most important producing countries tends to move in cycles, although the general trend in world numbers has been upward in the last 30 years. Sheep numbers in Australia, South Africa, and the United States have increased greatly since 1922. Australia is the largest sheep-producing and wool-exporting country in the world. In New Zealand and Argentina, also important wool-exporting countries, sheep numbers have increased gradually during recent years. Because of the large imports of wool into the United States, wool prices in this country are influenced considerably by the world production of wool.

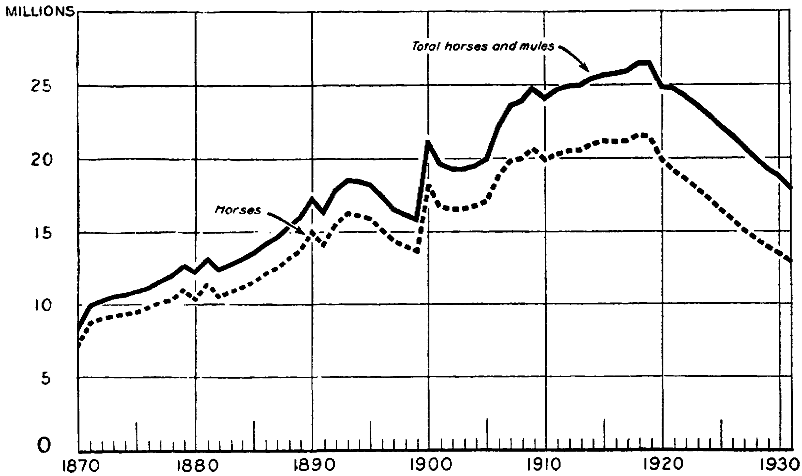

FIGURE 23.—HORSES AND MULES: NUMBERS ON FARMS, 1870–1931

Total numbers of horses and mules in the United States increased from around 10,000,000 head in the early seventies to more than 25,000,000 at the end of the World War. Since 1918 the trend in horse numbers has been downward, and the total now is the smallest in more than 40 years. The number of mules continued to increase until 1926 but has since decreased slightly. The reduction in horse numbers in the last decade has been due to decreased demand caused by the increased use of mechanical power in carrying on farm operations and by the replacement of horses by motor vehicles in towns and cities.

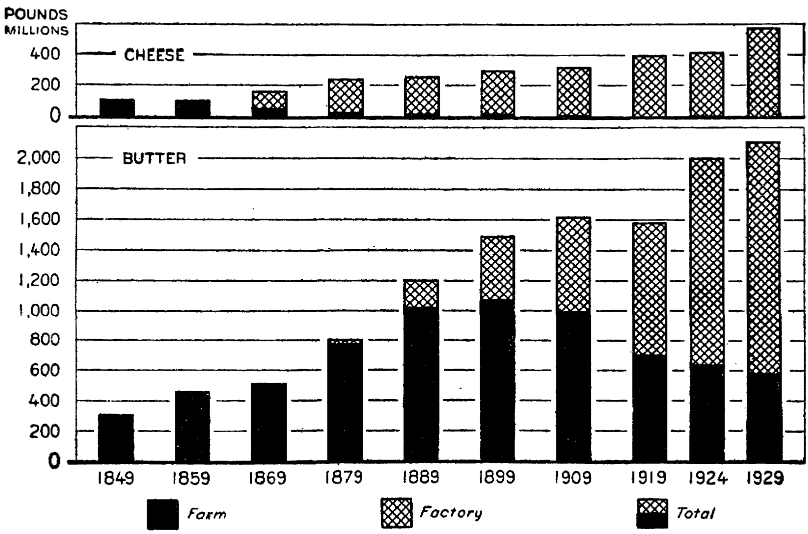

FIGURE 24.—PRODUCTION OF FARM AND FACTORY CHEESE AND BUTTER, UNITED STATES, CENSUS YEARS, 1849–1929

Production of butter in the United States has shown a more marked upward trend than population. During the last 50 years there has been a pronounced shift from the production of butter on farms to factory production. The rate of increase in cheese production has been considerably less than that for butter. Since 1869 only a small percentage of the total cheese produced has been made on farms.

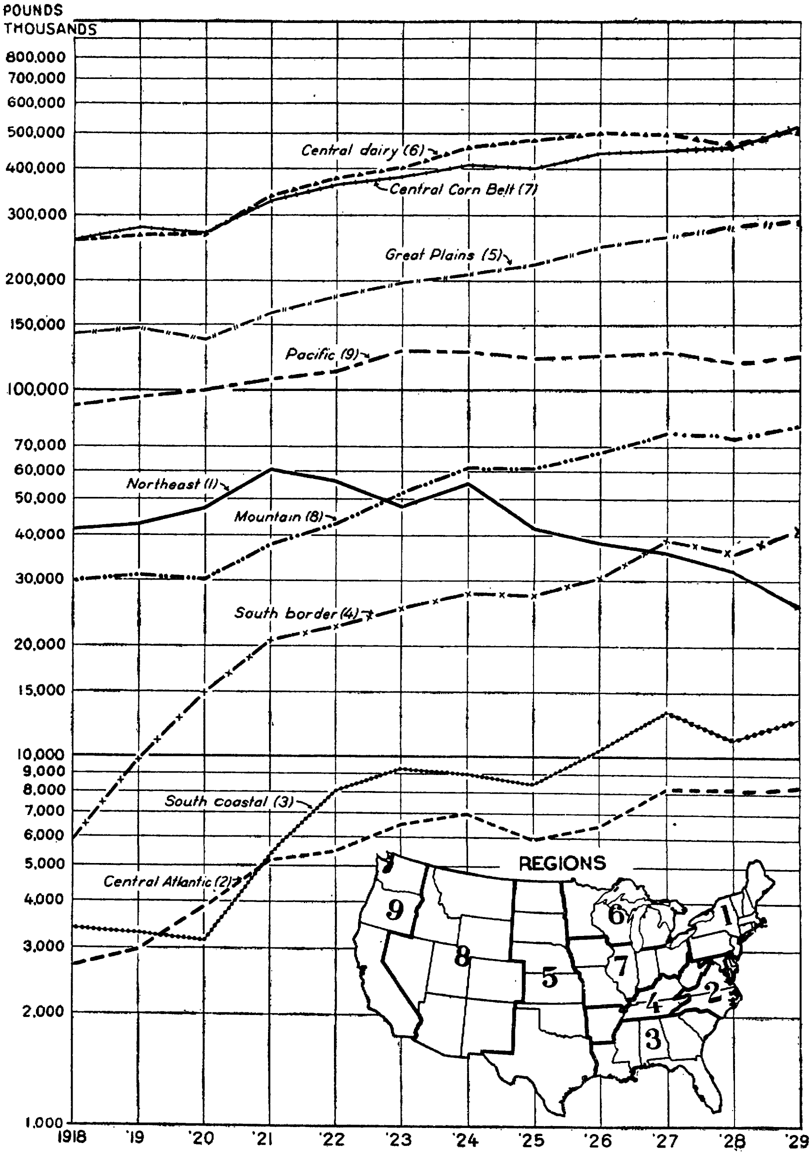

FIGURE 25.—YEARLY PRODUCTION OF CREAMERY BUTTER, BY REGIONS, UNITED STATES, 1918–1929

The trend in butter production in all regions of the United States was upward during the years of 1918 to 1929 with the exception of the northeastern region, where the trend has been downward since 1921. Since 1918 the greatest percentage increases in creamery-butter production have occurred in the Southern States, although as yet their total production is relatively small.

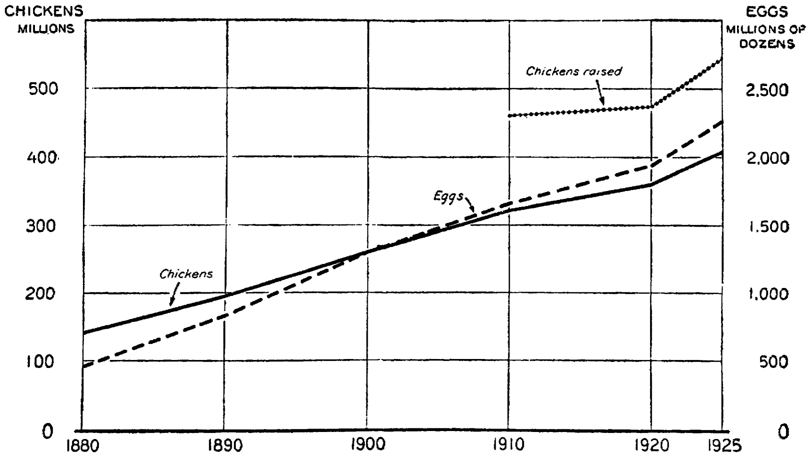

FIGURE 26.—NUMBER OF CHICKENS ON HAND JANUARY 1, AND PRODUCTION OF EGGS IN THE UNITED STATES, CENSUS YEARS, 1880–1925

The trend in poultry and egg production has been markedly upward during the last 50 years, the peak in production being reached in 1928. During this period poultry numbers tripled, while yearly egg production more than quadrupled. United States census figures adjusted.

AGRICULTURAL STATISTICS

UNITED STATES DEPARTMENT OF AGRICULTURE YEARBOOK, 1931

Prepared under the direction of the Statistical Committee: Joseph A. Becker, chairman, Lewis B. Flohr, secretary, S. W. Mendum, C. A. Burmeister, L. M. Davis, and E. J. Working.

INTRODUCTION

The statistical section of this Yearbook brings together in one place what seem from experience to be the most important agricultural statistics for the United States, and for the world so far as the agriculture of this country is concerned. Historical and geographical series have been given. These are basic data helpful to the producer in his problems of production and marketing.

For greater detail on individual commodities than can be shown in the Yearbook, the Statistical Bulletin series of the department may be consulted.

For current statistics to supplement the Yearbook statistics the following sources should be used: (1) Crops and Markets—a monthly publication of the department carrying the latest current statistics available on agriculture in the United States; (2) Foreign Crops and Markets—issued weekly by the Bureau of Agricultural Economics and devoted to current world statistics of crops, livestock, and markets; (3) foreign commodity news—published by the Bureau of Agricultural Economics and showing the latest world information on single commodities and released as important information is received; (4) market news reports of the Bureau of Agricultural Economics—issued daily, weekly, monthly, quarterly, or at irregular intervals, at Washington and at the principal markets.

Statistical data from the following bureaus are included: Weather Bureau, Bureau of Plant Industry, Bureau of Animal Industry, Forest Service, Bureau of Public Roads, Bureau of Agricultural Economics, Bureau of Dairy Industry, Extension Service, Biological Survey, Plant Quarantine and Control Administration, and Grain Futures Administration.

The crop and livestock reporting service estimates acreage, condition of crop, yield per acre, production, and farm prices of crops, and numbers, production, farm prices, and values of livestock and livestock products. The organization of this work outside of the crop-reporting board and the office force in Washington consists of 41 State field offices, each with an agricultural statistician in charge. There is one field office for the New England States, one for Maryland and Delaware, and one for Utah and Nevada.

Acreages for the year 1909 are as reported by the Bureau of the Census; acreages in 1919 and 1924 are based upon the census supplemented by State enumerations. In the intercensal years, from 1910 to 1915, estimated acreages were obtained by applying estimated percentages of decrease or increase to the published acreage in the preceding year. The estimates from 1916 to 1918, from 1920 to 1923, and from 1925 to 1930 are based upon acreage changes from year to year as shown by a sample of over 2 per cent of the crop acreages in each year, supplemented by State enumerations. Yields per acre are estimates based upon reports of one or more farmers in each agricultural township on the average yield per acre in their localities. Production is acreage times yield per acre.

Estimates of farm stocks, shipments, quality, crop condition, and miscellaneous information concerning crops are based either upon sample data or upon estimates of crop reporters for their localities.

The term "commercial" is used in connection with certain crop estimates to distinguish some part of the total production of a crop. Except for indicating that the entire production is not represented in the estimate, "commercial" does not have the same meaning in each instance where used. The commercial apple estimate, for example, represents that portion of the total apple crop which is sold or available for sale for consumption as fresh fruit. That portion of the crop which is used for cider, vinegar, canning, evaporating, or other manufacture is not included in the commercial estimate as defined in this case. The commercial orange and grapefruit crops in Florida represent the portion shipped or to be shipped by rail or boat as differentiated from the portion canned, juiced, sold, or consumed locally, wasted, etc. Until recently, cherry estimates represented the commercial sales in certain States and included only the quantities shipped to market or utilized by canners, cold packers, and other processors. The estimates now include the total production in these commercially important States. Estimates of commercial truck-crop production are concerned only with those areas growing the crops primarily to supply the larger consuming markets more or less distant from the producing center. Production in home and market gardens, intended principally for local sale, is excluded. Similarly with truck crops grown for commercial canning or manufacture the estimates include only amounts grown for use by canning or packing establishments and exclude amounts canned in the home. The truck and canning crop estimates are designed to include the total quantity produced on the commercial acreage in the areas concerned, whether or not the entire crop finds a market or a use.

Monthly estimated prices received by producers on the specified dates are based upon reports from special price reporters, who are mostly country dealers, on the average price paid to farmers and do not relate to any specified grade.

Farm values of crops as shown are mostly computed by applying the December 1 farm price to the total production. These prices are reported by the crop reporters, who are mostly farmers. The average price received for the portion of the crop sold may be greater or less than this price, depending upon the prices previous and subsequent to December 1 and the amount of the crop sold at the different prices. For commercial truck and canning crops, and for certain fruit crops, the prices shown are the estimated seasonal averages of the prices received by growers at the shipping point, the cost of the container included if a customary requirement of delivery.

Numbers of livestock on farms on January 1, 1920 and 1925, are based upon the census enumeration as of that date, supplemented by enumerations by State agencies, such as assessors and brand inspection boards, and by records of shipments during 1920 and 1925. In the intercensal years, from 1911 to 1916, the numbers of livestock were obtained by methods identical with those used for crop acreages. Estimates from 1917 to 1919, from 1921 to 1924, and from 1926 to 1931 are based upon a sample of over 2 per cent, supplemented by trends derived from assessors' enumerations, reports of brand inspection boards, market movements, and stockyard receipts. The census bases are not always comparable from one decade to another, because of changes of dates and classifications.

The average value per head on January 1 is estimated from reports of correspondents relating to livestock in their vicinity. These tend to reflect inventory values as distinguished from the monthly prices which relate to sales. The farm value on January 1 is computed by applying the average value per head to the number on farms.

The Federal market news service supplies much of the information on market prices and movements. The leased-wire system in use by the service extends from the Atlantic to the Pacific and reaches most of the important markets of the country. At each of the branch offices commodity specialists gather information regarding the supply, the demand, and prices for the products on which they report. They observe the sales actually made on the markets and are constantly in touch with the traders, who in many instances give them access to their office records in order that they may have specific information on which to base their reports. Car-lot shipments are reported by officials and agents of railroads, express companies, and boat lines. Data on receipts, slaughter, and shipments of livestock are obtained from monthly reports submitted by the public stockyards. Data on cold-storage stocks are obtained directly from all important cold-storage warehouses, and data on commercial stocks of grain are reported by boards of trade, etc. Leaf-tobacco stocks are reported directly by dealers and manufacturers.

Where a weighting factor is available, market prices as shown are weighted averages; but in many cases a weighting factor is not available, and the prices shown are usually the means of ranges of quotations without reference to quantity. The weighted market prices of grain are based on the number of carload sales reported. The weighted average price of hogs at Chicago is based on total sales of butcher and packer hogs to slaughterers.

Prices derived from different sources may not be strictly comparable, although for most general purposes they are satisfactory. The data as to commercial stocks and movements of various commodities are as nearly complete as practicable and feasible, and are considered fairly representative.

The statistics of grain grading are based on work done by licensed grain inspectors located throughout the United States.

Statistics of acreage and production in foreign countries are compiled as far as possible from official sources and are therefore subject to whatever errors may result from shortcomings in the reporting and statistical services of the various countries. Inaccuracies also result from differences in nomenclature and classification in foreign countries. Except where otherwise stated, pre-war data refer to pre-war boundaries. Yields per acre are calculated from acreage and production, both rounded to thousand units, and are therefore subject to a greater possibility of error when calculated for countries with small acreage.

The tables of international trade cover substantially the international trade of the world. The total imports and the total exports in any one year can not be expected to balance, although disagreements tend to be compensated over a series of years. Among the sources of disagreement are: The different periods covered by the "year" of various countries; imports received in the year subsequent to the year of export; lack of uniformity in classification of goods as among countries; different trade practices and varying degrees of failure in recording countries of origin and ultimate destinations; different practices in recording reexported goods; and different methods of treating free ports. The exports given are domestic exports and the imports given are imports for consumption whenever it is possible to distinguish such imports from general imports, that is, "special" or net instead of general. General imports are all imports reported. In foreign countries "special" trade is imports for consumption, or net imports, or imports less reexports. In the United States imports for consumption are those entered for actual consumption and include withdrawals from warehouse for consumption. Special or net figures are used in the international trade tables for the following countries: Belgium, Denmark, Egypt, Irish Free State, China, Dutch East Indies, France, and United Kingdom. In the United States trade tables and wherever United States figures are given, they are domestic exports and general imports unless otherwise specified. While there are some inevitable omissions, there may be some duplication because of reshipments which do not appear as such in the official reports. In the trade tables, figures for the United States include Alaska, Porto Rico, and Hawaii, but not the Philippine Islands.

As an aid to the comprehension and use of these statistics, the following table of weights, measures, and conversion factors will be useful:

Weights, measures, and conversion factors used in the Department of Agriculture

Commodity	Unit [1]	Weight in pounds
Alfalfa seed	Bushel	60
Almonds	Short ton	2,000
Apricots	do	2,000
Do	Bushel	48
Asparagus	Short ton	2,000
Barley	Bushel	48
Beans, snap	Short ton	2,000
Beans, dry	Bushel	60
Beet sugar	Short ton	2,000
Broomcorn	do	2,000
Buckwheat	Bushel	48
Cabbage	Short ton	2,000
Cane sugar	do	2,000
Clover seed	Bushel	60
Corn, shelled	do	56
Corn, ear, husked	do	70
Cottonseed	Short ton	2,000
Cotton, ginned	Bale	[2] 478 [3] 500
Cottonseed oil	Gallon	7.5
Cranberries	Barrel	100
Flaxseed	Bushel	56
Figs	Short ton	2,000
Grapefruit	Box	[2] 70
Grapes	Short ton	2,000
Hay	do	2,000
Hempseed	Bushel	44

Commodity	Unit [1]	Weight in pounds
Lemons	Box	[2] 74
Milk	Gallon	8.6
Oats	Bushel	32
Oranges (Calif.)	Box	[2] 70
Oranges (Fla.)	do	[2] 80
Orchard grass	Bushel	14
Peanut oil	Gallon	7.5
Plums	Short ton	2,000
Potatoes	Bushel	60
Prunes	Short ton	2,000
Rapeseed	Bushel	50
Raisins	Short ton	2,000
Rice, rough	Bushel	45
Rice, cleaned	do	60
Rye	do	56
Rye flour	Barrel	196
Soybean oil	Gallon	7.5
Spelt	Bushel	40
Sugar	Short ton	2,000
Sugar beets	Short ton	2,000
Sugarcane	do	2,000
Timothy seed	Bushel	45
Tomatoes	do	56
Wheat	do	60
Wheat flour	Barrel	196
Walnuts	Short ton	2,000

Commodity	Equivalents
Almonds	1 pound shelled is equivalent to about 3⅓ pounds unshelled.
Apples	1 pound dried is equivalent to about 5 pounds of fresh.
Barley flour	1 barrel (196 pounds) is equivalent to about 9 bushels of barley.
Buckwheat flour	1 barrel (196 pounds) is equivalent to about 7 bushels of buckwheat.
Filberts	1 pound shelled is equivalent to about 2.22 pounds unshelled.
Malt	1.1 bushel (34 pounds) is equivalent to about 1 bushel of barley.
Oatmeal	1 barrel (196 pounds) is equivalent to about 10⅚ bushels of oats.
Do	18 pounds is equivalent to about 1 bushel of oats.
Peanuts	1 pound shelled is equivalent to about 1½ pounds unshelled.
Peaches (Calif.)	1 pound dried is equivalent to about 5½ pounds fresh.
Prunes	1 pound dried is equivalent to about 2½ pounds fresh.
Rye flour	1 barrel (196 pounds) is equivalent to about 6 bushels of rye.
Raisins	1 pound is equivalent to about 4 pounds of grapes.
Wheat flour	1 barrel (196 pounds) is equivalent to about 4.7 bushels of wheat.[4]
Walnuts (English)	1 pound shelled is equivalent to about 2.38 pounds unshelled.

[1] Standard bushel used in the United States contains 2.150.42 cubic inches; the gallon, 231 cubic inches.
[2] Net.
[3] Gross.
[4] Due to changes in milling processes, equivalents have varied as follows: 1790–1879, 5; 1880–1908, 4.75; 1909–1917, 4.7; 1918–1919, 4.5; 1920, 4.6; 1921–1927, 4.7.

STATISTICS OF GRAINS

TABLE 1.—*Wheat, all: Acreage, production, value, exports, etc., United States, 1849, 1859, 1866–1930*

Year	Acreage harvested	Average yield per acre	Production	Price per bushel received by producers Dec. 1	Farm value Dec. 1	Spring wheat, price per bushel at Chicago, year beginning July 1 [1]	No. 2 red winter wheat, price per bushel at Chicago, year beginning July 1 [2]	Foreign trade, including flour, year beginning July 1 [3]			
								Domestic exports [4]	Imports [5]	Net exports [6]	
										Total	Percentage of production
	1,000 acres	*Bush.*	*1,000 bush.*	*Cts.*	*1,000 dolls.*	*Cts.*	*Cts.*	*1,000 bush.*	*1,000 bush.*	*1,000 bush.*	*Per cent*

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board; italic figures are census returns.

[1] Spring wheat prices compiled as follows: 1849–1870, from Chicago newspapers, quoted; 1849, spring wheat, contract grade; 1859, standard spring, contract grade; 1866–1870, No. 1 spring, contract grade; 1871–1884, annual reports of Chicago Board of Trade, quoted as No. 2 spring, contract grade; 1885–1896, Bartel's Red Book, quoted as No. 2 spring; January, 1897–June, 1904, Chicago Daily Trade Bulletin, average of daily ranges; quotations used; January–October, 1897, No. 3 spring; November, 1897–June, 1898, No. 3 spring, hard varieties; July, 1898–June, 1904, No. 1 spring; from February, 1897, "free on board" was used when available; July, 1904–December, 1918, Bartel's Red Book, average of daily ranges, quoted as No. 1 northern. Subsequently from the Chicago Daily Trade Bulletin and are averages of the daily cash price per bushel weighted by car-lot sales.

[2] Prices, 1839–1898, are from the Price Current Grain Reporter 1924 Yearbook, p. 4, and are average cash prices for calendar years; subsequently from the Chicago Daily Trade Bulletin and are averages of the daily cash price per bushel weighted by car-lot sales.

[3] Compiled from Commerce and Navigation of the United States, 1849, 1859, 1866-1917; Foreign Commerce and Navigation of the United States, 1918; Monthly Summary of Foreign Commerce of the United States, June issues, 1919–1926; January and June issues, 1927-1930. Wheat flour converted to terms of grain on the following basis: 1849, 1859, 1866–1879, 1 barrel is the product of 5 bushels of grain; 1880–1908 4.75; 1909–1917, 4.7; 1918–1919, 4.5; 1920, 4.6; 1921–1930, 4.7.

[4] Includes flour milled from imported wheat.

[5] Includes wheat imported for milling in bond and export.

[6] Total exports (domestic plus foreign) minus total imports.

[7] Imports of flour estimated.

TABLE 1.—*Wheat, all: Acreage, production, value, exports, etc., United States, 1849, 1859, 1866–1930*—Continued

Year	Acreage harvested	Average yield per acre	Production	Price per bushel received by producers Dec. 1	Farm value Dec. 1	Spring wheat, price per bushel at Chicago, year beginning July 1	No. 2 red winter wheat, price per bushel at Chicago, year beginning July 1	Foreign trade, including flour, year beginning July 1: Domestic exports	Foreign trade: Imports	Net exports: Total	Net exports: Percentage of production

Bureau of Agricultural Economics. Production figures are for the harvesting season which begins in the spring, extends through the autumn in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere.

[1] Includes all Russian territory reporting for years named.
[2] The average production for the 1909–10 to 1913–14 period as computed from figures given here for estimated world total, Northern Hemisphere total, European total, and European countries whose boundaries were changed by the World War will not agree with estimates appearing elsewhere for present territory, due to changes in boundary.
[3] Total Russian Empire exclusive of the 10 Vistula Provinces of Russian Poland and the Province of Batum in Transcaucasia.
[4] Exclusive of Russian Poland, Lithuania, parts of present Latvia and Ukraine, and 2 Provinces of Transcaucasia.
[5] Beginning with this date estimated production is within present boundaries of the Union of Socialist Soviet Republics, excluding Turkestan, Transcaucasia, and the Far East, which regions in 1924 produced 51,706,000 bushels, and in 1925, 58,000,000 bushels.
[6] Beginning with this date production is within postwar boundaries and therefore not comparable with earlier years.
[7] Preliminary.

40442°—31——38

TABLE 9.—*Wheat: Acreage, yield per acre, and production in specified countries, average 1909–10 to 1913–14, 1921–22 to 1925–26, annual 1928–29 to 1930–31*

Bureau of Agricultural Economics. Prior to 1918 stocks in mills and elevators not included.

[1] Based on percentage of crop on farms as estimated by crop reporters.
[2] Based on percentage of crop as estimated by about 3,500 mill and elevator operators.
[3] Stocks in mills and attached mill elevators, reporting to Bureau of the Census, raised to represent all merchant mills.
[4] Includes grain stored at approximately 50 interior and seaboard points of accumulation and grain in transit by canals and lakes; also Pacific coast stocks at Portland, Tacoma, and Seattle.
[5] Based on estimates of crop reporters on Nov. 1.
[6] Based on percentage shipped out as estimated by crop reporters.
[7] Preliminary.

Bureau of Agricultural Economics. Compiled from weekly reports to the grain, hay, and feed market news service. Data are for stocks on the Saturday nearest the 1st day of the month.

[1] Includes wheat in store in public and private elevators in 39 important markets and also the wheat afloat in vessels or barges in the harbors of lake and seaboard ports. Wheat in transit either by rail or water, mill stocks, or small private stocks of wheat intended only for local purposes, not included.
[2] Includes wheat stored at lake and seaboard ports, exclusive of wheat in transit on lakes and canals.

Bureau of Agricultural Economics. Estimated production by classes based on questionnaire surveys of local authorities; supplemented by judgment of cereal specialists. Inspections of United States wheat for export data furnished monthly by Federal grain supervision officers at the export markets. Inspections are made at the ports of export.

[1] Production estimates are based on the estimate of percentage classification by States as reported for 1920–21, 1923–24, and 1924–25; the percentages for 1921–22 and 1922–23 were interpolated from the 1920–21 and 1923–24 percentages. The estimated production for 1929–30 and 1930–31 is subject to revision.

[2] White wheat in the Pacific Northwest region consists of both spring and winter wheat; no attempt has been made to classify this wheat as other than white wheat, part of which is spring and part winter.

[3] Mixed wheats exported from Atlantic coast ports are estimated as approximately 70 per cent durum and the remainder as hard red spring; that exported from Gulf ports as approximately half and half hard and soft winter; and that exported from Pacific coast ports as approximately 90 per cent white and the remainder as hard and soft red winter wheats.

[4] Exports of wheat other than reported as "Federal inspected" including exports through Canada. These exports are not "Federal inspected" and are exported largely through the customs districts of Buffalo, Chicago, Duluth and Superior, Wisconsin, and Ohio.

[5] The representative grades and markets selected are No. 1 dark northern spring, Minneapolis; No. 2 amber durum, Minneapolis; No. 2 hard winter, Kansas City; and No. 2 red winter, St. Louis.

Bureau of Agricultural Economics. Compiled from daily trade papers of markets named. The markets are Chicago, Minneapolis, Kansas City, St. Louis, Omaha, and Duluth.

[1] Average of daily prices weighted by car-lot sales. The prices in this table are comparable with prices paid to producers, in that the latter are averages of the several prices reported which cover all classes and grades sold by producers.

Bureau of Agricultural Economics. Compiled as follows: July, 1909–August, 1916, Winnipeg Farmers Advocate; September, 1916–June, 1921, annual reports of the Winnipeg Grain Exchange; July, 1921–July, 1928, Reports on the Grain Trade of Canada; August, 1928 to latest date shown, Minneapolis Daily Market Record. Conversions at current rate of exchange January, 1917–March, 1925. Exchange rates used are: January, 1917–June, 1919, mean of the monthly low and high, compiled from the Commercial and Financial Chronicle; July, 1919–March, 1925, monthly averages as reported by the Federal Reserve Board.

[1] Average of daily cash closing prices, basis, in store at Fort William and Port Arthur. Prices fixed by the Government Sept. 12, 1917–Aug. 17, 1920.

Bureau of Agricultural Economics. Price per bushel of 60 pounds, good average imported red, July, 1914–June, 1926, compiled from Broomhall's 1921, 1925, and 1927 Corn Trade Yearbooks. Price per bushel of 60 pounds July, 1926, to date, compiled from Broomhall's Corn Trade News. These prices are simple averages of daily sales prices of parcels at Liverpool. Conversions at par beginning with January, 1926. Prior to that date conversions were made at monthly average rate of exchange as given in Federal Reserve Bulletins.

[1] No. 2 hard winter when available, otherwise No. 2 red winter. [2] No quotations.

TABLE 26.—*Wheat ground in merchant mills in the United States, census years, 1899–1929* [1]

Year	Merchant mills	Year	Merchant mills	Year	Merchant mills
	1,000 bushels		*1,000 bushels*		*1,000 bushels*

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board; italic figures are census returns. See 1927 Yearbook, page 764, for data for earlier years.

[1] Prices are from Minneapolis Daily Market Record and are averages of daily prices weighted by car-lot sales.

[2] Compiled from Commerce and Navigation of the United States, 1909–1917; Foreign Commerce and Navigation of the United States, 1918; Monthly Summary of Foreign Commerce of the United States, June issues, 1919–1926; January and June issues, 1927–1929, and official records of the Bureau of Foreign and Domestic Commerce. Rye—General imports, 1909; imports for consumption, 1910–1929. Rye flour—Imports for consumption, 1909–1930. Rye flour converted to rye on the basis that 1 barrel of rye flour is the product of 6 bushels of grain.

[3] Total exports (domestic plus foreign) minus total imports.

[4] Net imports.

[5] Preliminary.

Bureau of Agricultural Economics. Official sources and International Institute of Agriculture. Acreage and production figures are for the harvesting season which begins in the spring, extends through the autumn in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere.

* Preliminary.

[1] Where changes of boundary have occurred, averages are for estimates for territory within present boundaries.

[2] 3-year average.

[3] 4-year average.

[4] The estimate for the 5-year period, 1909–10 to 1913–14, given in this table is somewhat larger than the figures obtained by averaging the five years in Table 39. This is because in this table estimates for warring countries are for postwar boundaries, whereas in Table 39 they are for pre-war territory. As a result, in excluding Russia, which country lost territory in the war, a smaller area is excluded in this table than in Table 39.

[5] 2-year average.

[6] Less than 500 acres.

TABLE 38.—*Rye: Yield per acre, average 1919–1928, annual 1925–1930, and estimated price per bushel December 1, average 1924–1928, and annual 1925–1930, by States*

Bureau of Agricultural Economics. Production figures are for the harvesting season which begins in the spring, extends through the autumn in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere.

[1] Includes all Russian territory reporting for the years shown.
[2] The average production for the 1909–10 to 1913–14 period as computed from figures given here for estimated world total, Northern Hemisphere total, European total and European countries whose boundaries were changed by the World War, will not agree with estimates appearing elsewhere for present territory due to changes in boundary.
[3] Exclusive of the 10 Vistula Provinces of Russian Poland and the Province of Batum in Transcaucasia.
[4] Exclusive of Russian Poland, Lithuania, parts of Latvia and the Ukraine, and the two Provinces of Batum and Elizabetpol in Transcaucasia.
[5] Beginning with this year estimates for the present territory of the Union of Socialist Soviet Republics exclusive of Turkestan, Transcaucasia, and the Far East, which territory in 1924 produced 8,646,000 bushels.
[6] Beginning with this year postwar boundaries, therefore not comparable with earlier years.
[7] Preliminary.

Bureau of Agriculture Economics. Compiled from weekly reports to the grain, hay, and feed market news service. Data are for stocks on the Saturday nearest the 1st day of the month.

[1] Includes rye in store in public and private elevators in 39 important markets and also the rye afloat in vessels or barges in harbors of lake and seaboard ports. Rye in transit either by rail or water, mill stocks or small private stocks of rye intended only for local purposes, not included.

[2] Includes rye stored at lake and seaboard ports, exclusive of rye in transit on lakes and canals.

Bureau of Agricultural Economics. Based on returns from special price reporters. Monthly prices weighted by production of rye for each State; yearly price obtained by weighting monthly prices by monthly marketings. Mean of prices reported on 1st of month and 1st of succeeding month, July, 1909-December, 1923.

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board and relate to equivalent production of grain on entire acreage grown for all purposes; italic figures are census returns. See 1927 Yearbook, p. 774, for data for earlier years.

[1] Prices 1890–1898 are averages of the weekly quotations for No. 2 or better in annual reports of Chicago Board of Trade; subsequently prices are compiled from the Chicago Daily Trade Bulletin, average of daily prices weighted by car-lot sales, No. 3 yellow.

[2] Compiled from Commerce and Navigation of the United States, 1890–1917; Foreign Commerce and Navigation of the United States, 1918; Monthly Summary of Foreign Commerce of the United States, June issues, 1919–1926; January and June issues, 1927–1930 and official records of the Bureau of Foreign and Domestic Commerce. Corn—General imports 1890–1909 and 1912–1929; imports for consumption 1910–11. Corn meal—Imports for consumption, 1890–1930. Corn meal converted to terms of grain on the basis of 4 bushels of corn to a barrel of meal.

[3] Total exports (domestic plus foreign) minus total imports.

[4] Net imports, i. e., total imports minus total exports (domestic and foreign).

[5] Corn harvested for grain; total acreage of corn in 1924 is 98,401,627 acres.

[6] Preliminary.

Bureau of Agricultural Economics. Official sources and International Institute of Agriculture. Figures in parentheses indicate unofficial estimates. Acreage and production figures are for the harvesting season which begins in July, extends through the autumn in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere.

* Preliminary.
[1] Where changes in boundary have occurred, the averages reported are estimates for the crop within present boundaries.
[2] 1 year only.
[3] 2-year average.
[4] 4-year average.
[5] The estimate for the 5-year period 1909-10 to 1913-14 given in this table is somewhat larger than the figure obtained by averaging the same 5-year period in Table 54. This is because in this table estimates for warring countries are for post-war boundaries, whereas in Table 54 they are for pre-war territory. As a results in excluding Russia, which lost territory in the war, a smaller area is excluded in this table than in Table 54.
[6] Includes some sorghum.

TABLE 53.—*Corn: Yield per acre, average 1919–1928 and annual 1925–1930, and estimated price per bushel December 1, average 1924–1928 and annual 1925–1930 by States*

Bureau of Agricultural Economics. Official sources and International Institute of Agriculture. Production figures are for the harvesting season, which begins in July, extends through the autumn in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere.

[1] Includes all Russian territory reporting for the years shown.
[2] Total Russian Empire exclusive of the 10 Vistula Provinces of Russian Poland and the Province of Batum in Transcaucasia.
[3] Exclusive of Russian Poland, Lithuania, parts of present Latvia and the Ukraine, and the Provinces of Batum and Elizabetpol in Transcaucasia.
[4] Beginning this year, estimates within present boundaries of the Union of Socialist Soviet Republics, exclusive of Turkestan, Transcaucasia, and the Far East, which territory in 1924-25 produced 26,048,000 bushels.
[5] Production in present boundaries beginning this year, therefore not comparable with earlier years.
[6] Preliminary.

Bureau of Agricultural Economics. Compiled from weekly reports to the grain, hay, and feed market news service. Data are for stocks on the Saturday nearest the 1st day of the month.

[1] Includes corn in store in public and private elevators in 39 important markets and also the corn afloat in vessels or barges in the harbors of lake and seaboard ports. Corn in transit either by rail or water, mill stocks, or small private stocks of corn intended only for local purposes, not included.

TABLE 62.—*Corn: Stocks of old corn on farms November 1, by selected States and by geographic divisions, 1909–1930*

[In millions of bushels]

Year	Principal producing States							Geographic divisions

Bureau of Agricultural Economics. Compiled from estimates which are based on percentages of crop on farms as estimated by crop reporters. Stocks as given here are comparable with United States totals in Table 56, except for 1909 and 1910, for which years revisions are not available by States and geographic regions to make them comparable with the latest revisions of the United States total.

Bureau of Agricultural Economics. Based on returns from special price reporters. Monthly prices weighted by production of corn for each state; yearly price obtained by weighting monthly prices by monthly marketings. Mean of prices reported on 1st of month and 1st of succeeding month, November, 1909–December, 1923.

Bureau of Agricultural Economics. Compiled from Chicago Daily Trade Bulletin, St. Louis Daily Market Reporter, Omaha Daily Price Current, Kansas City Grain Market Review, Minneapolis Daily Market Record, Cincinnati Daily Trade Bulletin. The prices in this table are comparable with prices paid to producers in that the latter are averages of the several prices reported which cover all classes and grades sold by producers.

[1] Average of daily prices weighted by car-lot sales.

[2] Markets are Chicago, St. Louis, Omaha, Kansas City, Minneapolis, and Cincinnati (not included November, 1918, December, 1919, and November, 1928–December, 1930).

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board; italic figures are census returns. See 1927 Yearbook, p. 788, for data for earlier years.

[1] From Chicago Daily Trade Bulletin, averages of the daily cash quotations of No. 3 white oats weighted by car-lot sales.

[2] Compiled from Commerce and Navigation of the United States, 1900–1917; Foreign Commerce and Navigation of the United States, 1918; Monthly Summary of Foreign Commerce of the United States, June issues, 1919–1926; January and June issues, 1927–1930; and official records of the Bureau of Foreign and Domestic Commerce. Oats—general imports, 1900–1929; oatmeal—general imports, 1900–1909; imports for consumption, 1910–1930.

[3] Total exports (domestic plus foreign) minus total imports.

[4] Net imports. Total imports minus total exports (domestic plus foreign).

[5] Less than 0.05 per cent.

[6] Preliminary.

Bureau of Agricultural Economics. Official sources and International Institute of Agriculture. Figures in parentheses indicate unofficial estimates. Acreage and production figures are for the harvesting season which begins in the spring, extends through the autumn in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere.

* Preliminary.

[1] Where changes in boundary have occurred the averages are estimates for territory within present boundaries.

[2] 1 year only.

[3] 4-year average.

[4] The estimate for the 5-year period, 1909–10 to 1913–14, given in this table is somewhat larger than the figure obtained by averaging the same 5 years in Table 74. This is because in this table estimates for warring countries are for postwar boundaries, whereas in Table 74 they are for pre-war territory. As a result, in excluding Russia which lost territory in the war, a smaller area is excluded in this table than in Table 74.

[5] 2-year average.

TABLE 73.—*Oats: Yield per acre, average 1919–1928 and annual 1925–1930, and estimated price per bushel, December 1, average 1924–1928 and annual 1925–1930, by States*

Bureau of Agricultural Economics. Official sources and International Institute of Agriculture. Production figures are for the harvesting season, which begins in the spring, extends through the autumn in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere.

[1] Includes all Russian territory reporting for the years shown.

[2] Total Russian Empire, exclusive of the 10 Vistula Provinces of Russian Poland and the Province of Batum in Transcaucasia.

[3] Exclusive of Russian Poland, Lithuania, parts of present Latvia and the Ukraine, and the Provinces of Batum and Elizabetpol, in Transcaucasia.

[4] Beginning this year, estimates for the present territory of the Union of Socialist Soviet Republics, exclusive of Turkestan, Transcaucasia, and the Far East, which territory in 1924-25 produced 20,248,000 bushels.

[5] Beginning with this year post-war boundaries and therefore not comparable with earlier years.

[6] Preliminary.

Bureau of Agricultural Economics. Based on returns from special price reporters. Monthly prices weighted by production of oats for each State; yearly price obtained by weighting monthly prices by monthly marketings. Mean of prices reported on 1st of month and 1st of succeeding month, August, 1909–December, 1923.

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board; italic figures are census returns. See 1927 Yearbook, p. 799, for data for earlier years.

[1] From Bureau of Labor Statistics as follows: Bulletin No. 39, 1900–1901. August, 1900–December, 1901, choice to fancy malting, by samples. Wholesale price bulletins—monthly quotations, January, 1902–December, 1913, choice to fancy malting; January, 1914–September, 1927, fair to good malting. Beginning October, 1927, grade reported as feeding, but as quality remained unchanged, no change was made in comparative prices.

[2] Compiled from Commerce and Navigation of the United States 1900–1917: Foreign Commerce and Navigation of the United States, 1918; Monthly Summary of Foreign Commerce of the United States, June issues; 1919–1926; January and June issues, 1927–1930, and official records of the Bureau of Foreign and Domestic Commerce. Malt converted to terms of barley on the basis that 1.1 bushels of malt is the product of 1 bushel of barley. Barley flour converted on the basis that 1 barrel of flour is the product of 9 bushels of barley. Exports of flour not reported prior to 1919. Barley—general imports, 1900–1909; imports for consumption, 1910–1930. Malt—general imports, 1909–1914; imports for consumption, 1915–1929. Imports of flour not reported prior to 1915; imports for consumption, 1915–1930.

[3] Total exports (domestic exports plus reexports) minus total imports.

[4] Average for 11 months.

[5] Net imports. Total imports minus total exports (domestic plus foreign).

[6] Preliminary.

Bureau of Agricultural Economics. Official sources and International Institute of Agriculture. Figures in parentheses indicate unofficial estimates. Acreage and production figures are for the harvesting season which begins in the spring, extends through the autumn in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere.

* Preliminary.
[1] Where changes in boundary have occurred, averages are estimated for territory within present boundaries.
[2] 1 year only.
[3] 4-year average.
[4] The estimate for the 5-year period, 1909–10 to 1913–14, given in this table is somewhat larger than the figure obtained by averaging the same 5 years in Table 90. This is because in this table estimates for warring countries are for post-war boundaries, whereas in Table 90 they are for pre-war territory. As a result, in excluding Russia, which lost territory during the war, a smaller area is excluded in this table than in Table 90.
[5] Excludes native locations which produced 38,550 bushels in 1917–18 and 29,056 bushels in 1920–21.

TABLE 90.—*Barley: World production, 1894–95 to 1930–31*

Bureau of Agricultural Economics. Official sources and International Institute of Agriculture. Production figures are for the harvesting season which begins in the spring, extends through the autumn in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere.

[1] Includes all Russian territory reporting for the years shown.
[2] Total Russian Empire exclusive of the 10 Vistula Provinces of Russian Poland and the Province of Batum in Transcaucasia.
[3] Exclusive of Russian Poland, Lithuania, parts of present Latvia and the Ukraine, and two Provinces of Transcaucasia.
[4] Beginning this year estimates within present boundaries of the Union of Socialist Soviet Republics excluding Turkestan, Transcaucasia, and the Far East, which regions in 1924–25 produced 20,897,000 bushels.
[5] Postwar boundaries beginning this year and therefore not comparable with earlier years.
[6] Beginning this year weighed bushels, those reported for the earlier years being measured bushels.
[7] Preliminary.

Bureau of Agricultural Economics. Compiled from weekly reports to the grain, hay, and feed market news service. Data are for stocks on the Saturday nearest the 1st day of the month.

[1] Includes barley in store in public and private elevators in 39 important markets and also barley afloat in vessels or barges in harbors of lake and seaboard ports. Barley in transit either by rail or water, mill stocks, or small private stocks of barley intended only for local purposes, not included.

[2] Includes barley stored at lake and seaboard ports, exclusive of barley in transit on lakes and canals.

[2] Average for season 1911–12 to 1913–14.
[3] Average for calendar year 1909–1913.
[4] Average for season 1909–10 to 1911–12.
[5] Figures for pre-war years are included in the countries of the pre-war boundaries.
[6] Monthly Crop Report and Agricultural Statistics.
[7] Calendar year.
[8] Average for season 1912–13 to 1913–14.
[9] Includes rye and oats.

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board; italic figures are census returns. See 1927 Yearbook, page 809, for data for earlier years.

[1] The figures shown, 1909–1920 are averages of daily closing prices compiled from annual reports of the Minneapolis Chamber of Commerce; 1921–1928, are averages of daily prices weighted by car-lot sales, compiled from Minneapolis Daily Market Record.

[2] Compiled from Commerce and Navigation of the United States, 1909–1917; Foreign Commerce and Navigation of the United States, 1918; Monthly Summary of Foreign Commerce of the United States, June, July, and August issues, 1919–1929, January issues, 1927–1929, and official records of the Bureau of Foreign and Domestic Commerce. 1 bushel of flaxseed weighs 56 pounds; 1 bushel of seed yields 2½ gallons of oil; and 1 gallon of oil weighs 7½ pounds.

[3] Production minus net exports or plus net imports.

[4] Preliminary.

Bureau of Agricultural Economics. Compiled from weekly reports to the grain, hay, and feed market news service. Data are for stocks on the Saturday nearest the 1st day of the month.

[1] Includes flaxseed in store in public and private elevators in 39 important markets and also the flaxseed afloat in vessels or barges in the harbors of lake and seaboard ports. Flaxseed in transit either by rail or water, mill stocks, or small private stocks of flaxseed intended only for local purposes, not included.

[2] Includes flaxseed stored at lake and seaboard ports, exclusive of flaxseed in transit on lakes and canals.

Bureau of Agricultural Economics. The figures shown for 1909–1920 are averages of daily closing prices compiled from annual reports of the Minneapolis Chamber of Commerce; 1921 to date are averages of daily prices weighted by car-lot sales, compiled from Minneapolis Daily Market Record. Data 1899–1908 available in 1924 Yearbook, p. 646, Table 125.

Bureau of Agricultural Economics. Compiled from Oil, Paint, and Drug Reporter, average of weekly ranges. Data for 1910–11 to 1920–21 are available in the 1930 Yearbook, p. 666, Table 103.

[1] Beginning October, 1925, prices are quoted on pound basis and have been converted to price per gallon by multiplying by 7.5.

Bureau of Agricultural Economics. Production figures are for the harvesting season which begins in the spring, extends through the calendar year in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere. Estimates of world rice production for the period 1900–1901 to 1909–1910 appear in Agriculture Yearbook, 1924, p. 653.

[1] China is an important producing country, but official statistics are not available.
[2] Irrigated rice.
[3] Estimated figures obtained by multiplying acreage under rice as classified for revenue purposes up to 1912–13, and acreage as reported by the Department of Land and Agriculture from 1912–13 on by an average yield for the years 1920–21 to 1923–24, for which years official estimates have been published of acreage, yield, and total production.
[4] Preliminary.

Bureau of Agricultural Economics. Official sources except where otherwise noted. Mostly cleaned rice. Under rice is included paddy, unhulled, rough, cleaned, polished, broken, and cargo rice, in addition to rice flour and meal. Rice bran is not included. Rough rice, or paddy, where specifically reported, has been reduced to terms of cleaned rice at the ratio of 162 pounds of rough or unhulled to 100 pounds of cleaned. "Rice, other than whole or cleaned rice," in the returns of the United Kingdom is not considered paddy, since the chief sources of supply indicate that it is practically all hulled rice. Cargo rice, a mixture of hulled and unhulled, is included without being reduced to terms of cleaned. Broken rice and rice flour and meal are taken without being reduced to terms of whole cleaned rice.

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board; italic figures are census returns. See 1927 Yearbook, p. 825, for data for earlier years.

[1] Compiled from Commerce and Navigation of the United States, 1909–1917; Foreign Commerce and Navigation of the United States, 1918; Monthly Summary of Foreign Commerce of the United States, June issues, 1919–1926; January and June issues, 1927–1929 and official records of the Bureau of Foreign and Domestic Commerce. Buckwheat and buckwheat flour—imports for consumption, 1909–1929. Buckwheat flour converted to terms of grain on the basis that 1 barrel of flour is the product of 7 bushels of grain.

[2] The difference between total exports (domestic exports plus reexports) and total imports. Net exports indicated by +; net imports indicated by −.

Bureau of Agricultural Economics; italic figures are census returns; other acreage, yield, and production figures are estimates by the crop-reporting board; acreage revised on census basis.

[1] 500-pound gross weight bales, from 1899–1930.

[2] Compiled from Cotton Fluctuation, 1849–1888, and are averages for crop year beginning September. From New York Commercial and Financial Chronicle, 1889–1899, and from reports of New York Cotton Exchange since 1900. Since 1889 the averages are for crop year beginning August.

[3] Excluding linters from 1914 to 1920.

[4] Compiled from Commerce and Navigation of the United States, 1849–1917; Foreign Commerce and Navigation of the United States, 1918; Monthly Summary of Foreign Commerce of the United States, June and July, 1919–1930, and January 1927 and 1930.

[5] Bales of 500 pounds gross weight.

[6] Bales of 478 pounds net, which are equivalent to bales of 500 pounds gross weight.

[7] Total exports (domestic plus foreign) minus imports.

[8] Year beginning July 1.

[9] Estimated from value of imports. Average import price per pound calculated by assuming that the percentage change in import price from the previous year is equal to the percentage change in the export prices.

TABLE 134.—*Cotton: Acreage, production, value, exports, etc., United States, 1849 1859, 1866–1930*—Continued

Bureau of Agricultural Economics. Compiled from reports of the Bureau of the Census.

[1] Preliminary estimate of the Department of Agriculture.
[2] Slight differences from census figures on ginnings are due to ginnings in one State of cotton grown in another.
[3] Year beginning Aug. 1.

TABLE 139.—*Cotton: Acreage and yield of lint per acre in specified countries, average 1909–10 to 1913–14, 1921–22 to 1925–26, annual 1927–28 to 1930–31*

Bureau of Agricultural Economics. Compiled from official sources and International Institute of Agriculture unless otherwise stated. The crop year is from Aug. 1 to July 31. For the United States prior to 1914 the figures apply to the year beginning Sept. 1.

[1] Chinese Cotton Mill Owners' Association. Figures represent the crop in the most important cotton-producing Provinces where the commercial crop is grown. Most of the cotton produced in other Provinces is used for home hand-loom consumption.

[2] Figures as reported by the U. S. Bureau of the Census, including the cotton destined to enter commercial channels for factory purposes. Estimates of the commercial crop in China are included.

[3] Bales of 478 pounds net.

[4] American in running bales and foreign cotton in bales of 478 pounds net.

[5] Bales of 500 pounds net.

[6] Preliminary.

[7] Approximate, mid-point of range of reports.

Bureau of Agricultural Economics. Compiled from Bureau of Census Reports. Linters are excluded. Quantities are in running bales, round bales counted as half bales and foreign in 500-pound bales.

[1] Total distribution usually is greater than total supply due principally to the inclusion, in all distribution items, of the "city crop," which consists of rebaled samples and pickings from cotton damaged by fire and weather.

Compiled from reports of the Bureau of the Census, U. S. Department of Commerce, except consumption figures for American cotton in foreign countries which are from the 1930 Cotton Year Book of the New York Cotton Exchange. The consumption figures for Other Growths in the world and in foreign countries were obtained by deduction.

[1] Year beginning Aug. 1, except 1913 which is the year beginning Sept. 1.

[2] American in running bales and other growths in bales of 478 pounds net. Prior to 1919–20 the quantities given for world consumption of all growths were reported in bales of 500 pounds net and have been converted to equivalent 478 pound bales.

Bureau of Agricultural Economics. Official sources except where otherwise noted.

Bales of 500 pounds gross weight or 478 pounds net. The figures for cotton refer to ginned and unginned cotton and linters, but not to mill waste, cotton batting, scarto (Egyptian and Sudan). Wherever unginned cotton has been separately stated in the original reports it has been reduced to ginned cotton in this statement at the ratio of 3 pounds unginned to 1 pound ginned. Wherever linters are stated separately, they have been excluded from these figures.

* Preliminary.
[1] Calendar year.
[2] Figures for pre-war years are included in the countries of the pre-war boundaries.
[3] 3-year average.
[4] Average for Austria-Hungary.
[5] International Crop Report and Agricultural Statistics.

Bureau of Agricultural Economics. Based upon returns from special price reporters. Monthly prices weighted by production of cotton for each State; yearly price obtained by weighting monthly prices by bales marketed monthly. Mean of prices reported on 1st of month and 1st of succeeding month, August, 1909–December, 1923.

Bureau of Agricultural Economics. Prior to Aug. 16, 1915, compiled from quotations in Market Reports of the New York Cotton Exchange, except Sept. 23 to Nov. 16, 1914, when the exchange was closed, quotations for which time were taken from the New York Commercial and Financial Chronicle, from Aug. 16, 1915, compiled from daily reports to the bureau from the cotton exchanges of the various markets. Prices 1900-01 to 1908-09 for New Orleans and 1914-15 to 1926-27 for other markets are available in 1924 Yearbook, p. 756, Table 313, p. 757, Table 314, and 1927 Yearbook, Table 254, p. 920.

[1] Market closed.
[2] No quotations prior to Sept. 23. Average for 7 days' business.
[3] Does not include New Orleans.
[4] Does not include Savannah.

TABLE 150.—*Cotton: Average monthly premiums*[1] *for staple lengths for Middling spot cotton at New Orleans, 1923–24 to 1929–30*

Bureau of Agricultural Economics.

[1] White standards.
[2] Based on 7/8-inch staple.
[3] These grades are not deliverable on future contracts.
[4] The differences are stated in terms of points or hundredths of a cent per pound. By "On" is meant that the stated number of points is to be added to the price of Middling and by "Off" is meant that the stated number of points is to be subtracted from the price of Middling.

Bureau of Agricultural Economics. Compiled from the Oil, Paint, and Drug Reporter; prices, 1921–22 to 1927–28 are averages of weekly quotations; beginning 1928–29, averages of daily quotations.
Data for 1909–10 to 1920–21 are available in the 1930 Yearbook, p. 695, Table 149.

[1] Quoted as follows: 1921, as f. o. b. mills; 1922, southeastern, pounds; 1923–1927, southeastern, tanks; beginning August, 1928, immediate southeastern.

Bureau of Agricultural Economics. Estimates of the crop-reporting board.

[1] Year shown is that in which beets were grown. Sugar-making campaign extends into succeeding year.
[2] Including, in some years, a small acreage in Canada used by United States factories.
[3] Percentages of sucrose (pure sugar) in the total soluble solids of the beets.
[4] Based upon weight of beets sliced, except possibly in a very few factories.
[5] Sucrose actually extracted by factories (as percentage of weight of beets).
[6] Preliminary.

TABLE 164.—*Sugar: Production in continental United States, Hawaii, Porto Rico, and the Philippine Islands, 1909–10 to 1930–31*

Bureau of Agricultural Economics. Cane sugar production 1910–10 to 1900–11 from Willett & Gray; subsequently from U. S. Department of Agriculture. Hawaiian production from Hawaiian Sugar Planters' Association. Figures for earlier years appear in previous issues of the Yearbook.

[1] Cane sugar, raw, converted to refined basis by multiplying by the following factors: Louisiana and other States, 0.932: Porto Rico, 0.9393; Hawaii, 0.9358; Philippine Islands, 0.95.
[2] Exports 1909–10 to 1911–12, production subsequently.
[3] Unofficial.
[4] Unofficial estimate of commercial crop.

TABLE 165.—*Cane sugar: Production in Louisiana, 1911–1930*

Year [1]	Factories operating	Cane used for sugar: Acreage	Cane used for sugar: Average yield per acre	Cane used for sugar: Production	Sugar produced: As made	Sugar produced: Equivalent refined [2]	Recovery of equivalent refined sugar from cane ground [3]	Sugar made per ton of cane	Molasses made: Total [4]	Molasses made: Per ton of sugar made	Molasses made: Per ton of cane used

Bureau of Agricultural Economics. Estimates of the crop-reporting board.

[1] Sugar campaign, usually not ended before February following season of growth of cane.
[2] 1 ton of sugar as made is assumed to be equivalent to 0.932 tons of refined as tentatively recommended by the joint committee on sugar statistics of the Department of Commerce and the Department of Agriculture.
[3] Based upon tonnage of cane used.
[4] Figures for molasses, 1911–1914, are as reported by the Louisiana Sugar Planters' Association. Figures for later years as reported by Division of Crop and Livestock Estimates. For sirup production see Table 175.
[5] Preliminary.

* Preliminary.

[1] Averages are for a 5-year period wherever available, otherwise for any year or years within this period. Figures for Europe are estimates of production in territory within present boundaries.

[2] Unofficial estimate.

[3] No sugar produced.

[4] Too small to report.

[5] Included with cane-sugar production in Japan.

[6] Exclusive of production in minor producing countries for which no statistics are available.

[7] Preliminary reports indicate that the crop will be limited to this amount, without restriction, the crop is expected to be equal to that of 1929–30.

Bureau of Agricultural Economics. Official sources and International Institute of Agriculture except as otherwise stated. Figures are for the crop years 1909–10 to 1930–31 for the countries in which the sugar-harvesting season begins in the fall months and is completed during the following calendar year, except in certain cane-sugar producing countries where the season begins in May or June and is completed in the same calendar year. Production in these countries is for the calendar years 1909 to 1930.

[2] Unofficial estimate.
[4] Too small to report
[6] Exclusive of production in minor producing countries for which no statistiets are available.
[8] The figures quoted for India are for the production of gur, a low grade of sugar polarizing between 50° and 60°. This sugar is mostly consumed by the natives.
[9] All grades of sugar reduced to terms of head sugar, a grade of sugar which contains at least 96.5 per cent of sucrose.
[10] Figures for the total crop are not yet available. Trade reports place the 1929–30 commercial crop at 854,000 short tons and that of 1930–31 at 840,000 short tons.

Bureau of Agricultural Economics. Trade figures from the Bureau of Foreign and Domestic Commerce.

[1] Beet and cane sugar only.
[2] Duty free, from Hawaii, Porto Rico, and the Philippine Islands (Virgin Islands included 1917 and subsequently).
[3] No account taken of sugar imported in other forms. Imports from the Philippine Islands excluded, reexports deducted.
[4] Shipments to Hawaii and Porto Rico included. Direct exports to foreign countries from Hawaii and Porto Rico excluded.
[5] Sugar used in the manufacture of other commodities for export on which drawback was paid.
[6] No account taken of stocks at the beginning or end of year.
[7] Not available.
[8] Raw sugar converted to refined by multiplying by the following factors: Cuba and Hawaii, 0.9358; Porto Rico, 0.9393; Philippines, 0.95; all others (Santo Domingo, British West Indies, Louisiana, etc.), 0.932.

Bureau of Agricultural Economics. Estimated world total sugar production for the period 1895–96 to 1908–09 in Agriculture Yearbook, 1924, p. 808.

[1] Figures are for the crop years 1909–10 to 1930–31 for the countries in which the sugar-production season begins in the fall months and is completed during the following calendar year, except in certain cane-sugar producing countries where the season begins in May or June and is completed in the same calendar year. Production in these countries is for the calendar years 1909 to 1930.

[2] Production of cane and beet sugar in terms of raw sugar.

[3] The figures quoted for India are for the production of gur, a low grade of sugar polarizing between 50° and 60°. This sugar is mostly consumed by the natives.

[4] All grades of sugar reduced to terms of head sugar, a grade of sugar which contains at least 96.5 per cent sucrose.

[5] Figures for 1909–10 to 1917–18 are for pre-war boundaries.

[6] Figures are incomplete through 1920–21; 1914–15 includes Prussian Poland only; 1915–16 to 1919–20 include Prussian Poland and Congress Poland; 1920–21 includes Prussian Poland, Congress Poland, and Galicia.

[7] Figures for 1909–10 to 1918–19 refer to pre-war boundaries, 1914–15 to 1918–19 are exclusive of invaded territory.

[8] Bohemia, Moravia, and Silesia only.

[9] Preliminary.

[10] Preliminary reports indicate that the crop will be limited to this amount; without restriction, the crop is expected to be equal to that of 1929–30.

[11] Unofficial estimate.

Bureau of Agricultural Economics. Official sources except where otherwise noted. The following kinds and grades have been included under the head of sugar: Brown, white, candied, caramel, chancaca (Peru), crystal cube, maple, muscovado, panela. The following have been excluded: "Candy" (meaning confectionery), confectionery, glucose, grape sugar, jaggery, molasses, and sirups.

* Preliminary.
1 International Yearbook of Agricultural Statistics.
2 Figures for pre-war years are included in the countries of the pre-war boundaries.
3 1 year only.
4 4-year average.
5 Average for Austria-Hungary.
6 3-year average.
7 Year ended Mar. 20.

Bureau of Agricultural Economics.

[1] The data for 1917–1923 include 11 States: Maine, New Hampshire, Vermont, Massachusetts, Connecticut, New York, Pennsylvania, Ohio, Indiana, Michigan, and Wisconsin; data for 10 States, excluding Connecticut, are shown for 1924 and 1925; and data from 9 States excluding Indiana, are shown from 1926 to 1930. In 1919 the 9 States now included produced about 97 per cent of the maple sugar and about 92 per cent of the maple sirup, as reported by the Bureau of the Census.

[2] 1 gallon of sirup taken as equivalent to 8 pounds of sugar.

Bureau of Agricultural Economics. Official sources and International Institute of Agriculture except as otherwise stated. Acreage and production figures are for the harvesting season which begins in the spring, extends through the calendar year in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere, except in the Dutch East Indies, where the harvest is largely completed within the calendar year.

* Preliminary.
[1] Export crop.
[2] French Guinea only.
[3] Unofficial estimate.
[4] European production only; native production insignificant.
[5] Cultivation by Europeans.
[6] Estate production only. Figures for native production not available. Total production of the islands is estimated on the basis of average yield of 311 pounds per acre for the native area, with the addition of the estate production, at 205,000,000 pounds in 1928–29 and 178,000,000 in 1929–30.
[7] Estate production only.
[8] No data are available for the total production of China, which is of considerable importance.

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board; italic figures are census returns. Prices to producers are based upon returns from crop reporters.

1 For years 1920–1922, it is assumed that the car lots averaged 600 bushels per car. For years 1923 to 1929, inclusive, the estimates of bushels shipped have been calculated according to estimated loadings in each State.

2 Compiled from Commerce and Navigation of the United States, 1890–1917; Foreign Commerce and Navigation of the United States, 1918; Monthly Summary of Foreign Commerce of the United States, June issues, 1919–1926; January and June issues, 1927–1930, and official records of the Bureau of Foreign and Domestic Commerce.

3 Total exports (domestic plus foreign) minus imports.

4 Figures 1889–1922 from Boston Chamber of Commerce reports, average of weekly quotations of price actually paid by wholesale dealers on days quoted. Figures 1924–1929 from Special Apple Market Report issued by Mass. Dept. of Agr., Div. of Markets, based on prices "for sales by original receivers."

5 Preliminary.

6 December forecast of total shipments from 1930 crop.

Bureau of Agricultural Economics. Compiled from daily and monthly reports received by the bureau from officials and local agents of common carriers throughout the country. Shipments as shown in car lots include those by boat reduced to car-lot basis. See preceding Yearbooks for data for earlier years.

[1] Beginning January, 1930, figures are subject to revision.
[2] Crop movement season extends from June of one year through June of the following year.

Bureau of Agricultural Economics. Compiled from reports made by cold-storage establishments.

[1] All apples, except those packed in western-style boxes, are tabulated in terms of barrels, on the basis of 3 bushels to the barrel; since Oct. 1, 1923, apples packed in bushel baskets are also included in this tabulation; 3 boxes are considered the equivalent of 1 barrel.

Bureau of Agricultural Economics. Official sources.

* Preliminary.
1 Foreign weights are converted to bushels on the basis of 48 pounds per bushel; domestic, 1 barrel equals 3 boxes (or bushels).
2 Includes pears.
3 Year ended June 30.
4 Figures for pre-war years are included in the countries of the pre-war boundaries.

Bureau of Agricultural Economics. Compiled from daily market reports from bureau representatives at these markets. Average prices as shown are based on stock of good merchantable quality and condition; they are simple averages of daily range of selling prices. See 1927 year book, p. 837, for data for 1921–1926.

[1] Commodity reports were issued for season as follows: 1927–28, Aug. 29–May 26; 1928–29, Aug. 29–May 25; 1929–30, Sept. 3–May 24; 1930–31, Sept. 2.
[2] Quotations on 2½-inch stock unless otherwise stated.
[3] Less than 10 quotations.
[4] Quotations on medium-large stock unless otherwise stated.
[5] Quotations include very large stock.

Bureau of Agricultural Economics. Preliminary estimates.

[1] See notes 1 and 2, Table 194.
[2] 34 years and over.
[3] Less than 500 trees.
[4] Figures for Nebraska are for the 7 counties of Richardson, Nemaha, Otoe, Cass, Sarpy, Douglas, and Washington.
[5] Figures for California are for the 3 commercial apple districts of Watsonville, Sebastopol, and Yucaipa.
[6] Includes trees 34 years and over, for New England States, and for New Jersey.
[7] Does not include trees for New England States, and for New Jersey.

Bureau of Agricultural Economics. Preliminary estimates.

[1] In this study all orchards of 100 or more apple trees were classed as "commercial" orchards and all smaller orchards as "farm" orchards, irrespective of the age or productiveness of the trees. The numbers shown in Tables 194, 195, and 196 are estimates which were based on the 1925 census figures and on reports received from apple growers in practically all commercial sections of the United States, in 1927. Trees for which the varieties were unknown or not reported were assumed to include the same proportion of each variety as orchards in the same area for which varieties were reported. The varieties for which the age was unknown or not reported were assumed to include the same proportion of trees in each age group as those varieties in the same area for which age was reported. The figures in Tables 194, 195, and 196 have been rounded to the nearest thousand to avoid an appearance of meticulous accuracy. It has been assumed that all trees were planted in the spring; that is, trees reported set in 1927 were assumed to be 1 year old on January 1, 1928.

[2] Estimated numbers of trees in commercial orchards in the States omitted are as follows: North Dakota, none; South Dakota, 59,000; Florida, none; Mississippi, none; Louisiana, none; Texas, 89,000; Nevada, 20,000.

[3] While the 16 varieties listed in Tables 194 and 196 are the most important in numbers for the United States as a whole, in some States varieties other than those mentioned were of more importance in numbers but are included under "all other varieties." Since estimates of the numbers of trees were made only for varieties which constituted 0.1 per cent of the total trees in a State, blank spaces in Tables 194 and 196 do not always mean that there were no trees of the variety reported but rather that the number was so small that it was included under "all other varieties." "All other varieties" also include various mixtures of trees of little commercial importance, some trees of unknown variety, seedlings, crabs, and some minor varieties.

[4] Less than 500 trees.

[5] Figures for Nebraska are for the 7 counties of Richardson, Nemaha, Otoe, Cass, Sarpy, Douglas, and Washington.

[6] Figures for California are for the 3 commercial apple districts of Watsonville, Sebastopol, and Yucaipa.

Bureau of Agricultural Economics.

[1] The figures in this table of production include fruit consumed on farms, sold locally and used for manufacturing purposes, as well as that shipped. The figures do not include fruit which repened on the trees, but which was destroyed by freezing or storms prior to picking. For California the figures relate to the crop produced from the bloom of the year shown, fruiting through the winter and through the spring and summer of the following year, being picked from Nov. 1 of the year shown to Oct. 31 of the following year. Fruit not picked until after the latter date is included with the crop of the following year. For all States except California the estimates include all fruit picked after about Sept. 1 of the year shown. The estimates for oranges include tangerines.

[2] From prospects on Dec. 1, commercial shipments of Florida citrus fruits from the 1930 crop were estimated at 13,500,000 boxes of oranges, and 9,000,000 boxes of grapefruit, compared with 7,900,000 boxes of oranges and 6,300,000 boxes of grapefruit shipped from the 1929 crop.

[3] For years 1919–1930, equivalent in standard boxes, each equal to about 2 of the "half straps" commonly used.

[4] Census. Size of boxes not specified.

[5] 500 boxes or less.

[6] As estimated from prospects on Dec. 1.

Bureau of Agricultural Economics. Compiled from daily and monthly reports received by the bureau from officials and local agents of common carriers throughout the country. Shipments as shown in car lots include those by boat reduced to car-lot basis.

[1] Include tangerines.
[2] Crop-movement season extends as follows: California, from Nov. 1 through October of the following year except for grapefruit which extends from Sept. 1 through August of the following year; all other States from Sept. 1 through August of the following year except for lemons from Nov. 1 through October of the following year.
[3] Preliminary.
[4] Includes 1 car in August, 1921.
[5] Reported in October, 1924.
[6] No reports available before 1922.

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board. Trade figures compiled from Monthly Summary of Foreign Trade of the United States, June issues.

[1] Estimates include only certain States where total production can be calculated from commercial sales (shipments, canning, cold pack, etc.) and differs from previously published commercial estimates for some States by an increased allowance for farm and local use.
[2] Fresh cherries not separately reported.
[3] Preliminary.

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board. Prices are based upon returns from crop reporters.

[1] For years 1925–1930, the average price for the States reporting price, except California, is used for computing the value of the grape crop in the less important States for which no price is determined. Price and value are based on quantities actually harvested.
[2] Compiled from Monthly Summary of Foreign Commerce of the United States, June issues, 1923–1926; January and June issues, 1927–1930.
[3] Total exports (domestic plus foreign) minus total imports.
[4] Net imports equals total imports minus total exports (domestic plus foreign).
[5] Less than 0.05 per cent.
[6] Includes fruit in California not harvested as follows: 138,000 tons in 1925, 15,000 in 1926, 142,000 in 1927, 153,000 in 1928, and 124,000 in 1930. (See also last sentence of Note 1.)
[7] Preliminary.

1930 [6]	[5] 53,286	.90	42,340				

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board; italic figures are census returns. Prices based upon return from crop reporters.

[1] Dried peaches converted to terms of fresh on the basis that dried peaches equal 19 per cent of fresh. Canned peaches converted to terms of fresh on the basis that 25 pounds of fresh equal 1 dozen cans of 1 pound each; 48 pounds fresh equals 1 bushel. In practice, 1 bushel of fresh fruit is figured as the equivalent of 2 dozen cans of 1 pound each.

[2] From 1918 to 1922, Sept. 15 price; 1923–1925, Sept. 15 price in North, Aug. 15 price in South; 1926–1930, approximate average price for the season, as reported Dec. 1.

[3] Canned peaches were reported in value only prior to July 1, 1922.

[4] No exports reported prior to Jan. 1, 1922; figures for 1921 represent exports Jan. 1, 1922, to June 30, 1922.

[5] Includes fruit not harvested as follows: 1926, 1,462,000 bushels in Georgia and northern States; 1927, 2,708,000 bushels in California; 1928, 2,917,000 bushels in California and 1,000,000 bushels in Georgia; 1930, 6,376,000 bushels in California. Values are based on the quantity actually harvested.

Bureau of Agricultural Economics. Compiled from daily and monthly reports received by the bureau from officials and local agents of common carriers throughout the country. Shipments as shown in car lots include those by boat educed to car-lots basis. See 1927 Yearbook, p. 855, for data for earlier years.

[1] Crop movement season extends from May 1 through October of a given year.
[2] Preliminary.
[3] No shipments in 1930 because of frost killing.
[4] Includes 1 car in November.
[5] Includes 5 cars in November.

Bureau of Agricultural Economics. Production figures are estimates of the crop-reporting board; italic figures are census returns. Prices are based upon returns from crop reporters.

[1] Canned pears converted to terms of fresh on the basis that 1 pound canned fruit is equivalent to 2 pounds fresh; dried pears converted to terms of fresh on the basis that dried pears equal 25 per cent of fresh; 48 pounds fresh equals 1 bushel. No imports of pears reported.
[2] From 1918 to 1925, Nov. 15 price; 1926 to 1930 approximate average price for the season, as reported Dec. 1.
[3] Exports were reported in value only, prior to July 1, 1922.
[4] January–June, 1929. Not previously reported.
[5] Preliminary.

Bureau of Agricultural Economics. Compiled from daily and monthly reports received by the bureau from officials and local agents of common carriers throughout the country. Shipments as shown in car lots include those by boat reduced to car-lot basis.

[1] Preliminary.
[2] Figures for Florida include shipments in December of preceding year as follows: 1921, 8 cars; 1924, 3 cars; 1925, 10 cars; 1927, 2 cars; 1929, 1 car; 1930, 107 cars.
[3] Not reported by separate divisions.

Bureau of Agricultural Economics. Compiled from daily market reports from bureau representatives in the various markets. Average prices as shown are based on stock of good merchantable quality and condition; they are simple averages of daily range of selling prices. In some cases conversions have been made from larger to smaller units or vice versa in order to obtain comparability.

[1] Commodity reports were issued for season as follows: 1919, Apr. 7–June 20; 1920, Apr. 12–June 10; 1921, Mar. 17–June 3; 1922, Mar. 23–June 6; 1923, Mar. 28–June 13; 1924, Mar. 31–June 17; 1925, Mar. 19–June 9; 1926, Mar. 29–June 19; 1927, Mar. 7–June 20; 1928, Feb. 27–June 12; 1929, Apr. 1–June 7; 1930, Mar. 27–June 12. Quotations for March, 1929, and 1930, taken from miscellaneous reports.

1930	577,000	20.00	8,480

[1] For products largely marketed by Dec. 1, prices represent approximate seasonal averages to that date.
[2] Includes some fruit not harvested on account of market conditions (but not included in computing value), as follows: Apricots, 1930—18,000 tons; peaches, clingstone, 1927—65,000 tons, 1928—70,000 tons, 1930—153,000 tons; grapes, table varieties, 1925—100,000 tons, 1926—15,000 tons, 1927—142,000 tons, 1928—75,000 tons, 1930—104,000 tons; grapes, wine varieties, 1928—18,000 tons, 1930—20,000 tons; grapes, raisin varieties for fresh market, 1925—38,000 tons, 1928—60,000 tons.
[3] Dried basis. To calculate the approximate quantity of fresh grapes used for raisins multiply the production of raisins by 4.
[4] For years prior to 1923 the quantity of raisins marketed fresh was small and has been included with other table grapes.

Bureau of Agricultural Economics: California estimates in cooperation with California Department of Agriculture; 1930 estimates are preliminary.

[5] The production shown includes a small quantity of prune varieties shipped fresh but does not include prunes dried.
[6] Dried basis. To calculate in terms of fresh fruit multiply the quantity of dried prunes produced by 2½.
[7] Representing the commercial crop year beginning Nov. 1 of the year shown; the numbers for 1930, for instance, represent the fruit that set during the season of 1930 and will be picked and marketed from Nov. 1, 1930, to Oct. 31, 1931.
[8] Includes value of quantity of grapefruit as shown below.

Bureau of Agricultural Economics.

[1] Incomplete. Estimates for some States are not available. See also Table 228.
[2] For products not entirely marketed by Dec. 1, prices represent approximate seasonal averages to that date.
[3] Includes 13,000 tons not harvested on account of market conditions. Price and value computed on quantity actually harvested.
[4] Estimates for dried figs include some not of merchantable quality.

Bureau of Agricultural Economics. Compiled from daily and monthly reports received by the bureau from officials and local agents of common carriers throughout the country. Shipments as shown in car lots include those by boat reduced to car-lot basis.

[1] Crop-movement season covers 17 months; from December through the second following April; i. e., the 1920 season begins December, 1919, and ends April, 1921.
[2] Preliminary.
[3] Figures include shipments in May of succeeding crop year as follows: New York, 1922, 1 car; 1926, 3 cars; 1927, 25 cars; 1928, 1 car; Pennsylvania, 1920, 1 car; Michigan, 1927, 1 car; 1928, 2 cars.
[4] Figures include shipments in November of preceding crop year as follows: Florida, 1928, 5 cars; Texas, 1920, 2 cars; 1922, 4 cars; 1923, 22 cars; 1924, 9 cars; 1925, 12 cars; 1928, 30 cars; 1929, 12 cars.

Bureau of Agricultural Economics. Compiled from daily market reports from bureau representatives in the various markets. Average prices as shown are based on stock of good merchantable quality and condition; they are simple averages of daily range of selling prices. In some cases conversions have been made from larger to smaller units or vice versa in order to obtain comparability.

[1] Unless otherwise stated, quotations are on bulk per ton sales.
[2] The season during which Danish cabbage prices are obtainable usually runs from October to March of the following year.
[3] Sacked per ton delivered.
[4] Converted from hundredweight price.

Bureau of Agricultural Economics. Compiled from daily and monthly reports received by the bureau from officials and local agents of common carriers throughout the country. Shipments as shown in car lots include those by boat reduced to car-lot basis.

[1] Includes Honeydew and other miscellaneous melons not separately reported until 1923. The shipments of melons, other than cantaloupes, amounted in 1923 to 1,152 cars; in 1924 to 2,565; in 1925 to 3,654 in 1926 to 6,484; in 1927 to 6,516; in 1928 to 9,719; in 1929 to 11,894; and in 1930 to 12,273.
[2] Crop-movement season extends from Apr. 1 through November of a given year.
[3] Preliminary.
[4] Figures for California include shipments in December as follows: 1920, 1 car; 1925, 18 cars; 1926, 3 cars; 1927, 4 cars; 1928, 2 cars.

Bureau of Agricultural Economics. Compiled from daily market reports from bureau representatives in the various markets.

Average prices as shown are based on stock of U. S. No. 1 grade; they are simple averages of daily range of selling prices. In some cases conversions have been made from larger to smaller units or vice versa, in order to obtain comparability.

[1] Commodity reports were issued as follows: 1921-22, Aug. 22–June 14; 1922-23, Aug. 7–May 29; 1923-24, Aug. 14–June 4; 1924-25, Aug. 22–June 10; 1925-26, July 22 to end of season. For subsequent years onion reports have run through the entire year.
[2] Car-lot sales.

Bureau of Agricultural Economics. Compiled from daily and monthly reports received by the bureau from officials and local agents of common carriers throughout the country. Shipments as shown in car lots include those by boat reduced to car-lot basis.

[1] Crop movement season is for calendar year except for Imperial Valley, California; Florida; and Texas which begins in October of the preceding year.
[2] Preliminary.
[3] Figures for certain States include shipments in preceding year as follows: California, 1926, 4 cars in October, 220 in November, and 94 in December; 1927, 1 car in October, 223 in November, and 38 in December; 1928, 202 cars in November and 92 in December; 1929, 259 cars in November and 148 in December; 1930, 4 cars in October, 188 in November and 243 in December. Florida, 1927, 2 cars in December; 1928, 5 cars in November and 4 in December; 1929, 1 car in December. Texas, 1927, 1 car in December; 1928, 1 car in November.

Bureau of Agricultural Economics. Acreage, yield, and production figures are estimates of the crop-reporting board; italic figures are census returns. Prices received by producers are based upon returns from crop reporters. See 1927 Yearbook, p. 881, for data for earlier years.

[1] Compiled from Producers Price Current. Prices 1909–1919 are averages of the high and low weekly quotations of New York potatoes, October–June, converted from dollars per 180 pounds to cents per bushel beginning 1920, season September–May.

[2] Compiled from Commerce and Navigation of the United States, 1909–1917; Foreign Commerce and Navigation of the United States, 1918; Monthly Summary of Foreign Commerce of the United States, June issues, 1919–1926, January and June issues, 1927–1930 and official records of the Bureau of Foreign and Domestic Commerce.

[3] The difference between total exports (domestic exports plus reexports) and total imports + indicates net exports and − indicates net imports.

[4] For some of the early and midseason States prices represent approximate seasonal average.

[5] Preliminary.

Bureau of Agricultural Economics. Compiled from daily and monthly reports received by the bureau from officials and local agents of common carriers throughout the country. Shipments as shown in car lots include those by boat reduced to car-lot basis. Figures for earlier years appear in 1927 and earlier Yearbooks.

[5] Totals for April include cars moved in March, as follows: 1 in 1928 and 6 in 1929.
[6] Includes 50 cars in December, 58 in January, 67 in February, and 276 in March.
[7] Includes 16 cars in December, 58 in January, 68 in February, and 1,282 in March.
[8] Includes 6 cars in December, 40 in January, 183 in February, and 602 in March.

Bureau of Agricultural Economics. Based upon returns from special price reporters. Monthly prices weighted by production of potatoes for each State; yearly price obtained by weighting monthly prices by car-lot shipments. Mean of prices reported on 1st of month and 1st of succeeding month, July, 1909–December, 1923. For previous data see 1930 or earlier Yearbooks.

Bureau of Agricultural Economics. Compiled from daily market reports from bureau representatives in the various markets. Average prices as shown are based on stock of U. S. No. 1 grade; they are simple averages of daily range of selling prices. In some cases conversions were made from larger to smaller units, or vice versa, in order to obtain comparability.

[1] Crop-movement season extends from April of one year through May of the following year, with irregular quotations continuing through June and July.
[2] Less-than-carload sales to jobbers.

Bureau of Agricultural Economics. Compiled from daily and monthly reports received by the bureau from officials and local agents of common carriers throughout the country. Shipments as shown in car lots include those by boat reduced to car-lot basis.

[1] Crop-movement season extends from October of the preceding year through December of the year shown
[2] Preliminary.
[3] Figures include shipments in January of succeeding crop year as follows: Maryland, 1922, 5 cars; 1923, 4 cars; Washington, 1925, 4 cars; New Jersey, 1923, 1 car.
Includes 1 car from New Mexico in March, 1921.

Bureau of Agricultural Economics. Compiled from daily and monthly reports received by the bureau from officials and local agents of common carriers throughout the country. Shipments as shown in car lots include those by boat reduced to car-lot basis.

[1] Crop movement season extends from July 1 of 1 year through June of the following year.

[2] Preliminary.

[3] Figures for certain States include shipments in July of succeeding crop year as follows: New Jersey, 1920, 15 cars, 1922, 3 cars; Indiana, 1926, 1 car; Virginia, 1928, 1 car; North Carolina, 1926, 3 cars, 1927, 10 cars; South Carolina, 1922, 1 car; Georgia, 1927, 2 cars; Kentucky, 1921, 1 car, 1926, 12 cars, 1928, 5 cars; Tennessee, 1921, 17 cars, 1924, 3 cars, 1925, 11 cars, 1926, 309 cars, 1927, 6 cars, 1928, 135 cars, 1929, 10 cars; Arkansas, 1921, 1 car, 1926, 1 car; Louisiana, 1926, 1 car; New Mexico, 1921, 5 cars, 1928, 1 car; Tennessee, 1926, 19 cars in August.

[4] Includes 3 cars in June, 1923.

[5] Includes 10 cars in June, 1929.

Bureau of Agricultural Economics. Compiled from daily market reports from bureau representatives in the various markets.

Average prices as shown are based on stock of good merchantable quality and condition; they are simple averages of daily range of selling prices. In some cases conversions have been made from larger to smaller units or vice versa, in order to obtain comparability.

[1] Commodity reports were issued for season as follows: 1921–22, Aug. 23–May 26; 1922–23, Sept. 1–May 4; 1923–24, Sept. 18–Apr. 15; 1924–25, Sept. 2–Apr. 3; 1925–26, Aug. 25–Apr. 16; 1926–27, Aug. 16–Apr. 19; 1927–28, Aug. 19–Apr. 3; 1928–29, Aug. 22–Apr. 5; 1929–30, Aug. 19–Apr. 11; 1930–31, Aug. 12.

[2] Kiln-dried.

Bureau of Agricultural Economics. Italic figures are census returns; census figures include all States; other figures, estimates of crop-reporting board, principal producing States only.

[1] Table includes, besides the ordinary edible beans and limas, the blackeye of California which is identical with the blackeyed pea of the South. Soybeans not included.

[2] Farm prices are as of Nov. 15, 1914–1924.

[3] Prices 1899 and 1909 from Chicago Board of Trade annual reports, quotations for navy, good to choice; 1914–1929 from Daily Trade Bulletin, pea beans (quoted per 100 pounds; converted to bushels of 60 pounds).

[4] Imports and exports compiled from Commerce and Navigation of the United States, 1910–1917; Foreign Commerce and Navigation of the United States, 1918; Monthly Summary of Foreign Commerce of the United States, June issues, 1919–1926; January and June issues, 1927–1930; and official records of the Bureau of Foreign and Domestic Commerce.

[5] Not separately reported prior to 1918.

[6] Not separately reported.

[7] 11 months.

[8] Preliminary.

Bureau of Agricultural Economics. Based upon reports by growers on proportion of total production made up of each variety, supplemented by investigations of field statisticians.

[1] Table includes, besides the ordinary edible beans and Limas, the blackeye of California, which is identical with the blackeyed "pea" of the South. Soybeans not included.
[2] Limas include baby Limas: 1928, 668; 1929, 810; 1930, 1,150.
[3] "Other" include Bayo: 1928, 20; 1929, 20; 1930, 25.
[4] Large white in New York is the marrow.
[5] Including garden or seed beans: Idaho, 1928, 195; 1929, 291; Wyoming, 1929, 72; 1930, 65; and Colorado, 1930, 136.
[6] Including also Pintos in Kansas: 1928, 36; 1929, 140; 1930, 144; and small whites in Oregon: 1929, 35; 1930, 12.

Bureau of Agricultural Economics. Estimates of the crop-reporting board.

1 Acres from which all or part of the beans grown were gathered.
2 Including acres planted in corn reduced to equivalent solid acres as well as the acreage grown alone.
3 Including beans grazed or otherwise utilized as well as those gathered.
4 Total production (except hay) multiplied by price of gathered beans to give approximate total value.

Bureau of Agricultural Economics. Estimates of the crop-reporting board.

[1] Acres from which all or part of the peas grown were gathered.
[2] Including acres planted in corn reduced to equivalent solid acres as well as the acreage grown alone. Acreage cut for hay is included in table of legume hay.
[3] Including peas grazed or otherwise utilized as well as those gathered.
[4] Total production (except hay) multiplied by price of gathered peas to give approximate total value.

Bureau of Agricultural Economics. Estimates of the crop-reporting board.

[1] The figures refer to the yield and entire production of velvetbeans in the hull and not merely to those gathered. The pods are gathered from one-fourth to one-third of the acreage and most of these are ground for feed, only enough being shelled to supply seed. A large proportion of the crop is grazed.
[2] Preliminary.

Bureau of Agricultural Economics.

[1] Storage stocks reported by dealers include manufacturers' stocks held by dealers at country shipping points.
[2] Nov. 1 estimate.
[3] Less than 100 tons.
[4] For crop year, June 1–May 31.
[5] Includes broomcorn destroyed by warehouse fire.

Bureau of Agricultural Economics. Based on returns from special price reporters. Monthly prices weighted by production of hay for each State; yearly price obtained by weighing monthly prices by monthly marketings. Mean of prices of all loose hay reported on 1st of month and 1st of succeeding month, July, 1909–December, 1923. For previous data on alfalfa, clover, timothy, and prairie hay see 1930 or earlier Yearbooks.

Bureau of Agricultural Economics. Official sources and International Institute of Agriculture except as otherwise stated. Acreage and production figures are for the harvesting season which begins in the summer, extends through the calendar year in the Northern Hemisphere, and is completed in the early part of the following year in the Southern Hemisphere.

*Preliminary.

[1] British Columbia.

[2] Principal producing states.

[3] About 17 per cent of this acreage was left unpicked.

[4] Yield based on total acreage under hops; if allowance were made for the unpicked area the average yield per acre would compare favorably with that of 1929.

[5] Unofficial estimate.

[6] Exclusive of acreage and production in minor producing countries for which no data are available.

Bureau of Agricultural Economics. Official sources except where otherwise noted. Includes shelled and unshelled, assuming the peanuts to be unshelled unless otherwise stated. When shelled nuts were reported they have been reduced to terms of unshelled at the ratio of 3 pounds unshelled to 2 pounds shelled.

Bureau of Agricultural Economics.

[1] Prior to 1900 estimates for each 10-year period represent an index of annual changes applied to census as base on first report after census data were available. Figures for 1900–1919 are tentative revised estimates of the Bureau of Agricultural Economics as first published in 1927 yearbook.

[2] Obtained by subtracting the estimates of "milk cows on farms" shown in Table 438 from the estimates of "all cattle on farms" shown in this table.

[3] Series for 1867–1899 are estimates as currently reported.

[4] Data for beef cattle on farms and elsewhere as of Jan. 1 estimated by the Bureau of Animal Industry. Prior to 1920 census figures were adjusted to a Jan. 1 basis and to include all ages and all animals in towns villages and ranges, as well as on farms. For methods, see Department Circular 241. Revisions have been made by the Bureau of Animal Industry for 1900–1927 in line with revision of estimates of cattle on farms; 1928–1931 estimates of Bureau of Agricultural Economics.

[5] Data for 1900–1925 are an old series adjusted on basis average relationship between the old and new series from 1926 to 1928. Old series was weighted averages of prices by age groups only and was shown in 1928 Yearbook. The conversion factor was 0.9466 (base is old series). Data for 1926–1931 are a new series referred to above, of average values by age and sex classification weighted by numbers in each class.

[6] Italic figures for Census years represent classification of cattle as follows: 1840 reported as "neat cattle," 1880 and 1890 exclude an estimated number of unenumerated cattle on ranges as follows: 1880, 3,750,022; 1890, 6,285,220. No estimate made prior to 1880. Figures for censuses prior to 1900 were nominally exclusive of calves, though some calves may have been included. 1900, 1910, and 1920 include calves. 1850–1890 exclude working oxen as follows: 1850, 1,700 744; 1860, 2,254, 911; 1870, 1,319,371; 1880, 993,841; 1890, 1,117,-494. Not seperately reported after 1890. Census dates were June 1, from 1840 to 1900; April 15, 1910; January 1, 1920 and 1925.

[7] Original estimate of the Bureau of Agricultural Economics.

Bureau of Agricultural Economics. Estimates of the crop-reporting board.

[1] Sum of total value of subgroups (classified by age and sex) divided by total number and rounded to nearest dime for States. Division and United States averages not rounded. State figures are new weighted value series not comparable to State figures previously published for the years prior to 1925.

[2] Preliminary.

Estimated world total, including Russia.[8]		561,600	646,700					

Bureau of Agricultural Economics. Compiled from official sources and the International Insitute of Agriculture unless otherwise stated.

[1] Average for 5-year period if available; otherwise, for any year or years within this period except as otherwise stated. In countries having changed boundaries the pre-war figures are estimates for 1 year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.

[2] Year 1902.
[3] Census.
[4] Incomplete.
[5] Year 1918.
[6] Year 1908.
[7] Countries reporting as of December have been considered as of Jan. 1 of the following year—i. e., figures for number of cattle in France as of Dec. 31, 1925, have been put in the 1926 column, etc.
[8] This total includes interpolations for a few countries not reporting each year and rough estimatse for some others.
[9] Unofficial.
[10] Buffaloes included.
[11] Year 1920.
[12] June, 1914, and 1930.
[13] In rural communities only.
[14] September.
[15] Year 1906.
[16] Year 1916, from Soviet Union Review, April, 1928. Years 1924–1926, Statistical Review, October, 1928, p. 6; year 1927, Agricultural Statistics of the U. S. S. R., Lenin Academy, 1927–1930-Planned Economy No. 12, 1930, State Planning Board.
[17] Year 1916.
[18] Year 1915.
[19] Number in towns assumed to be same as in 1927—i. e., 177,000, and added in for purposes of comparison with preceding years.
[20] Including 1925 estimate of 1,324,500 cattle and buffaloes in order to compare with preceding estimates.
[21] Comparable totals for number of countries indicated.

Bureau of Agricultural Economics. Calculated from quotations in the Review of the River Plate. Prices prior to May, 1924, originally quoted on basis of price per head supplemented from 1916 by price per pound of dressed carcass weight. Calculations assume average dressed weight of 730 pounds or live weight of 1,259 pounds. Live-weight quotations per pound from May, 1924. Converted at average monthly rate of exchange as given in Federal Reserve Bulletins.

Table 362.—*Cattle and calves: Monthly average price per 100 pounds, Chicago, 1900–1930*

Bureau of Agricultural Economics. Beef-steer prices prior to 1922 from Chicago Drovers Journal Yearbook, general average native beef cattle. Subsequent figures are the weighted average price of all grades of beef steers sold out of first hands at Chicago. Veal-calf prices prior to 1919, from Chicago Drovers Journal Yearbook, average native veal calves. Later figures from the livestock and meat reporting service of the bureau.

[1] Western steers not included.

TABLE 363.—*Cattle and calves: Average price per 100 pounds at Chicago and Kansas City, by months, 1928–1930*

Bureau of Agricultural Economics. Compiled from official sources and cabled reports from agricultural commissioners abroad.

[1] Including municipal and private slaughterhouses, the figures were as follows in thousands—averages, pre-war, 3,272, 1921–1925, 5,961. The numbers killed in freezing and chilling plants alone were as follows in thousands—1925, 3,342; 1926, 3,067; 1927, 3,234; 1928, 2,830; 1929, 2,792.
[2] Slaughtering in freezing and chilling plants alone were as follows in thousands—1925, 651; 1926, 714; 1927, 695; 1928, 697; 1929, 880; 1930, 1108.
[3] For years ended Mar. 31, following.
[4] Average for five years immediately preceding war if available, otherwise for any year or years, within that period, unless otherwise stated.
[5] Excluding farm slaughter which averaged only 7,493 for the 10 years 1917–1926.
[6] Preliminary estimate.

Bureau of Agricultural Economics.

[1] Prior to 1900 estimates for each 10-year period represent an index of annual changes applied to census as base on first report after census data were available: 1900–1919 are tentative revised estimates of the Bureau of Agricultural Economics as first published in 1927 Yearbook.

[2] Series for 1867–1899 are values of all hogs as reported.

[3] Data for swine on farms and elsewhere as of Jan. 1 prior to 1900 estimated by the Bureau of Animal Industry. Census figures prior to 1920 were adjusted to a Jan. 1 basis and to include all ages and all animals in towns, villages, and ranges, as well as on farms. For methods see Department Circular 241. Figures from 1900–1927 are the estimates of the Bureau of Agricultural Economics of swine on farms plus an estimate made by the Bureau of Animal Industry of swine in towns and villages; 1928–1931 are estimates of Bureau of Agricultural Economics.

[4] Data for 1900–1925 are an old series for all hogs as reported, adjusted on basis average relationship between the new and the old series from 1926 to 1928. Old series was shown in 1928 Yearbook. Conversion factor was 1.057 (base was old series). Data for 1926–1931 are a new series, referred to above, of average values by age and sex classification weighted by numbers in each class.

[5] Italic figures are from the census. Figures for census years 1880 and 1890 exclude estimate of unenumerated swine on ranges as follows: 1880, 2,093,970; 1890, 17,276. Census dates were June 1 from 1840 to 1900; Apr. 15, 1910; Jan. 1, 1920 and 1925.

[6] Original estimate of the Bureau of Agricultural Economics.

Bureau of Agricultural Economics. Estimates of the crop-reporting board.

[1] Sum of total value of subgroups (classified by age and sex), divided by total number and rounded to nearest dime for States. Division and United States averages not rounded. State figures are new weighted value series not comparable to State figures previously published years prior to 1925.

[2] Preliminary.

Pre-war to 1929 (29) [19]		137,014	135,587	127,571	137,050	149,640	136,734	
Pre-war to 1930 (15) [19]		116,423	118,548	109,956	120,126	132,411	119,818	108,599
Estimated world total including Russia [5]		264,236	266,424					

Bureau of Agricultural Economics. Official estimates and International Institute of Agriculture unless otherwise stated.

[1] Average for 5-year period if available, otherwise for any year or years within that period unless otherwise stated. In countries having changed boundaries, the figures are estimated for one year only for numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.
[2] Year 1902.
[3] Census figure.
[4] Incomplete.
[5] These totals include interpolations for a few countries not reporting each year, and rough estimates for some others.
[6] Year 1915.
[7] Year 1920.
[8] Year 1908.
[9] Estimates reported as of December have been considered as of Jan. 1 of the following year, i. e., the figure for the number of swine in France as of Dec. 31, 1925, has been put in the 1926 column.
[10] June, 1914 and 1930.
[11] Year 1922.
[12] Number in rural communities.
[13] September.
[14] Year 1906.
[15] Unofficial.
[16] Year 1916, from the Soviet Union Review, April, 1928, p. 52. Years 1924–1926, Statistical Review, October, 1928. Year, 1927, Agricultural Statistics of the U. S. S. R., Lenin Academy, 1927–30. Planned Economy No. 12, 1930 State Planning Board.
[17] Year 1916.
[18] Number in towns assumed to be same as in 1927, i. e., 22,000, and added in for purposes of comparison with preceding years.
[19] Comparable totals for the number of countries indicated.

Bureau of Agricultural Economics. Monthly figures prior to 1920 are general average hog prices as published in the Chicago Drovers Journal Yearbook; subsequent figures compiled from reports of packer and shipper purchases; such purchases do not include pigs, boars, stags, extremely rough sows, or cripples. The yearly figures are the simple average of the October to September prices.

Bureau of Agricultural Economics. Compiled from official sources and cabled reports from agricultural commissioners abroad.

[1] For years ended May 31 following.
[2] Average for five years immediately preceding war period if available, otherwise for any year or years within that period unless otherwise stated. In countries having changed boundaries, the figures are estimates for one year only for numbers within present boundaries.
[3] Not available for present boundaries. For former boundaries, the numbers slaughtered are as follows in thousands—1914, 19,441; 1915, 13,293; 1916, 6,548; 1917, 5,795; 1918, 2,430.

Bureau of Agricultural Economics. Compiled from Agricultural Market Report, Ministry of Agriculture and Fisheries, Great Britain. Average for the last week of each month 1909–1923. Average of weekly averages 1924–1930. Converted at monthly average rate of exchange as given in Federal Reserve Bulletins to December, 1925, inclusive; subsequently at par of exchange.

[1] Entire half of hog in one piece, head off, backbone out, ribs in.

NOTE.—A table similar to Table 396, 1928 Yearbook, British pork prices, is omitted.

Bureau of Agricultural Economics.

[1] Prior to 1900 estimates for each 10-year period represent an index of annual changes applied to census as base on first report after census data were available. Figures for 1900–1919 are tentative revised estimates of the Bureau of Agricultural Economics as first published in 1927 Yearbook.

[2] Data for sheep on farms and elsewhere as of Jan. 1, prior to 1900, estimated by the Bureau of Animal Industry. Census figures prior to 1920 were adjusted to a Jan. 1 basis and to include all ages and all animals in towns, villages, and ranges, as well as on farms. For methods see Department Circular 241. Figures from 1900–1927 are the estimates of the Bureau of Agricultural Economics of sheep on farms plus an estimate made by the Bureau of Animal Industry of sheep in towns and villages; 1928–1931 are estimates of the Bureau of Agricultural Economics.

[3] Italic figures are from the census. Figures for census years 1860, 1880, and 1890 exclude an estimated number of unenumerated sheep on ranges, as follows: 1860, 1,505,810; 1880, 7,000,000; 1890, 4,940,948. Censuses prior to 1900 excluded lambs. Census dates were June 1 from 1840 to 1900; Apr. 15, 1910; Jan. 1, 1920 and 1925.

[4] Original estimate of the Bureau of Agricultural Economics.

[5] Preliminary.

Estimated world total, including Russia.[5]		692, 200	647, 100					

Bureau of Agricultural Economics. Official sources and International Institute of Agriculture unless otherwise stated. Figures in parentheses are interpolated.

[1] Average for 5-year period if available, otherwise for any year or years within this period except as otherwise stated. In countries having changed boundaries the pre-war figures are estimates for 1 year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.
[2] Year 1902.
[3] Census figures.
[4] Incomplete.
[5] These totals include countries with less than 100,000 interpolations for a few countries not reporting each year and rough estimates for some others.
[6] Year 1916.
[7] Unofficial.
[8] Countries reporting as of Dec. 31, are considered as of Jan. 1, of the following year, i. e., figures for number of sheep in France as of Dec. 31, 1925, have been placed in 1926 column.
[9] Year 1925.
[10] Year 1920.
[11] Year 1908.
[12] Year 1915.
[13] June, 1914 and 1930.
[14] December, 1922.
[15] In rural communities only.
[16] 1906.
[17] For Austria average of range from 300,000 to 325,000 and for China average of range from 25,000,000 to 45,000,000.
[18] Year 1916 from Soviet Union Review April, 1928, p. 62. Years 1924–1926. Statistical Review, October, 1928, p. 6. Year 1927. Agriculture Statistics of the U. S. S. R. Lenin Academy, 1927–1930. Planned Economy number 12, 1930. State Planning Board.
[19] Goats included.
[20] Number in towns assumed to be same as in 1927, i. e., 162,000 and added for purposes of comparison with preceding years.
[21] Estimate based on increase reported in June, 1930, compared with June, 1929.
[22] Comparable totals for number of countries indicated.

Bureau of Agricultural Economics. Figures prior to 1921 are from the Chicago Drovers Journal Yearbook, average native and western sheep and average aged lambs. Subsequent figures are bulk of sales prices from data of the livestock and meat reporting service of the bureau. For lamb prices 1901–1904, see 1927 Yearbook, p. 1031.

[1] Simple average of monthly prices.

TABLE 408.—*Sheep and lambs: Average price per 100 pounds at Chicago and Omaha, by months, 1928–1930*

Year and month	Chicago							Omaha						
	Lambs		Yearling wethers, 110 pounds down, Medium to Choice	Ewes		Feeder lambs		Lambs		Yearling wethers, 110 pounds down, Medium to Choice	Ewes		Feeder lambs

Bureau of Agricultural Economics.

[1] In State where sheep are shorn twice a year, principally Texas and California, this figure covers wool per head of sheep shorn and not weight per fleece.

[2] Include fleeces taken at commercial feeding plants. California figure includes some fleeces taken from early lambs.

TABLE 416.—*Wool: Production, imports, exports, and amount available for consumption, United States, 1910–1930*

Bureau of Agricultural Economics. Production figures 1910–1913 from the National Association of Wool Manufacturers; 1914–1928 from the bureau; imports and exports from the Bureau of Foreign and Domestic Commerce.

[1] Hair of Angora goat, alpaca, and other like animals included in imports and reexports prior to 1914 and in exports for all years.
[2] Total imports minus domestic exports and reexports.
[3] Exports for fiscal years ended June 30 of the years shown.
[4] Included in all other articles.
[5] No transactions.
[6] Preliminary.

Bureau of Agricultural Economics. Official sources except where otherwise noted. "Wool" in this table includes washed, unwashed, scoured, pulled wool, and slipe, also hair—camel's, mohair, angora goat, cashmere goat, and alpaca. The following items have been considered as not within this classification: Carded, combed, dyed wool, flocks; sheep, lamb, and goatskins with hair on; mill waste, noils, and tops.

* Preliminary.

[1] International Yearbook of Agricultural Statistics.

[2] Figures for pre-war years are included in the countries of the pre-war boundaries.

[3] 3-year average.

[4] Figures for Persia are for 12 months ended Mar. 21 of the year following year shown.

[5] 4-year average.

[6] 1 year only.

Bureau of Agricultural Economics. Includes wool shorn in the spring in the Northern Hemisphere and that shorn in the last few months of the same calendar year in the Southern Hemisphere. Includes small quantities of pulled wool in certain countries. For table showing all countries up to 1930 see Foreign Crops and Markets, Mar. 23, 1931, and for current information see World Wool Prospects, issued monthly by the Bureau of Agricultural Economics.

* Preliminary.

[1] Average for 5 years whenever available, otherwise for any year or years within this period for which estimates are available.

[2] Estimate furnished by cable from the International Institute of Agriculture.

[3] Estimates of Dalgety & Co.

[4] Estimate of total production based on an estimated decrease of 2 per cent in wool shorn on farms only, as furnished by the International Institute of Agriculture. In addition to the wool shorn on farms there is the wool pulled from slaughtered sheep to be considered as well as that exported on skins.

[5] Estimates based on exports, stocks, and domestic consumption.

[6] Estimate of Buenos Aires branch of the First National Bank of Boston.

[7] Includes some wool imported from neighboring colonies.

[8] Estimates of the Yorkshire Observer. These figures have been used instead of official estimates, as comparable figures are available up to 1930.

[9] Estimate based on sheep numbers at the date nearest shearing time.

[10] Totals subject to revision. Few countries published official wool production estimates. In the absence of official figures for most countries, various estimates have been used. Some have been supplied by Government representatives abroad; others by multiplying official sheep numbers by an average weight per fleece. For some principal exporting countries, exports alone, or exports, stocks, and domestic consumption have been used as representing production. In the case of some Asiatic countries, rough commercial estimates have been used, while the figures of the U. S. Department of Commerce or the National Association of Wool Manufacturers have been used for some other countries.

[11] Year 1916.

[12] Exports.

Bureau of Agricultural Economics. These data were obtained from prices given by Kreglinger and Fernau for the opening and closing of each series of the London wool sales. For months when no sales were held the figures are interpolations of nearest actual prices. Conversions at monthly average rate of exchange as given in Federal Reserve Bulletins to December, 1925, inclusive; subsequently at par.

Bureau of Agricultural Economics.

[1] Figures for 1923, 1924, and 1925 are revisions of department's estimates previously published.
[2] Most goats clipped twice a year. In Texas, kids are clipped in the fall of year of birth. Figures include both goats and kids clipped.
[3] In States where goats are clipped twice a year figures include both spring and fall clip.

Estimated world total [7]		121,300	106,400					

Bureau of Agricultural Economics. Compiled from official sources or the International Institute of Agriculture.

[1] Average for 5-year period if available, otherwise for any year or years within this period except as otherwise stated. In countries having changed boundaries the pre-war figures are estimates for one year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.
[2] Census.
[3] 1903.
[4] 1920.
[5] Estimates for countries reporting as of December have been considered as of Jan. 1 of the following year, i. e., horses as reported in France for Dec. 31, 1926, have been placed in the 1927 column.
[6] Interpolated.
[7] Includes interpolations for a few countries not reporting each year and rough estimates for some others.
[8] 1915.
[9] 1908.
[10] 1916.
[11] 1918.
[12] Incomplete. Refers to horses used in agriculture only for Northern Ireland and Irish Free State.
[13] Rural communities only.
[14] September.
[15] Unofficial.
[16] 1906.
[17] Estimated for present boundaries. Estimates for former boundaries were as follows: Mar. 19, 1908, 955,878, and for April 6, 1918, 989,876.
[18] Includes army hourses.
[19] Includes mules and asses.
[20] Comparable totals for the number of countries indicated.

Total all countries reported all periods, pre-war to 1929 [12]		5,162	6,539	6,559	6,486	6,331	6,216	
Estimated world total [7]		8,600	10,800					

Bureau of Agricultural Economics. Compiled from official sources and the International Institute of Agriculture. Figures in parenthesis are interpolated.

[1] Average for 5-year period if available. Otherwise for any year or years within this period except as otherwise stated. In countries having changed boundaries the pre-war figures are estimates for 1 year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.

[2] Census.

[3] 1920.

[4] 1902.

[5] Estimates for countries reporting as of December have been considered as of Jan. 1, of the following year—i. e., mules reporting as of Dec. 31, 1926, in France have been placed in 1927 column.

[6] April.

[7] Includes interpolations for a few countries not reporting each year and rough estimates for some others. It is probable that mules are found in many other countries for which no estimates at all are available and for which no estimates are included in these totals.

[8] 1915.

[9] June.

[10] 1906.

[11] Included with asses.

[12] Comparable totals for the number of countries indicated.

Bureau of Agricultural Economics.

[1] Prior to 1920, estimates for each 10-year period represent an index of annual changes applied to the census as a base on first report after census data were available. Figures for 1920 to date are revised estimates of the Bureau of Agricultural Economics for numbers on Jan. 1.

[2] Values for 1867–1899 relate to "milk cows." Data for 1900–1925 are an old series of values of "milk cows" adjusted to relate to "milk cows and heifers, 2 years old and over" on basis of relationship between the 2 series from 1926 to 1928. Conversion factor was 0.955 (base is old series). Data for 1926–1931 are values relating to "milk cows and heifers 2 years old and over."

[3] Data for dairy cattle, including young animals and bulls of that type on farms and elsewhere as of Jan. 1, estimated by the Bureau of Animal Industry. Census figures for milk and dairy cows were adjusted to a Jan. 1 basis and to include all ages and all animals in towns, villages, and ranges, as well as on farms. For methods see Department Circular 241. Revisions have been made by the Bureau of Animal Industry for 1900–1927; 1928–1931 estimates of the Bureau of Agricultural Economics.

[4] Italic figures are from the census. Figures for census years 1850–1890 represent "milk cows"; 1900, "cows kept for milk 2 years and over"; 1910, "cows and heifers kept for milk, born before Jan. 1, 1909" (15½ months and over); 1920, "dairy cattle 2 years old and over kept mainly for milk production." For comparison with 1920 the number of dairy cows and heifers 2 years old and over on Jan. 1, 1910, has been estimated by the census as 17,125,471; 1925, number of cows milked. Census dates were June 1 from 1850 to 1900; Apr. 15, 1910; Jan. 1, 1920 and 1925.

[5] Preliminary.

Bureau of Agricultural Economics.

[1] Calculated by multiplying average daily production per cow by the number of days in the year. Daily production derived from milk production and milk cows reported on the 1st of each month for about 20,000 herds.

Bureau of Agricultural Economics. Compiled from reports made direct to the bureau.

NOTE.—These statistics were compiled from reports furnished voluntarily by more than 12,000 firms which manufacture dairy products. The 1929 statistics are the most complete of any year since these reports were inaugurated in 1918. Some allowance therefore should be made for this when comparing 1929 production with that of previous years. It is estimated that of the above quantities the following amounts of the major products are the result of more complete returns in 1929: Creamery butter, 50,000,000 pounds; American cheese (whole milk), 30,000,000 pounds; ice cream, 10,000,000 gallons.

TABLE 456.—*Fluid milk and fluid cream: Receipts at New York, by State of origin, 1927–1929, and by months, 1930*

Bureau of Agricultural Economics. Danish Butter Journal (Smor Tidende) official quotations. For earlier years, 1882–1913, see the United States Department of Agriculture Yearbook, 1923, p. 923.

Conversions from Danish quotations in ore per pound (1.1023 pounds) at par of exchange (100 ore=26.8 cents) to July, 1914; beginning July, 1914, to December, 1926, inclusive, from weekly quotations in kroner per 100 kg., at average monthly exchange rate as quoted by Federal Reserve Board. Beginning January, 1927, to date at par of exchange.

Bureau of Agricultural Economics. Compiled from reports made by cold-storage establishments.

[1] Quantities given are net weight.

[2] The term "American cheese" is intended to cover only those varieties known as twins, flats, daisies, Cheddars, longhorns, and square prints. It does not, therefore, include all kinds of cheese made in America.

Bureau of Agricultural Economics.

[1] Calculated by multiplying average daily layings per flock by the number of days in the year. Daily production derived from number of eggs laid on the first day of each month, as reported for about 22,000 farm flocks.

Bureau of Agricultural Economics. Prices 1910–1922 are averages of daily prices in New York Journal of Commerce, Price Current and Chicago Dairy Produce, Philadelphia Commercial List; average of weekly prices quoted in Boston Chamber of Commerce and Pacific Dairy Review. Beginning 1923, monthly prices from the Bureau of Labor Statistics, except San Francisco, which is from the Pacific Dairy Review. Earlier data are available in 1925 Yearbook, p. 1224, Table 636, and 1927 Yearbook, p. 1105.

Bureau of Agricultural Economics. This table supercedes Table No. 472 in the Yearbook of Agriculture, 1927; the value of total imports and exports has been given and the imports of "rubber and similar gums" have been deducted from "imports of forest products" and added to "imports, agricultural." Also reexports of "rubber and similar gums" have been deducted from "reexports of forest products" and added to "reexports, agricultural."

Does not include forest products.
Excess of exports.
[3] Excess of agricultural imports.
[4] Preliminary.

Bureau of Agricultural Economics. Compiled from Monthly Summary of Foreign Commerce of the United States, June issues, 1928 and 1930. In the statistics of foreign commerce of the United States, the Philippine Islands are treated as a foreign country. The statistics of foreign commerce include the trade of the customs districts of Alaska, Hawaii, and Porto Rico with foreign countries, but do not include the trade of these Territories with the United States.

Bureau of Agricultural Economics. Compiled from Foreign Commerce and Navigation of the United States, 1900–1918, and Monthly Summary of Foreign Commerce of the United States, June issues 1921–1930.
Conversion factors used: Corn meal, 1 barrel=4 bushels corn; oatmeal, 18 pounds=1 bushel oats; rye flour, 1 barrel=6 bushels rye; malt, 1.1 bushels=1 bushel barley; wheat flour, 1 barrel=1900–1908, 4.75 bushels grain; 1909–1917, 4.7 bushels; 1918 and 1919, 4.5 bushels; 1920, 4.6 bushels; 1921–1929, 4.7 bushels; apples, 3 boxes=1 barrel.

* Preliminary.
1 Includes canned, fresh, salted, or pickled pork, lard, neutral lard, lard oil, bacon, and hams.
2 Reported in value only.
3 Includes canned, cured, and fresh beef, oleo oil, oleo stock, oleomargarine, tallow, and stearin from animal fats.
4 Bales of 500 pounds gross; lint cotton and linters not separately reported prior to 1915.
5 Includes maple sugar, 1919–1929.
6 Includes barley flour 1919–1922. Barley flour not separately reported prior to 1919 nor since 1922.
7 Includes "Stems, trimmings, and scrap tobacco."
8 Included with "Starch" prior to 1918.
9 Given in value only prior to 1923.
10 Jan. 1 to June 30.

TABLE 506.—*Imports of selected agricultural products, averages 1899–1900 to 1908–9, annual 1908–9 to 1929–30*

Year beginning July	Butter	Cheese	Beef and veal, fresh	Cattle hides	Goatskins	Total hides and skins except furs	Silk [1]	Cotton, unmanufactured	Wool, unmanufactured, including mohair, etc.	Total, tobacco, unmanufactured

Bureau of Agricultural Economics. Compiled from Commerce and Navigation of the United States, 1900–1918, and Monthly Summary of Foreign Commerce, June issue, 1919–1930.

*Preliminary.
[1] Includes "Silk, raw or as reeled from cocoon," "Silk waste," and "Silk cocoons."
[2] Not separately classified.
[3] Reported in value only.
[4] 2-year average.
[5] 3-year average.
[6] Beginning Jan. 1, 1924.
[7] Conversion factors used: Almonds, 30 per cent unshelled equals shelled. Peanuts, 3 pounds unshelled equals 2 pounds shelled. Walnuts, 42 per cent unshelled equals shelled.
[8] Includes broken, or shredded, desiccated or prepared and copra.
[9] Included with "All other nuts."
[10] Beginning Sept. 22, 1922.
[11] July 1–Dec. 31, 1923.

[1] Pounds
[2] Total except hay.
[3] Trees tapped.
[4] Per tree.
[5] Includes some quantities not harvested.
[6] Production is the total for fresh fruit, juice, and raisins.
[7] Includes production used for canning or manufacture.

1930	85	112	137	99	122	119	113	107

Bureau of Agricultural Economics.

[1] These indexes are based on estimates of production for sale and for consumption in the farm home. Production fed to livestock or used for seed is not included. For example, instead of total production, only the amounts of cornand oats shipped out of county where grown and only a small percentage of the hay crops are included. The index of dairy products represents total milk production for all purposes. Production of meat animals is represented by total slaughter, including slaughter for farm use. Calendar-year production of livestock and livestock products are here compared with crop production of the same year. Each group index as well as the total is obtained by multiplying the yearly quantities by a 1919–1927 average farm price received by producers for each of the commodities, and the sum of these yearly values at average prices, divided by the corresponding average sum for the period 1919–1927, taken as 100. The following commodities included in the index contribute about 90 per cent of the gross income from agricultural production: Grains—wheat, corn, oats, barley, rye, buckwheat, kafir, rice; fruits and vegetables—grapes, apples, apricots, peaches, pears, cranberries, figs, grapefruit, lemons, olives, oranges, potatoes, sweetpotatoes, dry edible beans; truck crops—asparagus, snap beans, cabbage, cantaloupes, cauliflower, celery, cucumbers, lettuce, onions, peas, spinach, strawberries, tomatoes, watermelons; meat animals—cattle, calves, sheep, lambs, hogs; dairy products—milk, total production; poultry products—chickens and eggs; cotton and cottonseed; total includes also tobacco, wool, and hay.

Table 518.—*Acreage of 51 crops and value of 75 crops, by States, average 1924–1928, annual 1928–1930*

Bureau of Agricultural Economics. Estimates of the crop-reporting board.

[1] State figures have been rounded to thousands and do not necessarily add exactly to the division and United States totals shown. Values based upon Dec. 1 prices or seasonal prices to December and differ from prices used in Tables 512 and 516.

TABLE 519.—*Farm value, gross income, and cash income from farm production, average, 1924–1928 and 1929*

State	Farm value [1]				Gross income [2]			
	Crops		Livestock and livestock products		Crops		Livestock and livestock products	
	Average, 1924–1928	1929	Average, 1924–1928	1929	Average, 1924–1928	1929	Average, 1924–1928	1929
	1,000 dollars	*1,000 dollars*	*1,000 dollars*	*1,000 dollars*	*1,000 dollars*	*1,000 dollars*	*1,000 dollars*	*1,000 dollars*

Bureau of Agricultural Economics.

[1] Commodities included are those shown in Table 516. Estimated quantities produced by States, times weighted annual prices, by States.
[2] Estimated quantities sold and consumed in farm households, by States, times weighted annual prices by States.
[3] Includes $3,507,000 for sugar beets in "Other States."
[4] Includes $4,846,000 for sugar beets in "Other States."
[5] Estimated quantities sold, by States, times weighted annual prices, by States; gross income equals cash income plus value of quantities consumed in farm households, times weighted annual prices.

TABLE 520.—*Farm value, gross income, and cash income from farm production, United States, average 1924–1928 and 1929*

Product	Farm value		Gross income		Cash income	
	Average, 1924–1928	1929	Average, 1924–1928	1929	Average, 1924–1928	1929

Bureau of Agricultural Economics. Estimated quantities produced, sold, and consumed in farm households times weighted annual prices. Cash income plus value of commodities consumed in farm households equals gross incomes. For feed and seed crops, horses and mules, value include sales by farmers in some States eventually bought by farmers in other States. These interfarm sales tend to overestimate the total income from farm production for the country as a whole.

1929	11,851	2,951	1,231	490	681	920	6,273	5,578	882

Bureau of Agricultural Economics.

1 All of the operating costs except 7.5 per cent of total fertilizer costs, 9.5 per cent of feed, 10 per cent of binder twine, 15 per cent of ginning costs, and 20 per cent of repairs on buildings and insurance. These deductions are estimated as paid by nonfarmer landlords.

2 Estimates of cash wages and board, and 10 per cent allowance for perquisites and hired domestic labor contributing to production.

3 70 per cent of estimated total taxes on all farm real estate paid by operators, less 10 per cent to allow for taxes on farm dwellings.

4 Paid on all bank loans and on 90 per cent of total farm mortgage debt held by nonfarmers, 10 per cent of the total mortgage debt being assigned to farm dwellings.

5 Paid on 72 per cent of all rented farms to nonoperators.

6 Estimated number of farms January, 1925, 6,572,000, reduced by 15,000, the 1920–1925 rate of decline in number of farms.

TABLE 523.—*Current value of capital employed in agriculture and income available for capital and management as percentage of capital used in production, 1924–1929*

Year	Current value of—			Income available for capital and management			
	All agricultural capital [1]	All capital used in production [2]	Operators' capital used in production [2]	On all capital used in production [3]		On operators' capital used in production	
	Million dollars	*Million dollars*	*Million dollars*	*Million dollars*	*Per cent*	*Million dollars*	*Per cent*
1924	57,712	51,496	27,563	2,286	4.4	1,081	3.9
1925	56,931	50,771	27,255	2,502	4.9	1,206	4.4
1926	54,926	48,834	26,010	2,068	4.2	1,006	3.9
1927	54,659	48,624	26,124	2,210	4.5	1,072	4.1
1928	54,904	48,923	26,590	2,127	4.3	984	3.7
1929	54,074	48,141	26,119	2,200	4.6	1,055	4.0

Bureau of Agricultural Economics.

[1] As of Dec. 31. Includes lands, buildings, machinery, livestock, and 1 per cent cash working capital.

[2] All capital excluding value of dwellings. This total includes value of automobiles used for pleasure which probably offsets value of dwellings used for production.

[3] Income available for all capital, labor, and management, less wage allowance for labor of operators and families. Operators are here allowed an annual hired-hand wage without board, and family labor is taken as 22 per cent additional to the operators' labor. The value of the operators' labor is here understated in so far as hired hands receive perquisites in addition to cash and board, and it may be overstated in so far as the operators' time is not entirely spent on farm work.

Bureau of Agricultural Economics. Compiled from reports of individual farms operated by their owners. Division averages for 1922 in Agriculture Yearbook, 1924, pp. 1131–1132; for 1923–1924 in Agriculture Yearbook, 1925, pp. 1342–1343; for 1925 in Yearbook of Agriculture, 1927, pp. 1132–1133; for 1926 in Yearbook of Agriculture, 1928, pp. 1038–1039; for 1927 in Yearbook of Agriculture, 1930, pp. 972–973.

[2] Averages of farms for which the item was reported.

TABLE 526.—*Farm business studies: Summaries of 30,191 farm records from 336 localities in 25 States, 1924–1929*

This table presents some results, in terms of averages per farm, from most of the farm-business studies that have been made in the United States east of the Mississippi River from 1924 to 1929. The table is a supplement to Table 652, pp. 1285 to 1311, Agriculture Yearbook, 1925. Data prior to 1924 for a few localities were omitted from Table 652 (1925) and are included here. The data for 1924 in certain localities were published in Table 652 (1925) and those for other localities in this table.

The data presented were compiled from figures obtained directly from farmers, by the Bureau of Agricultural Economics, U. S. Department of Agriculture, by the State colleges of agriculture or agricultural experiment stations, or by the Bureau of Agricultural Economics cooperating with the State colleges of agriculture or the agricultural experiment stations. They include those obtained through research projects, extension projects, or joint research and extension projects, and whether obtained by the survey method, or from records or farm account books kept by farmers. In this table a larger percentage of the data are from records or farm account books kept by farmers than in Table 652 (1925).

EXPLANATION OF TERMS

Interpretation of the terms used in this table is essentially in accord with their use in Farmers' Bulletin No. 1139, A Method of Analyzing the Farm Business. They are briefly described as follows:

Year covered by study.—In many instances the year is not the calendar year, but the farm year as determined by the project leader. When not a calendar year, the year given is that in which the crops were usually harvested. Thus, 1929 may mean the calendar year 1929 or from Mar. 1, or Apr. 1, 1929, to Feb. 28 or Mar. 31, 1930. There has been a tendency in late years to make the farm year correspond to the calendar year.

Size of farms: Total.—The acreage of land operated as one farm, or unit. All, or practically all, of the area is operated by one set of machinery, horses, workmen, etc. The farm may consist of all-owned, all-rented, or both owned and rented land. When two or more farms are owned by the same person, or persons, but operated rather independently of each other, they are considered separate farms.

Size of farms: Crops.—The acreage in fruits, tilled, intertilled, and hay crops. Does not include pasture except annual crops when used as pasture. If more than one crop is grown on any of the land during the year, the acreage is counted but once in computing the acres in crops.

Capital: Total.—The value of all real estate, machinery, livestock, and other property used to carry on the year's business. It usually includes the value of the farm dwelling, but not of the household furnishings.

Capital: Real estate.—The value of the farm, including buildings, fences, and water supply.

Receipts.—Proceeds from the sale of crops produced during the farm year, the increase from livestock, and the receipts from work off the farm, rent of buildings, etc. The increase from livestock is found by subtracting the sum of the amount paid for livestock purchases and the inventory value at the beginning of the year from the sum of the receipts from livestock products, sales of livestock, and the inventory value at the end of the year. Receipts do not include the family living from the farm. Differences in method of calculating receipts and expenses employed in the original computations of the data for some of the studies have been eliminated in many instances when the data were assembled for this table. For the occasional study in which it was impracticable to eliminate these differences, receipts and expenses as shown may be slightly higher or lower than they should be in order to be strictly comparable with those for the other studies. In a table of this sort, where only averages for a study are given, these differences are rarely of more than minor significance as they affect the receipts and expenses, and there is no difference in the farm income.

Expenses.—Annual expenditures made in carrying on the farm business. They include depreciation on buildings and equipment, and the unpaid labor performed by members of the farm family, but do not include the farmer's own labor, or any household and personal expenses.

Farm income.—The difference between receipts and expenses. It does not include the family living from the farm.

Family income.—The farm income plus other unpaid family labor.

Labor income.—Farm income less 5 per cent interest charge for the use of the capital. It does not include the family living from the farm. In some of the studies, as originally published, other rates of interest were used. In certain localities the unpaid family labor was not obtained. In those localities with no entries for farm income, expenses, and labor incomes are not comparable with those in the other localities with entries for farm income. Had other unpaid family labor been obtained, expenses would have been higher and labor incomes lower than reported by the amount of this item. In these cases the figure carried in the labor-income column is family labor income, and not operator's labor income.

Return to capital.—The rate returned to the capital after the estimated value of the farmer's labor is deducted from the farm income. (See "Farmer's labor," below.)

Family living from the farm.—The food products set aside from the year's production, and the fuel, and house rent furnished by the farm for the living of the farm family. This is in addition to receipts, farm income, and labor income.

Operator's earnings.—Labor income plus family living from the farm.

Farmer's labor.—An allowance for the farmer's own labor and management at the rate he would have to pay another man to take his place. It does not include the family living from the farm.

Other unpaid family labor.—The unpaid family labor other than the labor of the farmer himself determined on the basis of what it would cost to have the same work done by hired labor, or on the amount of additional labor that would need to be hired to carry on the same sized business if the family labor had not been available.

Principal sources of receipts.—These are named in order of importance and in most instances include enough enterprises to amount to 75 per cent or more of the total receipts. Under this heading cotton includes sales of cottonseed; poultry includes sales of eggs; sheep includes lambs and wool; horses include mules and colts; work includes man, man and team, and machine work which the farmer did off the farm for hire; wood includes sales of timber, lumber, posts, firewood, etc. Cattle does not include sales of dairy products. In some instances receipts were grouped as crops, livestock, miscellaneous, and are not available in such detail of enterprises as just indicated.

Specific exceptions to the above explanations of terms are indicated by references to footnotes at end of the table.

Key.—The numbers indicate the agency which obtained the data, and the letters following the method used in obtaining the data, as follows:
1.—Bureau of Agricultural Economics, U. S. Department of Agriculture.
2.—State college of agriculture or agricultural experiment station.
3.—Bureau of Agricultural Economics, U. S. Department of Agriculture in cooperation with State college of agriculture or agricultural experiment station.
S—Farm business survey.
R—Records, or farm account books.
Thus a study with key 3R means the data were obtained by the Bureau of Agricultural Economics, U. S. Department of Agriculture, in cooperation with the State college of agriculture or agricultural experiment station, and they were taken from records or farm account books kept by the farmers.

[1] Does not include other unpaid family labor.
[2] Family-labor income.
[6] In all of the localities of Illinois expenses for feeds purchased have not been included in expenses but deducted from crop sales. Receipts and expenses therefore are lower for the localities in Illinois than for those in other States by the amounts of feeds purchased.

TABLE 526.—*Farm business studies: Summaries of 30,191 farm records from 336 localities in 25 States, 1924–1929*—Continued

State, county, locality	Key	Principal sources of receipts	Year covered by study	Farms included	Size of farms		Capital		Receipts	Expenses	Farm income	Family income	Labor income	Return to capital	Family living from the farm	Operator's earnings	Farmer's labor	Other unpaid family labor

Bureau of Agricultural Economics. From returns to mail inquiry sent to crop reporters. For figures by yield groups for 6 years, 1923–1928, see Agriculture Yearbooks, 1924, p. 1133; 1925, p. 1328; 1926, p. 1210; 1927, p. 1136; 1928, p. 1041; and 1930, p. 984. For figures by geographical divisions for 6 years, 1923–1928, see June issues of Monthly Supplement, Crops and Markets, 1924, p. 176; 1925, p. 180; 1926, p. 170; Crops and Markets, June issues, 1927, p. 202; 1928, p. 196; 1929, p. 202.

[1] The States included in the geographical divisions are as follows: North Atlantic—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, and Pennsylvania. South Atlantic—Delaware, Maryland, Virginia, West Virginia, North Carolina, South Carolina, Georgia, and Florida. East North Central—Ohio, Indiana, Illinois Michigan, and Wisconsin. West North Central—Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas. South Central—Kentucky, Tennessee, Alabama, Mississippi, Louisiana, Texas, Oklahoma, and Arkansas. Western—Montana, Wyoming, Colorado, New Mexico, Arizona, Utah, Nevada, Idaho, Washington, Oregon, and California.

[2] Includes miscellaneous labor, irrigating and water, and seed treatment and material.

[3] Sacks and twine, crop insurance, use of implements, use of storage buildings, and overhead.

[4] Winter-wheat belt as used here included Kansas, Nebraska, Missouri, and Oklahoma.

[5] Spring-wheat belt as used here includes western Minnesota, North Dakota, eastern South Dakota, and eastern Montana.

TABLE 528.—*Corn: Cost of production by yield groups and geographical divisions, 1929*

Bureau of Agricultural Economics. From returns to mail inquiry sent to crop reporters. For figures by yield groups for 6 years, 1923–1928, see Agriculture Yearbooks, 1924, p. 1135; 1925, p. 1332; 1926, p. 1213; 1927, p. 1139; 1928, p. 1044; and 1930, p. 985. For figures by geographical divisions for 6 years, 1923–1928, see June issues of Monthly Supplement, Crops and Markets, 1924, p. 176; 1925, p. 180; 1926, p. 170; Crops and Markets, June issues, 1927, p. 202; 1928, p. 196; and 1929, p. 202.

[1] The States included in the geographical divisions are as follows: North Atlantic—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, and Pennsylvania. South Atlantic—Delaware, Maryland, Virginia, West Virginia, North Carolina, South Carolina, Georgia, and Florida. East North Central—Ohio, Indiana, Illinois, Michigan, and Wisconsin. West North Central—Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas. South Central—Kentucky, Tennessee, Alabama, Mississippi, Louisiana, Texas, Oklahoma, and Arkansas. Western—Montana, Wyoming, Colorado, New Mexico, Arizona, Utah, Nevada, Idaho, Washington, Oregon, and California.

[2] Includes miscellaneous labor, irrigating and water, and seed treatment and material.

[3] Sacks and twine, crop insurance, use of implements, use of storage buildings, and overhead.

[4] Corn Belt as used here includes Indiana, Illinois, Iowa, western Ohio, southeast corner of South Dakota, eastern Nebraska, northeast corner of Kansas, and the northern three-fourths of Missouri.

Bureau of Agricultural Economics. From returns to mail inquiry sent to crop reporters. For figures by yield groups for 6 years, 1923–1928, see Agriculture Yearbooks, 1924, p. 1137; 1925, p. 1335; 1926, p. 1217; 1927, p. 1143; 1928, p. 1048; and 1930, p. 986. For figures by geographical divisions for 6 years, 1923–1928, see June issues of Monthly Supplement, Crops and Markets, 1924, p. 176; 1925, p. 180; 1926, p. 170; Crops and Markets, June issues, 1927, p. 202; 1928, p. 196; 1929, p. 202.

[1] The States included in the geographical divisions are as follows: North Atlantic—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, and Pennsylvania. South Atlantic—Delaware, Maryland, Virginia, West Virginia, North Carolina, South Carolina, Georgia, and Florida. East North Central—Ohio, Indiana, Illinois, Michigan, and Wisconsin. West North Central—Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas. South Central—Kentucky, Tennessee, Alabama, Mississippi, Louisiana, Texas, Oklahoma, and Arkansas. Western—Montana, Wyoming, Colorado, New Mexico, Arizona, Utah, Nevada, Idaho, Washington, Oregon, and California.

[2] Includes miscellaneous labor, irrigating and water, and seed treatment and material.

[3] Sacks and twine, crop insurance, use of implements, use of storage buildings, and overhead.

Bureau of Agricultural Economics. From returns to mail inquiry sent to crop reporters.

[1] The average yield of lint cotton in the United States has been as follows: 1924, 157.4 pounds; 1925, 167.2 pounds; 1926, 182.6 pounds; 1927, 154.5 pounds; 1928, 152.9 pounds; 1929, 155.0 pounds.
[2] The average cost per pound for the yield groups which closely approximated the average yields for the United States are as follows: 1924, 18 cents; 1925, 18 cents; 1926, 15.5 cents; 1927, 17 cents; 1928, 17 cents; 1929, 16 cents. At least a part of the yearly variations in costs in some of the upper and lower yield groups may be due to the small number of reports, and to the relative number of reports received each year from various sections of the Cotton Belt.

TABLE 532.—*Cost of producing wheat, corn, and oats, 1924–1929*

Bureau of Agricultural Economics. Prices of farm production received by producers collected monthly from a list of about 12,000 special price reporters. This list is made up almost entirely of country-town dealers, elevator managers, buyers, and merchants.

The commodities by groups are as follows: Grains—wheat, corn, oats, barley, rye, kafir; fruits and vegetables—apples, oranges, grapefruit, potatoes, sweetpotatoes, beans, onions, cabbage; meat animals—beef cattle, calves, hogs, sheep, lambs; dairy products—butter (represents butter, butterfat, and cream), milk; poultry products—chickens, eggs; cotton and cottonseed; all groups includes also horses (represents horses and mules), hay, flax, tobacco, and wool.

[3] Kafir, onions, and cabbage omitted.

Bureau of Agricultural Economics. Compiled from prices reported to the Department of Agriculture by retail dealers throughout the United States. The index numbers include only commodities bought by farmers; the commodities being weighted according to purchases reported by actual farmers in farm management and rural-life studies from 1920 to 1925.

[1] 1912-1914=100.

[2] Includes food, clothing, household operating expenses, furniture and furnishing, and building material for house.

[3] 1914=100.

TABLE 536.—*Index numbers of general trend of prices and wages 1910–1930*

[1910-1914=100]

Bureau of Agricultural Economics. Average tax per acre in 1924 based on the 1925 Census of Agriculture. Trends in the United States as a whole and in each geographic division since 1924 are based on weighted averages of replies to questionnaires sent each year to farmers in all parts of the country.

Bureau of Agricultural Economics.

[1] Yearly averages are from reports by crop reporters, giving average wages for the year in their localities.
[2] This column has significance only as an essential step in computing the wage index.
[3] Years 1866 to 1878 in gold.
[4] 1877 or 1878, 1878 or 1879 (combined).
[5] Weighted average of quarterly reports, April (weight 1), July (weight 5), October (weight 5), and January of the following year (weight 1).

Bureau of Agricultural Economics. Based on values as reported by crop reporters. Values as reported by the census for 1910, 1920, and 1925 will be found in Table 511 of the 1927 Yearbook.

[1] All farm land with improvements, as of Mar. 1. Owing to rounding of figures, 1912–1914 will not always equal exactly 100 per cent.

TABLE 541.—*Number of farms per 1,000 changing ownership by various methods, by States and geographic divisions, 12 months ended March 15, 1927–1930*

Geographic division and State	Voluntary sales and trades [1]				Forced sales and related defaults												Inheritance and gift				Administrators' and executors' sales [3]				Miscellaneous and unclassified				Total, all classes			
					Delinquent taxes				Foreclosure of mortgages, bankruptcy, etc. [2]				Total

Bureau of Agricultural Economics. Compiled from the Bureau of the Census figures. Owing to a change in the instructions to the census enumerators in connection with farm population, it appears that a large number of small farms, mostly only those requiring a part of the farmer's time, which had been included in 1925, and a lesser number included in 1920, were omitted in 1930.

[1] Preliminary. [2] Less than 0.1 per cent.

1931	27, 430				

[1] Estimated.
[2] Net loss equals number of persons leaving farms for cities plus deaths on farms, minus the number of persons going to farms from cities plus births.
[3] From census enumerations.
[4] Estimated, Census Bureau.
[5] Estimated by distributing decrease in farm population Jan. 1, 1920, to Jan. 1, 1925, evenly, by years.
[6] Not estimated.
[7] Net gain in farm population during 1930, the first gain reported during the entire period.

TABLE 547.—*Rural and farm population, percentage of total population gainfully employed in agriculture, and percentage of total in stated years*

Census year	Percentage of population			Percentage gainfully employed in agriculture
	"Rural" outside of places 8,000 or more	"Rural" outside of places 2,500 or more	On farms	
1820	95.1			83.1

	Total		183, 975, 930	23, 885, 113	160, 090, 817

REGIONAL HEADQUARTERS

Region 1.—Northern region: Office, Federal Building, Missoula, Mont. Embracing Montana, northeastern Washington, northern Idaho, and northwestern South Dakota.

Region 2.—Rocky Mountain region: Office, Federal Building, Denver, Colo. Embracing Colorado, eastern Wyoming, South Dakota, Nebraska, and western Oklahoma.

Region 3.—Southwestern region: Office, Gas and Electric Building, Albuquerque, N. Mex. Embracing Arizona and New Mexico.

Region 4.—Intermountain region: Office, Forest Service Building, Ogden, Utah. Embracing Utah, southern Idaho, western Wyoming, Nevada, and northwestern Arizona.

Region 5.—California region: Office, Ferry Building, San Francisco, Calif. Embracing California and southwestern Nevada.

Region 6.—North Pacific region: Office, Post Office Building, Portland, Oreg. Embracing Washington and Oregon.

Region 7.—Eastern region: Office, Atlantic Building, Washington, D. C. Embracing Alabama, Arkansas, Florida, Georgia, Louisiana, Maine, New Hampshire, North Carolina, Pennsylvania, Porto Rico, South Carolina, Tennessee, Virginia, and West Virginia.

Region 8.—Alaska region: Office, Goldstein Building, Juneau, Alaska. Located in Alaska.

Region 9.—Lake States region: Office, Customs Service Building, Milwaukee, Wis. Embracing Illinois, Michigan, Minnesota, and Wisconsin.

TABLE 554.—*National forest areas*—Continued

NATIONAL MONUMENTS

The following national monuments situated within national forests and administered by the Department of Agriculture have been created under the act of June 8, 1906 (34 Stat. 225), for the perservation of objects of historic or scientific interest:

Name	National forest	State	Area	Latest change in boundary
			Acres	
Bandelier	Santa Fe	New Mexico	22,075	Feb. 11, 1916
Chiricahua	Coronado	Arizona	4,480	Apr. 18, 1924
Devil Postpile	Sierra	California	800	July 6, 1911
Gila Cliff Dwellings	Gila	New Mexico	160	Nov. 16, 1907
Holy Cross	Holy Cross	Colorado	1,392	May 11, 1929
Jewel Cave	Harney	South Dakota	1,280	Feb. 7, 1908
Lava Beds	Modoc	California	45,967	Nov. 21, 1925
Lehman Caves	Nevada	Nevada	593	Jan. 24, 1922
Mount Olympus	Olympic	Washington	298,730	Jan. 7, 1929
Old Kasaan	Tongass	Alaska	38	Oct. 25, 1916
Oregon Caves	Siskiyou	Oregon	480	July 12, 1909
Sunset Crater	Coconino	Arizona	3,040	May 26, 1930
Timpanogos Cave	Wasatch	Utah	250	Oct. 14, 1922
Tonto	Tonto	Arizona	640	Dec. 19, 1907
Walnut Canyon	Coconino	do	960	Nov. 30, 1915
Wheeler	Cochetopa Rio Grande	Colorado	300	Dec. 7, 1908
Total area			381,185	

NATIONAL GAME REFUGES

The following national refuges situated wholly or in part within national forests have been designated under special act of Congress for the protection of game:

Name	National forest	State	Area	Latest change in boundary
			Acres	
Cherokee National Game Refuge No. 1	Cherokee	Tennessee	30,000	Aug. 5, 1924
Cherokee National Game Refuge No. 2	do	Georgia	14,000	Do.
Custer State Park Game Sanctuary	Harney	South Dakota	44,840	Jan. 14, 1929
Grand Canyon	Tusayan Kaibab	Arizona	792,163	Feb. 26, 1919
Ozark National Game Refuge No. 1	Ozark	Arkansas	8,420	Apr. 26, 1926
Ozark National Game Refuge No. 2	do	do	5,300	Do.
Ozark National Game Refuge No. 3	do	do	3,620	Do.
Ozark National Game Refuge No. 4	do	do	4,160	Do.
Pisgah	Pisgah	North Carolina	98,381	Oct. 17, 1916
Sequoia	Sequoia	California	15,770	July 3, 1926
Sheep Mountain	Medicine Bow	Wyoming	28,318	Aug. 8, 1924
Tahquitz	San Bernardino	California	27,573	July 3, 1926
Wichita	Wichita	Oklahoma	60,800	June 2, 1905

The following national forests, or parts of national forests, established under section 9 of the Clarke-McNary Act of June 7, 1924 (43 Stat. 653), were on July 1, 1925, designated game refuges by the acting Secretaries of War and Agriculture:

National forest	State	Area
		Acres
Black Hills (Meade district)	South Dakota	5,548
Manzano (Zuni district)	New Mexico	45,515
Medicine Bow (Pole Mountain district)	Wyoming	56,132
Michigan (Brady district)	Michigan	2,680

RANGE RESERVES

The following reserves have been established by Executive order for use by the Forest Service in conducting studies of grazing and range management:

Name	State	Area	Latest change in boundary
		Acres	
Jornada	New Mexico	193,686	July 10, 1925
Santa Rita	Arizona	52,399	Mar. 2, 1927

Forest Service.

TABLE 555.—*Lumber consumption, per capita census years* [1]

Year	Per capita consumption	Year	Apparent per capita consumption
	Feet b. m.		*Feet b. m.*
1809	55	1904	505
1819	55	1909	475
1829	65	1914	400
1839	95	1919	325
1849	235	1924	310
1859	260	1925	325
1869	340	1926	305
1879	365	1927	280
1889	435	1928	270
1899	460	1929	290

Forest Service.

[1] This table takes into account the exports and imports of lumber, but not the increases and decreases of mill and yard stocks.

TABLE 556.—*Lumber consumption of softwoods and hardwoods per capita, 1928*

State	Per capita consumption	State	Per capita consumption	State	Per capita consumption
	Feet b. m.		*Feet b. m.*		*Feet b. m.*
Alabama	205	Maine	330	Oklahoma	190

Forest Service in cooperation with the Bureau of the Census.

TABLE 557.—*Lumber used in manufacture, 1928* [1]

BY STATES AND REGIONS

	Quantity		Quantity		Quantity
State and region:	*1,000 ft. b. m.*	State and region—Continued.	*1,000 ft. b. m.*	State and region—Continued.	*1,000 ft. b. m.*
Alabama	417,556	Missouri	275,675	West Virginia	115,746
Arizona	33,284	Montana	100,011	Wisconsin	695,029
Arkansas	459,865	Nebraska	46,881	Wyoming	2,477
California	1,385,822	Nevada	6,836		
Colorado	64,918	New Hampshire	189,869	All States	18,698,440
Connecticut	68,169	New Jersey	237,197		
Delaware	35,888	New Mexico	59,291	Regional summary:	
District of Columbia	4,385	New York	817,284	New England	1,002,870
Florida	266,316	North Carolina	690,607	Middle Atlantic	1,888,278
Georgia	427,190	North Dakota	3,286	Lake States	2,229,495
Idaho	297,087	Ohio	560,592	Central hardwood	3,057,192
Illinois	784,534	Oklahoma	72,806	North Carolina pine	1,439,566
Indiana	561,128	Oregon	1,338,179	Southern pine	3,381,939
Iowa	220,388	Pennsylvania	632,049	Pacific (north)	3,385,273
Kansas	62,154	Rhode Island	22,547	Pacific (south)	1,392,658
Kentucky	245,486	South Carolina	271,162	Rocky Mountain (north)	397,098
Louisiana	648,970	South Dakota	21,508		
Maine	219,575	Tennessee	514,031	Rocky Mountain (south)	169,854
Maryland	161,475	Texas	444,902		
Massachusetts	414,202	Utah	9,884	Prairie	354,217
Michigan	1,252,627	Vermont	88,508		
Minnesota	281,839	Virginia	477,797	All regions	18,698,440
Mississippi	644,334	Washington	2,047,094		

[1] In addition to lumber the amounts given in this table include also 2 other classes of raw material quantities for which have been converted into board feet; bolts and logs comprise 3 per cent and veneer and ply wood 2 per cent of the total.

TABLE 557.—*Lumber used in manufacture, 1928*—Continued

BY INDUSTRIES

Industry	Quantity	Industry	Quantity
	1,000 ft. b. m.		*1,000 ft. b. m.*
Airplanes	9,044	Matches	115,943
Agricultural implements	142,943	Toothpicks	7,483
Artificial limbs	698	Mine equipment	22
Boot and shoe findings	48,742	Motion picture and theatrical scenery	16,223
Baskets and fruit packages	261,530	Patterns and flasks	29,996
Boxes and crates	4,719,700	Paving material and conduits	3,350
Boxes, cigar and tobacco	38,429	Pencils and penholders	39,982
Brooms and carpet sweepers	28,452	Pipes, tobacco	1,411
Brushes	17,033	Planing-mill products	[2] 5,063,583
Bungs and faucets	2,980	Plumbers' woodwork	16,273
Butcher's blocks and skewers	4,888	Printing material	5,984
Car construction and repair	1,009,408	Pulleys and conveyors	900
Caskets and coffins	156,108	Pumps and wood pipe	10,831
Chairs and chair stock	165,392	Refrigerators and kitchen cabinets	145,745
Clocks	3,511	Rollers, shade and map	24,236
Dairymen's, poulterers' and apiarists' supplies	41,037	Saddles and harness	751
Woodenware and novelties	142,299	Sash, doors, blinds, and general millwork	3,317,346
Dowels	15,087	Sewing machines	12,760
Elevators	46	Ship and boat building	128,342
Equipment, playground	4,672	Shuttles, spools, and bobbins	44,022
Firearms	1,741	Signs and supplies	48,597
Fixtures	130,030	Sporting and athletic goods	29,973
Frames and molding, picture	20,947	Tanks and silos	66,328
Furniture	1,198,612	Toys	39,410
Gates and fencing	1,572	Trunks and valises	21,346
Handles	124,654	Vehicles (nonmotor)	80,841
Instruments, professional and scientific	15,510	Vehicles (motor)	867,875
Instruments, musical	107,502	Weighing apparatus	19
Laundry appliances	38,674	Whips, canes, and umbrella sticks	1,250
Machine construction	39,627		
Machinery and apparatus, electrical	66,750	All industries	18,698,440

[2] "Planing-mill products" includes products worked to pattern, such as flooring, ceiling, and siding, but excludes lumber merely dressed.

BY KINDS OF WOOD

Kind of wood	Quantity	Kind of wood	Quantity	Kind of wood	Quantity
	1,000 ft. b. m.		*1,000 ft. b. m.*		*1,000 ft. b. m.*
Cedar, eastern red	31,600	Cottonwood	182,309	Cedar, Spanish	6,964
Cedar, eastern white	11,206	Dogwood	3,414	Cocobola	542
Cedar, western	204,835	Elm	166,136	Ebony	175
Cypress	279,276	Hackberry	4,559	Eucalyptus	311
Douglas fir	2,547,429	Hickory	145,720	Hazel	18
True firs	72,598	Holly	32	Khaya ("African mahogany")	1,852
Hemlock	575,124	Hornbeam	65	Laurel	75
Larch	34,646	Locust	9,273	Lignum-vitæ	709
Pine, southern yellow	4,708,833	Maple	752,371	Mahogany	63,305
Pine, western yellow	[3] 2,109,344	Myrtle	70	Oak, Japanese or English	155
Pine, white	[4] 1,407,092	Oak	1,408,756	Padouk	22
Redwood	145,920	Osage-orange	20	Philippine hardwoods	24,341
Spruce	503,097	Pecan	2,523	Prima vera	31
Yew	2	Persimmon	2,158	Rakuda	25
Miscellaneous native softwoods	30	Red (and sap) gum	1,226,285	Rosewood	521
Alder	18,358	Sycamore	37,477	Satinwood	61
Apple	60	Tupelo	255,723	Snakewood	103
Ash	179,979	Walnut	78,210	Teak	1,297
Basswood	163,324	Willow	7,170	Walnut, Circassian	224
Beech	148,387	Yellow poplar	[5] 450,549	Miscellaneous foreign woods	2,084
Birch	515,230	Miscellaneous native hardwoods	920		
Buckeye	2,357	Balsa	306	All woods	18,698,440
Butternut	372	Beech, European	10		
Cherry	7,255	Box, Turkish	129		
Chestnut	194,664	Box, West Indian	422		

Forest Service in cooperation with the Bureau of the Census.

[3] Includes lodgepole pine.
[4] White pine includes northern white pine, western white pine (often called Idaho white pine), sugar pine, and Norway pine.
[5] Yellow poplar includes also cucumber and magnolia.

Prairie	[11] 408, 036	[11] 179, 024	64, 808	[11] 63, 283	[11] 63, 891	[11] 67, 875	[11] 81, 458

Forest Service in cooperation with Bureau of the Census.

[1] Includes cut of Nevada.
[2] Included in "All other."
[3] Included with California.
[4] Includes cut of North Dakota.
[5] Reported as cut of Alaska.
[6] Includes cut of Nebraska and Nevada.
[7] Includes both merchant and custom sawing.
[8] Includes 2,655 mills cutting less than 50,000 feet each per year.
[9] Mills cutting less than 50,000 feet each year excluded.
[10] Excludes custom mills.
[11] Includes "All other."

TABLE 559.—*Average value of lumber at the mill per thousand feet board measure, in stated years*

Kind of wood	1899	1909	1919	1927	1928
Softwoods:	*Dollars*	*Dollars*	*Dollars*	*Dollars*	*Dollars*

Bureau of the Census in cooperation with the Forest Service. Cords of 128 cubic feet. Tons of 2,000 pounds.

1 Includes Washington.
2 Included with Oregon.
3 Included in "All other States."
4 Includes California.
5 Included with California.

TABLE 561.—*Pulpwood consumption, by kinds, 1909, 1919, and 1929*

Kind of wood	1909	1919	1929 [1]
	Cords	*Cords*	*Cords*
Spruce:			
Domestic	1, 653, 249	2, 313, 419	2, 038, 500
Imported	768, 332	873, 795	1, 023, 200
Hemlock:			
Domestic	559, 657	795, 154	122, 600
Imported			15, 400
Pine:			
Southern yellow pine	(2)	234, 463	1, 016, 800
Jack pine	(2)	51, 581	194, 600
Miscellaneous pines	90, 885	7, 566	
Poplar:			
Domestic	302, 876	180, 160	334, 600
Imported	25, 622	158, 220	157, 800
Balsam fir:			
Domestic	95. 366	181, 840	316, 500
Imported		106, 974	45, 400
Yellow poplar		72, 605	129, 700
White fir	37, 176	31, 138	77, 900
Beech, birch, and maple	31, 390	[3] 183, 426	77, 000
Gum		30, 355	39, 700
Tamarack (larch)		44, 042	51, 800
Other wood	188, 077	38, 013	147, 100
Slabs and mill waste	248, 977	175, 081	548, 800
Total	4, 001, 607	5, 477, 832	7, 437, 400

Bureau of the Census in cooperation with the Forest Service. Cords of 128 cubic feet.

[1] Preliminary figures as of Dec. 31, 1930. [2] Included in "Miscellaneous pines." [3] Includes chestnut.

Forest Service. A computed table based on census and Forest Service bulletins.

[1] Imports added to United States production and domestic exports deducted.
[2] Domestic production only, value of exports and imports being approximately equal.
[3] Preliminary, based on figures in report of the Bureau of the Census released Feb. 2, 1931.

Forest Service, with cooperation by the Bureau of the Census.

[1] Northern white pine in States east of the Great Plains. In Lake and Northeastern States may include some Norway pine. Western white pine in Idaho and Washington. Sugar pine in Oregon and California.

[2] Includes all sales of southern pines. Virgin long-leaf in large quantities may sell for $12 or more.

[3] Balsam fir in Eastern States; white fir in Western States.

[4] Red, black, and white spruce in Eastern States; Sitka spruce in Oregon and Washington; Engelmann spruce in Idaho.

[5] Eastern and western hemlock, for Eastern and Western States, respectively.

[6] Northern white cedar in Maine and Michigan; Port Orford cedar in Oregon; western red cedar in other States.

[7] Includes aspen.

Forest Service with cooperation by Bureau of the Census. Log prices were not compiled for Oregon, Washington, Idaho, and Montana in 1928.

[1] Sugar pine in California. Northern white pine, which may include some Norway pine, in other States.
[2] Includes all sales of southern pines.
[3] White fir in California; balsam fir in other States.
[4] Western red cedar in California; eastern red cedar in Alabama, Florida, Kentucky, South Carolina, and Tennessee; northern white in other States.
[5] Includes aspen.

TABLE 567.—*Turpentine and rosin: Industrial consumption, calendar years 1927–1929*

Industry	Turpentine			Rosin		
	1927	1928	1929	1927	1928	1929
	Gallons	*Gallons*	*Gallons*	*500-pound barrels*	*500-pound barrels*	*500-pound barrels*
Automobiles and wagons	242,022	158,901	100,815	1,029	1,214	2,797

Bureau of Biological Survey.

[1] Includes amounts received from combined hunting and fishing licenses, but not from licenses to fish only.
[2] No resident license required.
[3] Combined hunting and fishing license.
[4] Totals are exclusive of Mississippi, for which figures are not available, and include figures for combined hunting and fishing licenses, which for many States can not be separated, many such licenses being taken out by anglers only.

Bureau of Public Roads.

[1] Initial Federal-aid construction refers to projects which are being improved with Federal aid for the first time. Such projects may or may not have been previously improved.

[2] The term "stage construction" refers to additional work done on projects previously improved with Federal aid. In general, such additional work consists of the construction of a surface of higher type than was provided in the initial improvement.

[3] Includes apportionment of $125,000,000 for fiscal year 1931 but does not include apportionment of funds for fiscal year 1932 which have since been apportioned.

TABLE 570.—*Federal-aid highway system: Mileage, Federal-aid apportionment for fiscal year 1932, and total apportionment for years 1917 to 1932, inclusive*

State	Mileage in approved system June 30, 1930 [1]	Apportionment for fiscal year 1932	Aggregate of apportionments for fiscal years 1917 to 1932, inclusive

Sulphur produced	2, 111, 618	1, 981, 873	2, 362, 389	----------	----------	----------
Sulphur sold[1]	2, 072, 109	2, 082, 924	2, 437, 238	[5] 38, 300, 000	[5] 37, 500, 000	[5] 43, 800, 000
Pyrites produced	215, 786	182, 049	333, 465	804, 006	605, 459	1, 250, 141

Bureau of Agricultural Economics. Compiled from annual reports of the Bureau of Mines. Figures for earlier years appear in previous issues of the Yearbook.

[1] Sold by producers.
[2] Sold or used by producers.
[3] Idaho and Wyoming.
[4] Idaho, Wyoming, and Montana.
[5] Approximate.

TABLE 582.—*Fertilizer and fertilizer materials. Production, consumption, imports, and exports, United States, 1925–1929*

Item	Calendar year 1925	1926	1927	1928	1929[1]
Sulphate of ammonia (equivalent of all forms):	*Short tons*	*Short tons*	*Short tons*	*Short tons*	*Short tons*
Production[2]	639, 019	690, 976	717, 460	798, 887	884, 306
Sales[2]	604, 457	682, 967	741, 866	764, 355	----------
Imports for consumption	26, 613	9, 392	19, 211	42, 133	21, 338
Exports	137, 918	202, 860	155, 335	104, 177	162, 133
Nitrate of soda, imports for consumption	1, 245, 693	1, 024, 009	838, 636	1, 156, 860	1, 042, 113
Sulphuric acid:					
Production[3]	1, 979, 292	1, 745, 759	1, 656, 871	2, 126, 860	2, 166, 892
Imports for consumption	18, 191	27, 969	17, 434	13, 164	8, 104
Exports	3, 769	4, 612	3, 756	3, 500	3, 480
Consumption[3]	1, 316, 316	2, 058, 683	2, 137, 129	2, 440, 121	2, 418, 851
Superphosphate:					
Production[3 4]	3, 846, 401	3, 799, 054	[5] 3, 699, 579	4, 472, 341	4, 294, 967
Sales[3 6]	3, 550, 762	3, 536, 552	1, 915, 913	1, 283, 732	1, 380, 565
Potash:					
Production, domestic	51, 565	46, 324	76, 819	104, 129	107, 820
Sales, domestic	52, 823	51, 369	94, 722	105, 208	101, 370
Imports for consumption:					
Kainit	204, 767	203, 702	115, 345	119, 897	85, 042
Manure salts	430, 340	354, 413	311, 357	453, 242	437, 728
Muriate of potash	180, 351	223, 049	183, 475	261, 644	258, 682
Sulphate of potash	77, 226	78, 258	77, 172	96, 833	89, 051
Other potash-bearing substances[7]	29, 002	52, 357	10, 531	12, 076	706
Total imports for consumption	921, 686	911, 779	697, 880	943, 692	871, 209

Bureau of Agricultural Economics. Compiled from annual reports of the Bureau of the Census, Bureau of Foreign and Domestic Commerce, and the Bureau of Mines.

[1] Subject to revision.
[2] By-product of coke ovens: Production from other sources (coal, gas, bone carbonizing, etc.) accounted for less than 5 per cent of the total production for these years.
[3] Fertilizer establishments only.
[4] Bulk superphosphate and superphosphate for mixed fertilizers.
[5] Bulk superphosphate.
[6] Quantity sold as superphosphate or used in manufactured goods sold.
[7] Includes ashes (wood) beet root, other potash-bearing substances (alunite, leucite, etc.) used for fertilizer.

TABLE 583.—*Inorganic nitrogeneous materials: Production and imports, United States, 1901–1929*

Year	Production			Imports								
	By-product ammonia	Air nitrogen (estimated)	Total	Chilean nitrate	Ammonium sulfate	Cyanamide	Calcium nitrate	Ammonium chloride	Ammonium nitrate	Sodium cyanide	Ammonium sulphate-nitrate	Total nitrogen

1929 [3]	122, 066	20, 318	142, 384	1. 172	1. 246	1. 073

Bureau of Agricultural Economics. Compiled from December issues of Monthly Summary of Foreign Commerce of United States prior to 1918. Subsequent years are from annual issues of Commerce and Navigation of United States Department of Commerce. Production figures are from Yearbook of the Department of Commerce. Prices are from bulletins of the United States Bureau of Labor Statistics.

[1] Net imports are imports minus reexports, years 1911 through 1924; and imports minus exports and reexports, 1925–1929.
[2] The count indicates the number of deniers or one-half decigram units, in weight, of a standard length of 450 meters. Since the standard is based on an arbitrary fixed length and a variable weight, the finer the yarn the smaller the count; 150 denier count, a size commonly used, is fine and 300 denier count is coarse.
[3] Preliminary.
