No. 1

THE FIFTY-FOURTH CONVENTION OF THE ASSOCIATION OF LAND-GRANT COLLEGES AND UNIVERSITIES

Democracy and agriculture, participation in the national defense program, inter-American relations, problems of rural youth, the preservation of institutional integrity and responsibility, training for public service, and the need for further development of home economics were the dominant themes of the 1940 convention. In their selection the association again revealed itself as alert and responsive to the needs of the hour. The topics were considered sympathetically and constructively. The result was a convention which rose above routine proceedings to provide much information and inspiration to the representative gathering of several hundred delegates and visitors in attendance.

Traditionally, these annual conventions afford a unique opportunity to visualize the current trends and problems of American agricultural education and research. Primarily, of course, they are held for the transaction of the association's business, and since under the system in vogue preliminary consideration of many business matters by subordinate groups as well as their final disposition by the executive body has been taking place increasingly behind closed doors, much goes on as to which the general public may go away somewhat unevenly informed. Nevertheless there still remains available, if not the comparatively complete picture obtainable in the earlier days, an extensive program of addresses and discussions which includes most of the urgent problems with which the land-grant institutions are confronted.

The convention was held in Chicago from November 11 to 13, 1940. Following recent practice, it was preceded by 3 days of pre-convention sessions of subsections and committees. In these sessions much preparation and consideration of committee reports was accomplished, and among the results were a speeding up of convention business and an appreciable absence of congestion in both general and sectional sessions.

The opening address of the convention was that of its president, President F. D. Farrell of Kansas. Taking as his subject *Lest We Forget*, President Farrell briefly reviewed the accomplishments of the constituent land-grant institutions, which collectively now enroll over

250,000 students each year, carry on one of the world's largest research programs, and reach millions of farms and farm homes in extension work. He attributed their outstanding influence and popularity to their usefulness, and this in turn to their adherence to such fundamental principles as the judicious blending of practical and liberal elements in their curriculum and their demonstration in both peace and war of the feasibility of joint action of State and Federal agencies in research and education. The land-grant institutions, he maintained, are not and never should be "policemen, promoters, or propagandists," but should restrict their service to research and education.

The subject of the address of the Secretary of Agriculture, Hon. Claude R. Wickard, was Democracy: Think It, Strengthen It, Work at It. In this address, Secretary Wickard called attention to the work of the land-grant colleges in cooperation with the Department in helping farmers to set up discussion groups, and announced his plan to call a conference to develop ways and means for furthering the use by thousands of such groups and 4-H Clubs of educational materials on democracy which are expected to be available. He pointed out that "the weakest sectors of democracy on the agricultural front are in the low-income groups. . . . There must be productive work for these people to do, and they must be . . . rewarded fairly for doing it. Starting at rock bottom, one kind of work for them to do is obviously to produce a better supply of food for their own families and more of their own clothing and shelter and simple equipment with their own hands. Helping them to develop this sort of work is a job that our science and our education has shirked. We need research that will develop the types of vegetables and fruit and feed crops which will do best for the low-income farm family using part of its working hours in producing its own food. . . . A basic thing that could be done and isn't now being done is the revamping of our research and educational and action programs to give them guidance in good subsistence farming and good homemaking and good handicraft work."

The theme of national defense was developed by several speakers and from several angles. Thus, Mr. Emmett F. Connely, president of the Investment Bankers' Association of America, argued for the desirability of retaining as much as possible of the existing business structure and the preservation of private initiative even in a defense program, particularly as regards methods of financing. On the other hand, Mr. Chester C. Davis, Commissioner of Agriculture in the National Defense Advisory Commission, predicted that, regardless of the outcome of the struggle in the Eastern Hemisphere, the entire world of the future will be far different, and that in the inevitable readjustments capital, labor, and agriculture must make substantial

concessions and adopt a constructive attitude based on the general welfare of the Nation. He counseled a restudy of agricultural research and extension projects in the light of the new conditions.

Specific contributions to the defense programs were outlined for education by Dr. F. J. Kelly of the Office of Education, substituting for Commissioner J. W. Studebaker. Dr. Kelly described the Federal legislation of October 9, 1940, making available \$60,500,000 for defense vocational training. This legislation supplemented a grant of \$15,000,000 in June for vocational education of less than college grade, under which about 130,000 students were enrolled and 75,000 had already completed short training courses in mechanical trades, such as riveting. The new appropriation is partly in extension of this program, but also includes \$9,000,000 for short engineering courses of college grade, \$7,500,000 in connection with the work of the National Youth Administration, and \$10,000,000 for out-of-school rural youth and nonrural youth in agricultural high schools and related institutions in an attempt to equalize the opportunities for youth in rural areas to share in preparation for service in the national defense program. The training provided will be largely in mechanical occupations common to the farm but also basic to defense industry needs.

Still another defense phase to be considered was that of nutrition needs, to which the home economics section devoted a session with Director M. L. Wilson of the Department's Extension Service as the principal speaker. A discussion followed as to how various agencies may contribute to a nutrition program, led by Dr. Louise Stanley, Chief of the Bureau of Home Economics, and participated in for extension phases by Director J. W. Burch of Missouri, State nutrition councils by Miss Mildred F. Horton of Texas, land utilization by Director A. E. Bowman of Wyoming, farm security by Miss Leila Ogle of Indiana, and experiment stations by Miss Sybil L. Smith of the Office of Experiment Stations. Subsequently, in the experiment station subsection, the need was pointed out for nutritional family inventories and for study of food habits and causes of the decline in home production of foods.

Some idea of what is going on in agriculture was afforded by the address by Dr. T. W. Schultz of Iowa on the subject of The Outlook for American Agriculture. Because of the operation of world economic forces, Dr. Schulz pointed out that agriculture both in this country and abroad needs much more guidance and attention by governments than formerly. Disintegration of foreign trade in particular has created a situation where individualism is no longer adequate and control measures may be inevitable regardless of the outcome of the war. The problem, in his opinion, is the best combination of public and private management with a minimum of centralization in action programs pending research as to their permanent effectiveness.

The need of promoting hemisphere solidarity was brought before the convention as a whole by Mr. Charles A. Thomson, Chief of the Division of Cultural Relations of the U. S. Department of State, in a paper entitled *Toward Inter-American Cooperation*. Mr. Thomson referred especially to efforts under way to improve economic relations by the development in South and Central America of crops now imported by the United States from other sources and also the necessary step of deepening cultural contacts. In the latter direction he indicated that the land-grant institutions might be of special service through exchange relationships, development of courses, and the stimulation of interest. A report from the Committee on Inter-American Cooperation in Agricultural Education (E. S. R., 83, p. 289), which in cooperation with the State Department and the Office of Education is acting as a clearing house for information along these lines, was also presented by its chairman, Dean K. A. Ryerson of California and received consideration in a number of groups.

One of the most distinctive features of the convention was its interest in the problems of rural youth. An address by Dr. O. E. Baker of the U. S. D. A. Bureau of Agricultural Economics entitled *Rural Youth in the Farm Picture* was included in the program of the general sessions, and the joint session of the three subsections of agriculture was given almost entirely to a consideration of older youth and its interests and problems. At this session the topic *Situations and Problems of Older Rural Youth* was discussed by Dr. C. C. Taylor of the Bureau of Agricultural Economics, and there was also the innovation of a panel discussion in which eight representatives of older youth groups and workers with such groups participated. In these ways a considerable breadth of viewpoint was obtained. Apparently the diminished opportunity for employment in the cities has created more desire to remain on the farms, but such handicaps are encountered as shortage of desirable farms, lack of capital, inadequate social and recreational opportunities, and an imperfectly realized group solidarity. Additional assistance to prospective farmers was advocated, but also greater attention to the preparation of rural youths for other pursuits.

Problems of training naturally received much attention from the subsection of resident teaching. At a luncheon meeting held jointly with the section of graduate work, the general theme was discussed by Dean S. W. Fletcher of Pennsylvania under the title *Are Our Graduates Properly Trained?* Later, a panel discussion on *Training for Public Service in the Field of Agriculture* was led by Mr. R. W. Trullinger, Assistant Chief of the Office of Experiment Stations, and participated in by Dr. E. C. Auchter, Chief of the Bureau of Plant Industry; Dr. S. S. Board of the Office of Personnel; Extension Direc-

tor H. C. Ramsower of Ohio; and Deans W. C. Coffey of Minnesota, C. B. Hutchison of California, H. H. Kildee of Iowa, I. O. Schaub of North Carolina, and S. W. Fletcher of Pennsylvania. At the joint session of the three subsections of agriculture, Dean C. L. Christensen presented a paper on Pre-theological Training in Colleges of Agriculture, in which he indicated the appropriateness of certain courses in these colleges for pre-theological students. Still another paper, by Associate Extension Director W. W. Clark of Wisconsin, took up Undergraduate Training for Extension.

Home economics has become increasingly important in the Nation's welfare. Under the title of Milestones and Guideposts in Agriculture and Home Economics, Dr. Lita Bane, head of the home economics department of the University of Illinois, gave data which showed an estimated enrollment in 1938-39 of 1,500,000 girls and 41,300 boys in home economics courses in junior and senior high schools, a total of 1,118,519 women in home economics extension courses, and approximately 580,000 girls who completed homemaking projects in 4-H Clubs. Less encouraging, however, was her feeling that "home economics teaching has outdistanced research to the point where we are in grave danger of crippling our teaching program unless some means can be found to further our research. . . . Specifically, we need more research in the fields of human feeding, housing, clothing, and relationships, using the tools of chemistry, bacteriology, physiology, psychology, economics, sociology, and such other fields as will help in discovering important facts that will promote human welfare."

Aside from those noted, the programs of the sections and their subdivisions followed for the most part along accustomed lines. Extensive consideration was given to research, but following the usual custom, discussion of this topic is reserved for the February issue of the *Record*.

The presidency of the association was bestowed upon Dean Emeritus F. B. Mumford of Missouri, with President A. G. Crane of Wyoming becoming vice president and Dean T. P. Cooper of Kentucky continuing as secretary-treasurer. On the executive committee, Dean Mumford was succeeded by Dean W. C. Coffey of Minnesota, and President C. A. Lory of Colorado by President E. G. Peterson of Utah. A list of section officers, committee changes, and related information may be found on page 144 of this issue.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

The effect of clipping and drying immature grasses on their yield and chemical composition, M. W. GOODWIN (*Delaware Sta. Bul. 223 (1940), pp. 21, figs. 8*).—The experiments reported in this bulletin were carried out by means of a two-tray, batch drier, heated by an oil burner and provided with a fan driven by a 15-hp. motor to draw the hot gases first through a tray of partly dried grass and then through another layer of fresh grass. The inlet temperature is thermostatically controlled at 250°–300° F., and practically all the heat is utilized in evaporating moisture by the time the gases are exhausted into the air. The grass brought in from the field is forked into one tray, which is conveyed upon rollers into the oven. When the grass is half dried the tray is withdrawn, its contents are forked into the second tray, the first is refilled with wet grass, and the two are then drawn back into the oven. As soon as the moisture content of the herbage in the partly dried tray has been brought below 10 percent, the drying is considered sufficient. A duplicate set of trays is provided on the opposite side of the drier, one set being always in the oven while the grass is being transferred from the other. From 15 to 30 min. are usually required for each stage of drying, depending upon the quantity of water to be evaporated. The baling, done immediately after cooling, was performed in a power baler capable of forming compact bales of about 125 lb. each without pulverizing the dried grass.

The total cost of production was about \$28 per ton under the experimental conditions obtaining.

The product retained its original green color. Comparative annual acreage yields of dry matter from frequently clipped artificially dried grass were greater than those of sun-cured hay. Frequent clipping of the immature grasses increased the acreage yields of protein from 40 to 60 percent over that recovered by the usual haymaking procedure. Artificial dehydration preserved more than five times as much carotene as did field curing. Only insignificant losses of carotene occurred during the artificial drying and baling of immature grasses. Loss of carotene during storage in bales was found most rapid during the first few months, particularly in hot weather. While the loss averaged 50 percent during the 10-mo. experimental period, the final product still contained from two to five times as much carotene as was found in the hay at time of storage. Reduction of moisture of herbage below 10 percent by artificial drying was valueless.

“The study indicates that it is possible to produce in Delaware a high yield of a high-protein, low-fiber, and high-carotene feed from a grass and clover mixture, and that it can be well preserved by artificial drying followed by storage in bales.”

Microscopical studies of peanuts with reference to processing, J. G. WOODROOF and J. F. LEAHY. (Coop. Univ. Tenn.). (*Georgia Sta. Bul. 205 (1940), pp. 39, figs. 17*).—Starch grains were stained with iodine solution, cellulose cell walls being counterstained with fast green in clove oil and alcohol.

Aleurone grains were stained with eosin. Oil distribution was found to be best indicated by Sudan Black B or by Oil Red O. These fat stains penetrated tissue only slowly, but saturated solutions of the stains in 70 percent alcohol stained untreated sections of peanuts sufficiently in 1 min. Free oil on the surfaces of sections was avoided by chilling before cutting to 35° F. and examining the sections at this temperature.

The microscopic appearances of the epidermis, spongy parenchyma, vascular bundles, inner epidermis, and perisperm of the seed coat and of the epidermis, bunches, and parenchyma cells and cell contents of the embryo are described and illustrated, together with some changes in the microscopic structure of the embryo cells and their contents occurring during processing. Indications as to desirable and undesirable processing treatments obtained from the microscopic study are reported upon.

The Sudan Black B stain, applied and studied at 35°, indicated that the oil is distributed through the cells in the form of an extremely fine emulsion. Treatment of ground peanut meats for 12 hr. with vapors of ether, chloroform, or gasoline was found to break up this emulsion so effectively as to result in a 33 percent increase in the oil yield obtainable by cold-pressing. The hot-pressing yield was about the same as that from untreated material. Hot-pressed, vapor-treated nuts, however, yielded from 15 to 25 percent more oil than did hot-pressed, previously cooked nuts. Dry roasting had the effect that the aleurone grains, starch grains, and nucleus are drawn away from the cell walls into a hard mass near the center of the cell. "While heating lowers the viscosity of the oil and causes larger droplets to form, the hard mass in each cell renders pressing relatively ineffective in removing oil from the center of the mass." The microscopic indication was again confirmed in pressing practice, in which it was found that the yield of oil from grinding and pressing dry roasted peanuts was 35 percent less with cold-press, and 21 percent less with hot-press, than was the yield from raw nuts. Other relations between microscopic appearances and processing practice are brought out.

Hemicelluloses of alfalfa hay, M. PHILLIPS and B. L. DAVIS. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 11, pp. 775-780).—The authors isolated and fractionated the hemicelluloses of alfalfa hay, finding them to consist almost entirely of a fraction which, on hydrolysis, yielded *d*-xylose, together with a small amount (0.8 percent) of *l*-arabinose. This fraction contained also a uronic acid that was probably glucuronic acid or one of its methyl derivatives.

Hemicelluloses of wheat straw, H. D. WEIHE and M. PHILLIPS. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 11, pp. 781-786).—The hemicelluloses of wheat straw were isolated and freed of nitrogen and lignin. On fractionation, 100 gm. of the lignin- and nitrogen-free material, dissolved in aqueous sodium hydroxide, made slightly acid with acetic acid and precipitated with acetone yielded 79.2 gm. of a fraction which, on hydrolysis, yielded *d*-xylose, *l*-arabinose, and a uronic acid that was probably glucuronic acid or a methyl derivative of it. The molar ratio of uronic acid to *l*-arabinose and *d*-xylose in this fraction was found to be 1 : 0.9 : 23, respectively. On adding 95 percent alcohol to the filtrate from the major fraction until no more precipitate was formed, there was obtained 9 gm. of a further fraction which contained 3.66 percent ash and yielded uronic acid, as the anhydride, 9.64 percent, and pentosans 70.53 percent. This fraction was found to contain 3.74 percent methoxyl.

Improved rasp for securing pulp from sugar beets for analysis, J. G. LILL. (U. S. D. A. and Mich. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 6, pp. 474, 475, fig. 1).—The beet rasping machine is described and illustrated.

"The basic idea embodied in the machine which has been devised is that the whole sugar beet roots comprising the sample, after being washed or cleaned, are individually placed in carrier boxes which move over the disk rasp in such a manner that a radial sector is removed from each root. The machine has the advantage of making unnecessary the splitting of the roots of the sample, an operation which in sugar analysis procedure usually requires the time of one man. The whole roots after sampling commonly are accepted by the sugar factory, whereas half or quarter beets may be refused as not usable."

The determination of lead in biological materials, S. L. TOMPSETT (*Biochem. Jour.*, 33 (1939), No. 8, pp. 1231-1236).—The method, consisting of destruction of organic material by ashing, extraction of the lead with ether as a complex with sodium diethylthiocarbamate, and colorimetric estimation of lead with dithizone, is given in detail with regard to apparatus and reagents, and procedures as applied to urine, soft tissues, blood, feces, bone, and milk. Substances of high mineral content, chiefly phosphates, are ignited directly, but those of low mineral content (blood and soft tissues) are ignited with the addition of sodium phosphate to prevent volatilization of the lead. The reaction with diethylthiocarbamate is carried out in an alkaline solution in the presence of cyanide and citrate which inhibit interfering reactions. The cyanide in alkaline medium inhibits the formation of copper or iron complexes, while the citrate, which also inhibits the formation of the iron complex, prevents the precipitation of phosphates from the alkaline medium. The lead complex is extracted with ether, the extracted lead being converted to the sulfate by digestion with sulfuric acid. After digestion and dilution, and addition of acetic acid and excess ammonia, the alkaline acetate solution of lead is treated with potassium cyanide and carbon tetrachloride and the reagent is added. The lead complex dissolves in the carbon tetrachloride to give a red solution from which any unchanged dithizone is extracted by shaking with potassium cyanide solution. The lead is estimated colorimetrically against a standard of comparable concentration similarly treated. Data reported in a series of recovery experiments indicate satisfactory recovery of added lead and satisfactory determinations over a range of 22 μ g. to 1.03 mg.

The determination of sulphur in biological material, M. MASTERS (*Biochem. Jour.*, 33 (1939), No. 8, pp. 1313-1324, fig. 1).—Four methods, three of them oxidation processes and the fourth involving hydrogenation, were studied. The sodium peroxide fusion method, adopted as Official by the A. O. A. C. (1935), was found to give accurate results but is considered unsuitable for routine sulfur determinations because of the constant care and attention (to prevent explosions) and the time involved. Of the wet ash procedures, the Benedict-Denis method was found unreliable, probably because of its failure to determine methionine sulfur accurately. The nitric-perchloric acid method, in which destruction of the organic material by a mixture of nitric and perchloric acids is followed by gravimetric estimation of the sulfate, gave reliable results, however, and was found adaptable to routine analyses. Large amounts of material could be taken if necessary and many determinations could conveniently be run simultaneously. This method is considered with regard to the digestion procedure adopted, the experience with explosions, the negligible effect of iron on the precipitation of barium sulfate, the loss of sulfur during oxidation, analyses of casein and compounds containing known amounts of sulfur, and recovery of added sulfur. Data on the latter point indicated very satisfactory recoveries.

The hydrogenation method, depending upon the reduction of S to H_2S which is estimated iodimetrically, was found satisfactory with the modifications

adopted. The reduction, catalyzed by platinized asbestos and effected by hydrogenation, was carried out in a quartz combustion tube under careful application of heat. The reagents, the apparatus, the hydrogenation procedure, the subsequent estimation of H_2S , the interference of metals, and the advantages and disadvantages of the method are considered in detail. Data presented show that the results compare favorably with those obtained by the fusion and the nitric-perchloric methods. The hydrogenation method was found quicker and more sensitive than the oxidation procedures studied and is considered the best available for the routine determination of sulfur.

The estimation of vitamin B_1 in blood.—II, A further modification of Meiklejohn's method, H. M. SINCLAIR (*Biochem. Jour.*, 33 (1939), fig. 12, pp. 2027–2036, fig. 1).—In this continuation of the series noted previously (E. S. R., 82, p. 298), a further modification of the Meiklejohn method is described in which the adjuvant action of blood upon the growth of the fungus is corrected by multiplying the weight of the fungus obtained in the presence of blood by the factor

$$\frac{\text{weight of fungus obtained with excess vitamin } B_1}{\text{weight of fungus obtained with excess vitamin } B_1 + \text{blood.}}$$

By this means the apparent values obtained by the original method can be translated into true values. In proof of the validity of this correction, data are presented showing that the unlike values obtained by the original method with the use of different volumes, 1, 2, and 3 cc., of blood became approximately the same when corrected by the method proposed, that high apparent values for recovery of added vitamin B_1 are reduced to within the limits of experimental error upon correction, and that the higher values previously obtained for large (more than 3 cc.) samples of blood without, rather than with, added vitamin B_1 are reversed when correction is applied. The question of proper size of blood samples to use for the test is discussed with evidence leading to the conclusion that the apparent values for normal blood can be estimated with greatest accuracy in a 1-cc. sample of blood but that in samples with an abnormally low content of vitamin B_1 2 cc. may be preferable. Inasmuch as the true or corrected values are approximately the same with 1-, 2-, and 3-cc. samples, it is considered legitimate to compare values obtained on samples of these three different sizes. In the present paper data on normal human blood were obtained on 1-cc. samples.

From the values obtained in 44 observations on different samples of his own blood over a period of 3 yr. and observations on 47 male and 26 female normal adults, the author considers the range of true or corrected values for vitamin B_1 in normal adults to be from 4.6 to 10.2 $\mu\text{g.}$ per 100 cc., with a value of 4.5 $\mu\text{g.}$ or less to be abnormally low. Differences between males and females were statistically insignificant.

Previous work by others on the vitamin B_1 content of the blood is discussed, with the comment that "the uselessness of most of the work done so far upon the amount of vitamin B_1 in blood or serum is distressing." In the author's opinion the thiochrome method "promises to be useful for whole blood, and even for serum or plasma if great care is taken to avoid hemolysis or contamination with blood cells and if the vitamin is freed from protein by warming or digestion with pepsin."

Quantitative estimation of nicotinic acid in urine, E. BANDIER (*Biochem. Jour.*, 33 (1939), No. 11, pp. 1787–1793, fig. 1).—The method outlined is based on the colorimetric method, involving the use of $CNBr$ and metol, previously reported by Bandier and Hald (E. S. R., 82, p. 586). Since urine contains substances that mask the color reaction, the nicotinic acid is first extracted with a large excess of acetone from urine saturated with $NaCl$, the salt serving to flocculate the

precipitate that forms on adding the acetone. After the addition of water and evaporation of the acetone in vacuo, the reaction with CNBr and metal in the presence of KH_2PO_4 is permitted to take place, the mixture being left at room temperature protected from light for 1 hr. for color development. The color is read off in a Pulfrich photometer (filter S 43) against a solution containing the same amounts of the reagents and made up to volume with distilled water. The color of a blank, represented by the acetone extract similarly treated except that no metal is added, is measured and subtracted. From this result and the coefficient of extinction on a standard solution (0.1 mg. of nicotinic acid), the amount of nicotinic acid corresponding to the color developed can be calculated. The intensity of color, however, does not give a quantitative measure of nicotinic acid, since nicotinamide, nicotine (in the urine of smokers), and nicotinic acid give the same yellow as nicotinic acid.

Coenzyme and cozymase, which contain nicotinamide in combination, do not respond to the color test. Preliminary hydrolysis of the urine with strong NaOH serves to hydrolyze these complexes, as well as nicotinamide and nicotinic acid to give free nicotinic acid. Combining preliminary hydrolysis with the procedure outlined determines, therefore, the total amount of free and conjugated nicotinic acid.

Analyses by alkaline hydrolysis of the urines of 10 normal persons gave color-producing substances equivalent to 1.5–5 mg. of nicotinic acid. Ninety mg. of orally ingested nicotinic acid was almost quantitatively recovered in the urine within 6 hr., 14 percent being excreted in the first hour. After oral ingestion of nicotinic acid, part of it was excreted in a combined form, which was hydrolyzed under the same conditions as synthetic nicotinic acid.

Preliminary study on the use of coconut oil for the determination of the moisture content of native style cheese, F. A. SOLIVEN (*Philippine Jour. Anim. Indus.*, 6 (1939), No. 6, pp. 449–457).—A simple method patterned after that described by Gould (*E. S. R.*, 78, p. 588), but using coconut oil instead of olive oil, is described. Slightly, although not significantly, higher moisture readings were obtained by the coconut oil-salt method than by the oven-drying method.

A wet-crushing mill for micro-organisms, V. H. BOOTH and D. E. GREEN (*Biochem. Jour.*, 32 (1938), No. 5, pp. 855–861, pl. 1, figs. 3).—The essential feature of the mill described is a roller bearing so modified, by forcing a specially made inner race onto a tapered shaft, as to have no clearance between rollers and races, whereas the clearance of the usual type of precision roller bearing is never less than about 2.5μ , which would permit micro-organisms of average size to pass through intact. A diagrammatic drawing shows the main working parts of the mill. Some mechanical difficulties encountered are noted, and means by which they were overcome are described. With water cooling of the working parts and continuous passing of the suspension through a vaned cooling unit immersed in ice water, the bulk temperature of a yeast suspension rose only 2° [C.] in 60 min. of operation. The cell count of the yeast suspension was halved in 5 min. and was reduced below 10 percent of the original number in 30 min. Photomicrographs show the crushing effect on yeast cells and on *Bact[erium] coli*.

AGRICULTURAL METEOROLOGY

Milestones in meteorology, W. H. WENSTROM (*Sci. Mo.*, 51 (1940), No. 3, pp. 226–232).—A review setting forth the high lights of meteorological progress from earliest historical times to the present.

Agricultural meteorology (*Indian Sci. Cong. Proc.* [Lahore], 26 (1939), pp. 200–202).—Abstracts of the following papers are included: On Radiation Mini-

imum Temperatures, by L. A. Ramdas and K. M. Gadre; Dates of Onset of the South-West Monsoon on the West Coast of India, by L. A. Ramdas, V. Satakopan, and S. Gopal Rao; Studies on Evaporation From the Surfaces of Soil Layers Resting on a Water Table, by L. A. Ramdas and A. K. Mallik; A Study of Transpiration in Relation to Meteorological Factors, and The Invisible Condensation of Water Vapour on the Soil and on Plant Materials Like Stalk, Leaves, and Grain, both by A. K. Mallik; and The Use of the Hot-Wire Anemometer in Studies of Micro-climates, by P. K. Raman.

[**Agricultural meteorology in the Philippines**] (*Natl. Res. Council Philippines Bul. 23 (1939)*, pp. 93, 94, 100, 107-109, 124, 125).—Abstracts are given of the following papers: The New Pluviometric System of the Philippines, The Drought of 1938 in the Philippines, and A Bibliography of Typhoons, all by M. Selga; and Some Characteristics of Philippine Typhoons, by C. E. Deppermann.

Hydrology of Virginia.—II, Flood studies; storms that have caused great floods; great rainfalls, P. H. MCGAUHEY and H. B. SNYDER, JR. (*Va. Engin. Expt. Sta. Bul. 44 (1940)*, pp. 94, pls. 8).—This study, supplementing part 1 of the series (*E. S. R.*, 79, p. 157), concerns the maximum recorded flows of Virginia streams, the 1-, 2-, 3-, and 5-day rainfalls producing such floods, and the relationship between these rainfalls and the maximum recorded rainfalls. It is believed that existing data thus classified will be more readily available and useful.

Agricultural meteorology: A statistical study of conservation of precipitation by summer fallowed soil tanks at Swift Current, Saskatchewan, J. W. HOPKINS (*Canad. Jour. Res.*, 18 (1940), No. 8, Sect. C, pp. 388-400, figs. 4).—"Changes in the moisture content of summer fallowed soil in tanks 15 in. in diameter and 5 ft. deep set in pits in the center of field plats at the Dominion Experimental Station, Swift Current, Sask., which have been recorded at fairly frequent intervals during the summer months since 1922, provided two series of data, comprising observations in May and June and those in July and August. These have been analyzed statistically in order to relate conservation to precipitation after making allowance for other variable factors. Five-factor regression equations, fitted by the method of Least Squares, gave multiple correlation coefficients of 0.95 and 0.96 between the computed and observed conservation in the two series. It is inferred from these equations that under average conditions a 1-day rain to the amount of 0.36 in. in May-June and 0.46 in. in July-August would be required just to offset the subsequent evaporation during a 10-day period. Increased penetration and retention of the heavier rainfalls is very definitely indicated, and it is calculated that whereas on the average 66 percent of a 1-day rain of 1 in. in May-June would still be conserved at the end of 10 days, only 30 percent would be retained if the same amount was received in 5 daily showers each of 0.2 in. The intensity as well as the total amount of precipitation is thus emphasized as a factor of prime importance in its relation to soil moisture under semiarid conditions."

The drouth of 1939 (*Arizona Sta. Rpt. 1939*, pp. 44, 45).—A brief note on the drought and the consequent shortage of water in the Gila River projects, and a progress report on the snow courses and snow surveys on the headwaters of the Gila River and Salt River (coop. U. S. D. A.).

What the summer has taught us about hurricane damage, P. E. ALDEN (*Natl. Shade Tree Conf. Proc.*, 15 (1939), pp. 100-109, figs. 5).—A summary of the damage to trees by the hurricane of September 21, 1938, and of the results of efforts toward reclaiming individual trees, and comparisons of the wind resistance of various species.

Salt spray damage from recent New England hurricane, R. H. WALLACE and A. E. MOSS. (Univ. Conn.). (*Natl. Shade Tree Conf. Proc.*, 15 (1939),

pp. 112-119).—A general discussion from observations of the damage undergone by conifers and broadleaf trees, with more detailed descriptions of the injuries to individual tree species. Broadleaf plants are said to present some hopes for recovery, but badly damaged conifers are probably not worth saving.

Influence of forest cover on wind velocity, W. L. FONS. (U. S. D. A. and Univ. Calif.). (*Jour. Forestry*, 38 (1940), No. 6, pp. 481-486, figs. 5).—In studying wind velocity as influenced by height above ground and by vegetation in grassland, brush, and even-aged ponderosa pine, the shapes of wind-velocity distribution curves proved distinctly different for each cover type. The results indicated that wind velocities at any two heights bear a linear relation to each other. The linear slope and intercept depended on the temperature difference between the two levels and on the height of the lower level above the ground. Wind velocity was greatly decreased at the top of the crowns and remained nearly constant in the canopy zone. In general, the velocity in the forest was not a constant percentage of the velocity above the tree crowns. For midday conditions, when the air temperature decreased with height, this percentage decreased as the wind velocity above the crown increased.

Note on the freezing of soil, R. K. SCHOFIELD (*Quart. Jour. Roy. Met. Soc. [London]*, 66 (1940), No. 285, pp. 167-170, figs. 4).

Weather and crops, B. A. KEEN (*Quart. Jour. Roy. Met. Soc. [London]*, 66 (1940), No. 285, pp. 155-166, figs. 5).—This is the Presidential address before the Royal Meteorological Society on January 24, 1940.

Climate and acclimatization: Some notes and observations, A. CASTELLANI (*London: John Bale, Sons & Curnow*, 1938, 2. ed., pp. X+198, [pls. 4], figs. [13]).—This book is "a collection of notes based chiefly on personal experience gathered in long sojourns in many different tropical countries" regarding the effects of climate on the health and well-being of man, and on acclimatization.

Climatological data for the United States by sections, [1939] (*U. S. Dept. Agr., Weather Bur. Climat. Data*, 26 (1939), No. 13, pp. [278], pls. 2, figs. 33).—Summaries are given of climatological data for each month of 1939 and for the year as a whole for each State.

[**Weather data**], N. W. NANCE (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 1939, Sup. 119, pp. 124, 125-134, figs. 20).—A summary of climatic data for the United States following the general plan of the previous report (E. S. R., 82, p. 17).

The weather and climate of Connecticut, J. M. KIRK (*Conn. State Geol. and Nat. Hist. Survey Bul.* 61 (1939), pp. 242+XI, figs. 12).—Much of the material used in this report was compiled from the files of the Boston, Hartford, and New Haven offices of the U. S. D. A. Weather Bureau, but many of the precipitation records were furnished by public and private water-supply organizations. Records from ± 75 stations are included, and for 12 of them 50 yr. or more are covered. At New Haven there is one of the longest records in the United States, viz, with few interruptions, from June 1778 to the present time. Brief discussions of the atmosphere and some atmospheric phenomena, the measurement of meteorological elements, weather forecasting, and climate are included. The main body of the report is taken up with the general conditions in the State, climatic characteristics, temperature, frost, precipitation, snowfall, humidity, sunshine, wind, great rainstorms, heavy snowstorms, destructive hailstorms, severe windstorms, abnormal seasons, droughts, temperature trends, meteorological stations and observers, miscellaneous climatological data, crest stages of floods at Hartford, yearly maximum gage heights at Falls Village and at Jewett City, dates of earliest and latest snow in New Haven, time of flowering of fruit trees in New Haven, monthly and annual precipitation and

snowfall by stations, and frost records by stations. An index and list of 60 references are included.

Weather (*Rhode Island Sta. Rpt.* [1939], pp. 58, 59).—A brief summary of climatological data.

SOILS—FERTILIZERS

[**Soil investigations at the Alabama Station**] (*Alabama Sta. Rpt.* 1938, pp. 9, 10, 11).—This report notes work on elements required in small quantities for plant growth in soils, by A. L. Sommer; further studies of the influence of liming on boron availability in soils, by J. A. Naftel; and the leaching of potassium below the feeding zone of plants, by N. J. Volk.

[**Soil investigations by the Arizona Station**] (*Arizona Sta. Rpt.* 1939, pp. 29–38).—Data are reported on gypsum in irrigation water, soil erosion and rate of infiltration (coop. U. S. D. A.), distribution and activity of *Azotobacter* in Arizona soils, inoculation experiments with certain of the native Leguminosae, fertilizer requirement of citrus, acidulated fertilizers, sulfur placement, oxidation-reduction studies, and bound water in normal and puddled soils.

[**Soil investigations by the Rhode Island Station**] (*Rhode Island Sta. Rpt.* [1939], pp. 26–34).—These have included studies on the effect of crops on soil acidity, on the effect of chloropicrin in overcoming the influence of the previous crop, on optimum levels of nitrate nitrogen for vegetable crops, on the relative availability for plants of various compounds of magnesium, and on the relative rates of production of asparagine and of glutamine in beets and spinach as influenced by the calcium supply and the pH value of the medium.

[**Soil Survey Reports, 1934 and 1936 Series**] (*U. S. Dept. Agr., Bur. Plant Indus.* [*Soil Survey Rpts.*], Ser. 1934, No. 18, pp. 39, figs. 2, maps 2; 1936, No. 3, pp. 78, figs. 6, map 1).—These surveys were made in cooperation with the respective State experiment stations: 1934, No. 18, Uinta County, Wyo., T. W. Glassey, T. J. Dunnewald, and D. M. Stevens; and 1936, No. 3, Kaufman County, Tex., E. H. Templin and J. W. Huckabee, Jr.

A key to Kentucky soils, P. E. KARBAKER and W. S. LIGON. (Coop. U. S. D. A.). (*Kentucky Sta. Cir.* 51 (1940), pp. 36, fig. 1).—This key presents in a brief and logical arrangement the soil series that are known or thought with reasonable certainty to occur in Kentucky. It is expected to be of distinct service to workers in soils and related lines in the State in view of the fact that only a relatively small number of detailed surveys have been made in Kentucky, and most of these are so old that many of the soils involved have been reclassified since the surveys were made.

Relative infiltration and related physical characteristics of certain soils, G. R. FREE, G. M. BROWNING, and G. W. MUSGRAVE (*U. S. Dept. Agr., Tech. Bul.* 729 (1940), pp. 52, figs. 12).—The authors determined, by the tube method of Musgrave and Free (*E. S. R.*, 76, p. 303), the relative infiltration in situ of 68 soils from New York to New Mexico and from Georgia to Oregon.

Definite association of infiltration with all factors affecting pore size was found for the 68 soil sites. Particularly, noncapillary porosity, degree of aggregation, organic matter, and proportion of clay in the subsoil may be regarded as determinants of infiltration. Factors that determine the permanency of large pores, such as suspension percentage and dispersion ratio, were also associated with infiltration rates. Further, indications of correlations between soil properties that do not so directly affect infiltration were found in many of the data. Among these were the positive correlation between organic matter and moisture equivalent and between clay and moisture equivalent, the significant negative correlation between suspension percentage and pH value, and the

negative correlation between content of silt and clay and volume weight. These correlations were found to be in accord with the observations of numerous other workers and with well-recognized principles of soil physics. For maintaining or increasing the infiltration rate of field soils the study indicates the value of the commonly recommended soil-management practices, including the incorporation of organic matter and its maintenance at a reasonably high level, proper tillage practices, and a good cropping program. Conversely it is indicated that those practices tending to reduce the degree of aggregation, decrease the stability of aggregates, and increase the turbidity of water available for infiltration are usually conducive to a reduction in the rate of intake of natural rains.

Related studies conducted on 13 sites during the course of the main investigation covered by this report indicated that variation in turbidity of water available for infiltration was one of the most important factors tending to make infiltration rates determined by the rainfall-simulator method lower than those determined by the tube method. This and the fact that some lateral movement of subsurface water was observed for both these methods of determining infiltration rates, which involve the artificial application of water, suggest that these rates and others that are found when water is artificially applied should probably be considered relative rather than absolute, and that these values should always be considered as relative if used in the design of control measures.

Elements of life: A study of the effect of mineral differences on soils, plants, animals, living conditions, comparing the Central Basin area and the Highland Rim area (*Tennessee Sta. Pop. Bul. 1 (1940), pp. [17], figs. 14*).—Largely through illustrations, with but brief verbal statements, this bulletin shows the differences in nutrient content, and in crop-, livestock-, and profit-producing capacity between the phosphate-rich lands of the Central Basin and the Highland Rim lands containing less than one-sixth as much phosphate in the plow layer. A final set of illustrations and text points out the gradual depletion of the State's phosphate rock resources.

Arsenic distribution in soils and its presence in certain plants, K. T. WILLIAMS and R. R. WHETSTONE (*U. S. Dept. Agr., Tech. Bul. 732 (1940), pp. 20, fig. 1*).—For the determinations here reported the authors used a method in which the arsenic is separated from interfering elements by distillation with hydrobromic acid and determined colorimetrically by the molybdenum blue method.

Profile samples as well as surface soils alone from various great soil groups were examined. These soils, representative of widely separated areas, all contained arsenic in quantities varying from 0.3 to nearly 40 p. p. m. Soils from Mexico were found to have an arsenic content similar to that of soils of the United States. The arsenic content of widely varied vegetation growing on diverse soils was found to reach maximum values about 10 p. p. m. under normal conditions. Many samples contained less than 0.1 p. p. m. Some plants contain more than others growing on the same soil. Also, as a rule, roots contain more than tops of plants. Soils contaminated with arsenic may, in some cases, produce vegetation of an arsenic content higher than that found on any natural soil. In general, however, it appears that plant growth is limited by the presence of arsenic in soils before injurious quantities are absorbed. In a few marine algae examined, the arsenic content was found to range from 1 to 12 p. p. m.

No clearly defined relationship was found between arsenic content of soils and climatic conditions or geological formations on which the soils were developed.

Selenium occurrence in certain soils in the United States, with a discussion of related topics.—Fourth report, K. T. WILLIAMS, H. W. LAKIN, and H. G. BYERS (*U. S. Dept. Agr., Tech. Bul. 702 (1940), pp. 60, figs. 7*).—This bul-

letin reports the results of a survey of part of Montana which establish toxic areas in Big Horn, Yellowstone, Teton, Pondera, Chouteau, Fergus, Lewis and Clark, Cascade, Hill, and Judith Basin Counties. Indicator plants were used as guides in the survey work. *Astragalus pectinatus* was found to be a better absorber of selenium than *A. bisulcatus*. Radishes, peas, lettuce, spinach, beets, and squash raised in an irrigated garden on highly seleniferous soil in Lyman County, S. Dak., had selenium contents below the limits normally considered toxic for rats. An area in Utah was found to produce vegetation of sufficient selenium content to be toxic. A wide variation in the selenium content with geographical location was found in the Mobridge member of the Pierre shale. Certain portions of the Eagle Ford formation in Texas were found to contain significant quantities of selenium.

An extension of the examination (E. S. R., 79, p. 597) of the selenium content of sea-floor samples has shown that the floor of the Atlantic Ocean contains selenium from Halifax, Nova Scotia, to Falmouth, England. Data on seleniferous soils of Hawaii and Puerto Rico that do not produce toxic vegetation are given. Soil and vegetation samples collected near Fajardo, P. R., are given as a special example. Selenium has been established as the cause of a 200-year-old disease which occurs near Iraquato, Mexico. In addition to the examination of soils and vegetation collected over the area, vegetables from the public market were examined and found to contain from 0 to 70 p. p. m. of selenium.

Recent publications on topics related to the selenium problem are reviewed.

Mississippi soils are acid, or are becoming acid, C. D. HOOVER (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 8, pp. 1, 7).—The author considers that, for soils of a sandy texture which are quite acid an application of from 500 to 1,000 lb. of lime per acre broadcast will give immediate results, especially with legumes, while soils of a silt and clay texture will require from 1,000 to 2,000 lb. of lime per acre broadcast.

Neutral versus acid fertilizer, J. L. ANTHONY, J. PITNER, and C. DORMAN (*Mississippi Sta. Bul.* 338 (1940), pp. 15).—Although all Mississippi soils are acid or are becoming acid because of leaching, crop removal, erosion, and the use of acid-forming fertilizers, soils of a sandy texture responded favorably to the effect of lime in applications of fertilizer, whereas soils of a silt and clay texture responded but slightly or negatively to the lime used to neutralize acid fertilizers. The average response to neutral fertilizers on soils of a sandy texture was an increased yield of 90 lb. of seed cotton per acre in the 5-yr. experiment, 104 lb. in the 4-yr. experiment, and 72 lb. in the 3-yr. period. The weighted average increase on soils of a sandy texture was 88 lb. of seed cotton per acre. On the basis of these results, "1 ton of neutralized fertilizer applied on 5 acres of sandy textured soil would produce an increase over acid fertilizer of 450 lb. seed cotton."

Commercial fertilizers in Kentucky in 1939, H. E. CURTIS, J. D. TURNER, H. R. ALLEN, and L. GAULT (*Kentucky Sta. Regulat. Ser. Bul.* 22 (1940), pp. 55).—This contains the 1939 fertilizer analysis data and information designed to assist the farmer in using these figures.

AGRICULTURAL BOTANY

Abstracts of the papers presented before the physiological section of the Botanical Society of America, Columbus, Ohio, December 28 to 30, 1939 (*Amer. Jour. Bot.*, 26 (1939), No. 10, Sup., pp. 14-24).—Of interest to agricultural botany are the following: The Toxicity of Sulfanilamide in Tobacco, by E. L. Spencer; The Mineral Composition of Yeast Ash From Spectroscopic

Analysis, by O. W. Richards and M. C. Troutman; Glycoside Formation in Plants From Absorbed Ethylene Chlorohydrin, *o*-Chlorophenol, and Chloral Hydrate, by L. P. Miller; A Study of Cellular Changes and Dry Matter Content in the Growing Region of the Primary Root of Cowpea Seedlings, and Relation of Vitamin C to Cell Size in the Growing Region of the Primary Root of Cowpea Seedlings, both by M. E. Reid; Anatomy of the Starch Grain, by S. H. Eckerson; A Differential Volumeter for Micro-respiration Measurements, by K. V. Thimann and B. Commoner; Oxygen Intake and Carbon Dioxide Output of Dormant *Gladiolus* Bulbs, by N. C. Thornton and F. E. Denny; Respiration and Oxygen Requirements for Growth of *Nuphar advenum* and Other Water Plants, by H. E. Laing; Hydrogen Assimilation in Green Plants, by H. Gaffron; The Relation Between Respiration and Catalase Based on Studies of Intact Dormant Seed and Seed With Certain Membranes Removed, by W. E. Davis (Kans. State Col.); Influence of the Velocity of Crystallization on the Freezing Point of Living Tissues, by B. J. Luyet and M. Sheeley; Differential Inhibition of Initiation and Development of Adventitious Buds of the Hypocotyl of Flax, by G. K. K. Link and V. Eggers; Factors Influencing Protoplasmic Streaming in the Oat Coleoptile, by R. A. Olson; Evidence Relative to the Supposed Permeability of Sieve-Tube Protoplasm, by O. F. Curtis and G. N. Asai (Cornell Univ.); Initial Water-Supplying Power of Different Kinds of Soil at Onset of Permanent Wilting in Wheat and Coleus, by B. E. Livingston and M. Wolf; The Drought Resistance of Some Western Grasses, by L. F. Bailey; Effect of Relative Humidity on Germination of Spores of Certain Parasitic Fungi, by C. N. Clayton (Univ. Wis.); Breaking the Dormancy of Buds of Pear Trees with Glutathione, by J. D. Guthrie; An Explanation of the Advantage of Alternating Temperatures Over Constant Temperatures in the Germination of Certain Seeds, by W. E. Davis (Kans. State Col.); A Rapid Method for Determining the Germinative Power of Some Hard-Coated, Dormant Seeds, by F. Flemion; The Development of Excised Maize Embryos in an Atmosphere of Nitrogen, by C. D. La Rue and J. Merry; Cause of Decreased Germination of Bean Seeds Soaked in Water, by H. C. Eyster; Germination of Seed of *Poa compressa* L. and *Poa pratensis* L. at Different Alternating Temperatures, by A. M. Andersen (U. S. D. A.); Growth of Cereal Plants From Dry and Soaked Irradiated Grains, by E. L. Johnson; Flower Production in *Digitalis* and *Crassula rubicunda* by Low Temperature and Light, by J. M. Arthur; The Absorption Spectra of Water Extracts of Several Species of Photosynthetic Purple Bacteria, by C. S. French; Use of the Dropping Mercury Electrode in Photosynthesis Studies with *Chlorella pyrenoidosa*, by W. E. Moore and B. M. Duggar, The Contribution to Photosynthesis of Light Energy Absorbed by Carotenoids in the Diatom *Nitzschia closterium*, by H. J. Dutton and W. M. Manning, and Effects of Monochromatic Ultraviolet Radiation on the Growth of Fungous Spores Surviving Irradiation, by A. E. Dimond and B. M. Duggar (all Univ. Wis.); Photochemistry and Absorption Spectroscopy of the Pyrimidine Component of Vitamin B₁, by F. M. Uber and L. A. Fourn, and Ultra-violet Inactivation of the Pyrimidine Component of Vitamin B₁, by F. Verbrugge and F. M. Uber (both Univ. Mo.); Effect of Light of Different Wave Lengths on Plant Growth, by F. W. Went; Effects of Light Quality on *Serratia marcescens*, by K. W. Kreitlow (La. State Univ.); Auxin Content in Ovaries and Young Fruits at Different Stages of Development, and Auxin Content in *Cuscuta* and Its Host, both by F. G. Gustafson; Some Chemical Agents in the Production of Overgrowths on Plants, by M. Levine; The Relation Between Respiration, Protoplasmic Streaming, and Auxin Transport in the *Avena* Coleoptile, by H. G. du Buy and R. A. Olson, and Effect of Various Growth Regulating Substances on the Growth of Lettuce

Seedlings (Variety Grand Rapids), by R. B. Stephenson (both Univ. Md.); The Production and Inhibition of Adventitious Organs and Some Effects of Growth Substance Vapors, by P. W. Zimmerman and A. E. Hitchcock; Comparative Root-Inducing Activity of Individual Substances and Mixtures, by A. E. Hitchcock and P. W. Zimmerman; Further Studies on the Vegetative Propagation of Some Gymnosperms, With Indole Acetic Acid, by A. L. Delisle; The Hormone Content of Maize Endosperms as Determined by Different Extraction Methods, and Growth Hormones and Heterosis, both by G. S. Avery, Jr., H. B. Creighton, and B. Shalucha; Auxins of *Hyalopterus arundinis* and of Its Host, by G. K. K. Link and V. Eggers; Distribution of Auxin in Subtropical Fruit Plants, by W. C. Cooper and K. R. Knowlton (U. S. D. A.); Production of Auxin by Tobacco Callus Cultured in Vitro, by F. Skoog; Some Effects of Wounds and Wound Hormones, by C. D. La Rue; The Influence of the Stage of the Rest Period on Rooting at the Cut Surface of Potato Tubers, by J. D. Guthrie; Further Studies on Growth Substances in Relation to the Mechanism of the Action of Radiation on Plants, by H. R. C. McIlvaine and H. W. Popp (Pa. State Col.); Note Regarding Trimethylamine as a Plant Sex Hormone, by L. H. Flint and F. McGoldrick (La. State Univ.); Maintaining a High Potential Growth Rate in *Avena* Coleoptiles by Pre-treatment With Auxin, by C. L. Schneider; and Histological and Anatomical Changes Induced by Indole-Acetic Acid in Rooting Cuttings of *Pinus strobus*, by A. L. Delisle.

[Symposium papers on botany] (In *Cold Spring Harbor Symposia on Quantitative Biology*, VII. *Cold Spring Harbor, N. Y.; Biol. Lab., 1939, vol. 7, pp. 195-215, 260-268, 349-361, 377-393, figs. [35]*).—The following papers are of special interest to botany: The Relation Between the "Oxidation-Reduction Potential" and the Oxygen Consumption Rate of Yeast Cell Suspensions, by J. P. Baumberger (pp. 195-215); Enzymatic Breakdown and Synthesis of Carbohydrate, by C. F. Cori (pp. 260-268); Respiratory Enzyme Systems in Symbiotic Nitrogen Fixation, by R. H. Burris and P. W. Wilson (pp. 349-361); A Tentative Picture of the Relation Between Photosynthesis and Oxidation Reactions in Green Plants, by H. Gaffron (pp. 377-384); and Carbohydrate and Lipid Assimilation in Bakers' Yeast, by T. J. B. Stier (pp. 385-393).

[Botanical studies by the Arizona Station] (*Arizona Sta. Rpt. 1939, pp. 59, 60*).—A report regarding the completion of studies of the grass flora of the State, including 90 genera and 370 species, and on plant collections, identifications, and other taxonomic studies, including a note on the monographing of 78 species and 63 varieties of the genus *Ranunculus* occurring in North America.

[Agricultural botany in the Philippines] (*Natl. Res. Council Philippines Bul. 23 (1939), pp. 172, 173, 181, 203, 204*).—Abstracts are given of the following papers: Macrosporogenesis and Development of the Female Gametophyte of *Asparagus sprengeri* Regel, by J. K. Santos; Some Physiological and Anatomical Features of Corn Seedlings Grown in Nutrient Solution With and Without Nitrogen, by A. R. Peliño; and A Study of Root Nodule Bacteria of Certain Leguminous Plants, by D. I. Aquino and A. L. Madamba.

[Plant physiology] (*Indian Sci. Cong. Proc. [Calcutta], 26 (1939), pp. 125, 126*).—Abstracts of the following papers are of interest: Phosphorus Nutrition of Wheat, and A Study on the Rate of Respiration in Relation to Nitrogen Metabolism of Potato Tuber, both by S. M. Sircar; and March of Transpiration of a Leaf From the Earliest Stage to Its Fall, by P. Parija and B. Samantarai.

Laboratory equipment for temperature and humidity control, G. F. MILES (*Agr. News Letter, 8 (1940), No. 4, pp. 50-52*).—Methods of research on the way environmental factors influence the effects of seed treatment chemicals on seed

viability are discussed. Results with treated and untreated lima bean seeds are used to show the value of laboratory tests in evaluating the usefulness of seed treatment materials under various temperatures, etc., in field or storage.

An electronic relay for heat control, A. C. HALL and L. J. HEIDT (*Science*, 92 (1940), No. 2380, pp. 133, 134, fig. 1).—A simple and inexpensive electronic relay is described and illustrated which is said to control a bath temperature to 0.02° C. It requires only a 115-v. power source (A. C. or D. C.) and permits only a few microamperes to pass through the thermoregulator contacts.

A spatulate pipette serving as section lifter, E. M. SCHLEICHER. (Univ. Ill.). (*Science*, 92 (1940), No. 2382, p. 182, fig. 1).—A glass tube with flattened lumen attached to a rubber bulb is used to suck in the microtome section along with some of the suspending fluid and to expel it gently onto the microscope slide.

An electron microscope for the research laboratory, V. K. ZWORYKIN (*Science*, 92 (1940), No. 2377, pp. 51-53, figs. 5).—Based on examination of the pictures so far obtained, it is estimated that the electron microscope described and illustrated possesses a resolving power 20 times that of the best light microscopes with oil immersion.

An osmic impregnation method for mitochondria in plant cells, E. H. NEWCOMER. (Mich. State Col.). (*Stain Technol.*, 15 (1940), No. 3, pp. 89, 90, fig. 1).—A modification of the osmium tetrachloride Kolatchev method, long used in animal cytology.

Old Gruebler hematoxylin and eosin compared with current American stains, T. M. McMILLION (*Stain Technol.*, 15 (1940), No. 3, pp. 119, 120).

The use of plastic as a substitute for cover glasses, V. SUNTZEFF and I. SMITH (*Science*, 92 (1940), No. 2375, pp. 17, 18).—Of a number tested, the solution found suitable was approximately 1 part of isobutyl methacrylate polymer to 2.5 parts of xylol. Under these conditions the drying required no more than a day, and thus far no curling of the plastic cover slips has occurred.

Evaluation of isobutyl methacrylate polymer as a mounting medium, R. A. GROAT. (Univ. Wis.). (*Science*, 92 (1940), No. 2386, p. 268).—Some of the shortcomings of this medium are discussed.

The use of outline maps on herbarium labels, E. C. ABBE and D. B. LAWRENCE. (Univ. Minn.). (*Science*, 92 (1940), No. 2382, pp. 181, 182, fig. 1).—The described inclusion of an outline map of the collecting area on the printed specimen label and marking on it the exact location where the specimen was collected leads to precision in recording the source locality of natural objects with little additional cost in time or money.

A method for stamping serial numbers on celloidin sections, G. L. RASMUSSEN (*Stain Technol.*, 15 (1940), No. 3, pp. 113, 114).—The procedure used with India ink and a rotating rubber stamp, such as a dime-store stamp with the year and month bands removed, is described.

Inexpensive microphotographic records, J. F. McCLENDON (*Science*, 92 (1940), No. 2380, p. 134).—An adaptation of the Univex camera, without destroying the lens or using up the entire film for one photomicrograph.

Shadowgraph recording of Avena coleoptile curvatures, H. G. ALBAUM and S. KAISER (*Science*, 92 (1940), No. 2379, p. 114, fig. 1).—The advantages of growing oats in battery jars for the Went coleoptile assay method are noted, including the ease with which shadowgraph records may be obtained with a simple device described and illustrated.

Avena coleoptile assay of ether extracts of aphids and their hosts, G. K. K. LINK, V. EGGERS, and J. E. MOULTON (*Bot. Gaz.*, 101 (1940), No. 4, pp. 928-939).—Ether extracts of the aphids *Hyalopterus arundinis*, *Aphis maidis*, and

Brevicoryne brassicae and of their respective hosts, *Phragmites communis*, *Zea mays*, and *Brassica oleracea*, consistently produced negative curvatures in the *Avena* coleoptile test, extracts of cabbage aphids and leaves being active in amazingly high dilutions. Residues of equal samples of aphid and host extracts were not equally active. Extracts of the aphids *H. arundinis* and *Brevicoryne brassicae* and of the hosts *P. communis* and *Brassica oleracea* each contained a fraction active after acid, and another active after alkali, hydrolysis. The results were characterized by lack of proportionality between the amount of sample extracted and the activity of the residue of the ether extract in agar. Distillates from the extracts of cabbage leaf and aphid contained substances active in the coleoptile test. Dry residues of the extracts of cabbage leaf and aphid were active after 6 days' storage and also after 13 days' storage in the dark at 0° C., following a second solution in ether and evaporation to dryness. Better proportionalities between concentration and activity were obtained when the extracts were not evaporated to dryness.

Criteria for purity of chlorophyll preparations, G. MACKINNEY. (Univ. Calif. et al.). (*Jour. Biol. Chem.*, 132 (1940), No. 1, pp. 91-109, fig. 1).—In this paper the author reports "the values of absorption coefficients for several preparations of chlorophylls a and b. The coefficients from five different laboratories are so incompatible that their application to spectroscopic assay of the green pigments is useless, until independent verification yields acceptable standards. As an aid to this, and to the correct evaluation of our preparations, we consider methods in some detail, our procedure being considerably simplified. This is particularly true of the step involving the precipitation of chlorophyll from petroleum ether. As criteria for purity, correct analyses and the various tests, phase, cleavage, etc., are of course essential. When we then apply the highly sensitive spectroscopic method, we find, in the last analysis, that purity is assured only when the pigment is homogeneous and forms an entirely separate zone on the Tswett column. The means to this end depend on the selection and standardization of the adsorbent."

Some difficulties encountered in the extraction of growth hormones from plant tissues, F. G. GUSTAFSON (*Science*, 92 (1940), No. 2386, pp. 266, 267).—Experimental comparisons of various methods of extraction are briefly presented.

Regeneration and vegetative propagation, C. F. SWINGLE. (U. S. D. A.). (*Bot. Rev.*, 6 (1940), No. 7, pp. 301-355).—In this comprehensive review (287 references), the first part deals with various anatomical, physiological, and practical reports on regenerative and propagation problems apart from growth substances; the second part considers various theoretical and practical problems tied up with those materials; and finally some consideration is given to more or less miscellaneous studies (some of which involve application of growth substances) on the lower plants and on leaf cuttings.

Origin of adventitious shoots in decapitated cranberry seedlings, H. F. BAIN. (U. S. D. A.). (*Bot. Gaz.*, 101 (1940), No. 4, pp. 872-880, figs. 15).—"The cranberry belongs to the increasing list of plants for which hypocotyledonary regeneration of growing points has been demonstrated. Adventive shoots in severed cranberry hypocotyls originate in the epidermal cell layer."

Rôle of glutathione in the breaking of the rest period of buds by ethylene chlorohydrin, J. D. GUTHRIE (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 4, pp. 261-270, figs. 2).—Treatment of freshly harvested potato tubers with solutions of glutathione shortened the rest period, this effect being about the same as that of ethylene chlorohydrin treatments inducing a similar glutathione content of the tissues. Injection of glutathione solutions into pear and peach branches shortened the rest period of the buds. It thus appears that ethylene

chlorohydrin breaks the rest period by increasing the glutathione content of the tissues.

Induced formation of β -gentiobiosides in gladiolus corms and tomato plants treated with chemicals, L. P. MILLER (*Science*, 92 (1940), No. 2376, pp. 42, 43).—The preliminary results here reported appear to indicate that gentiobiose is more widely distributed in plants than was previously supposed (see below).

Formation of β -*o*-chlorophenyl-gentiobioside in gladiolus corms from absorbed *o*-chlorophenol, L. P. MILLER (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 4, pp. 271-279, fig. 1).—"When gladiolus corms are treated with *o*-chlorophenol, the absorbed *o*-chlorophenol is converted into a β -glycoside. Through the synthesis of β -*o*-chlorophenyl-gentiobioside heptaacetate and heptapropionate, which were found to be identical with the corresponding derivatives of the glycoside formed in the treated corms, this glycoside has been shown to be β -*o*-chlorophenyl-gentiobioside. Since gladiolus corms had previously been found to form β -2-chloroethyl-*d*-glucoside from absorbed ethylene chlorohydrin, the results show that in the same plant tissue the sugar component of glycosides arising as a result of the absorption of chemicals which serve as aglucons may differ with different chemicals."

Auxin in marine plants, II, J. VAN OVERBEEK (*Bot. Gaz.* 101 (1940), No. 4, pp. 940-947).—In further studies (E. S. R., 83, p. 318), auxin was found in practically all the marine plants (brown and red algae, diatoms, *Phyllospadix*, *Zostera*, etc.) analyzed during the summer of 1939, details of which are given.

Effect of naphthalene acetic acid on mobile auxin in bean seedlings, W. S. STEWART. (U. S. D. A.). (*Bot. Gaz.*, 101 (1940), No. 4, pp. 881-889, fig. 1).—"In 7-day-old bean seedlings, applications of a 2 percent lanolin paste of naphthalene acetic acid applied as a band 1-2 mm. wide around the middle of the first internode caused in less than 2 hr. an increase in the amount of mobile auxin in the terminal bud, internode, and hypocotyl. The treatment likewise established a new gradient of mobile auxin. It also increased the ether-extractable auxin (which includes the mobile auxin) in the first internode. Ether extractions of bean seedlings showed large amounts of auxin in the terminal bud, while in other parts of the plant a substance was found capable of causing *Avena* coleoptile growth inhibition."

Enzymatic liberation of auxin from plant tissues, F. SKOOG and K. V. THIMANN (*Science*, 92 (1940), No. 2377, p. 64).—Using *Lemna minor* and the standard *Avena* test, the results obtained by several methods indicated that the slowness of auxin extraction is due to its very gradual liberation from some bound form. It is concluded from this study that the auxin in *Lemna* is bound to a protein, from which it is liberated on hydrolysis. It is deemed probable that this conclusion applies to a variety of plant tissues.

A new application of chemistry to plant improvement [trans. title], A. LEVAN (*Sveriges Utsädesför. Tidskr.*, 50 (1940), No. 2, pp. 66-76, figs. 4).—A review of work with colchicine in the development of new plant forms.

Growth response of plants to riboflavin and ascorbic acid, R. DENNISON (*Science*, 92 (1940), No. 2375, p. 17).—Grown in silica gravel with Withrow's solution, riboflavin increased the growth of eggplant and ascorbic acid that of tobacco. The data also suggested definite species differences in response to riboflavin and ascorbic acid, as well as the marked stimulatory effect of riboflavin not previously reported.

Growth substances for fungi.—II, Critical survey of literature 1936-37, V. G. LILLY. (W. Va. Expt. Sta.). (*W. Va. Univ. Bul.*, 40 ser., No. 5-I (1939), pp. 72-78).—A continuation (E. S. R., 79, p. 175), with 28 literature references.

Mutations and reversions in reproductivity of *Aspergilli* with nitrite, colchicine and *d*-lysine, R. A. STEINBERG and C. THOM. (U. S. D. A.). (*Natl. Acad. Sci. Proc.*, 26 (1940), No. 6, pp. 363-366).—Continuing such studies (E. S. R., 83, p. 177), the ease with which "mutants" were induced by nitrite suggested that its effect might consist in the destruction of a varying number of free amino groups included in the hereditary mechanism. In attempting to test this theory various compounds were used, among them *d*-lysine and sodium thiosulfate, both of which induced reversion mutants showing partial to complete recovery of reproductivity in *Aspergillus niger*. Positive results were also obtained with colchicine in several *Aspergilli*. In all these tests the nutrient solutions contained excess calcium carbonate. The mechanisms and implications of these responses are discussed. "An important, if not most important role is here assigned to *d*-lysine in the process of differentiation and reproduction, and concomitantly as a possible basis for strain differences in fruitfulness and certain growth characteristics. Progressive increase in sterility in successive transfers of fungi may, in some instances, have its origin in this process and may be found possible of counteraction in the presence of excess calcium carbonate by means of *d*-lysine or of ammonium salt and thiosulfate."

Glycine—an essential factor for the growth of bacteriophage, E. L. ELLIS and J. SPIZIZEN (*Science*, 92 (1940), No. 2378, p. 91).—Bacteriophage was found to multiply in bacterial cells suspended in dilute glycine solutions. Failure in distilled water and other pure solutions tested (as distinguished from broth) is ascribed to the necessity of specific substrates for phage growth.

Bacteriophage of *Rhizobia* in relation to symbiotic nitrogen fixation by alfalfa, S. C. VANDECAVEYE, W. H. FULLER, and H. KATZNELSON. (Wash. Expt. Sta.). (*Soil Sci.*, 50 (1940), No. 1, pp. 15-27, pls. 2).—*Rhizobium*-phage infected soil placed in pails and treated variously with *Rhizobium*-phage in fluid cultures and with phage-resistant and -susceptible strains of *R. meliloti*, used (3½ yr.) for growing alfalfa, gave normal growth and yields the first year (1936), but declined beginning in the second year. Additions of nitrogenous fertilizer in the third year to two series after the first alfalfa cutting (which lacked vigor and yielded poorly regardless of previous treatments) resulted in greatly improved vigor and nearly threefold increase in yield. Another application after the second cutting had even more striking effects. On the other hand, phosphate and potash fertilizers added to one of the fertilized series as supplements to nitrogen had no beneficial effects. Soil samples taken from various pails in 1937 and 1938 readily revealed a very active phage, the potency of which was high regardless of previous applications of *Rhizobium*-phage or phage-resistant or -susceptible *R. meliloti* to the soil. When the phage-resistant strain of *R. meliloti* was used as soil inoculant, it had no appreciable beneficial effect on alfalfa growth.

The presence of phage in the nodules of plants grown on infected soil was demonstrated by lysis tests and by disintegration and granulation of *Rhizobium* cells as revealed in stained smears of crushed nodules. Careful examination of representative alfalfa plants from variously treated soils failed to disclose symptoms of disease. These factors being eliminated, the only logical factor accountable for the poor growth in these tests was the action of the *Rhizobium*-phage resulting in lysis of *R. meliloti* and in a consequent drastic reduction of symbiotic nitrogen fixation. Some of the complicating factors that should be considered in relation to the *Rhizobium*-phage problem are briefly discussed.

The growth metabolism of *Rhizobium*, with evidence on the interrelations between respiration and synthesis, S. R. HOOVER and F. E. ALLISON. (U. S. D. A.). (*Jour. Biol. Chem.*, 134 (1940), No. 1, pp. 181-192, figs. 5).—Essentially the only products formed by *R. meliloti* growing in cultures supplied with am-

monia and nitrate N were CO_2 , H_2O , and bacterial cells of nearly constant composition with respect to age of culture and N source. The Q_{10} was analyzed graphically, and empirical equations were established describing the basal respiration and synthetic growth reactions occurring. A theoretical maximum growth efficiency or economic coefficient was calculated from the findings. Direct determinations of economic coefficient by two methods agreed well with the theoretical value.

Boron as a plant nutrient: A bibliography of literature published and reviewed, January 1939 through December 1939 (with index), D. H. JAMESON and C. M. SCHMIDT (*Washington, D. C.: Amer. Potash Inst., Inc., 1940, Sup. 2, pp. [2]+81+XVIII*).—Additions to the bibliography previously noted (E. S. R., 81, p. 768).

Absorption of selenium and arsenic by plants from soils under natural conditions, O. E. OLSON, L. L. SISSON, and A. L. MOXON. (S. Dak. Expt. Sta.). (*Soil Sci., 50 (1940), No. 2, pp. 115-118*).—Analyses of several soil and plant samples indicated no correlation between Se and As contents of the soils. The As in the soils studied was considerably less available to plants than the Se.

Vitamin B₁ in relation to the growth of green plants, D. I. ARNON. (Univ. Calif.). (*Science, 92 (1940), No. 2386, pp. 264-266*).—Evidence is presented that several widely differing plant species, when grown from seed under carefully controlled but favorable conditions, are not limited in their growth by an inherently low rate of vitamin B₁ synthesis, nor do the results indicate that such plants can benefit from additions of this vitamin to an otherwise favorable medium. However, the beneficial effects of vitamin B₁ on the rooting of certain cuttings is not inconsistent with these findings, since cuttings are not characterized by the storage of nutritive and growth substances to the extent observed in seeds.

Fungi for thiamin (vitamin B₁) assay, V. G. LILLY. (W. Va. Expt. Sta.). (*W. Va. Univ. Bul., 40. ser., No. 10-1 (1940), pp. 72-77*).—The author reviews the literature on thiamin assay fungi to May 1939 (26 references), and establishes the standard curve for *Phytophthora erythroseptica* which is shown to be suitable for thiamin assay. The possibility of using *Mucor ramannianus* on solid media for assay is also presented.

The relationship of inositol, thiamin, biotin, pantothenic acid, and vitamin B₆ to the growth of yeasts, R. J. WILLIAMS, R. E. EAKIN, and E. E. SNELL (*Jour. Amer. Chem. Soc., 62 (1940), No. 5, pp. 1204-1207, figs. 3*).—Growth curves of three highly different strains of *Saccharomyces cerevisiae* cultured in media containing different combinations of growth substances indicated that at least two strains could grow continuously without inositol, and that thiamin was especially important for only one. Biotin alone would not immediately stimulate the yeast growth from small seedlings, but in proper combination its effect was striking and evident even in very minute doses. Pantothenic acid or its precursor β -alanine was highly essential for immediate growth, and when added alone was able to induce continued growth. Vitamin B₆ proved relatively unimportant as a constituent of the media. Substances of unknown nature in liver and yeast extracts play an important role in promoting rapid growth. Yeasts during a long incubation period show considerable ability to grow in the absence of various nutrilites, and under such conditions one nutrilitite alone may serve, whereas for rapid growth several are necessary.

The efficacy of ultra-violet light sources in killing bacteria suspended in air, B. A. WHISLER (*Iowa State Col. Jour. Sci., 14 (1940), No. 3, pp. 215-231, figs. 8*).—The bacterial killing power of ultraviolet irradiation varied directly with the time of exposure to it and with the light intensity. The bactericidal

effects may be expressed as simple mathematical relationships. The killing effect was 10 or more times as effective in dry as in humid air. Use of glass filters indicated that over 94 percent of the killing effect of the quartz mercury arc lies in the spectrum region below 280 $m\mu$. For a given high pressure quartz mercury arc, the killing power varied as the fourth power of the voltage drop across the lamp. The efficiencies as to power consumption v. bactericidal power of several types of apparatus are compared. Among different bacterial genera there were great variations in resistance to such irradiation.

General bacteriology, D. B. SWINGLE (*New York: D. Van Nostrand Co., 1940, pp. XII+313, [pl. 1], figs. 157*).—A textbook comprising a general introduction to the field, in which the author attempts to present a thorough study of the organisms themselves as a basis for applied work.

Elementary bacteriology, J. E. and E. O. GREAVES (*Philadelphia and London: W. B. Saunders Co., 1940, 4. ed., rev., pp. XIV+587, [pls. 6], figs. [158]*).—This textbook, in its 48 chapters, considers the history and fundamentals of bacteriology and the more important nonpathogenic and pathogenic bacteria.

Fundamentals of bacteriology, M. FROBISHER, JR. (*Philadelphia and London: W. B. Saunders Co., 1940, 2. ed., rev., pp. XVII+653, [pls. 3], figs. [323]*).—A revised edition of the textbook previously noted (*E. S. R., 77, p. 694*).

Bactericidal filtrates from a mold culture, E. C. WHITE (*Science, 92 (1940), No. 2380, p. 127*).—A mold, tentatively identified as *Aspergillus flavus*, growing readily in liquid media was found to yield filtrates that are definitely bactericidal for some gram-negative as well as gram-positive bacteria. Other *Aspergillus* forms examined in this way have given widely varying results.

Germination of chlamydo-spores of *Cintractia leucoderma* [trans. title], A. P. VIÉGAS (*Jor. Agron., 3 (1940), No. 1, pp. 33-42, pls. 2*).—A cultural and cytological study of the fungus.

A new species of *Hypocrella* [trans. title], H. P. KRUG (*Jor. Agron., 3 (1940), No. 1, pp. 69-82, pls. 5; Eng. abs., p. 80*).—The fungus *H. fluminensis* n. sp., occurring on aleyrodids, is described.

The Myxomycetes, G. W. MARTIN (*Bot. Rev., 6 (1940), No. 7, pp. 356-388*).—The slime molds have been known and studied for over two centuries. Quite naturally, the earlier references to the group are almost entirely taxonomic. A full review of that literature is beyond the present scope, which includes critical analyses of the questions of spore germination, nutrition and culture, morphology and cytology of the fructifications, nuclear cycle, physiology, ecological relations, and the more recent taxonomic problems of the group. In the light of present information, it is deemed best to restrict the name Myxomycetes to include only the Exosporeae, represented by the single genus *Ceratiomyxa*, and the Myxogastres (Endosporeae). There are 203 references.

A second note on Georgia Discomycetes, E. K. CASH. (U. S. D. A.). (*Jour. Wash. Acad. Sci., 30 (1940), No. 7, pp. 299-305, figs. 4*).—New species are described under the genera *Sphaeropezia*, *Lachnum*, *Pyrenopeziza*, and *Phaeangium*.

Effect of emanations from several species of fungi on respiration and color development of citrus fruits, J. B. BIALE. (Univ. Calif.). (*Science, 91 (1940), No. 2367, pp. 458, 459, fig. 1*).—This is a preliminary report.

Alcoholic fermentation by *Fusaria* juice obtained with a wet crushing mill, J. C. WIRTH and F. F. NORD (*Science, 92 (1940), No. 2375, p. 15*).—The authors investigated an artificial enzyme system from *Fusarium lini* extracted by the aid of the Booth-Green wet crushing mill noted on page 10. The measurable capacity of the juice at 28° [C.] amounted to $\pm 35-40$ percent of the phosphorylation in the living cell system. In some cases this appeared

to have been preceded by a dephosphorylation of the organic phosphate donors originally present in the living cells. The esterification brought about by the quantity of inorganic phosphate present amounted to $\pm 3-4$ percent. The quantity of CO_2 obtained by action of the zymases compared favorably with that of the living system. This enzyme system exhibited none of the deficiencies or distortions of the usual maceration juices obtained from yeasts.

The herbaceous vegetation of the Edwards Plateau, V. L. CORY. (Tex. Expt. Sta.). (*Southwest. Sheep and Goat Raiser*, 10 (1940), No. 10, pp. 5, 6, 34, 35).—In this Texas plateau region—beginning in May 1931 and ending in December 1936—vegetation counts were made at several stations in the turf grasslands at each ranch by means of meter quadrats, selected and counted once or twice each month throughout the period of 5.5 yr. In no two years was the herbaceous vegetation of the range exactly alike. The stable elements were the perennial grasses, while the greatest variation from year to year was with the forbs. Detailed information is presented concerning the species of economic importance in the latter group.

Common range plants (Arizona and New Mexico), G. B. ARTHUR (*U. S. Dept. Int., Civ. Conserv. Corps, P. T. Ser. No. 13* (1939), pp. [6]+118, figs. 35).—This illustrated manual is designed primarily to assist range survey personnel in the identification and study of important plants. It is divided into grasses, browse plants, and weeds, each of these sections being preceded by an index, by common and Latin names, of the plants described therein. Palatability ratings are given for each of the range species, and keys to the genera are provided.

The floristic significance of shrubs common to North and South American deserts, I. M. JOHNSTON (*Jour. Arnold Arboretum*, 21 (1940), No. 3, pp. 356-363).—In the southwestern United States and northern Mexico (in North America) and in Argentina and Chile and adjacent Bolivia and Peru (in South America) there are vast areas characterized by a low atmospheric humidity and rainfall. The climatic and edaphic conditions of these two regions are rather similar and so is their general type of vegetation. Though their component species are almost entirely different, there are identities which indicate former connections and interchange, and there is every reason for believing in the past existence of a widely distributed American desert flora. All the evidence indicates that, relatively isolated and free from competition, it has persisted in South America, while in North America, diluted by new xerophytes originating in the northern temperate lands, it has been giving way before their competition. Certain northern desert shrubs are deemed the remnants of an old desert flora which has found a haven in South America, but has been decimated in the more keenly competed desert terrains of the north.

Wood anatomy and pollen morphology of Rhus and allied genera, C. HEIMSCH, JR. (*Jour. Arnold Arboretum*, 21 (1940), No. 3, pp. 279-291, pls. 3).—A detailed study of the secondary xylem and the pollen grains of the *Rhus* group of plants (genera *Rhus*, *Cotinus*, *Toxicodendron*, *Metopium*, *Malosma*, and *Actinocheita*) indicated that on the basis of each of these structures plants of the *Rhus* complex are segregated into the same six groups. Whether these should be considered as genera or subgenera is a matter of interpretation. However, the xylem structure here is distinctive. Thus, in a relatively small taxonomic group such as this, anatomical studies can provide data significant for classification.

The physiology of trees with special reference to their food supply, A. J. HEINICKE. (Cornell Univ.). (*Natl. Shade Tree Conf. Proc.*, 15 (1939), pp. 26-35).—A brief conspectus of the subject.

Solution gardening: A new application of science to an ancient art, B. E. LIVINGSTON (*Sci. Mo.*, 51 (1940), No. 1, pp. 15-21).—A semipopular summary of the practical application of mineral nutrient supply to plants in solutions, with brief reviews of eight recent popular books on the new "gardening" method.

Sketch of the development of the water culture method of growing plants, J. W. SHIVE. (Rutgers Univ.). (*Sci. Mo.* 51 (1940), No. 3, pp. 233-240).—A review (bibliographical footnotes) of progress from the eighteenth century on.

The mechanism of plant respiration, H. HIBBERT (*Jour. Amer. Chem. Soc.*, 62 (1940), No. 4, pp. 984, 985).—A preliminary note.

An attempt to record internal tree-trunk pressures, A. P. BEILMANN (*Ann. Missouri Bot. Gard.*, 27 (1940), No. 3, pp. 365-370, pl. 1, fig. 1).—Using an automatic "dash-pot" instrument developed for the purpose, the records obtained either from the back of glass-fronted cavities or from bore holes in sound tree trunks showed clearly that the so-called "internal pressures" were due to temperature changes within the instrument. When a mass of putty replaced the tree trunk, identical records were obtained. Internal pressures—if they exist—cannot be recorded either with manometers or with the instrument described. Fluctuating barometric pressures of stormy periods were simulated by applying pressure or suction forces to a tree trunk. With the equipment used it was found that suction forces were the easier to obtain. Equilibrium, following evacuation, was so quickly established that accurate measurements could not be made. It was physically impossible to read manometers placed 1 m. apart from top to bottom of a mature tree. The "lag" in establishing equilibrium was shown to be ± 90 sec. for a certain Spanish oak. From these results it appears that "internal pressure" differing from atmospheric does not occur in normal sound trees.

Studies on the developing cotton fiber.—II, Identification and estimation of the reducing sugars, J. COMPTON and F. E. HAVER, JR. (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 4, pp. 281-290).—Continuing this series (E. S. R., 83, p. 605), it was found that "the reducing sugars of developing cotton fibers are composed of glucose, fructose, and pentoses. Throughout the period of fiber development the sugars are present in variable relative proportions. During the period of rapid cell wall elongation, 1 to 20 days, the reducing sugar component is high relative to the mass of the crude fiber, but progressively decreases during cell wall thickening, 'secondary wall formation,' until maturity is reached. The mechanism of the transformation of the various sugars into the many cotton fiber constituents lies as yet in the realm of speculation." There are 26 references.

The course of photosynthesis and fluorescence, E. D. McALISTER and J. MYERS (*Science*, 92 (1940), No. 2385, pp. 241-243, figs. 4).—Using wheat and *Chlorella pyrenoidosa*, it was found that the behavior observed in several hundred induction curves, obtained over a wide range of conditions, may be described in terms of two processes. One of them involves an inverse relation between the rate of CO₂ uptake and the intensity of fluorescence, and the other a direct relation. As to the nature of these processes, more study is needed.

The time course of photosynthesis and fluorescence observed simultaneously, E. D. McALISTER and J. MYERS (*Smithsn. Misc. Collect.*, 99 (1940), No. 6, pp. [2]+37, figs. 16).—Simultaneous measurements of intensity of fluorescence and rate of CO₂ assimilation during and following the induction period in wheat and *Chlorella* are reported. Although these observations are regarded as exploratory and preliminary, they are believed to permit of certain

conclusions, which are discussed. Briefly, these are: Any sudden change in illumination conditions or CO₂ concentration that produces a large increase in the photosynthetic rate also gives rise to a "burst" in the intensity of fluorescence. The changes in CO₂ assimilation rate observed in the induction period of wheat under normal air conditions are caused by two processes, one of which exhibits an inverse relation to intensity of fluorescence and the other is directly related. In *Chlorella* the induction behavior is greatly influenced by the previous conditions of culture. Under CO₂ concentrations greater than that of normal air the induction phenomenon in wheat is complicated by a second maximum in fluorescence occurring after ± 1 -min. illumination. At the same time a minimum in CO₂ uptake rate is observed which clearly bears an inverse relationship to this second maximum of fluorescence. Curves relating intensity of fluorescence and CO₂ uptake rate to incident intensity were obtained from measurements made under steady-state conditions following the induction period. These show a marked change in fluorescence in passing from light-limiting to CO₂-limiting conditions. The CO₂ assimilation rate in wheat in high light and 0.03 percent CO₂ is 30-50 percent higher in 0.5 than in 20 percent O₂, suggesting that for young wheat a reaction of large proportions opposing photosynthesis is always depressing the CO₂ assimilation rate under natural growing conditions.

Sex expression in willows, E. C. SMITH. (Colo. State Col.). (*Bot. Gaz.*, 101 (1940), No. 4, pp. 851-861, figs. 4).—"Dioeciousness in willows probably expresses a terminal condition or climax in an evolutionary process which is impressed to a high degree on the germ plasm. The potentialities for the expression of both sex tendencies are present in all individuals of the genus, but expression of one of them is ordinarily in nature inhibited by the genetic constitution. Whether this is due to an inhibiting factor, to a realizator factor, or to a varying balance between genes and autosomes is not yet clear. Whatever accounts for the dioecious character, some of the variations from that condition are demonstrably due to external agents; others are just as demonstrably due to internal changes. Under the natural conditions in which willows occur, triploidy and polyploidy are common results of hybridization, but occur also in pure lines. In some cases, but not in all, these conditions bring about various abnormalities of sex expression. Even though the underlying causes are in the germ plasm, the action at the point of segregation for stamens and pistils is that of the hormones, and that action may be modified by external factors."

GENETICS

The breeding of improved selfed lines of corn, H. K. HAYES and I. J. JOHNSON. (Minn. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 8, pp. 710-724).—Inbred lines were bred by the pedigree method from crosses between inbreds where, as a rule, one parent at least of each cross was outstanding in resistance to lodging and to smut. Selection during the segregating generations was made in selfed lines for these characters and for plant vigor. In general, the methods used appeared to lead to distinct improvement in many characters. When the inbreds produced by the pedigree method were studied in inbred-variety crosses, lines of good combining ability were obtained oftener from crosses between good combining inbreds than from crosses between inbreds low in combining ability, suggesting that this character is inherited. Twelve characters of the inbreds, by means of total correlations, were found to be related significantly to yielding ability in inbred-variety crosses. The correlations ranged from +0.1902 for tassel index of inbreds and yield of inbred-variety crosses to +0.5430 for root volume of inbreds and yield of inbred-

variety crosses. A multiple correlation coefficient of 0.6660 was obtained for association between yield of inbred-variety crosses and characters of inbred lines, including date silked, plant height, ear height, leaf area, pulling resistance, root volume, stalk diameter, total brace roots, tassel index, pollen yield, yield index, and ear length. Inbreds of good combining ability were selected from inbred-variety crosses. When F_1 combinations of these inbreds were studied in groups, group I crosses with no parents in common were superior to those of group II with one parent in common and far superior to group III, those with two parents in common.

The value in hybrid combinations of inbred lines of corn selected from single crosses by the pedigree method of breeding, I. J. JOHNSON and H. K. HAYES. (Minn. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 7, pp. 479-485).—A study made to determine the relation between the performance of inbreds in inbred-variety crosses and in single crosses is reported. Evidence from 12 single crosses between relatively low-combining inbreds (bred by the pedigree method from single crosses) indicated that single crosses between low combiners may be expected to average somewhat lower in yield than single crosses from relatively high-combining inbreds when the single crosses are between inbreds of diverse genetic origin. Single crosses between low-combining inbreds with high combiners yielded as well, however, as single crosses between high combiners, and provided as high a proportion of high-yielding single crosses. Additional data from crosses between related inbred lines showed that diversity in genetic origin is an important factor in obtaining maximum expression of hybrid vigor. In a comparison of 147 single crosses between inbreds of unrelated origin with recommended double crosses, 63 yielded significantly higher than double crosses used as a standard, suggesting the desirability of selecting inbreds for use in double crosses from crosses between inbred lines with superior characters. See also a note by Wu (*E. S. R.*, 83, p. 325).

Genetic studies with foxtail millet, *Setaria italica* (L.) Beauv., H. W. LI, J. C. MENG, and C. H. LI (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 6, pp. 426-438, fig. 1).—From studies of progenies grown at Honan University (Kaifeng), six color types for the seed coat of foxtail millet were assigned the following factors: Black *KRB*; tawny buff *KRb*, korra buff *KrB* and *Krb*, sepia *kRB*, red *kRb*, and tawny red *krB* and *krb*. Endosperm characters are controlled by simple Mendelian factors, i. e., nonwaxy *Wx*, white *W*, waxy *wx*, and yellow *w*, with *wx* and *w* inherited independently. Earhead types may be palmatic or normal and are controlled by duplicate factors, P_1 and P_2 , as follows: Palmatic P_1P_2 and P_1p_2 , and normal p_1P_2 and p_1p_2 . Double earheads did not appear to be inherited.

Dormancy in fatuoid and normal oat kernels, F. A. COFFMAN and T. R. STANTON. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 6, pp. 459-466, fig. 1).—Freshly harvested seed of fatuoid and normal oats plants from 12 varieties of *Avena sativa* and 4 of *A. byzantina* were tested to determine the relationship in dormancy between fatuoid and normal plants of the same variety. When dormancy occurred in normal plants of a variety, it also occurred in fatuoids from that variety, and when germination was prompt, seed of the fatuoid of either the homozygous or heterozygous intermediate plant forms also germinated promptly. This seemed to support the belief that fatuoids result from mutations rather than from natural crosses with *A. fatua*, inasmuch as seed of the latter usually have a decided tendency toward dormancy. There also were indications that characters associated with fatuoids, such as the "suckermouth" form of base, presence of basal hairs on the callus,

etc., were unrelated to dormancy in oats. The authors (E. S. R., 79, p. 619) observed previously that these kernel characters were often found in oats varieties having a tendency to dormancy, but stated that their association with dormancy might be merely accidental.

Cytological investigations in *Desmodium* and *Lespedeza*, J. O. YOUNG (*Bot. Gaz.*, 101 (1940), No. 4, pp. 839-850, figs. 43).—The haploid number 11 is reported for the chromosomes of 15 species, and the diploid number 22 for 9 species of *Desmodium*. Gametic numbers observed in *Lespedeza* were 11 for 1 species, 10 for 7 species, and 9 for 3 species. Where the haploid number 9 is reported, the presence of 20 chromosomes in root-tip metaphases indicates that the true gametic number is 10. Diploid numbers reported are 20 for 6 species and 1 variety, and 22 for 2 species. In both genera the chromosomes were $\pm 1\mu-3\mu$ in length. Pollen grains exhibited size variation in possibly hybrid species of *Lespedeza*, but no caryological abnormalities were noted. The anthers of *L. capitata velutina* had withered before anthesis in material from 2 widely separated localities, and only a few unusually small pollen grains were found.

The wild bean *Phaseolus polystachyus* (L.) B. S. P.: Its chromosome number, H. A. and H. F. ALLARD. (U. S. D. A.). (*Jour. Wash. Acad. Sci.*, 30 (1940), No. 8, pp. 335-337).—Field notes, distribution, ecological relations, and chromosome number ($2n=22$) are briefly considered.

Physiologic specialization and genetics of the smut fungi, J. J. CHRISTENSEN and H. A. RODENHISER. (Minn. Expt. Sta. and U. S. D. A.). (*Bot. Rev.*, 6 (1940), No. 8, pp. 389-425).—As used in the Ustilaginaceae the term physiological race is said to designate a collection of chlamydo-spores that behave more or less consistently in parasitism on certain differential varieties of host plants and not on others. The authors give a comprehensive, critical review of the literature (132 references) on this type of specialization as related to breeding for smut resistance and the selective effect of the host on pathogenicity, and as related to the genetics of this fungus group including details of the mechanism of heredity, the inheritance of specific characters, and mutations.

A Mendelian situation in the birthcoat of the New Zealand Romney lamb, F. W. DRY, P. R. McMAHON, and J. A. SUTHERLAND (*Nature [London]*, 145 (1940), No. 3671, p. 390, fig. 1).—Lambs with an abundance of halo hairs appear from time to time in New Zealand Romney flocks. Breeding results indicate that the character is due to a single dominant factor linked with the sex-influenced factor for horns, with about 8-10 percent crossing over. Other data pointed toward the operation of two complementary factors for the halo condition. It is noted that halo lambs were produced by nonhalo parents.

Inheritance and linkage relations of mutant characters in the deer mouse, *Peromyscus maniculatus*, F. H. CLARK (*Contrib. Lab. Vert. Genet., Univ. Mich.*, No. 7 (1938), pp. 11).—Following a description of 16 known alleles in the deer mouse, investigations of the linkage relations between pink eye and albinism, hairless and albinism, yellow and albinism, yellow and dilute, yellow and hairless, and yellow and buff are presented. All seemed to be in separate chromosomes except pink eye and albinism. Between these two genes there was 19.94 ± 1.44 percent crossing over in ♀♀ and 13.16 ± 2.70 percent crossing over in ♂♂. The differences suggest that crossing over may be less frequent in ♂♂ than in ♀♀. The data on the other genes did not indicate that linkages existed, and they were considered to be located in different chromosomes.

Umbrous: A case of dominance modification in mice, K. MATHER and S. B. NORTH (*Jour. Genet.*, 40 (1940), Nos. 1-2, pp. 229-241, figs. 2).—The char-

acter umbrous consisted of a dark streak in the coat of agouti mice extending from the eyes to the tail. The character was a modifier of agouti not expressed in nonagouti animals. Breeding tests showed the original ♂ to be heterozygous *Uu*. Several different types of matings were made, and the types of progeny tabulated. Heterozygous agoutis were more affected by the *U* gene than the agouti homozygotes, and they were separable by the eye. The umbrous pattern was not so marked on *Uu* as on *UU* animals. Thus *U* is a dominance modifier. In a note, attention is called to Punnett's findings (E. S. R., 64, p. 530) that certain members of the *F* series in rabbits bring about various suppressions of the agouti character in homozygous and heterozygous animals resulting in the occurrence of refractory black. Attention is called to reasons why the two cases in rabbits and mice do not seem synonymous.

Inheritance of pinkeye in the fowl, D. C. WARREN. (Kans. Expt. Sta.). (*Jour. Hered.*, 31 (1940), No. 6, pp. 291, 292, fig. 1).—Three pink-eyed White Plymouth Rocks were found to produce only pink-eyed offspring. In a cross of 1 pink-eyed male mated with 3 normal-eyed heterozygous albinos, 46 chicks were produced, none of which was pink-eyed, suggesting that pink eye and albino were caused by different genes. Further results clearly demonstrated that pink eye is a recessive character which tends only to dilute the melanic pigment in the plumage pattern. Albinism and pink eye had similar effects on eye color, but the influence on plumage color was dissimilar.

Qualitative and quantitative differences in the morphology of spermatozoa from ring doves, Pearlnecks, and their F_1 and backcross hybrids, E. W. SHRIGLEY. (Wis. Expt. Sta.). (*Jour. Expt. Zool.*, 83 (1940), No. 3, pp. 457-479, figs. 3).—Morphologically, six classes of sperm were found in the F_1 and backcross hybrids between ringdoves and Pearlnecks. Each of the four groups of populations showed all six classes of sperm, with the proportions varying. A higher proportion of abnormal sperm was found in backcross individuals which possessed agglutinogens specific for the Pearlneck species and, therefore, some genes from this species (which were present in the F_1 s) than was found in the birds lacking these properties. No artificial method was found for producing anomalies of the sperm heads comparable to those observed, with the exception of one type involving an atypical staining reaction. It seemed that the spermatid nucleuses were unable to change from spherical to spearlike.

The isolation of oestrone from ox adrenals, D. BEALL (*Jour. Endocrinol.*, 2 (1940), No. 1, pp. 81-87).—The methods are described by which oestrone was isolated from two ox adrenal concentrates.

A comparison of the international gonadotropin standards, F. E. and M. C. D'AMOUR (*Endocrinology*, 27 (1940), No. 1, pp. 68-70, figs. 2).—Although the potency of the gonadotropin in pregnancy urine and pregnant-mare serum was comparable, pregnant-mare serum at higher levels proved more potent, especially in the ovarian response. A combination of the uterine weight-vaginal smear technic seemed most satisfactory for assaying preparations of unknown potency.

The rate of loss of activity of antigonadotrophic serum in vivo, M. R. A. CHANCE (*Jour. Endocrinol.*, 2 (1940), No. 1, pp. 99-103, figs. 2).—An antigonadotrophic serum of a goat immunized to human pregnancy urine lost 50 percent of its activity during the first day in vivo, with lesser losses in succeeding time intervals, as determined in tests with from 40- to 50-gm. rats.

The relation of diet to the restitution of the gonadotropic hormone content of the discharged rabbit pituitary, M. H. and G. S. FRIEDMAN (*Amer. Jour. Physiol.*, 128 (1940), No. 3, pp. 493-499, fig. 1).—The ability of does to restore the gonadotropic hormone to the pituitaries during the first 8 days of

pseudopregnancy following the complete discharge of the hormone at coitus was not related to diets containing from 0.007 to 2.56 percent of nitrogen. However, seasonal influences were pronounced and it was believed that protein requirements for gonadotropic hormone formation in the pituitaries can be fully met by nitrogen derived from the rabbit's own tissues.

The effect of heat on the gonadotropic pituitary antagonist, H. JENSEN, S. TOLKSDORF, and J. F. GRATTAN (*Amer. Jour. Physiol.*, 128 (1940), No. 3, pp. 532-536).—Comparative study in normal and hypophysectomized mature and immature ♀ rats of the effects of a boiling water bath for from 10 to 30 min. on the gonadotropic and antagonistic properties of sheep pituitary extracts containing follicle-stimulating and luteinizing hormones, administered with pregnant-mare serum, showed that heating destroyed the multiple physiological properties of the interstitial-cell-stimulating hormone, the luteinizing hormone, and antagonizing fractions at approximately the same rate.

Ovaries secrete male hormone.—V, A comparison of some synthetic androgens with the naturally occurring ovarian androgen in mice, R. T. HILL and M. T. STRONG (*Endocrinology*, 27 (1940), No. 1, pp. 79-82, figs. 5).—Continuing this series (*E. S. R.*, 80, p. 608), comparison is reported of the weights of the prostates and seminal vesicles in castrate ♂ mice following injection at daily intervals and on alternate days of testosterone, testosterone propionate, androstenedione, and dehydrosterone. Ovarian ear grafts were also made for study of their effects on normal and castrate ♂s. The weights of the accessories determined at 5, 10, 15, and 20 days showed essentially the same stimulation from testosterone propionate plus Progynon-B as from ovarian grafts, indicating the physiological similarity of the androgen and of the ovarian principle although they were chemically different.

Mechanism of action of a progonadotrophic serum, I. W. ROWLANDS and P. C. WILLIAMS (*Jour. Endocrinol.*, 2 (1940), No. 1, pp. 75-80, fig. 1).—The globulin fraction of the serum of a goat injected with pig anterior-pituitary extract showed no progonadotrophic activity in hypophysectomized rats, although this effect was made evident in normal animals.

Species variation in thyrotrophic, gonadotrophic, and prolactin activities of the anterior hypophyseal tissue, M. R. A. CHANCE, I. W. ROWLANDS, and F. G. YOUNG (*Jour. Endocrinol.*, 1 (1939), No. 3, pp. 239-260, figs. 7).—Comparison was made by the guinea pig thyroid stimulation, pigeon crop-gland response, stimulation of ovarian weights in the rat, and initiation of ovulation in the rabbit by extracts of the pituitaries of man, horse, pig, sheep, and ox. Gonadotropically, the human pituitary tissue was much more active than tissue from any of the other species, but it had a small although not negligible content of prolactin and thyrotropin. The horse pituitary was second in its content of gonadotropin, when measured by the rat ovary test, with only small amounts of stimulation to the growth of the rabbit ovary. The pituitaries of the sheep and ox contained the most prolactin, with negligible amounts in tissues from pig and horse. Pig pituitary tissues were most active thyrotropically, whereas horse tissue was negligibly active when considered as a source of this active hormone. Considering different methods of preparation, alkaline aqueous alcohol was found to be greatly inferior to simple aqueous alkali for the extraction of the gonadotropic activity in horse pituitary tissue.

Uterine changes in the rabbit with the advent of pregnancy, M. GRAUBARD and G. PINCUS (*Amer. Jour. Physiol.*, 128 (1940), No. 4, pp. 653-661).—Measurements were made of the content of ascorbic acid and other reducing substances in the ovaries, adrenals, and pituitaries of immature and mature rabbits in various stages of the oestrous cycle as a result of treatment with gonadotropic ma-

terial. Rabbits 3 days pregnant showed a definite increase in the ascorbic acid content of the uteri, but there was only a slight increase in the glutathione content. The adrenals and ovaries of pregnant animals showed similar increases. When injected with gonadotropic hormones, the pituitaries showed marked increases in ascorbic acid and glutathione. Increases in pregnant animals were noted up to 6 days of gestation. There was an increase of 75 percent in the respiration rate of the endometrium and whole muscle in 3-day pregnant rabbits.

Hypertrophy in the pseudopregnant uterus of the mouse following mechanical stimulation or treatment with vitamin E. I. SZABÓ (*Endocrinology*, 27 (1940), No. 1, pp. 125-128, figs. 2).—Oral administration of vitamin E to pseudopregnant mice resulted in uterine hypertrophy similar to that produced by mechanical stimulation of the cervix over a long period of time. Vitamin E did not cause uterine hypertrophy in the normal unstimulated mouse.

The influence of reproductive condition upon growth of the female rat. R. BOGART, G. SPERLING, L. L. BARNES, and S. A. ASDELL. (Cornell Univ.). (*Amer. Jour. Physiol.*, 128 (1940), No. 2, pp. 355-371, figs. 4).—The rate of growth was studied in 6 groups of 50 female rats each, which were subjected to the following conditions: (1) Bred at 9 mo. of age, (2) bred as early as they would breed, (3) bred at normal age (100 days), (4) never bred, (5) bred at normal age but not allowed to suckle young and rebred immediately after parturition, and (6) ovariectomized at about 40 days of age. Animals in groups 1, 2, and 3 nursed their young for 3 weeks and were then rebred. The ovariectomized rats grew more rapidly early in life than virgins or breeding animals. The virgins grew at a slower rate and reached a plateau in growth earlier than breeding animals, the growth period being approximately the same for the virgin and castrated animals. Animals breeding but not lactating grew more rapidly than the lactating animals or virgins and for a longer time than the latter. Breeding lactating animals grew more rapidly and for a longer time than virgins, also for a longer time than the castrated animals, but did not approach the growth rate of the castrated or breeding nonlactating animals. Early-bred animals were retarded in growth, due to lactation, but reached the same adult size as animals bred later. The late-bred females never attained the adult size of the other breeding animals but surpassed the virgins. Breeding stimulated growth even after animals had reached the growth plateau. It is suggested that oestrogens inhibit growth and that the corpus luteum removes this inhibition.

The reproductive efficiency of the albino rat under different breeding conditions. M. J. BABCOCK, R. BOGART, G. SPERLING, and S. A. ASDELL. ([N. Y.] Cornell Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 12, pp. 847-853).—Four groups of 50 rats each were subjected to the following breeding regimes until they were 22 mo. of age: (1) Bred as early as they would breed, (2) bred at 100 days of age, (3) bred at 280 days of age, and (4) bred at 100 days of age but not allowed to suckle young and rebred as soon as possible after parturition. Animals in groups 1, 2, and 3 suckled their young for 3 weeks and then were promptly rebred. The average number of young produced per rat was 49.7, 54.3, 25.1, and 79.7 for groups 1 to 4, respectively. Average weights of young at birth and at weaning age were similar for all groups, with group 3 slightly exceeding the others. The over-all reproductive efficiency of the early-bred rats was somewhat less than that of the rats bred at normal age, while that of the late-bred rats was much lower than that of any of the other groups. Those rebred immediately after parturition produced many more young than did the groups subjected to lactation.

Postnatal masculinization of the female rat by means of testosterone propionate. H. SELYE (*Anat. Rec.*, 76 (1940), No. 2, pp. 145-155, pls. 2).—To

determine the importance of the age of the animal to its response to testosterone treatment, 11 newborn rats were intraperitoneally injected daily with 1 mg. of testosterone propionate for 15 days, and the dose raised to 3 mg. subcutaneously for 15 more days. On autopsy at 30 days of age, the ovaries in ♀♀ could not be detected, the uteri were very thin and atrophic, and the oviducts, although detectable, assumed a gelatinous translucent appearance. These effects in the young postnatal rat were in contrast to the production of uterine enlargement from testosterone treatment of older ♀♀. In ♂♂ the genital organs, especially seminal vesicles, prostate, and penis, were extremely well developed without decrease in testicular size. The adrenals showed marked atrophy.

Sexual development of fowls derived from eggs treated with oestradiol benzoate. J. H. GAARENSTROOM (*Jour. Endocrinol.*, 2 (1940), No. 1, pp. 47-54, pl. 1).—Chicks from 400 White Leghorn eggs injected on the second day of incubation with 300 µg. of oestradiol benzoate were autopsied 1 week, 2 mo., and 9 mo. after hatching to study the effects on the gonads. Intersex chicks were found to have right gonads from 25 to 66 percent of the size of the left gonads, and the presence of both ovarian and testicular tissue. Study of the gonads and secondary sex characters showed, in the birds killed 1 week after hatching, that there were 1 ♂, 33 ♀s, and 8 intersexes. This ratio gradually changed so that there were in the group killed at 2 mo. no ♂s, 19 ♀s, and 22 intersexes, and in the group killed at 9 mo. 17 ♂s, 10 ♀s and no intersexes. Histological study showed that the feminized ♂s could not maintain their ♀ sex organs during postnatal life. Control birds did not depart significantly from normal sex ratios.

Microhistometric assay of thyrotropic hormone in day-old chicks. R. W. RAWSON and W. T. SALTER (*Endocrinology*, 27 (1940), No. 1, pp. 155-157, fig. 1).—A very sensitive method for assaying thyrotropic hormone is described, based on daily injection for 5 days of newly hatched chicks. Autopsy and histological examination of the acinar cells were made on the sixth day. The increase in height of the cells served as the criterion of the thyrotropic potency of the material tested.

The endocrine control of lipid metabolism in the bird, I-III. (Univ. Calif. et al.). (*Jour. Biol. Chem.*, 126 (1938), Nos. 1, pp. 133-139, fig. 1; 2, pp. 763-769; 134 (1940), No. 2, pp. 495-504).—Three reports are noted.

I. *The effects of pregnant mare serum upon the blood and liver lipids of the domestic fowl*, C. Entenman, F. W. Lorenz, and I. L. Chaikoff (pp. 133-139).—In a study of factors involved in the lipid metabolism of chickens it was found that continued injections (8-27 days) of pregnant mare serum into immature female birds produced a rise in the blood lipides similar to that observed in normal laying birds (E. S. R., 79, p. 674). The oviducts increased in size as a result of the injections, and a rise in blood lipides occurred when an oviduct growth of at least 10 gm. had been attained. Apparently the formation of yolks is not the stimulus for the rise in blood lipides, since no yolk growth was initiated in any of the experimental birds.

II. *The effects of estrin on the blood lipids of the immature domestic fowl*, F. W. Lorenz, I. L. Chaikoff, and C. Entenman (pp. 763-769).—Injections of an oestrogenic concentrate (prepared from pregnant mare urine) containing 25,000 rat units of oestrin per cubic centimeter into immature female birds raised the blood lipides. The effect occurred rapidly, an intramuscular injection of 3,000 rat units more than doubling the total lipide content of the blood within 12 hr. Injection of 2,000 rat units of the hormone into male birds caused a rise to over 1,000 mg. of total lipide per 100 cc. of whole blood. All lipide constituents were increased, but the most pronounced effect was upon the neutral fat.

III. *The effects of crystalline sex hormones on the blood lipids of the bird*, C. Entenman, F. W. Lorenz, and I. L. Chaikoff (pp. 495-504).—Compounds tested in these experiments included the oestrone, oestradiol, oestradiol benzoate, ethinyl oestradiol, and stilboestrol, all of which on intramuscular injections resulted in an increased concentration of total fatty acids, phospholipides, and cholesterol in the blood of chicks. Stilboestrol gave the most striking response. On the basis of rat units oestrone was more effective than oestradiol. Testosterone, progesterone, and desoxycorticosterone acetate had no influence on blood lipides, even when administered in excessive amounts.

FIELD CROPS

[**Agronomic work in Alabama, 1938**], H. R. ALBRECHT, E. L. MAYTON, H. B. TISDALE, J. B. DICK, E. V. SMITH, L. M. WARE, H. M. DARLING, and J. F. DUGGAR (*Alabama Sta. Rpt. 1938*, pp. 8, 9, 10, 17-21, 25, 26).—Research (E. S. R., 81, p. 33) reported on briefly dealt with development of *Crotalaria spectabilis* strains intermediate in maturity; time of turning winter legumes for cotton and corn; cotton varieties; seasonal activity of the bulbs of wild onion (*Allium vineale*) as related to its eradication from pastures and lawns by creosote-kerosene sprays; the life history of nutgrass (*Cyperus rotundus*) as related to possible methods of control; and yield differences in certified lots of seed potatoes.

[**Field crops work in Arizona**]. (Partly coop. U. S. D. A. et al.). (*Arizona Sta. Rpt. 1939*, pp. 39, 46-55, 60-63, 64, 81-88, figs. 6).—Reports of progress are made from experiments (E. S. R., 82, p. 174) at the station and substations, including variety tests with grain sorghum, sorgo, alfalfa, soybeans, and green manure crops; comparison of corn varieties and hybrids; planting tests with grain sorghum varieties; breeding work with wheat (for smut resistance), grain sorghum, barley, alfalfa, and cotton; cotton experiments, concerned with irrigation needs, seed-delinting and germination of delinted seed of varieties at different temperatures, fertilizers, and date of seedling emergence in relation to growth characters; studies of factors, especially soil moisture and ratooning, influencing maturity and length of cotton fibers; cultural and fertilizer tests and a study of seed setting with alfalfa; measurement of winter growth of alfalfa progenies for grazing value; sugar beet seed production studies, including varieties and effects of planting dates, soil temperature, and nitrogen supply; cultural and harvesting tests with soybeans; range studies concerned with water requirements and fertilizer tests of range plants; relation of climatic conditions to vegetation; life history and reproduction of burroweed and its distribution on Arizona ranges in relation to soil conditions; and control of bindweed, horsenettle, nutgrass, and burroweed by different treatments.

[**Field crops experiments by the Georgia Station**]. (Partly coop. U. S. D. A., Ga. Coastal Plain and Fla. Expt. Stas., et al.). (*Georgia Sta. Rpt. 1940*, pp. 9-16, 20-38, 51, 52, 57, 58, 78-83, 85, 86, figs. 5).—Research with field crops (E. S. R., 82, p. 762) at the station and Mountain Substation and outlying fields, reported on briefly, comprised breeding work with wheat, oats, cotton, and peanuts; variety tests with corn, cotton, oats, soybeans, cowpeas, sorgo, and potatoes; relation of plant and fiber characters to yield of cotton; cotton nutrition research on ammonium v. nitrate nitrogen, need for trace elements, and T. V. A. phosphates; fertilizer experiments concerned with relationship between available nutrients in the soil and response of cotton and corn to potash and phosphate; effects of different combinations of phosphate and lime

on the yield of cotton; kinds of liming materials; effects of crop rotation on the organic matter in surface soils; sources of phosphate for cotton with ammonium sulfate as the nitrogen carrier; value of calcium sulfate (gypsum) in superphosphate for cotton; superphosphates for cotton with and without limestone; effects of lime as a supplement to fertilizer on corn; response of soybeans to phosphate and lime and to inoculation; effects of fertilization on yield of summer and winter legumes; green manure and harvesting tests with potatoes; variety, seeding, and fertilizer tests with fiber and seed flax, and determinations of oil content and iodine number of Georgia- and Minnesota-grown flaxseed; and pasture research, dealing with fertilizers and limestone for Bermuda-lespedeza pasture production, winter pasture clovers as a nitrogen source for summer grass, effects of lime and phosphate on pasture soils, influence of pastures and cultivation on soil organic matter, time and method of seeding Dallis grass, 1939-40 winter survival of introduced grasses, tests of selections of *Lespedeza sericca*, effects of fertilization on production and composition of pasture herbage, and adaptation of Ladino clover and tall oatgrass.

[Field crops and related agronomic problems in Kansas] (*Kans. State Hort. Soc. Bien. Rpt.*, 45 (1938-39), pp. 77-80, 121, 122, 125-143, 279-281).—Papers of agronomic interest in this report include Soil Reaction and Plant Growth, by R. I. Throckmorton (pp. 77-80) (*Kans. Expt. Sta.*); Sweet Potatoes—Making the Best Better, by H. Theden (pp. 121, 122); Recent Trends and Preferences in Marketing Sweet Potatoes, by A. E. Mercker (pp. 125-129), and The Sweet Potato Finds New Fields, by H. G. Knight (pp. 131-135) (both U. S. D. A.); Further Studies and Technic in Sweet-Potato Breeding in Louisiana, by J. C. Miller (pp. 137-143) (*La. Sta.*); and Summer Care of Lawns, by L. R. Quinlan (pp. 279-281) (*Kans. State Col.*).

[Farm crops work in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 8, pp. 2, 6, 7, 8).—Progress results from experiments with field crops are reported in articles entitled Seeding Rates, Soybeans for Hay, by H. A. York; Placement of Superphosphate, Lime, Potash, Basic Slag in Relation to Planted Seed Influences Soybean, Austrian Pea, Vetch, by W. B. Andrews; Small Grain Variety Results Suggest Oats as Means of Increasing Feed for Livestock—State College and Substation Yields Given, by J. F. O'Kelly; and More Than a Bushel of Oats Secured From Each Pound Pure Nitrogen Applied in Tests Conducted at Stoneville Over 13-Year Period, by R. Kuykendall.

[Agronomic research in Rhode Island]. (Partly coop. U. S. D. A. and Mass. and Conn. Expt. Stas.). (*Rhode Island Sta. Rpt. [1939]*, pp. 8-16, 20-22, 23, 24, 34-37).—Reports of progress are made from variety tests with corn, potatoes, and lawn and turf grasses; fertilizer experiments with potatoes, mangels, rutabagas, onions, cabbage, mixed hay, and lawn and turf grasses, particularly varieties and strains of bents; boron studies; planting and pH range tests with potatoes; residual effects from different levels of fertilizer, as shown by yields of mixed hay; effects of crops on succeeding crops, involving soil treatment with chloropicrin; crop rotations; root development of pasture grasses, and their responses to different lengths of day and levels of soil moisture; breeding work with bentgrasses and alfalfa; control of lawn weeds; seed production of bentgrass varieties and strains, especially in response to cultural and fertilizer treatments; and comparisons of Sudan grass, millet, oats, and winter rye and wheat for supplementary pasture.

Factorial design in plant nutrition experiments in the greenhouse, C. H. WADLEIGH and W. H. THARP. (Coop. U. S. D. A.). (*Arkansas Sta. Bul.* 401 (1940), pp. 66).—Designs and analyses of four factorial cotton plant nutrition experiments carried out in the greenhouse are presented, with comments on

weaknesses in certain designs and on circumstances under certain greenhouse manipulations that tend to obviate the apparent inferiorities of the unorthodox arrangements. Satisfactory procedure for the analysis of variance is presented in each case with the inclusion of a few possible modifications.

Experiment A is a $3 \times 3 \times 2 \times 2$ design with four replicates comprising four blocks. Main effects were confounded with split-plots, and the procedure was presented for correctly taking into account such a contingency and for segregating the components of a two-degree-of-freedom factor into its individual components. A method applicable for studying plant disease data of the type presented on a proportionate basis was suggested. Experiment B presents a $3 \times 3 \times 3 \times 2 \times 2$ design with time of observation considered as one of the factors. The two degrees of freedom of each three-level factor were partitioned into individual degrees of freedom. The method of analyzing the data, according to single degrees of freedom with individual error terms, is presented. Comparison of results obtained by using individual error terms, the fully pooled error, and grouped errors provides a basis for discussing the relative merits of various methods of treatment of error.

Experiment C illustrates a $2 \times 2 \times 2 \times 2$ arrangement. It demonstrates the simplicity of the analysis by the tabular method possible in a 2^n design. The advisability of confounding a higher order interaction with subblocks, together with the procedure involved, is illustrated. Experiment D demonstrates the technic of confounding a $3 \times 2 \times 2 \times 2$ experiment, together with its analysis by the tabular method. The presence of a three-level factor appreciably complicates the procedure, but the method has been found to be satisfactory.

The effect of liming on the absorption of phosphorus and nitrogen by winter legumes, F. L. DAVIS and C. A. BREWER, JR. (La. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 6, pp. 419-425, figs. 2).—Austrian Winter peas and common vetch were grown with various fertilizer treatments at several locations on upland soils in Louisiana. Liming soils low in calcium content enabled the crops to utilize more of the phosphorus supplied by superphosphate. Lime alone produced an increase in percentage content of calcium only, while lime applied with superphosphate resulted in increased contents of calcium, phosphorus, and nitrogen. Review of earlier data on the relationship between readily available soil phosphorus and crop yields (*E. S. R.*, 68, p. 740; 75, p. 165) further showed that those soils, on which the yield of sorghum was unexplainably low in relation to the available phosphorus, were also low in exchangeable calcium. It is thought that a low calcium content of soils may explain lack of agreement between crop yields and rapid tests for phosphorus on many southern soils.

A division of the alfalfa cross-inoculation group correlating efficiency in nitrogen fixation with source of *Rhizobium meliloti*, J. C. BURTON and L. W. ERDMAN (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 6, pp. 439-450, figs. 11).—In nitrogen-fixation studies of strains of *R. meliloti*, the organism isolated from alfalfa and sweetclover failed to cause any significant fixation on bur-clover or fenugreek. Strains of the bacteria isolated from bur-clover or fenugreek showed an average percentage effective on all four hosts. It was concluded that the bacteria living in association with alfalfa and sweetclover lose some component not needed for high nitrogen fixation on these legumes but which is very necessary for fixation with bur-clover and fenugreek. The nodule-forming capacity of the legume bacteria evidently is not altered by association with any of the four legumes.

The uses of alfalfa, H. L. WESTOVER and W. H. HOSTERMAN (*U. S. Dept. Agr., Farmers' Bul. 1839* (1940), pp. [2]+36, figs. 16).—Dealing mainly with the

making and feeding of alfalfa hay; alfalfa hay standards; pasturing alfalfa; using the crop for silage, soiling, green manure, and as a cover crop; preparing and feeding ground alfalfa; alfalfa mixed feeds; and dehydrated alfalfa, this publication is a revision of and supersedes Farmers' Bulletin 1229 (E. S. R., 46, p. 531).

The establishment of Bahia grass, *Paspalum notatum*, G. W. BURTON. (U. S. D. A. and Ga. Coastal Plain and Ga. Expt. Stas.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 7, pp. 545-549, fig. 1).—Planting tests with two strains of Bahia grass, untreated and scarified with sulfuric acid (E. S. R., 81, p. 373), demonstrated that, regardless of the way in which the seed is planted, acid scarification will greatly increase the number of plants obtained per pound of seed. With the current high prices of seed, drilling seed from $\frac{1}{4}$ to 1 in. deep in well-prepared seedbeds, if possible, or covering seed with disk harrows in areas where good seedbeds cannot be made should be profitable. For seed production or as a less costly practice, drilling from 4 to 6 lb. of good scarified seed in rows 2 ft. apart followed by several cultivations is considered a very economical method. Emergence tests in a well-prepared Tifton sandy loam indicated that good Bahia grass seed, properly scarified, will germinate at least as soon as other grasses, such as carpet and Dallis grass, now being planted in the area.

A comparison of nitrogen carriers for bent grass fertilization, J. A. DEFRANCE and T. E. ODLAND. (R. I. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 1084-1090).—In a 6-yr. comparison, Colonial, creeping, and velvet bents received different nitrogen carriers, together with enough superphosphate and potassium chloride to make a 10-6-4 complete fertilizer. The standard 10-6-4 fertilizer carrying a mixture of organic nitrogen as activated sludge (3) and of ammonium sulfate (5) and sodium nitrate (2) was found most suitable and very satisfactory on a comparative cost basis. Inorganic nitrogen applied alone did not produce a uniform turf throughout the season. A 1:1 mixture of ammonium sulfate and activated sludge produced nearly as good a response as the standard, but cost 16 percent more per pound. Ammonium sulfate had a quick but not lasting effect. Clover was least on the ammonium sulfate plats and the ammonium sulfate-sludge mixture and the most on activated sludge and cottonseed meal plats. The organic sources seemed to stimulate more clover. Invasion of bent mixture into Rhode Island Colonial and Washington creeping bent was greatest on the activated sludge plats, and, in general, more was found on organic plats than on inorganic. No grasses invaded any of the plats of Piper velvet, probably because of its fine texture and density. The different fertilizers had very little effect on resistance to the brown patch and dollar spot diseases.

The growth habits and chemical composition of bromegrass, *Bromus inermis* Leyss, as affected by different environmental conditions, J. M. WATKINS. (U. S. D. A. and Ohio Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 7, pp. 527-538).—Fertilization of bromegrass with nitrogen (ammonium sulfate at the rate of 150 lb. per acre applied in September, March, and July) increased the rate of leaf production, height and total number of shoots, number of fertile shoots, and dry weight of tops, but decreased number of rhizomes and weight of the underground parts. Shade, provided by bleached sheeting over wooden frames, decreased numbers of shoots, rhizomes, and of fertile shoots, and dry weight of all plant parts, and increased number of elongated internodes and plant height. Internodes were more uniform in length than those on shoots from other plats. Associated growth of alfalfa with bromegrass decreased numbers of shoots and of rhizomes and dry weight of the brome-

grass plants. Plants fertilized with nitrogen and check plants at bloom stage were low in percentage of nitrogen and high in percentage of carbohydrates, although the absolute amounts of both were highest in the nitrogen-fertilized plants. Shaded plants were high in percentage of nitrogen and low in carbohydrates as compared to checks.

Brome grass plants grown under short days (8.5 hr.) produced a rosette type of growth, and the shoots developed in a decumbent position. Plants grown under normal days (15 hr.) and long days (18 hr.) developed in an upright position, the latter attaining the greater height. While the total number of shoots per plant was greatest under short days and least under long days, normal-day plants produced more fertile shoots. The maximum number of rhizomes was produced under normal day length in late spring or summer, but they attained greatest size and length under the long days. Dry weight of plant parts rose as the number of light hours per day was increased. Both percentage and absolute amounts of carbohydrates were highest in long-day plants. Short-day plants contained the highest percentage of nitrogen, yet the absolute amounts were about the same under each length of day.

The testing of buffalo grass "seed", *Buchloe dactyloides* Engelm, M. M. PLADECK. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 7, pp. 486-494).—The establishment of a good stand of buffalo grass from seed appeared to be influenced strongly by the character of the seed material. A poor seed set indicates a low percentage of burs which contain caryopses. Difficulty in harvesting material from the ground results in a low percentage of burs in the harvested material. Harvesting before burs are mature and have been weathered results in a low germination when planted.

Burs at least partially weathered in appearance were made to germinate in the laboratory to within 10 percent of the seed set or caryopsis count, either without treatment or by soaking or chilling. Burs immature and greenish, or mature but not weathered, gave increased germination after prolonged chilling or after warm stratification followed by cold treatment. Proof was obtained that the profound dormancy of this seed cannot be overcome appreciably without prolonged chilling at least for longer than a month. Harvesting burs after a period of natural weathering is, therefore, recommended. Optimum germination tests were made in sterilized soil in petri dishes at a daily temperature alternation of 20°-30°, or 20°-35° C., with light, and required from 6 to 8 weeks. No germination occurred at or below 10° (50° F.). Dormant grains were made to germinate by puncturing the pericarp. Most of the burs examined contained one or two caryopses per bur, and a few contained three or four, and likewise in germination tests the majority of burs germinating produced one or two seedlings and a small percentage three or four. Germination of healthy grains was changed in no way by the presence of diseased grains in the same bur. The presence on occasional plants and also in most seed samples of nematode galls suggested a disease widespread in Texas and of possible economic importance.

Effect of treating different horizons of Sassafras loam on root development of red clover, N. A. FERRANT, JR., and H. B. SPRAGUE. (N. J. Expt. Stas.). (*Soil Sci.*, 50 (1940), No. 2, pp. 141-161, figs. 8).—The root system of red clover grown in Sassafras loam with several cultural and fertilizer treatments was studied to determine the limiting factor or factors of root development in New Jersey. For all red clover plants examined, the root systems were less extensive than those reported in Western and Midwestern States. Soil acidity, texture, pore space, and nutrient supply apparently had little influence on root penetration. The deepest penetration and occupation of the B horizon by roots occurred in plats tilled in A₂ horizon without other treatment. Plats

receiving combinations of lime, manure, and fertilizer had an extensive root development in the A₁ horizon, a much more limited one in the A₂ horizon, and almost none in the B horizon. Indications were that some factor or factors in the A₂ horizon of certain New Jersey soils is corrected by tilling, and that this permits roots of red clover to pass through this horizon and develop extensively in the B horizon. See an earlier note by Farris (E. S. R., 72, p. 36).

Varietal and cultural experiments with corn, C. K. McCLELLAND (*Arkansas Sta. Bul. 402 (1940), pp. 31*).—Varietal experiments with corn (E. S. R., 57, p. 629) showed leading varieties at the station, 1927-38, to include Pride of Saline, Paymaster, Mexican June, Commercial White, Thatcher Golden Dent, Southern Beauty, White Wonder, and Surcropper; on upland at the Cotton Substation (1927-38) Paymaster, Delta Prolific, Hastings Prolific, Cocke Prolific, Jarvis Golden Prolific, White Wonder, Thatcher Golden Dent, and Whatley Prolific; on delta land at the Cotton Substation (1931-38) Mexican June, Surcropper, Delta Prolific, Southern Beauty, Ewing Mosby, Pride of Saline, and Thatcher Golden Dent; at the Fruit and Truck Substation (1927-38) Surcropper, Ferguson Yellow Dent, Pride of Saline, Mexican June, Delta Prolific, and Thatcher Golden Dent; and at Scott experimental field (1927-31) Surcropper, Delta Prolific, Ewing Mosby, Pride of Saline, Cocke Prolific, Mexican June, Whatley Prolific, and Ferguson Yellow Dent. In northwestern Arkansas, Paymaster and the western varieties were superior, in southwestern Arkansas the western corns, and in eastern and central Arkansas prolifics were in the lead. Paymaster, Pride of Saline, Delta Prolific, Surcropper, Mexican June, and Thatcher Golden Dent proved dependable in all parts of the State.

Planting tests suggested from April 15 to May 15 at the station, within the range from April 15 to June 1 at the Cotton Substation, and from May 15 to June 15 at Scott. To avoid heavy corn crop losses from adverse weather, part of the crop may be planted early and the remainder at a later date. In cultivation experiments significant reductions in yield at the station followed no cultivation, delay for 8 weeks after planting, and laying by when only 2 ft. high. At Scott similar results were obtained for the 8-week delay and no-cultivation methods; and also significant reductions resulted from very shallow cultivation and 6-week delay of cultivation. Evidently, one reasonable method of cultivating and keeping down weeds is as good as another, but delay in starting cultivation, terminating the work too quickly, or utter neglect of the crop will cause decreased yields.

Seed growers aid in evaluating new corn hybrids. G. H. STRINGFIELD. (Coop. U. S. D. A.). (*Ohio Sta. Bimo. Bul. 205 (1940), pp. 131, 132*).—Comment is made on the increasing number of commercial corn hybrids being sold in Ohio and on new hybrids under cooperative (E. S. R., 82, p. 765) development and evaluation. The estimated corn acreage planted to hybrids in Ohio has expanded from 1,100 (0.03 percent) in 1933 to 66,330 (1.80 percent) in 1936 and to 1,952,000 acres (57 percent) in 1939.

Economic aspects of one-variety cotton communities in Tennessee, C. E. ALLRED and B. D. RASKOPF (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 111 (1940), pp. III+37, figs. 11*).—A study of the character of the cotton produced and marketed and the marketing practices in two outstanding one-variety cotton communities in Tennessee, the Eaton Central Cotton Improvement Association in Gibson County and the Cerro Gordo One-Variety Community in Hardin County, is reported, with a brief review of the development of one-variety communities in the United States and Tennessee. Suggestions are made for the improvement of the enterprise which has grown in Tennessee since 1931 until in 1939 there were 125 such communities in the State, with an estimated acreage of 200,000.

Of the 718 bales of cotton produced by the Eaton-Central community (I) in 1939, 82 percent graded white middling and better and 77 percent stapled 1 in. and longer. In the Cerro Gordo community (II) with 150 bales, 80 percent was middling or better and 53 percent stapled 1 in. and longer. Where the seed was 4 yr. away from the breeder the average staple length decreased 0.4 of $\frac{1}{32}$ in. in community I and 1.5 of $\frac{1}{32}$ in. in community II. Cotton grown from seed longer than 4 yr. away from the breeder decreased 1.04 percent in lint turn-out in community I and 2.73 percent in community II. In community I, 29 percent of the bales weighed less than 450 lb. and 14 percent weighed over 550 lb., and in community II the percentages were 11 and 18, respectively. A need was shown for farmers to adjust size of loads brought to the gin to secure the more uniform bale weights desired by spinners. Ginning was 97 percent completed by November 14 in community I and 82 percent in community II. With the development of one-variety communities and early-maturing varieties in recent years, there has been a general increase in the percentage of cotton ginned to November 14. Of the cotton grown by community I, about 87 percent was purchased by the ginner on the same day ginned. The ginner resold over half the cotton purchased in from 1 to 5 days, and none was held longer than 15 days. The ginner paid prices to growers generally in line with the central market at Memphis.

Influence of mass selection within certain large-seeded Virginia-type peanut varieties, C. E. STEINBAUER, J. H. BEATTIE, and E. T. BATTEN. (U. S. D. A. and Va. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 685-688).—Further single-plant selections were made from strains of large-seeded Virginia-type peanuts (E. S. R., 70, p. 40). Initial selections were made in 1933 by weighing the crops produced by each of from 200 to 300 consecutive plants from each of 8 strains and placing in 1 lot for each strain nuts from hills yielding 100 gm. or over, a second lot nuts from hills making less than 100 gm., and a third (standard) seed from a random lot of hills not separated as to yield. From 1934 to 1937, inclusive, single 75-ft. rows of each of the 3 lots of each strain were planted every year under comparable conditions, and seed for the succeeding season was selected on an 80-gm. basis for high, low, and standard lots from the respective plantings. No deviations large enough to be detected by mass selection of seed stock over 4 yr. developed in any of the 8 strains since the original single-plant selections were made. Their behavior appeared to confirm the assumption that the strains are essentially pure lines. Variations between plats grown from mass-selected and unselected seed stock apparently were due to external factors and not transmissible or cumulative.

Peanut production, H. O. WEST (*Mississippi Sta. Bul.* 341 (1940), pp. 63, figs. 19).—Information compiled largely from reports of experiments by State experiment stations covers farm organization, soils and climate, land preparation, varieties, selection and preparation of seed, planting, fertilizers, cultivation, digging, stacking, picking, use of vines for hay, digging and hogging, labor requirements, marketing, insect pests and diseases, and peanuts for pork production.

The importance of border effect in certain kinds of field experiments with potatoes, W. C. JACOB. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 866-870).—The extent of border effect was studied in an experiment at Riverhead, N. Y., in which 4-ft., cropped, unfertilized aisles were maintained around every treatment plat and in another experiment in which the treatments bordered each other without buffer aisles. The border effects followed closely the actual differences between adjoining treatments. Even where treatments were separated by aisles, the effect of adjoining treatment

plats could be discerned in the first border row. Although manure treatments were largely broadcast, the border influence was practically the same as on plats in which fertilizers were applied in the row. Border effect was concluded to be an important factor in yield of outside rows of fertilizer experiments. Use of untreated aisles around treatment plats does not reduce and may increase the edge effect, since the difference between nil and any other treatment may be greater than between any two fertilizer treatments. In experiments having small differences between treatments and in which there are no aisles between plats, the discarding of one outside row from each edge of the plat will eliminate most of the border effect.

Seed preparation and cultural treatments in relation to stand of plants in fall crop potatoes in Oklahoma, H. B. CORDNER. (Okla. A. and M. Col.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 879-883, figs. 2).—Cut sets of Triumph potatoes consistently produced better stands than whole tubers in fall plantings with high soil temperatures. Early sprouting of the seed favored the possibility of establishment of a plant before the seed piece entirely disintegrated. There was some evidence that presence of sprouts on the set might delay disintegration. Delayed sprouting due to lack of soil moisture resulted in low stands. Indications were that presprouting, accomplished by placing ethylene chlorohydrin-treated tubers in moist excelsior, was more advantageous in the earlier (unirrigated) planting and especially in relation to whole seed. With irrigation, sprout emergence was unusually early for all seed types, and no marked difference was found between sprouted and unsprouted seed.

The rate of respiration in potato tubers at high temperatures in relation to treatment with ethylene chlorohydrin, N. M. WARD. (Okla. A. and M. Col.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 871-873, fig. 1).—Agreeing with findings of Kimbrough (E. S. R., 53, p. 636) and Appleman and Smith (E. S. R., 76, p. 627) on the influence of temperature changes in regard to respiration rate, the results reported show that the same response may be secured over a higher temperature range (from 70° to 95° F.). When treated tubers are placed at from 90° to 95°, their maximum capacity for respiration apparently is attained and continues until they undergo a complete physiological breakdown. Contrariwise, treated tubers at 70° have a high initial rate of respiration which declines rapidly and after 5 days does not greatly exceed that for untreated potatoes at the same temperature. After the stimulus of the chemical treatment is worn off, tubers respond to temperature rises similarly to untreated tubers. Tubers treated at from 70° to 80° and allowed to aerate at that temperature long enough to allow the rate of respiration to approximate that of untreated tubers may then be planted at a soil temperature of 90° with less danger of break-down due to the high rate of respiration.

Rice variety experiments in Arkansas, M. NELSON and C. R. ADAIR. (Coop. U. S. D. A.). (*Arkansas Sta. Bul.* 403 (1940), pp. 28).—Outstanding varieties (E. S. R., 65, p. 732) in field plat experiments (1931-39) at the Rice Substation were short-grain, Caloro 55.1 bu. per acre and Acadia 54.3 bu.; medium-grain, Zenith 50.7 bu. (recommended to replace Early Prolific 49.3 bu.) and Supreme Blue Rose 44.5 bu.; and long-grain, Arkansas Fortuna 52.4, Lady Wright 44.8, and Nira 43.3 bu. It seems advisable for a farmer to grow more than one variety of rice. Combinations of varieties suggested from the results are Zenith, and Nira or Supreme Blue Rose, with (1) Caloro or Acadia, or (2) Arkansas Fortuna. The nursery experiment with introductions and selections indicated that Nakata Shinriki, an early short-grain variety, might be grown to advantage in Arkansas.

Results of hybridization work indicate that medium- and long-grain varieties may be developed that may surpass the principal varieties now grown in the

State. A medium-grain selection either from Kameji \times Blue Rose or Caloro \times Blue Rose may eventually replace part of the Blue Rose acreage. An early long-grain selection from either Improved Blue Rose \times Fortuna or Edith \times Fortuna may sometime replace part of the acreage growing Edith, Lady Wright, and Nira.

I, Factors in soybean production; II, Variety recommendations and characteristics, R. L. LOVVORN (*North Carolina Sta. Agron. Inform. Cir. 126* (1940), pp. [1]+6).—A revision of Agronomy Information Circular 102 (E. S. R., 77, p. 330).

Hybrid vigor in sugar beets, D. STEWART, C. A. LAVIS, and G. H. COONS. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 11, pp. 715-738, figs. 7).—Field tests at Fort Collins, Colo., in which sugar beet hybrids arising as single crosses of inbred strains or as top crosses of inbred strains on an open-pollinated variety were compared with the parental sorts and the commercial brand Pioneer, are reported. Certain strains used as parents, the product of many generations of inbreeding, showed divergence in root yield, sucrose percentage, and disease resistance. Several of the strains were relatively productive even after a number of generations of inbreeding. More than two-thirds of the hybrid progenies obtained showed significant increase in root weight attributable to hybrid vigor. The average root weight of the 41 hybrids was found to be 38.9 percent greater than that of the Pioneer brand used as control. In crosses involving strains unlike in richness of sucrose, the percentage in the hybrid tended to approach the average of the parents. Certain crosses indicated that heterozygous varieties may be improved in specific characters by top crossing with inbred strains which can contribute some desired character. A tendency toward self-fertility with continued inbreeding might interfere with a high degree of intercrossing between strains when utilization of the F_1 generation is attempted in commercial seed production. U. S. 217, a synthetic sugar beet variety, produced by intercrossing five of the strains found to show heterosis response and also resistance to *Cercospora* leaf spot, represents an attempt to obtain an improved variety by purposeful crossing of inbred strains.

Relation of fertilization to the yield and keeping quality of sweet potatoes, N. D. MORGAN. (Iowa Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 849-854).—Sweetpotatoes grown on Buckner coarse sand responded to complete fertilizers in highly significant yield increases. Not more than 2 percent nitrogen was needed under the conditions, and on a fairly fertile soil with a legume in the rotation, nitrogen probably could be omitted. Superphosphate up to 10 percent was needed, and with heavy rainfall or proper irrigation higher percentages might give increased yields. Potash, a most important fertilizer constituent, gave significant and profitable yield increases up to 12 percent. Further increase in potash up to 18 percent gave additional although smaller yield increases. Sweetpotatoes grown with complete fertilizer containing a good proportion of potash kept better in storage than those grown without fertilizer. Sweetpotatoes from the 3-10-0 and no-fertilizer plats contained a slightly higher percentage of sugar than those from other treatments, although variations in the percentages of nitrogen, phosphorus, and potash in complete fertilizer did not seem to influence sugar content.

Starch in freshly dug sweet potatoes estimated from the moisture content, W. D. KIMBROUGH. (La. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 846-848).—Studies over several years in connection with sweetpotato breeding research revealed a high negative correlation between the moisture and carbohydrate contents of sweetpotatoes. High moisture content has meant relatively low carbohydrate content, and the sums of the two

percentages have been fairly constant. The sugar content of freshly dug sweet-potatoes of a given variety not left in the ground for longer than a day or so after vines have been removed or frost-killed has been practically constant. Tabulated results of determinations on the Triumph, Wennop, and Porto Blanco varieties planted and dug at various dates gave a wider range in potato maturity than normally found in those dug for starch production, yet the sums of moisture and starch percentages were fairly constant.

Spring wheat varieties in South Dakota, S. P. SWENSON. (Partly coop. U. S. D. A. et al.). (*South Dakota Sta. Bul. 342 (1940), pp. 55, figs. 8*).—Results of varietal experiments with common and durum spring wheats at the station and substations and cooperative with farmers are reported for 1930-39, supplementing previous reports (E. S. R., 66, p. 825; 73, p. 170). Data are also included on the wheat acreage and producing districts and the relative importance of common spring and durum wheats in South Dakota, and on results of milling and baking tests on a number of the varieties. Brief descriptions of varieties tested are appended.

The average annual acreage of 2,207,000 acres of wheat harvested in South Dakota, 1936-38, included 1,587,000 acres of common spring wheat and 508,000 acres of durum. Ceres and Thatcher, the most important hard red spring wheats in the State, were sown on 33.5 and 24.5 percent, respectively, of the total wheat acreage. Pentad (Red durum) with 8.6 percent and Mindum with 1.1 percent occupied the largest percentages of the acreage among named durum varieties.

Thatcher is the outstanding hard red spring wheat in eastern South Dakota where rust may be a serious hazard. Both Thatcher and Ceres may be grown in a transitional area farther west. Ceres is recommended in the western half of South Dakota or wherever grasshoppers, heat, and drought are more serious than black stem rust. Reward may be grown as an early-maturing variety in central and western portions of the northern, central, and southern hard red spring areas where stem rust epidemics are not likely. However, Reward is much more susceptible than Ceres or Thatcher to grasshopper attacks. Pilot, Rival, Renown, and Nordhaugen had not been grown long enough for definite recommendations. Mindum is the leading durum, although Arnautka and Kubanka also may be grown to advantage in districts indicated for Reward. A shift from durum to hard red spring wheat seemed desirable in areas where black stem rust had limited hard red spring wheat production and encouraged the growing of durum.

Quality studies on North Dakota durum wheats (1938 crop), R. H. HARRIS and D. KNOWLES. (N. Dak. Expt. Sta.). (*Cereal Chem., 17 (1940), No. 4, pp. 480-490, fig. 1*).—Durum wheats grown at the station were higher in semolina yield than those grown at Langdon, attributable to differences in test weights. The Langdon durums, however, were higher in protein content and produced macaroni of better and more acceptable color and scored higher in tenderness than station samples. No relationship was noted between color and cooking quality in this series. The determination of cooked weight, more rapid and precise, is deemed preferable to the determination of cooked volume. A negative relationship was evident between cooked weight and protein.

A biochemical and technological study of Punjab wheat varieties, R. SINGH and C. H. BAILEY. (Minn. Expt. Sta.). (*Cereal Chem., 17 (1940), No. 2, pp. 169-203, figs. 5*).—A biochemical and technological study of a number of Punjab wheat varieties grown by the Punjab Agricultural Research Institute, Lvallpur, India, 1935-36, is reported. Eight of the 31 samples used included 8A, 9D, C518, and C591, improved wheat types extensively grown by farmers in Punjab.

Of a total acreage of from 9 to 10 million acres annually cropped to wheat, these 4 types occupied as much as 50 percent, and 8A alone occupied 3,161,700 acres. The other 23 samples were recent hybrids still in the experimental stage. The status of the wheat crop in the Punjab and its improvement are described briefly.

Averages from the data were for 1,000-kernel weight 41.4 gm., weight per bushel 63.9 lb., moisture content 10.8–11.8 percent, flour yield 73.9 percent, crude protein 10.36 percent, diastatic activity 221–291, water absorption of flour 72.6 percent, loaf volume 502 cc., and carotenoid pigment of flour 2.50–1.42 p. p. m. Correlations were between bushel weight and flour yield $r=0.219$, crude protein in wheat and percentage of mottled grains in each sample -0.66 ± 0.06775 , and between water absorption of flour and protein content $+0.6747 \pm 0.066$. Under one set of conditions noted among these wheats the maximum viscosity occurred at pH 4.5, while in the other type it occurred at pH 2.8 to 3.0. Farinograms showed that the dough development times of these flours usually were short, and the range of dough stability was also comparatively narrow.

The breeding significance of after-harvest sprouting in wheat, J. B. HARRINGTON and P. F. KNOWLES (*Sci. Agr.*, 20 (1940), No. 7, pp. 402–413).—Moist weather resulted in the germination of ripe wheat standing in field nurseries at the University of Saskatchewan, in September 1938, and a study was made of the comparative sprouting behavior (*E. S. R.*, 68, p. 189) of 17 varieties and 157 purified hybrid lines from 4 crosses. The percentage sprouting of standard varieties ranged widely, averaging for Apex (Sask. 1789) 3.9, Thatcher 6.5, Renown 8.4, Marquis 11, Reward 34, Reliance 47.8, Ceres 57.9, and Garnet 78.8. The 3 varieties with highest resistance to sprouting are also stem rust resistant. Among hybrid lines of some crosses the parental range for sprouting was exceeded by 1 or more lines showing lower percentages of sprouting than the better parent. Results on sprouting from material which matured 3 and 6 weeks, respectively, before the rains agreed well with results obtained in dormancy studies on the same varieties.

The effect of ethylene on freshly harvested wheat, A. K. BALLS and W. S. HALE. (U. S. D. A.). (*Cereal Chem.*, 17 (1940), No. 4, pp. 490–494, fig. 1).—Small doses of ethylene (1/1,000 and 1/10,000) could mature freshly harvested combine wheat very quickly in the sense that it becomes suitable for bread making. An immediate increase in viability of the treated wheat was observed with a low concentration, but there was evidence that more ethylene is decidedly harmful.

Germination of seed of vine-mesquite, Panicum obtusum, and plains bristle-grass, Setaria macrostachya, V. K. TOOLE. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 7, pp. 503–512).—The alternating temperatures, room temperature to 35° C., or from 20° to 35°, were better for germination of seed of *P. obtusum* than other alternating or constant temperatures tested. Pretreatment with approximately 71 percent sulfuric acid for 90 min. overcame resistance of the seed to germination. There was no consistent improvement of germination with age, but the rate was increased by acid treatment regardless of age of seed. Seed of *S. macrostachya* germinated best at alternating temperature of from 10° to 35° or from 35° to 10°. The seed was benefited by prechilling or by pretreating with the sulfuric acid for from 15 to 30 min. Potassium nitrate solution improved germination of both species.

Three new weeds introduced into Utah, B. MAGUIRE (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 3, p. 3, figs. 3).—Bermuda grass, nutgrass, and leafy spurge, recently introduced potentially serious weed pests, are described and illustrated, with recommended control measures.

The rate and mode of penetration of herbicides.—I, Copper nitrate solutions, W. H. SILVERSIDES (*Sci. Agr.*, 20 (1940), No. 7, pp. 419–423, pl. 1).—

Dandelion leaves were collected at intervals from plants in the bluegrass lawn at the University of Manitoba sprayed with a 2-percent copper nitrate solution at the rate of 200 gal. per acre. Photomicrographs showed the gradual infiltration of the spray into the leaves. The epidermal cells generally were less damaged than those of the parenchyma, and in the treated areas of the leaf chloroplasts could not be distinguished and the damaged tissue tended to take on heavy staining. It appeared that the spray penetrated the epidermis chiefly. Complete penetration by the spray into the leaf was noticed first in the leaves collected 30 min. after treatment.

HORTICULTURE

[**Horticultural studies by the Alabama Station**], K. C. BARRONS and E. W. McELWEE (*Alabama Sta. Rpt. 1938, pp. 22-25*).—Included are reports on variety tests with pole beans and a comparison of ground peanut hulls and other organic materials for use in greenhouse soils.

[**Horticultural studies by the Arizona Station**]. (Partly coop. U. S. D. A. et al.). (*Arizona Sta. Rpt. 1939, pp. 66-75*).—Reports of progress are presented on the fertilization of lettuce; breeding and improvement of lettuce and cantaloups; storage requirements of lettuce seed; cultural needs of vegetables on the Yuma mesa; chemical and physical indexes of maturity in grapefruit; protection of Salt River Valley citrus groves from low-temperature injury; fertilization of citrus; factors affecting the quality and yield of grapefruit; N assimilation by citrus trees; storage requirements for grapefruit; factors influencing the maturity and storage of dates; factors affecting the yield of pecan varieties and the filling of pecan nuts; factors, such as shuck opening, that may be used as indicators of maturity in pecans; testing of rootstocks for the peach, fig, and grape; and the testing of cassava.

[**Horticultural studies by the Georgia Station**] (*Georgia Sta. Rpt. 1940, pp. 66-73, 83-85, 86-88, figs. 3*).—Included are reports on tomato variety trials, the detrimental effect of roasting and scalding pimiento pepper fruits on the planting value of the seed, fertilizers for pimiento peppers, influence of date of planting on yield of the pimiento pepper, breeding of squash and collards, testing of peach varieties, growth of peach roots, the use of hormones in the rooting of muscadine grapes and other plants, and cold injury to muscadine grapes.

Work reported from the Mountain Substation includes the effect of low-temperature injury on various fruits and on the lespedeza cover crop, the value of turning under crimson clover for vegetables, testing of tomato varieties, culture and fertilization of the tomato, fertilizers for beans, and testing of onion, bean, and rhubarb varieties.

[**Horticultural studies by the Rhode Island Station**] (*Rhode Island Sta. Rpt. [1939], pp. 16-20, 24-26, 37, 38, 42-46*).—Among studies the progress of which is considered are fertilizer requirements of vegetable crops, strain and variety tests of vegetables, culture and training of tomato plants, fertilization of the Rose Daphne, culture of *Lilium formosanum*, structure of the celery plant as influenced by the nitrate level in the solution, spraying of apples and tomatoes for the control of diseases, effect of sprays on the growth of young apple trees, and the sun-coloring of harvested apples.

Market quality and condition of California cantaloups as influenced by maturity, handling, and precooling, W. T. PENTZER, J. S. WIANT, and J. H. MACGILLIVRAY. (Coop. Calif. Expt. Sta.). (*U. S. Dept. Agr., Tech. Bul. 730 (1940), pp. 74, figs. 34*).—In a study of means of improving the edible quality of California cantaloups by modifications in picking, handling, and shipping

methods, it was observed that in precooling melons from 80° to 50° F. the meltage of 1,000 lb. of ice was needed for each 4.3° of cooling. Precooling with mechanical refrigeration was somewhat slower than with ice and salt accompanied by the use of portable fans. A considerable saving in precooling costs was made by picking and loading melons in the early morning while they were relatively cool. The requirements for the successful shipment of hard-ripe melons included the prompt cooling of the top layers in cars to 55° or less and shipment under standard refrigeration so that the average transit temperature was 48° or lower. Precooling was not found necessary for fancy (half-slip) melons. Choice fruits (nearly eating ripe) were shipped successfully only when pre-cooled to 45° or less or when loaded in the bottom layer of nonpre-cooled cars. Measured in terms of market behavior and eating quality, hard-ripe melons were best for eastern shipment. Fancy (half-slip) melons were poorer in flavor on arrival, although many of them ripened later with good quality. Choice melons were satisfactory for immediate consumption, but they lost flavor rapidly and were subject to decay. The coating of melons with wax had no apparent effect in retarding ripening and had no consistent effect on decay. Fumigation with nitrogen trichloride was effective in some cases in retarding decay.

Sweet-corn inbreds and crosses released by the Illinois Station, W. A. HUELSEN (*Illinois Sta. Bul. 466 (1940), pp. 277-355, figs. 20*).—Discussing the principles of corn improvement by inbreeding and recombination, the regional adaptability of crosses, etc., the author presents data on the characteristics and comparative yields of crosses involving eight Country Gentleman and four Narrow Grain Evergreen inbred lines. From the standpoint of yields of sweet corn, the superiority of good single crosses over good open-pollinated strains of the same variety was found to be chiefly a matter of greater yield uniformity from year to year and a significantly greater production of prime cut kernels per ton of unhusked ears. For example, during 6 yr., 1931 and 1933-37, including 3 yr. of severe drought, the coefficient of variability in yield of the well-adapted Cross 8 × 6 was 29.5 percent on the basis of tons of prime cut kernels per acre, as compared with 45.1 percent for the open-pollinated checks. During the same period the recovery of cut kernels per ton of unhusked ears was 22.6 percent higher from the cross. The yield of prime cut kernels was found a better estimate than that of sorted unhusked ears in determining the values of single crosses. Because of the segregation, mutation, and general deterioration of inbreds when removed to Idaho and Connecticut, seedsmen are now maintaining inbreds in the Middle West and having merely the crosses made elsewhere. Little progress was made toward improving crosses by means of selections within the inbred parents on the basis of physical characters. On the basis of field test, the various inbreds were classified as to their best use in crosses and recorded as compatible, incompatible, or antagonistic. Inbreds differed in quality, with No. 4 outstanding in its capacity to transmit quality, particularly in flavor. Most of the crosses were slightly earlier in maturity than the open-pollinated checks. Variation in smut resistance was observed in the inbred lines. In the Country Gentleman group, crosses of inbreds 8 × 6 and of 5 × 10 proved most desirable, and in the Narrow Grain Evergreen, Cross 14 × 13 was found most popular.

Fertilization of lettuce on alkaline-calcareous soils: Soil and plant studies, W. T. McGEORGE, M. F. WHARTON, and W. A. FRAZIER (*Arizona Sta. Tech. Bul. 85 (1940), pp. [2]+397-451, figs. 13*).—Part 1, by McGeorge and Wharton, discusses fertilizer experiments established in different producing areas which gave definite evidence that readily available forms of phosphate used alone

or in connection with N would greatly increase the yields of marketable heads. When an inorganic form of N (of low C:N ratio) was used in the mixture, effectiveness reached a maximum. Analyses of the soils showed that while lettuce makes a heavy initial demand on the soil there is a continuous need for available nutrients throughout the growing period. Analyses of the plants obtained from various localities showed surprisingly consistent composition, regardless of location or season. Both N and P fertilizers increased the contents of these elements in the plant, the most marked increases being noted on soils naturally low in these materials. Of the three major elements, K was apparently needed in the greatest amount, followed closely by N. Phosphate was needed by lettuce in smaller amounts and paralleled Ca absorption rather closely. Analyses of solid and of open heads showed no consistent differences in composition.

Part 2, by McGeorge and Frazier, confirms the earlier conclusion that ample supplies throughout the growing season of available phosphate and N are needed for maximum production of lettuce. All of various methods of applying fertilizer, namely, broadcast, drill, side dressing, and band, gave good results. In one trial 11-48 ammonium phosphate as a side dressing was significantly more effective than band placement. In another experiment, application in bands proved definitely more efficient than applications by drill with respect to N recovery, but only slightly more efficient in phosphate recovery. There was noted on the Mesa Experimental Farm a greater recovery of both N and phosphate by the spring crop than by the fall crop.

To grow a fall crop of lettuce, L. R. FARISH (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 8, p. 1).—General information is offered on the time of planting, methods of preparing the seedbed, varieties, etc. Based on observations over a period of years, the optimum planting date for fall head lettuce in central Mississippi is during the first few days in September.

English pea yields more than doubled by seed treatment, J. A. CAMPBELL (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 8, pp. 2).—Stating that the long-continued use of the soil in the Crystal Springs and Hazlehurst areas has increased soil-borne organisms and that unfavorable conditions in January and February add another handicap, the author discusses the results of experiments on seed treatment with fungicides. With check yields of 29.3 bu. per acre, certain of the treatments more than doubled the yields. The cost of the treatment was only 40 ct. per acre. The indications were that less seed would be required following treatment because of better stands.

Foliar diagnosis of differentially fertilized greenhouse tomatoes with and without manure, W. THOMAS and W. B. MACK. (Pa. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 12, pp. 811-832, figs. 7).—Analyses of the fifth leaf from the base of Marglobe tomatoes growing under greenhouse conditions with fertilizers applied as single elements, combinations of two or three elements (N, P, and K), or with and without dressings of manure showed that if yield is considered the criterion of the effect of fertilizer, then foliar diagnosis shows the course of nutrition with respect to the dominant fertilizer elements determining these yields. The order of yields in relation to fertilizer treatment was not the same in the manured and in the nonmanured series. In the nonmanured plats the highest yields were obtained with a complete fertilizer, while in the manured series phosphate and K without nitrate additions were most effective. In both manured and unmanured series increased additions of nitrate of soda reduced yields below those obtained with unit additions. In the unmanured series the four lowest-yielding plats were those which did not receive muriate of potash, and the foliar diagnosis showed

that the leaves of the two lowest-yielding plats had the lowest percentage of K throughout the cycle. Associated with the lowest yields were also the highest values for phosphoric acid throughout the cycle. In the unmanured series, because of far greater accumulations of phosphoric acid in certain treatments, a relationship existed between the intensity and yield only on the first sampling date. High yields were associated with high values for the intensities of nutrition in the manured series, and low yields with low values. The manured series as a group gave higher yields than the unmanured, and each manured plat had a higher yield than the unmanured plat receiving a similar application of commercial material. Relative to these facts, the foliar diagnosis showed that the increased yields in the manured plats were associated with higher intensities of nutrition throughout the cycle and with a great increase in the K of the NPK unit, but with N and phosphoric acid showing no consistent relationship.

The improvement of naturally cross-pollinated plants by selection of self-fertilized lines.—III, **Investigations with vegetatively propagated fruits**, D. F. JONES and W. R. SINGLETON (*Connecticut [New Haven] Sta. Bul.* 435 (1940), pp. 325-347, figs. 11).—Continuing this series (E. S. R., 74, p. 332), the authors discuss the theoretical aspects of inbreeding of heterozygous plants with a view to eliminating undesirable and intensifying desirable characters in the progeny and report on experiments with strawberries and raspberries.

In the work with strawberries involving five varieties, Howard 17, Chesapeake, Glen Mary, Marshall, and Progressive, inbreeding resulted in a reduction in size, viability, and reproductive capacity. Many of the inbreds were lost during the winter season. Abnormalities, such as the alteration of the flower bud into a proliferating mass of small leaves and defections in chlorophyll, were observed in some seedlings. The possible nature of the yellowing of strawberry foliage is discussed in some detail. Crossing of inbred lines restored vigor and size to full measure, and certain combinations of three or four inbreds were sufficiently promising to be named (Shelton and Hebron).

In raspberry breeding, Ranere, Columbian, and Cumberland were selfed from 1 to 3 yr. Ranere and Columbian seedlings showed marked reduction in growth. Cumberland black yielded selfed seedlings which retained full vigor and production through three generations of selfing. All three raspberries showed considerable segregation upon selfing. Since raspberry seedlings start free of mosaic, the technic may have promise for the development of true-breeding black raspberries as a nursery practice. Promising red-fruited raspberries were produced from hybrids of black and red raspberries backcrossed to reds. However, many of these produced neither root sprouts nor tip layers, limiting their increase. Hybrids from raspberry \times blackberry were more thorny than the parents and produced less fruit.

Longevity of pollen in apple, pear, plum, peach, apricot, and sour cherry, B. R. NEBEL. (N. Y. State Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 130-132).—Continuing the investigation (E. S. R., 77, p. 784), some germination of apple pollen was recorded after more than 4 yr. of storage under optimum conditions. Both a tetraploid, Kola, and a diploid, Sutton, were represented in the long-life pollen. In the pear, one sample of Seckel survived 4.5 yr., indicating a similar life span for the pollen of the apple and pear. The pollen of the Grand Duke plum reached the 4.5-yr. stage. Peach and apricot pollens were not so durable, showing marked degeneration after 2 yr. of storage. Montmorency cherry pollen survived 5.5 yr., with tests still incomplete. Apple pollen which had lost all apparent viability in storage under ordinary room conditions was restored by transfer to cool storage at 50 percent relative humidity for 1 week.

Care of orchard in summer and fall for best results, T. E. ASHLEY (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 8, p. 8).—Brief instructions are presented with reference to culture, pruning, spraying, and fertilization.

Soil atmosphere and the production of new rootlets by apple tree root systems, D. BOYNTON. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 19–26, fig. 1).—In the case of 1-year-old budded McIntosh and Delicious trees growing in 2-gal. glazed porcelain crocks with tight covers to permit the control of gas exchange, there was observed at soil temperatures between 55° and 70° F. a marked decrease in the formation of new rootlets as the O₂ level of the soil was reduced below 15 percent, particularly when the percentage of CO₂ was increased in compensating amounts. When the O₂ level dropped below 10 percent and the CO₂ increased to between 5 and 10 percent, so few rootlets were formed that top growth was markedly reduced. There was no consistent difference in the behavior of McIntosh and Delicious.

The severe trimming of the root systems accompanied by the removal of all roots smaller than 5 mm. in diameter resulted in the production of fewer new rootlets than were produced from unpruned root systems. The harmful effect of root pruning was particularly evident in plants with low O₂ supply. In the lowest O₂ series, from 5 to 10 percent O₂ and from 15 to 8 percent CO₂, severe trimming of the root system was accompanied both by a reduction in the number of new rootlets and of their total weight. Apparently, a higher O₂ level is necessary for the production of new rootlets than for the maintenance of life in existing roots. The results suggest the need of providing good aeration of the soil around newly planted trees.

Size relationships of trees of five varieties of apples on several clonal rootstocks, H. B. TUKEY and K. D. BRASE. (N. Y. State Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 299–304, figs. 2).—Stating that in the North-east there is an interest in apple trees smaller than the so-called standards, the authors present data on the comparative development at the end of the seventh growing season in trials at Geneva and Ithaca, N. Y., of five varieties—Baldwin, Delicious, Early McIntosh, McIntosh, and Northern Spy—on various clonal rootstocks and on French crab seedlings. Apparently, several factors, environmental as well as inherent, were concerned, but there was evident a general tendency with all varieties for a given rootstock to produce trees of the same general size. Malling IX, for example, produced consistently small trees, and USDA 227 produced consistently large trees. Malling I and XIII tended to produce intermediate trees. There was noted a somewhat parallel behavior of the same stock and scion combinations at the two locations, with a greater range of size differences at Geneva than at Ithaca.

The growth and production of topworked apple varieties, T. J. MANEY. (Iowa Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 287–290).—Records taken in 1939 in an orchard at Ames, Iowa, comprised of several varieties of apple top worked in 1925 on own-rooted trees of Virginia Crab and Hibernial showed the varieties, in practically all cases, to have made more growth and production on Virginia Crab than on Hibernial. Records taken on Jonathan trees on various stocks, including the conventional French crab seedlings, showed considerable variability in growth and production related to the stocks. Average height ranged from 9 ft. for Jonathan on Dudley to 16 ft. for Jonathan on Virginia Crab. Production totals for 2 yr., 1938 and 1939, varied tremendously.

That intermediate stocks may exert a profound influence on the tree was shown in the case of Virginia Crab intermediates. The Paragon trees averaged 19 ft. tall, and the Mammoth Black Twigs only 9 ft. Virginia Crab was

found highly incompatible with Stayman Winesap and partly so with Winesap. The results indicate the need of careful studies of the compatibility of stock and scion combinations before making general conclusions.

The effect of reaction of the nutrient solution on apple seedlings growing in sand, L. J. EDGERTON. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 7-10, fig. 1).—Seedlings of McIntosh and Delicious, grown in sand supplied with nutrient solutions the pH of which was varied over a wide range, showed essentially the same growth throughout the series. Determinations of the total N content of the seedlings showed little effect of the reaction differences on this constituent. Apparently, the amounts of phosphate buffer added to maintain the different pH levels were not sufficient to interfere with the normal growth. From the results it was evident that apple seedlings were tolerant to H-ion concentrations over a wide range, those of the experiment being from 3.6-3.9 to 6.6-6.5.

Germination and growth of crab-apple seedlings (*Pyrus baccata*) as influenced by fungicidal treatment, L. L. DAVIS. (S. Dak. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 359, 360).—Although Siberian crab apple is conceded to be highly desirable as a rootstock for the apple in South Dakota, low-percentage germination and slow growth have impeded its use. Treatment before stratification with various fungicides failed to give significant benefits in germination, except possibly in the case of one Cu compound where the average germination was 7.5, as compared with 2.8 percent for the control lot. There was no indication that the Cu stimulated the growth of the resulting seedlings, but results may have been masked by severe drought conditions during the growing season.

The effect of time of nitrogen application upon the response of Jonathan apples, E. L. OVERHOLSER and F. L. OVERLEY. (Wash. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 81-84).—In experiments conducted over the period 1927-36 and in which N was applied at different times of the year at the rate of 1 lb. of actual N per tree (half from nitrate of soda and half from ammonium sulfate) it was evident that the best times to apply N to Jonathan trees on Cashmere sandy loam near Wenatchee, Wash., are in February and December. Applications in September, especially nitrate of soda, may be partly lost by leaching. Applications in April and July were the most unsatisfactory of the types tested, chiefly because of their effect in depressing red color development in the fruit. N applications in July and September apparently increased preharvest dropping. The shortest terminal growth was associated with September applications. Firmness of flesh, as measured by the pressure test, was little influenced by the time of applying N.

The effect of certain forms of nitrogen carriers upon the response of Rome Beauty apples, F. L. OVERLEY and E. L. OVERHOLSER. (Wash. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 78-80).—In an experiment begun near Wenatchee, Wash., in 1929 in a then 23-year-old Rome Beauty orchard located on Cashmere sandy loam there was little evidence that annual applications of N in various forms (calcium nitrate, calcium cyanamide, ammonium sulfate, and whale meat and blood) had any material effect on growth or yield. The orchard had a good alfalfa cover crop in the beginning which was gradually killed by heavy disking and was replaced by grass and weeds. The form of N appeared to be of little significance, leading to the practical suggestion of using the most economical material available. The depressing effects of N on red color development were not as evident in Rome Beauty as in Jonathan.

A study of lateral movement of potassium and phosphorus in an orchard soil, I. W. WANDER and J. H. GOURLEY. (Ohio Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 27-31, figs. 9).—In an orchard located partially on well-drained Wooster silt loam and partially on the less well-drained Canfield silt loam, potassium sulfate and superphosphate were placed in holes systematically arranged around certain trees. After 3 yr., trenches were dug adjacent to certain of the holes, and samples of the soil were collected at measured distances from the original placement. Quick tests for K showed marked lateral movement, large amounts being found in some instances as far as 9 in. from the original hole. Quantitative tests of exchangeable K indicated the same general trends, although they did not follow exactly the results of the quick tests. On the other hand, both quick and quantitative tests for P showed very little, if any, lateral movement of available P. In every instance there was observed a considerable accumulation of roots intermingled with the fertilizer and sand in the holes.

Variations in potassium content of the foliage from certain New York orchards, W. REUTHER and D. BOYNTON. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 32-38, figs. 2).—Samples of leaves collected throughout the very dry summer of 1939 from the station orchard showed the amount of K to be rather constant until about September 1, when migration of the element from the leaves began. The percentage of K in the dry matter decreased fairly uniformly throughout the entire summer. Injury to the leaves induced by sprays, fertilizers, and other causes was found to have little effect on the percentage of K in the dry matter, suggesting that there should not be any material difficulty in distinguishing between necrosis due to K deficiency and that due to other causes. Based on analyses of samples of leaves collected in 36 normal-bearing McIntosh orchards, it was evident that there is a considerable variation in the percentage of K in the foliage of apparently normal trees. Where samples of foliage were taken from the McIntosh trees affected with some degree of marginal scorch and staining, the percentage of K in the dry matter was very low. Studies were begun to determine the effects of K applications upon these low-K trees.

Frost rings in fall fertilized McIntosh apple trees, W. W. SMITH and M. A. TINGLEY. (Univ. N. H.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 110-112, fig. 1; also *New Hampshire Sta. Sci. Contrib.* 77 (1939), pp. 110-112, fig. 1).—Observations on samples of wood taken on October 28, 1938, from McIntosh trees which had received highly different amounts of N fertilizer in the fall of 1937 showed an absence of severe frost rings in the control trees and in individual trees a greater number of frost rings on the north side of the tree. The number and severity of frost rings apparently was related to the amount of N applied, although some abnormal xylem was found in unfertilized trees. The more frequent occurrence of rings on the north side of the tree may have been due to less stored carbohydrates or to the fact that temperature may be actually lower than on the southern exposure.

Spraying with plant growth substances for control of the pre-harvest drop of apples, F. E. GARDNER, P. C. MARTH, and L. P. BATJER. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 415-428).—Having noted that applications of certain growth substances tended to delay abscission of certain plant parts, such as nonpollinated holly berries (E. S. R., 78, p. 761), the authors conducted experiments with apple trees, using a large number of different compounds, to discover the possible effects on fruit abscission. To reduce variability due to tree individuality, limbs on single trees were used in certain cases. More than 30 separate spraying experiments were conducted with 20-

odd varieties. Of the various chemicals tried, naphthaleneacetic acid and naphthaleneacetamide were outstanding in effectiveness, differing very little, if any, in potency. The use of both materials, when applied at 0.0001 percent (1 p. p. m.) appreciably reduced dropping. A concentration of 0.0005 percent of either compound applied at the right time is advised as a practical treatment. The duration of the effect of the chemical, as well as the degree of effectiveness, varied with varieties. Instead of a 2- to 3-week period of effectiveness, as for most varieties, McIntosh was in a class by itself, the effect diminishing rather abruptly after 8 or 9 days. In studies of different methods of application, the desirability of thorough spraying of trees with particular effort to contact the fruit was indicated.

The McIntosh drop, L. SOUTHWICK (*Massachusetts Sta. Bul. 372 (1940), pp. 19, fig. 1*).—Stating that the premature dropping of McIntosh is a serious problem for growers, reaching, at times, 50 percent or more of the crop, the author discusses experiments conducted to determine the underlying factors involved. Dropping was more extensive under cultural conditions which made for abundant soil nitrates, particularly late in the season. Heavy mulching, organic or mineral N applications, late cultivation, and injections of N into the tree all tended to increase the percentage of drop in the preharvest period. On the other hand, a low fertility level, sod culture, limited cultivation, low tree vigor, and late summer girdling tended to decrease dropping. In many cases, dropping was found to increase with larger crops per tree. In a planting of McIntosh on clonal rootstocks there was some indication that dropping varied with the different stocks, but not necessarily according to their vigor. Records taken over a 3-yr. period showed a positive correlation between the seed number and the date of drop of apples from individual trees. On any particular tree the apples with many seeds tended to hang longer than those with fewer seeds. Length of stem was not found an important factor in the dropping of McIntosh. There was no indication that mineral content of the fruit was concerned. No positive evidence was found that could definitely associate varietal strains with dropping tendency. Attempts to correlate various weather factors with dropping gave somewhat doubtful results, although there was some indication that high temperature may increase dropping. The recent work of Gardner, Marth, and Batjer, noted above, on the use of certain chemicals to delay fruit abscissions is cited.

Origin of mechanical injuries to apples, C. W. ELLENWOOD (*Ohio Sta. Bimo. Bul. 205 (1940), pp. 115-118*).—Continuing observations in 1939 (E. S. R., 82, p. 49), the author records data on five varieties—McIntosh, Jonathan, Baldwin, Delicious, and Stayman Winesap—all of which showed more bruises on fruits graded over mechanical sizers than on those graded by hand. The belt-type grader caused fewer bruises in most cases than did the weight-type machine. There were slightly more skin injuries in basket- than in crate-handled fruits. McIntosh was particularly susceptible to bruising, Jonathan and Stayman Winesap rather susceptible, Baldwin and Delicious reasonably resistant.

Cork experimentally produced on Northern Spy apples, A. J. HEINICKE, D. BOYNTON, and W. REUTHER. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc., 36 (1939), pp. 47-52, figs. 2*).—The excessive irrigation from August 25 to November 14, 1938, of a normal 27-year-old Northern Spy tree which had borne disease-free crops for many years caused no symptoms of abnormality in the fruits or foliage in 1938. However, when irrigation was continued the following year, April to August, there was curling of the leaves, and by the middle of June the fruits showed the characteristic early symptoms of surface cork. Internal

corky tissue was also observed. The leaves later showed pronounced scorch, with some abscission. Not all the fruits or all the leaves were affected, but at least half of the branches bore injured fruits.

An analysis of gases extracted from wells dug under the trees showed a rapid decline in O_2 following heavy irrigation. Analyses of the foliage showed a reduced percentage of ash in the dry matter and of the B in the ash and the amount of B in each leaf. There was an even greater reduction in the K content. N was low, also, as compared with the controls. Apparently the lack of O_2 in soil interfered more with the absorption of K than it did with other elements.

Experience with color development of apples after harvest, E. P. CHRISTOPHER. (R. I. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 44-46).—McIntosh apples harvested September 18, when not over 5-10 percent of the surface showed stripes of red, scalded badly when placed beneath one layer of cheesecloth. With another lot under five layers of cloth, no scalding occurred, and markedly improved color was secured. As indicated in December after storage, the sun-colored fruits had higher quality than those stored directly from the tree. Favorable results were also secured with Cortland, Baldwin, and Northern Spy. Oilcloth proved a better light-reflecting medium for placing beneath the coloring frames than did either gravel, paper, or grass.

Progress report on identification of peach varieties by leaf characteristics, E. M. MEADER and M. A. BLAKE. (U. S. D. A. and N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 203-207, fig. 1).—Presenting further data (E. S. R., 80, p. 490) on the usefulness of certain leaf characters in the identification of peach varieties, the authors describe seven varieties—Belle, Candoka, Elberta, Hiley, Illinois, Smock, and South Haven—with reference to length : width ratios, angles of base and of apex, and conformation. The mean width : length ratio was found the most reliable of the measurements. Leaves of 6- to 7-in. length, taken from the midportion of vigorous unbranched terminal shoots, were found most desirable when available. Other characters of the leaf, tree, and fruit were also valuable in identification, but sufficient work was done with leaves to indicate that their study is very much worth while in the identification of peach varieties.

45 plum varieties in station tests—some recommended, C. H. RAGLAND (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 8, p. 7).—Together with brief notes on quality, productivity, etc., a list is presented of varieties which have proved promising.

The effect of yields upon the apparent drying ratios of French prunes, A. H. HENDRICKSON and F. J. VEIHMEYER. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 178-182).—As part of an experiment on the irrigation of the French prune, ratios between the weight of the harvested fruit and the weight following drying were determined for the various plats. The records showed, on the average, only relatively small differences in drying ratios among the various irrigation treatments in any 1 yr. In fact, in several cases the drying ratios of the fruits from unirrigated plats were equal to or greater than those from irrigated plats. Apparently, a close relationship existed between yields and drying ratios, suggesting that in years of small crops the trees may have sufficient leaf area to produce fruits with a low drying ratio, while in years of heavy production this was not the case. This hypothesis was confirmed by severe thinning of certain trees, the fruits of which had lower drying ratios than those of the controls.

Sour cherry rootstocks, L. R. BRYANT. (Colo. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 322, 323).—In a planting of Montmorency cherry trees on mazzard and mahaleb rootstocks, significantly greater mortality at the

end of five seasons was recorded in the mazzard-rooted trees. Based on trunk measurements, the mahaleb-rooted trees had made significantly greater growth. Chlorosis was more evident in the mazzard-rooted trees.

Bramble fruits: Raspberries, blackberries, and dewberries, A. S. COLBY, H. W. ANDERSON, and W. P. FLINT (*Illinois Sta. Cir. 508 (1940), pp. 72, pl. 1, figs. 35*).—This is a revision of Circular 427 (E. S. R., 72, p. 778).

Relation of number of leaves in November to number of flowers the following spring in the Blakemore strawberry, E. B. MORROW and G. M. DARROW. (N. C. Expt. Sta. and U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc., 36 (1939), pp. 571-573*).—Records taken on spaced plants growing in single-, double-, and triple-row beds showed an increase in the number of flowers per plant for each increase in size of plant as measured by the number of leaves present on the preceding November 15. In plants above the 6- to 10-leaved group there was a decrease in the number of flowers per leaf as the number of leaves per plant increased. Apparently, plants averaging 7 or 8 leaves were the most efficient flower producers under the conditions of the study. The effect of age of plant appeared to be chiefly a matter of plant size, as measured by the number of leaves. The older plants produced the greater number of leaves and flowers, although the younger plants produced more flowers per leaf. The difference in efficiency is attributed, in part at least, to the greater competition for nutrients among the older and larger plants.

The effect of ice upon the survival of strawberry plants, W. G. BRIERLEY, R. H. LANDON, and R. E. NYLUND. (Minn. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc., 36 (1939), pp. 557-563*).—That the injury to strawberry plants attributed to ice smothering during the winter is more likely the result of low temperatures or excessive water at the time of growth resumption or of disease was concluded from the results of investigations in which plants were coated with ice or enclosed in ice-covered cylinders or in sealed jars, the internal atmosphere of which was altered with respect to CO₂ and O₂. Beaver plants sealed in jars and exposed at -3° C. (26.6° F.) for 1 week to concentrations of CO₂ ranging from 2.7 to 7.3 percent showed some retardation of growth when placed in the greenhouse but soon resumed vigorous development. Since laboratory experiments showed that a coating of ice and of frozen water-saturated soil are both highly impermeable to CO₂ and O₂, it is conjectured that plants in the field are exposed frequently under natural conditions to abnormal atmospheres without suffering serious injury.

The influence of straw mulch on strawberries, J. E. VAILE. (Ark. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc., 36 (1939), pp. 567-570*).—Observations on the behavior of mulched and nonmulched plants of 19 varieties showed significantly more severe winter killing of plants and crowns and greater flower killing by late frosts and freezes in the nonmulched areas. The difference in flower killing was greater in early-blooming than in late-blooming varieties. Early-blooming strawberries as a group were more productive when mulched. Late-blooming varieties failed to show this gain in yield, a situation attributed to the probable occurrence of late-opening cluster buds not revealed at the time of recording injured flowers. Varieties which showed the greatest benefit in 1939 from mulching, from the standpoint of crown survival, were Fairfax, McClintock, Grand Champion, Howard 17, and Catskill. The greatest yield gains from mulching were recorded in the 3 early-blooming varieties, Fairfax, Howard 17, and Dorsett. It was apparent that mulch did not protect all varieties in the same manner or to the same degree. In replicated trials with Blakemore, significant benefits were recorded from mulching with respect to plant and crown survival, decreased flower killing, and increased yields,

Tennessee Supreme strawberry, L. A. FISTER and B. D. DRAIN (*Tennessee Sta. Cir. 68 (1940), pp. 4, figs. 3*).—A description is presented of a new variety originated by the station from a cross of Missionary × Howard 17. The variety is characterized by resistance to leaf and root diseases, tolerance to drought, productiveness, good color, high U. S. No. 1 percentage of the fruit, and adaptability for freezing preservation.

Quantitative relationships between leaf, branch, and root systems of the Valencia orange tree, S. H. CAMERON. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc., 36 (1939), pp. 125, 126, fig. 1*).—Records averaged for 32 9-year-old unpruned Valencia orange trees, tops from buds of a single parent tree, and roots of single clones showed the leaves, twigs, trunk and branches, large roots, and rootlets to comprise, respectively, 25.2, 9.4, 44.5, 19.7, and 1.2 percent of the green weight of the trees. The average was used because there was no significant difference between the trees. The weight of leaves fluctuated sharply during the season, attaining a maximum in May and June and a minimum in February. Differences in weight of leaves noted from year to year were attributed to the limiting effect of production on vegetative development.

Growth of own-rooted and budded citrus trees, F. F. HALMA. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc., 36 (1939), pp. 279-282, figs. 3*).—Measurements taken on Eureka lemons and navel and Valencia oranges on their own roots and propagated on grapefruit, sweet orange, and sweet orange, respectively, showed that the lemon trees grew more rapidly when on their own roots than when on grapefruit. In the navel orange the results were practically neutral, with slight superiority for own roots in one plat. A similar inconsistency was exhibited by the Valencia trees, indicating that environmental factors may be more potent than the inherent nature in determining response.

Nitrate concentration and ion balance in relation to citrus nutrition, H. D. CHAPMAN and G. F. LIEBIG, JR. (*Hilgardia [California Sta.], 13 (1940), No. 4, pp. [1]+141-173, pls. 2, figs. 8*).—Stating that whereas from 150 to 250 lb. of N are applied annually per acre in citrus orchards there is an actual utilization by tree and fruit of not more than from 35 to 50 lb., the authors discuss the results of experiments to determine the minimum maintained concentrations of nitrate N needed for the optimum growth of citrus plants. In sand culture studies with sweet orange seedlings, plants with 0.14, 0.7, and 1.4 p. p. m. of N all showed typical symptoms of N starvation. Plants with 7 p. p. m. were green and vigorous and made almost as good growth as those with 70 p. p. m. When the concentration was increased to 840 p. p. m., growth was markedly reduced, and the leaves were markedly injured. Low concentrations of N were found effective in sulfate, chloride, and cation concentrations. Apparently, a balance between Ca and K favorable for K absorption exerted a favorable influence on nitrate absorption. Increased chloride and sulfate concentrations did not depress nitrate absorption or utilization. It was apparent that the increased absorption of K in proportion to that of Ca served in some manner to offset the potentially depressing effect of sulfate and chloride. With increasing and equivalent concentrations of both Ca and K in the nutrient solution, the absorption of Ca decreased and that of K increased. Increased nitrate concentration did not depress phosphate absorption. Plants not retarded in growth by a lack of N but supplied with various nitrate concentrations showed no significant evidence of decreased P absorption. It is suggested that Ca-K relations are probably important in influencing various ion-pair relations. When nitrate is used as the nutrient source of N the best criterion of excess is the accumulation of nitrate in the plant. From the

results the authors suggest that in the orchard it might be better to supply N in frequent small applications rather than in less frequent large amounts. The reduced losses in leaching and volatilization might well offset the additional cost of frequent applications.

Studies of grapefruit fertilization in Arizona, A. H. FINCH and W. T. McGEORGE. (Univ. Ariz.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 62-67, fig. 1).—In January 1936 an orchard of Marsh grapefruit trees, located on the Yuma Mesa, which had received uniform applications of stable manure from the time of planting in 1928 and which was in vigorous condition was divided into plats and treated with differential fertilization. Yields recorded for the following 3 yr. showed the striking effects of commercial N. Differences in yield among the various kinds and combinations of commercial N-carrying fertilizers apparently were not significant. K and P used alone or in combination with forms of N had little influence on yield. The use of more than the basic application of 3 tons of manure was not beneficial, and, in fact, 3 tons gave only slightly larger yields than none. The fruit on all plats was coarse and of mediocre commercial quality. Analyses of the leaves for N, P, Ca, and ash showed all trees receiving commercial N to be very similar in composition whether N, P, or K was added. The percentage N content was highest on the plats receiving commercial N, and this content was correlated with productivity. The percentage P was not correlated with P application but was rather negatively associated with the application of N-carrying materials. The percentage of Ca in the leaves was also more closely correlated with N content than with Ca applications. The leaves of trees receiving commercial N contained more ash, N, and Ca and less P than trees not receiving commercial N.

Soil moisture, root distribution, and aeration as factors in nut production in western Oregon, C. E. SCHUSTER and R. E. STEPHENSON. (Coop. U. S. D. A. et al.). (*Oreg. Sta. Bul.* 372 (1940), pp. 32, figs. 10).—Studies in a large number of orchards located on a number of different soil types indicated that under favorable conditions with respect to moisture and aeration the roots of walnut trees penetrate deeply and form a well-developed root system. Soils supporting the largest trees permitted free development of roots and free movement of moisture into the roots to a depth of soil of 8 or 10 ft. From 10 to 12 percent by volume of noncapillary pore space provided open spaces for the exchange of air and for easy root penetration. Heavy, waterlogged soil inhibited root development and limited the function of any roots that penetrated deeply. Upward movement of water from subsoils is probably both slow and, in most cases, limited in amount. There was noted a more or less uniform extraction of moisture at the different levels by trees with well-developed root systems. While not less than 5 or 6 ft. of effective soil depth may permit successful nut production, from 8 to 10 feet of penetrable aerated soil is conceded much more favorable. Under the climatic conditions of western Oregon, cover crops must be worked into the soil in early April, and the stored soil moisture conserved for the trees. Measurements of usable soil moisture cannot be restricted to the surface horizons but must include the moisture-root relations of the deep horizons as well.

Selected list of woody ornamental plants for Ohio, L. C. CHADWICK (*Ohio Sta. Bimo. Bul.* 205 (1940), pp. 135-143).—Lists are given of recommended plants arranged by types, such as vines, ground covers, shrubs, trees, and narrow-leaf and broadleaf evergreens. The upright types are further subdivided according to their expected height at maturity.

FORESTRY

[Forestry studies by the Georgia Station]. (Partly coop. U. S. D. A.). (*Georgia Sta. Rpt. 1940, pp. 88, 89*).—Included are brief statements on studies of the influence of various types of seedbed treatment on germination and survival of yellow poplar, spacing and rate-of-growth trials with white pine, testing of chestnut seedlings, and the effect of phosphate on newly set black locust trees.

Survival and growth of slash pine from different grades of planting stock, D. J. WEDDELL (*Alabama Sta. Rpt. 1938, pp. 21, 22*).—Comparing stock plants from 10 to 16 in. tall with smaller stock, the author recorded much better survival and height growth after two growing seasons for the larger stock.

Effect of certain chemical attributes of vegetation on forest inflammability, L. W. RICHARDS. (U. S. D. A.). (*Jour. Agr. Res. [U. S.], 60 (1940), No. 12, pp. 833-838*).—The work here noted, carried on at the Priest River Experimental Forest in northern Idaho, forms part of a three-phase study to ascertain measurable factors for fire-danger rating. The use of crude-fiber values, considered as a partial measure of fuel content, was abandoned because of a lack of significant variations corresponding to changes in fire behavior. Moisture content, calorific value, and crude fat (total ether extract) were determined on samples taken at 10-day intervals during the fire seasons of 2 successive years. Moisture content, which showed a wide range of variation, was apparently the most important factor affecting fire behavior. It is noted, however, that, "as critical fire conditions develop, factors other than total free moisture may gradually assume increased importance. The tenacity with which a given plant holds its free or chemically combined moisture may determine whether it exerts a retarding effect, no effect, or an accelerating effect on the rate of spread of forest fires." It is considered not to be possible, as yet, to relate the observed differences in calorific value with the effect of the vegetation on rate of fire spread. Only snowbrush and pinegrass, among the several species examined, showed marked variation in calorific value through the periods studied. With respect to the crude-fat data, it is noted that as a rule the calorific values of the crude fats are considerably higher, and their ignition temperatures are measurably lower, than those of cellulose. Any significant change in either quantity or nature of these constituents might readily alter the burning properties of the plants.

Cost of producing white pine lumber in New England, V. S. JENSEN, C. E. BEHRE, and A. O. BENSON (*U. S. Dept. Agr. Cir. 557 (1940), pp. 40, figs. 12*).—Discussing the history and significance of white pine production in the North-eastern States, the authors stress the need of a forest management policy which would provide a continuous supply of large, high-quality timber. Studies of six typical white pine lumbering operations at various locations in Maine, Massachusetts, and New Hampshire are described and discussed in detail. Log size, which is directly related to tree size, was the most important of various factors determining the costs of lumber production, the grade of lumber, the margin for profitable operation, and the price which could be paid the owners for stumpage. In the Waterboro, Maine, operation, which represented a fair average of conditions on the six projects, the highest returns were obtained from 17-in. logs. Large logs and trees not only were harvested more efficiently but also produced a much larger proportion of high-quality lumber. Small logs yielded mostly low-grade material salable only for boxboards or similar products. It was evident that under the usual conditions lumber cannot profitably be manu-

factured from trees less than 10 in. or logs less than 8 in. in diameter. Partial cutting, involving the selection of the larger trees, had certain advantages, namely, the production of a higher proportion of high-quality lumber, the maintenance of the stand, a reduction in fire hazard, etc. In one operation where part of the trees had been pruned, there was a notable increase in the output of the better grades of lumber. Data on certain of the operations showed that square edging of the lumber, though reducing the total output, materially increased the sale value and net returns. The value of grading lumber rather than selling it as mill run was indicated. The more effective disposal of slabs, sawdust, and other waste material is suggested as a means of increasing returns. Recommendations for the management of white pine forests on a sustained production basis are included.

Hardwood resources and industries in Arkansas, H. GARLAND (*Arkansas Sta. Bul. 404 (1940), pp. 50, figs. 20*).—Based on personal observations, interviews with mill operators and industrial consumers, and on published data, a picture is presented of the present situation, and plans and policies which would tend toward permanency are suggested. At present, small ownerships of second-growth hardwoods, rarely managed for sustained yields and cut for immediate cash returns without view to the future, have resulted in inefficient use and depletion of Arkansas hardwoods. The efficient use of hardwood logs is confined to a few large mills in the bottom lands. There is need for an effective State-wide fire protection plan and for education of forest owners and dwellers to the possibilities in good management. The establishment and general acceptance of grades for sawlogs and nonlumber raw material would lead to more effective marketing by the owner and better utilization by the mills. It is suggested that the mills should purchase or control sufficient forest areas to assure sustained yields of raw material. Cooperative forest management is suggested as an alternative to large single ownerships. Large areas of depleted forest are a major problem, suggesting the need of public management to restore them to a worth-while status.

Volume tables for some Arkansas hardwoods, R. D. STEVENS (*Arkansas Sta. Bul. 396 (1940), pp. 46, fig. 1*).—Based on direct measurements of felled trees on logging operations in various sections of the State, volume tables are presented for different species and types of hardwood. The tables are based on length of bole and Doyle, Scribner Decimal C, and International $\frac{1}{4}$ -Inch log rules. Where data were available, cordwood volumes from limbs and tops are included for each species under its volume table for the Doyle log rule. In the volume tables the data are rounded to the nearest 5 bd. ft. except in the case of Scribner Decimal C tables, which are constructed by rounding to the nearest 10 and dropping the cipher. Miscellaneous tables include data on the volume in linear feet of stave material for bottom-land hardwoods most commonly used for slack stave stock and for tight stave utilization in old-growth upland white oak.

DISEASES OF PLANTS

Insect transmission of plant diseases, J. G. LEACH (*New York and London: McGraw-Hill Book Co., 1940, pp. XVIII+615, [pl. 1], figs. 238*).—In this volume the author has endeavored to bring together the most important contributions in this field of study hitherto found only in widely scattered contributions, to evaluate and interpret the evidence in the light of the more recent advances in entomology and plant pathology, and to emphasize the importance and promise of the subject as a field of study and research. Following an introductory chapter, the main subjects dealt with are the interrelationships of plants and insects; symbiosis between insects and micro-organisms and its significance in plant pathology;

relation of insects to the spread and development of plant diseases; plant diseases caused by toxicogenic insects; insects in relation to diseases due to bacteria, fungi, viruses, and phytopathogenic protozoa; mites, nematodes, and other small animals as vectors of plant diseases; the anatomy and physiology of plants in relation to infection and insect vectors, and of insects in relation to the transmission of plant diseases; the inocula of plant pathogens in relation to insect transmission; feeding and breeding habits of insects in relation to the transmission of plant diseases; insect transmission of animal diseases compared with that of plant diseases; and methods of studying insect transmission of plant diseases. Tabulations of certain facts pertinent to the subject appear in an appendix, a glossary and a subject index are provided, and literature references occur at the ends of individual chapters.

Handbook of plant diseases, VI, founded by P. SORAUER (*Handbuch der Pflanzenkrankheiten. Berlin: Paul Parey, 1939, vol. 6, pts 2 and 3, pp. 208, figs. 68*).—Part 2 of this monograph series (edited by O. Appel, with the collaboration of W. Fischer, G. Hilgendorff, H. Sachtleben, E. Riehm, W. Trappmann, A. Winkelmann, and H. Zillig) continues discussions of the control of plant diseases and pests (*E. S. R.*, 81, p. 47), with a consideration of biological methods through the use of micro-organisms, vertebrates, and insect parasites. Part 3, the technical means of plant protection, takes up in detail the various methods and apparatus for disinfection (moist and dry), dusting, and spraying.

Report of the 1940 annual meeting of the Pacific division of the American Phytopathological Society (*Phytopathology, 30 (1940), No. 9, pp. 784-791*).—Abstracts of the following papers are given: Greenhouse Experiments for Control of Seedling Diseases of Sugar Beets, by M. M. Afanasiev and H. E. Morris; The Use of Calcium Cyanamid and Other Fertilizer Materials and Soil Amendments in the Destruction of Apothecia of *Sclerotinia fructicola* with Methods of Application, by K. Bauer and G. A. Huber; A Canker and Die-back Disease of Overwintered Youngberry and Boysenberry Canes, by E. C. Blodgett; The Strip Method of Soil Treatment for the Control of Black Root of Sugar Beets, by L. Campbell; Occurrence of Big Bud of Tomato in the Pacific Northwest, and Resistance and Susceptibility to Curly Top in Varieties of Common Bean, *Phaseolus vulgaris*, both by B. F. Dana; A Preliminary Report on the Inheritance of Resistance to Rust (*Uromyces appendiculatus*) in Beans (*Phaseolus vulgaris*), and A New Factor for Resistance to Powdery Mildew (*Erysiphe polygoni*) in Beans (*Phaseolus vulgaris*), both by B. Dundas; Curly-Top Virus Strains, by N. J. Giddings; The Origin and Inheritance of M Types in *Hypomyces*, by H. N. Hansen and W. C. Snyder; California Regulatory Laws and Fruit-Tree Viroses, by J. L. Hewitt; Net Necrosis of Potato in Western Washington, by G. A. Huber; The Stony-Pit Virus of Pears, by J. R. Kienholz; Influence of the Pathogen, Environment, and Host Response on the Efficacy of Seed Treatment With Sugar Beets and Some Vegetable Crops, by L. D. Leach; Separation of Tulip 1 Virus From Lily-Latent by Cytological Methods, by F. P. McWhorter; A *Phytophthora* Disease of *Chamaecyparis*, by J. A. Milbrath; Camellia Yellow Spot—A Virus Disease, by J. A. Milbrath and F. P. McWhorter; Further Studies on the Comparative Efficacy of Bordeaux Mixture and Some "Insoluble" Copper Sprays for the Control of Walnut Bacteriosis in Oregon, by P. W. Miller; Rusty-Mottle, A New Virosis of Cherry, by E. L. Reeves; A Sweet Clover Ring Spot From Alsike Clover (*Trifolium hybridum*), by S. Rich; An Apparently Undescribed Storage Rot of Grapefruit, by R. B. Streets; Results of Three Years' Treatment of Pecan Groves for Control of *Phymatotrichum* Root Rot, by R. B. Streets and L. A. Brinkerhoff; The Increase of Tobacco-Mosaic Virus and the Changes Accompanying Nitrogen Compounds in Detached Tobacco Leaves, by W. N. Takahashi;

Graft Transmission, Persistence and Migration of Some Viruses in Fruit Trees, by H. Earl Thomas; Tulip Anthracnose, by C. M. Tompkins and H. N. Hansen; Low Germination of Peas Associated With the Presence of Bacteria in the Seed, by W. J. Virgin; Therapeutic Action of Vapors From Sulphur Compounds, and Cultural Separation of Some Obligate Parasites, both by C. E. Yarwood; and A Phycmycete Affecting Roots of Raspberry, by S. M. Zeller and A. J. Braun.

[Phytopathological papers] (*Iowa Acad. Sci. Proc.*, 46 (1939), pp. 119-125, 179, 180).—The following are included: Diseases of Cultivated Lupines, by C. J. Gould, Jr. (pp. 119-125), and Studies in the Redistribution of Some Phytopathogenic Species of *Bacillus*, by E. L. Waldee, G. C. Kent, and I. E. Melhus (pp. 179, 180) (both Iowa State Col.).

Diseases of plants in the United States in 1938, N. W. NANCE (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 1939, Sup. 119, pp. 119-289, figs. 23).—This report follows the general plan of previous summaries (E. S. R., 82, p. 58), including weather data (see p. 12). Potato late blight, psyllid yellows, ring rot, and *Phytophthora* pink rot and wilt; leaf rust of wheat; northwestern apple tree anthracnose in Maine; persimmon wilt; and Dutch elm disease were noteworthy from the standpoints of severity, wide incidence, or extension of range.

The Plant Disease Reporter, [September 1 and 15, 1940] (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 24 (1940), Nos. 16, pp. 337-346; 17, pp. 347-359, figs. 3).—The following items of interest to phytopathology are included:

No. 16.—Mild streak disease of black raspberries in Maryland, by M. W. Woods and I. C. Haut; yellow-red virosis on chokecherry in Illinois, by H. W. Anderson and H. F. Seifert; tomato diseases found in western Tennessee in 1940, by M. C. Richards; incidence of wheat foot rots in Kansas and Colorado, by H. Fellows; foot and root rots of small grains and grasses in the Dakotas, by R. Sprague; new records of charcoal rot on hardy phlox in Illinois, and spotted wilt outbreak on tomatoes and peppers in Pennsylvania; and brief notes on bitter rot of apples in southern Illinois in 1940 and dwarf smut prevalent on wheat in Montana.

No. 17.—Present status of the Dutch elm disease; the status of onion bloat in 1940, by A. G. Newhall and B. G. Chitwood; the nematode *Eucephalobus oxyuroides* apparently causing disease of tobacco roots, by T. W. Graham; Crown injury on peach trees in New York, by M. B. Hoffman; origin of outbreaks of peach leaf curl, by W. D. Valleau; check list revision notes, by F. Weiss; and brief notes on unusual severity of dodder in Virginia and powdery mildew on rose in Connecticut.

Plant pathology (*Arizona Sta. Rpt. 1939*, pp. 88-95, figs. 4).—Progress notes are included on control of fungus fruit rot of dates by spraying; incidence of and seed treatment for angular leaf spot of cotton; *Phymatotrichum* (Texas or cotton) root rot, including chemical treatments and new methods of applying them, barriers by injection, and field surveys for incidence (coop. U. S. D. A.); and studies of *Fusarium* and bacterial wilts of cantaloups, cantaloup fruit disinfection, *Macrosporium* leaf blight of carrots, a bud rot of Washington palms apparently of fungus etiology, dodder on alfalfa, dry root rot of citrus possibly due to *Fusarium*, sclerotiniosis of lettuce, and *Graphiola* leaf spot of date palms.

[Studies in plant pathology by the Georgia Station]. (Partly coop. Ga. Coastal Plain Sta. and U. S. D. A.). (*Georgia Sta. Rpt. 1940*, pp. 16-20, 51-57, fig. 1).—Brief summaries of progress are included on studies of black rot of muscadine grapes; resistance of peppers to southern blight; peanut breeding

and selection for disease resistance and other desirable characters; sulfur dust for control of peanut leaf spots; the effects of peanut seed treatment on germination and yields; cold injury to peach trees; disease control on field-grown tomato plants; breeding and selection of watermelons for wilt resistance, and of snap beans, Austrian Winter peas, vetches, and lupines for resistance to various diseases; delinting and treating anthracnose-infested cottonseed; new nematode species (*Rotylenchulus reniformis* and two as yet unnamed) parasitic on cotton roots; relation of different nematode species to cotton wilt in Georgia; and effect of potash on yield and wilt of cotton in 1939.

[Plant disease work by the Rhode Island Station] (*Rhode Island Sta. Rpt.* [1939], pp. 22, 23, 24, 38-41, 42).—Brief reports are included on the incidence of diseases of grasses and of perennial and annual ornamental and crop plants, and on the first appearance of the "X"-virus disease of peach and choke-cherry and of the potato "sprain" disease in the State; studies on the bleeding canker (*Phytophthora cactorum*) of maple and beech and its control; varietal tests with eggplants yielding highly resistant strains; field tomato disease control work; field observations on apple scab; dieback of *Daphne cneorum* associated with fungi; potato spraying trials; soil fumigation with chloropicrin for tomatoes; factors in the killing of weed seeds and in turf injury by chloropicrin; and chemical soil treatments for root knot nematode control in greenhouse tomatoes.

[Plant diseases in the Philippines] (*Natl. Res. Council Philippines Bul.* 23 (1939), pp. 170, 176, 177, 179, 188, 189, 190, 192, 193, 194, 198, 199, 200, 201, 205, 206).—Abstracts are given of the following papers: A *Sclerotium* Stem Rot Disease of *Musa glauca* Roxb., by N. G. Teodoro; Damping-Off of Lettuce and Heart Rot of Petsai Caused by *Pythium aphanidermatum* (Edson) Fitz., by E. F. Roldan; Rootlet Rot of Avocado Seedlings, by E. F. Roldan and X. Raktakanishta; Mosaic of Abacá, by G. O. Ocfemia and M. S. Celino; Some Plant Diseases of Economic Importance Not Previously Known in the Philippines, by F. M. Clara; The Rice Cadang-Cadang in Albay Province—I, Its Probable Cause, by F. de Peralta and J. A. Agati; Study on the Root Knot Nematode Affecting Strawberries in Baguio, by T. G. Fajardo; "Palay Lalake," a Fungous Disease of Rice, by G. M. Reyes; The Bacterial Wilt of Abaca in Davao—A Progress Report, by M. A. Palo; A Comprehensive Study on Symptoms of Abaca Mosaic, by M. R. Calinisan; Further Studies on the Transmission of the Fiji Disease of Sugar Cane, by G. O. Ocfemia, M. S. Celino, and C. A. Calica; Progress in the Control of the Late Blight Disease (*Phytophthora infestans* Mont.) De Bary by Blight Resistant Potatoes, by T. G. Fajardo; and A New Gray Mould Found on Beans and Spineless Kulitis, by G. M. Reyes.

The symptoms and diagnosis of minor-element deficiencies in agricultural and horticultural crops.—I, Diagnostic methods: Boron, manganese, C. S. PIPER (*Empire Jour. Expt. Agr.*, 8 (1940), No. 30, pp. 85-96).—A critical review with 57 references.

"Potash hunger" is easiest identified on leaves of plants, R. COWART (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 8, p. 6).—The diagnostic value of leaf symptoms of potash deficiency are discussed briefly.

Preliminary host index to fungi of Mount Shasta, California, W. B. COOKE (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 1940, Sup. 123, pp. 125-133).

Action of some organic compounds on yield, sporulation, and starch formation of *Aspergillus niger*, R. A. STEINBERG. (U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 60 (1940), No. 11, pp. 765-773).—"The effects of 37 biological stains, 21 miscellaneous organic compounds, and 85 phenanthrene derivatives on

growth, sporulation, and starch formation of *A. niger* were studied at concentrations of 1, 10, 20, and 100 mg. per liter. An increase in yield above that of the control occurred only in a solution partially deficient in trace elements and was attributed to the presence of inorganic impurities in the organic compounds. Toxicity was greatest with malachite green (1 p. p. m.), though the hydroxyphenanthrenes (10 p. p. m.) were also quite toxic. Responses in yield, sporulation, and starch formation were not uniform, but were related to the chemical constitution of the compound. Starch formation was decreased by low nitrogen and by certain compounds. Low trace elements led to an increase in starch formation, as did also certain relatively toxic compounds."

Studies on *Caryospora putaminum*, W. F. JEFFERS. (Md. Expt. Sta.). (*Mycologia*, 32 (1940), No. 4, pp. 550-566, figs. 2).—A study of the life history, cultural characters, and taxonomy of *C. putaminum*, occurring chiefly on old peach stones, is presented, *C. minima* n. sp. is described, and an annotated list of previously described species of the genus is given.

The presence of *Fusarium scirpi* var. *acuminatum* in Argentina [trans. title], C. J. M. CARRERA (*Rev. Argentina Agron.*, 7 (1940), No. 2, pp. 89-94, figs. 3).—A fungus identified as *F. scirpi acuminatum* was found associated with a basal blight of carnation (*Dianthus caryophyllus*) and shown to be the cause. Since it had been demonstrated that this fungus is also pathogenic to flax, attention is called to the potential danger to this crop.

The effect of crop debris on the pathogenicity of cereal root-rotting fungi, L. E. TYNER (*Canad. Jour. Res.*, 18 (1940), No. 7, Sect. C, pp. 289-306, figs. 2).—The effect of wheat, barley, and oat straw composted with soil on the development of disease in the basal parts of wheat seedlings was studied during three seasons in greenhouse tests, the pathogens used being *Ophiobolus graminis*, *Helminthosporium sativum*, and *Fusarium culmorum*. Wheat straw composts proved distinctly more favorable to disease development than the others, while the least injury occurred with the oat straw. It is suggested that the microorganisms associated with the decomposition of oat straw brought about some degree of biological control of the pathogens. Although the amount of straw applied sometimes influenced the severity of disease, the effects were not consistent from planting to planting. The actual C:N ratio had less effect on disease development than the chemical nature of the straw. The kind and amount of straw in the composts also influenced seedling vigor, which in general was inversely proportional to the degree of infection. A short fallow between plantings decreased infection somewhat and increased vigor. The pathogenicity of the artificial inoculum added at the first planting was practically vitiated before the second. Subsequent infection ratings tended to increase and were about the same as those in uninoculated series. There are 27 references.

Studies on the natural inoculation of seed barley with covered smut (*Ustilago hordei*), V. F. TAPKE. (U. S. D. A. and [N. Y.] Cornell Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 60 (1940), No. 12, pp. 787-810, pl. 1, figs. 5).—Investigating the mechanism of spontaneous inoculation and the methods of artificial inoculation of barley with spores of *U. hordei*, the author found that spontaneous infection resulted largely from spores germinating under the glumes. Spores from disintegrated smutted heads were disseminated in the field before the barley had matured and later during harvesting and threshing. High humidity favored infection in inoculated stored seed. These findings are believed to explain the failure frequently met with in attempting to inoculate barley by dusting dry spores on the outside of glumes. Preliminary studies seem to indicate that the variety of barley, the physiologic race of smut, and the conditions under which the plants

are grown are factors concerned in the different types of emergence of the smutted head, viz, fully exerted or remaining half enclosed in the boot. The recently extended knowledge of the factors conditioning barley infection with *U. hordei* has aided in developing the spore-suspension method of seed inoculation. This new artificial method, patterned after the spontaneous method, has proved highly and consistently effective as well as practicable. There are 53 references.

The effect of nutrient salts in organic mercurial seed disinfectants on the germination and early growth of wheat, N. H. GRACE (*Canad. Jour. Res.*, 18 (1940), No. 5, Sect. C, pp. 151-157).—"Wheat seed was treated by dusting with a series of seed disinfectants containing 5 percent of ethyl mercuric halide . . . and three concentrations of each of KNO_3 , KH_2PO_4 , $\text{NH}_4\text{KH}_2\text{PO}_4$, and $\text{Ca}(\text{H}_2\text{PO}_4)_2 \cdot \text{H}_2\text{O}$. This method of applying nutrient salts failed to effect any general stimulation to germination or early growth. In one experiment with Marquis wheat, KNO_3 accelerated germination without increasing the final value, and all but KH_2PO_4 increased root weight 3 weeks after planting. In two subsequent experiments with only KNO_3 added to the mercurial but with four varieties of wheat, conducted at different temperatures, no stimulation was observed."

The use of water by wheat plants when inoculated with *Helminthosporium sativum*, B. J. SALLANS (*Canad. Jour. Res.*, 18 (1940), No. 5, Sect. C, pp. 178-198, figs. 4).—"The transpirational histories of wheat plants inoculated with *H. sativum* to produce root rot exhibited a marked reduction in water loss during the early growth stages as compared with uninoculated plants. This was accompanied by a corresponding reduction in the transpiring areas owing to reduced lengths and widths in the second, third, and fourth leaves. In the early stages of elongation of the culm the transpirational story reflected a recovery in the inoculated plants. Later leaves to appear were longer and with greater transpiring areas than in control plants. This combined with the death of the first three or four leaves resulted in greater transpirational and photosynthetic areas in the inoculated plants with the consequent higher yields of dry matter. It is deemed probable that similar recovery does not occur under competitive field conditions where weeds and healthy wheat are also both present. Poor light conditions and low soil moistures did not prove conducive to recovery of inoculated plants. The water requirements of wheat did not appear to be affected significantly by inoculation. Of two spring wheat varieties, Reward was more severely injured initially and recovered more quickly than Marquis. Several possible explanations of the recovery recorded are discussed.

The relationship of weeds to losses caused by common rootrot in wheat, B. J. SALLANS (*Sci. Agr.*, 20 (1940), No. 11, pp. 632-637, fig. 1).—"It was found that *Helminthosporium sativum*, a principal cause of common root rot of cereals in western Canada, may retard wheat in the seedling stage so that weeds become well established. The latter in turn may then prevent the normal tendency of the crop to recover, resulting in reduced grain yields.

A study of the transference of immunity to stem rust from *Triticum durum* var. Iumillo to *T. vulgare* by hybridization, R. F. PETERSON and R. M. LOVE (*Sci. Agr.*, 20 (1940), No. 11, pp. 603-623).—"A number of *T. vulgare* derivatives from *T. vulgare* \times *T. durum* var. Iumillo crosses have a degree of resistance to stem rust closely approximating the immunity of Iumillo. This resistance can be more readily transferred to other *vulgare* wheats by hybridization than can the immunity or resistance of Iumillo itself. In spite of the considerable amount of cytological irregularity found in the material studied, a number of lines, and particularly reselections from the lines, are relatively stable 42-chromosome wheats morphologically similar to standard *vulgare* types. The

effectiveness of intense selection is shown in that the rust reactions of the selected lines in the field were practically as stable as that of Iumillo. This was true notwithstanding the fact that many plants were aneuploids (having more or less than 42 chromosomes) or were heterozygous for the arrangement of one or more chromosome segments. The rigorous selection for stem rust immunity in the field had apparently eliminated all or most of the cytological irregularities involving the genes necessary for mature plant immunity. The practical value of cytological examination of hybrid derivatives in plant breeders' material is evident."

The influence of light and certain other environmental factors on the mature-plant resistance of Hope wheat to stem rust, T. JOHNSON and M. NEWTON (*Canad. Jour. Res.*, 18 (1940), No. 8, Sect. C, pp. 357-371, figs. 2).—A 60 percent reduction in light intensity during the whole growing period tended to influence the reaction of Hope wheat plants to race 21 of *Puccinia graminis tritici* toward increased susceptibility and caused a modification in morphology toward a softer, less rigid plant and a higher moisture content. This shift toward susceptibility was, however, not very marked, and in only one test did the plant reaction approach complete susceptibility. Plants receiving 6 hr. of light daily were less resistant than those with 10 hr. of light, and these in turn were slightly less resistant than those receiving full daylight for the period of the experiment (February-June). Temperature tests indicated that 75°-80° F. constantly applied is capable of causing a partial or even complete break-down of mature-plant resistance in Hope wheat. Some evidence was secured that abundance of soil moisture and of mineral nutrients also diminished rust resistance.

A Great Northern bean resistant to curly-top and common bean-mosaic viruses, D. M. MURPHY. (Idaho Expt. Sta.). (*Phytopathology*, 30 (1940), No. 9, pp. 779-784, fig. 1).—Curly top and common bean mosaic are said to be two of the most important bean diseases in Idaho and to have caused severe losses to the bean-growing industry in the State. Three Great Northern selections by the station now represent almost the entire Great Northern crop in Idaho. For several years a program of continuous plant selection and testing for resistant selections in this group has been carried out. A new selection, Great Northern U. I. 15, proved to be the most valuable from several standpoints and has been increased as rapidly as possible on the trial grounds. It is this selection which has proved resistant to the viruses of both curly top and common bean mosaic. Its virus-resistant properties and some of its other outstanding characteristics, as well as the symptoms of the two diseases, are discussed.

Cotton wilt and root-knot nematode, D. C. NEAL. (U. S. D. A. et al.). (*Better Crops With Plant Food*, 24 (1940), No. 2, pp. 36, 37).—A note calling attention to the recent surveys showing many cotton-growing areas of the Gulf Coastal Plain heavily infested with *Fusarium vasinfectum* and *Heterodera marioni* and the apparent breaking down of wilt resistance in special wilt-resistant cotton varieties when nematodes attack the plants. Rotations with nematode-resistant plants are recommended.

Methods of inoculating soil with the cotton wilt organism, H. B. TISDALE, and J. B. DICK (*Alabama Sta. Rpt.* 1938, p. 10).—Note on results of a 3-yr. study.

Soil sickness of flax in North Dakota, H. H. FLOR. (U. S. D. A. and N. Dak. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 9, pp. 749-760, figs. 2).—Varieties of flax varying in degree of wilt resistance were sown on soil cropped to flax almost continuously for 45 yr. The progress of root infection as shown by development of fungi isolated from roots and hypocotyls dug at 2- or 3-day intervals was determined. No preemergence injury occurred in the field and

no fungi developed from flax roots until well after cotyledon emergence (7-11 days). The Bison (wilt-resistant) became infected with *Fusarium lini* as soon as Damont and Newland (wilt-susceptible) varieties. The preponderance of *F. lini* (425 isolates, compared with 15 of *Alternaria* spp., 16 of *Thielavia basicola*, and 4 of *Rhizoctonia* spp.), together with the fact that the earliest infection of all varieties was by *F. lini*, indicates that injury in these tests was primarily due to wilt. *Fusarium* infection of wilt-resistant varieties was local in contrast to the apparent systemic infection of wilt-susceptible varieties. In greenhouse pot tests, severe seedling injury resulted in both steamed and nonsteamed soil when flax was sown immediately after inoculation with *Rhizoctonia* spp., but injury diminished in successive monthly sowings. In nonsteamed farm soil no injury was apparent, even when flax was sown immediately after inoculation of the soil with *Pythium*.

Wilt of pimento (*Capsicum annuum*) in the Province of Mendoza [trans. title], R. E. PONTIS (*Rev. Argentina Agron.*, 7 (1940), No. 2, pp. 113-127, pls. 2, fig. 1; *Eng. abs.*, p. 123).—The author describes the symptoms and the results of studies of the morbid anatomy, etiology, spread, and control of the disease, and factors influencing its development. The pathogen was identified as *Fusarium vasinfectum*. Other *Fusarium*s tested proved to be nonpathogenic to pepper. There are 39 references.

Resistance of certain potato varieties and seedling progenies to late blight in the tubers, R. BONDE, F. J. STEVENSON, and C. F. CLARK. (Maine Expt. Sta. and U. S. D. A.). (*Phytopathology*, 30 (1940), No. 9, pp. 733-748, figs. 4).—Seedlings of known parentage were tested for resistance to vine and tuber infection by *Phytophthora infestans* under field and laboratory conditions in Maine, a high percentage proving resistant to both types of infection when one or both parents were resistant. Resistance of the leaves, however, was not necessarily accompanied by resistance of the tubers. Seedlings with resistant tubers and foliage were secured by selfing the susceptible variety Katahdin, resistance in both cases apparently depending on morphological structure and on physiological properties. Tubers of some varieties were susceptible to late blight decay while immature but resistant when mature. The virulence of the pathogen had apparently not been increased by propagation on certain resistant varieties. Some potato varieties gave no evidence of loss of resistance to late blight infection after having been grown in Aroostook County for 10 yr.

Some evidence on the spread of bacterial wilt, C. H. METZGER and A. M. BINKLEY. (Colo. State Col.). (*Amer. Potato Jour.*, 17 (1940), No. 8, pp. 198-201).—Data taken from two fields of Katahdin potatoes under irrigation gave indications of spread of the disease in the field. A larger number of plants became infected down the row below a plant showing symptoms than up the row above it. Considerable evidence of spread was found in the rows above the plants showing symptoms and in the first and second rows on either side. It is concluded that while irrigation water seems to play some part in dissemination, spread in other directions could not be accounted for on this basis. Since the most prevalent insect was the flea beetle, it is suspected as the most logical agent of spread.

Report on potato virus diseases in 1939, T. P. DYKSTRA. (U. S. D. A.). (*Amer. Potato Jour.*, 17 (1940), No. 8, pp. 201-210).—A continuation of the series of annual reviews of international literature by this author (*E. S. R.*, 82, p. 638). There are 22 references.

Verticillium wilt of the sugar beet, J. O. GASKILL and W. A. KREUTZER. (U. S. D. A. and Colo. State Col.). (*Phytopathology*, 30 (1940), No. 9, pp. 769-774, figs. 3).—"In the latter part of August 1939 an unusual wilt of the

sugar beet (*Beta vulgaris* L.) was observed in fields in the vicinity of Ault, Colo. Isolations from the necrotic vascular tissues of the roots of affected plants yielded a species of *Verticillium* which was capable of inducing symptoms characteristic of the disease. The morphology of the causal organism resembled closely the description of *V. albo-atrum*. Eleven fields were examined in 5 agricultural districts in northern Colorado, and *Verticillium* wilt was found in 7 fields representing 3 districts. In paired comparisons of diseased and apparently unaffected roots at harvest, the former class was found to be significantly lower in average percentage of sucrose, coefficient of apparent purity, and gross and indicated available sucrose per root. The average weight of diseased roots was also lower than that of the controls, but the difference was not significant."

Studies on the transmission of sugar-beet yellows virus by the aphid, *Myzus persicae* (Sulz.), M. A. WATSON (*Roy. Soc. [London], Proc., Ser. B, 128 (1940), No. 853, pp. 535-552*).—The efficiency of *M. persicae* in transmitting this virus increased greatly with lengthening of feeding time on infected plants, infection following on a succession of healthy plants for 1, 2, and 3 days, depending on the length of the infection feeding. The infectivity of the vectors increased with length of feeding on healthy plants undergoing infection and decreased with length of feeding time on healthy plants prior to those used for the infection trial. There was no clearly defined "incubation period" of the virus in the vector below which no insect could induce infection, but there was variation in the time between cessation of infection feeding and initiation of infection in healthy plants. The virus-vector relation is said to differ from that of viruses described as "nonpersistent." For the latter, infectivity is lost by *M. persicae* soon after cessation of infection feeding. After fasting the vectors become optimally infective almost immediately on penetrating infected leaf tissues. Their infectivity decreases with lengthened feeding time on infected plants and increases only slightly with lengthened feeding time on healthy plants. The behavior of sugar beet yellows virus is compared to that of curly top, in which infectivity also persists for an indefinite period in the vector and increases with lengthened feeding time on infected and healthy plants.

White necrosis—a virus disease of *Nicotiana tabacum* and *N. sylvestris*, with delayed symptoms [trans title], A. S. COSTA, A. R. LIMA, and R. FORSTER (*Jor. Agron., 3 (1940), No. 1, pp. 1-26, pls. 10; Eng. abs., pp. 22, 23*).—The new virus disease of tobacco described was found spontaneously in *N. tabacum* and *N. sylvestris*. It was transmitted by grafting or rubbing to *N. glutinosa*, *N. rustica*, *N. alata*, *N. repanda*, *N. langsdorffii*, *N. longiflora*, *Solanum nodiflorum*, and *Nicandra physalodes*. The virus is said to induce three successive stages in the pathological picture, viz, white necrosis, apparent recovery, and a "cabbage-leaved" stage—described in detail. The virus properties are discussed, and it is believed closely related to the tobacco streak virus.

Wilt resistance of the Riverside variety of tomato to both *Fusarium* and *Verticillium* wilts, M. SHAPOVALOV and J. W. LESLEY. (Calif. Citrus Expt. Sta. coop. U. S. D. A.). (*Phytopathology, 30 (1940), No. 9, pp. 760-768, fig. 1*).—The Riverside tomato, developed cooperatively, proved highly resistant to *Verticillium* and *Fusarium* wilts under the test conditions employed. When attacked by both fungi the *Fusarium* infection appeared to be much less frequent than the *Verticillium*. In cultures from stems of diseased plants, *Fusarium* usually predominated in the hotter part of the season, but *Verticillium* gained the ascendancy in the cooler fall weather. Not infrequently *Fusarium* was superseded by *Verticillium* in the same plant with onset of

cooler weather. Riverside is said to be suitable for both shipping and canning and is adapted to localities with a long growing season. As a late shipping variety, it is especially promising because of its shape, firmness, late maturity, and relative freedom from radial stem-end cracks.

Root injury and recovery, A. J. HEINICKE (*Mass. Fruit Growers' Assoc. Rpt.*, 45 (1939), pp. 84-95).—An address discussing the general aspects of the question, with special reference to orchard fruit trees.

Root responses of noninfectious hairy root apple seedlings under different methods of propagation, E. A. SIEGLER and J. J. BOWMAN. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 11, pp. 739-754, figs. 5).—Experiments have confirmed field observations that seed of many commercial varieties of apples produced relatively high percentages of progeny exhibiting a disorder, probably genetic, characterized by excessive numbers of small lateral roots at the collar. It is proposed to call this disorder "noninfectious hairy root." Experiments, mainly with root cuttings and grafts, proved that by varying the growth conditions stem rooting could be either induced or prevented. By inducing stem rooting, the symptoms were suppressed; by precluding stem rooting, symptoms were made manifest. It is advised that no parts of affected seedlings be used for ordinary propagative purposes. It is further suggested that affected seedlings might readily furnish sources for dwarfing rootstocks.

Eradicant treatments to aid in the control of apple scab, D. H. PALMITER and J. M. HAMILTON. (N. Y. State Expt. Sta.). (*N. Y. State Hort. Soc. Proc.*, 85 (1940), pp. 306-309).—This progress report points to the possibility of reducing the danger in orchards with a heavy carry-over of scab to such an extent that a light schedule of wettable sulfurs may be used with comparative safety. The only effective treatments are made before any spores can be discharged to start infection.

Boron deficiency and internal cork of apples, A. B. BURRELL. (Cornell Univ.). (*N. Y. State Hort. Soc. Proc.*, 85 (1940), pp. 84-89).—This is a general discussion of the disease and a progress report on several years' experiments, with recommendations for commercial use of boric acid or borax in control.

Apple spray injury, C. F. TAYLOR (*W. Va. Univ. Bul.*, 40, ser., No. 5-1 (1939), pp. 36-43).—A review, with 40 references.

The "X" disease, or yellow-red virosis, of peach, E. A. WALKER. (Univ. Md.). (*Md. Agr. Soc., Farm Bur. Fed., Rpt.*, 24 (1939), pp. 154-156).—A general review of this disease on peach and chokecherry, with field observations by the author.

Protecting peach orchards from yellow-red viruses (X-disease), D. H. PALMITER and E. M. HILDEBRAND. (N. Y. State Expt. Sta. and Cornell Univ.). (*N. Y. State Hort. Soc. Proc.*, 85 (1940), pp. 183-186).—A general discussion of the present status of knowledge on the disease, with recommended procedures for eradicating the wild host chokecherry.

New developments in the control of diseases of small fruits, R. F. SUIT. (N. Y. State Expt. Sta.). (*N. Y. State Hort. Soc. Proc.*, 85 (1940), pp. 262-269).—A summary of recent work with spur blight of red raspberries, raspberry mosaic, gooseberry powdery mildew, and leaf spots of gooseberry and currant.

Density of stomata and oil glands and incidence of water spot in the rind of Washington Navel orange, F. M. TURRELL and L. J. KLOTZ. (Calif. Citrus Expt. Sta.). (*Bot. Gaz.*, 101 (1940), No. 4, pp. 862-871, figs. 9).—The mean stomatal density for fruits of this variety was 13.86 per square millimeter, and it was greater for small than for large oranges. The mean density of oil glands was 2.33 per square millimeter, and they also were more densely dis-

tributed in small than in large fruits. The density of neither stomata nor oil glands proved to be related to water-spot incidence. The radial arrangement of stomata in narrow circular zones about oil glands, as reported by others for citrus leaves, was also found in the fruit rind of the Washington Navel orange.

The "wound" or "pruning" disease of the coffee tree [trans. title], F. CHOUSSY (*Café El Salvador*, 10 (1940), No. 112, pp. 312-315, figs. 2).—A brief note on studies of a disease ascribed to a fungus of the *Rostrella* group or possibly to a *Fusarium*.

Experiments on the control of mango anthracnose by spraying, R. K. MCKEE (*Trop. Agr. [Trinidad]*, 17 (1940), No. 6, pp. 115-117).—"A spraying trial for the control of mango anthracnose which was carried out for 3 yr. is described. Results show that good control is obtained by spraying with a 1 percent Burgundy mixture. Spray schedules are discussed. It is suggested that spraying in any one year continues to give a beneficial effect in the next year." The disease is due to *Colletotrichum gloeosporioides*.

Bacterial blight of filberts and its control, P. W. MILLER (*Oreg. Agr. Col. Ext. Bul.* 532 (1939), pp. 8, figs. 9).—An informational leaflet on the nature and course of the disease, due to *Phytopomonas* sp., and on its control.

The pathogen of filbert bacteriosis compared with *Phytopomonas juglandis*, the cause of walnut blight, P. W. MILLER, W. B. BOLLEN, J. E. SIMMONS, H. N. GROSS, and H. P. BARSS. (*Oreg. Expt. Sta. coop. U. S. D. A.*). (*Phytopathology*, 30 (1940), No. 9, pp. 713-733, figs. 5).—Comparing a considerable number of isolates of the filbert blight pathogen and of *P. juglandis*, the cause of walnut bacteriosis, essentially no differences in morphology, staining reactions, cultural characters, or biochemical characteristics were found. No differences were found between the pathogens in regard to carbon sources utilized. Differences appeared in the rate of utilization of certain carbon sources by different isolates, but these were fortuitously distributed among all isolates of both pathogens and were thus of no differential value. Both pathogens utilized the same nitrogen sources. Variations in rate of utilization of nitrogen sources by different isolates were less pronounced than variations in rate of utilization of carbon sources. However, the results of preliminary cross-agglutination studies suggested that the filbert-blight pathogen may be serologically separated from *P. juglandis*. Distinct differences in pathogenic behavior between the two pathogens were also demonstrated. In field cross-inoculation studies all isolates from walnut were negative or practically so on filbert branches, whereas all filbert isolates were negative on walnut stems of current growth. On the basis of these pathological and serological differences, it is proposed to designate the filbert-blight organism *P. corylina* n. sp.

A flower-spot disease of cultivated azaleas, F. WEISS and F. F. SMITH (*U. S. Dept. Agr. Cir.* 556 (1940), pp. 28, figs. 14).—The symptoms are described of a destructive disease, unknown prior to 1931, attacking flowers of cultivated azaleas, especially of the Indian and Kurume types. The disease occurs in all the Southeastern and Gulf States from Wilmington, N. C., to Houston, Tex., and has been found in most of the prominent city and town plantings of azaleas in the Coastal Plain. Infected flowers tend to cling to the twigs, producing an extremely unsightly appearance. Under favorable conditions the disease may spread so rapidly as to destroy practically all the flowers of an extensive azalea planting within a few days. The causal fungus (*Ovulinia azaleae*) (E. S. R., 83, p. 80) produces sclerotia in the blighted flowers which overwinter in the soil. From them fruiting bodies develop in the spring during the early part of the flowering season; they bear spores which may infect only relatively

few flowers, but secondary spores are produced in large numbers on the initial infections. The latter are responsible for widespread and destructive outbreaks of flower spot.

Air currents and rain are the principal dispersal agents from flower to flower or among closely planted bushes, but flower-visiting insects, especially bumblebees of several species, are important carriers of spores to greater distances. The disease may be spread in this way to distances of 1 to several miles. In the secondary spore stage the fungus may be transported on blooming azaleas and as sclerotia in the surface litter and soil beneath dormant plants. When dormant plants are cleaned of surface litter and soil, as in balling them for transplanting, dissemination of the fungus appears to be prevented. The first step in control is to reduce the sclerotial survival to a minimum by destroying infected flowers before and after flower fall, and by removing the surface soil from around infected plants after flower fall and replacing it with new earth or a thick leaf mulch. Control of secondary spread by sprays or dusts applied to the flowers has not proved practicable without first reducing primary infections from overwintering sclerotia to the lowest possible minimum. Copper and acetic acid sprays and soil drenches, and copper-clay dust have shown promise of control under conditions of minimal primary infection and when their application is begun with the first appearance of colored buds.

Root knot of peony, P. E. TILFORD (*Ohio Sta. Bimo. Bul.* 205 (1940), pp. 132-134, fig. 1).—The experimental evidence presented indicates that *Heterodera marioni* is not a serious pest to peonies in the locality of Wooster, provided the plants are growing in a rich, heavy soil. In Ohio it is seldom possible to attribute poor growth of peonies in gardens to nematodes, but the stock in many nurseries is affected. When the roots are sold to gardeners, the knots or galls are cut off. It is impossible to eliminate all the nematodes this way, but the roots usually produce satisfactory plants when set in rich garden soils. It was evident that hot water treatments will reduce the nematodes in peony roots, but treatments that are noninjurious to the roots do not completely free them of living nematodes.

An undescribed fungus on Japanese cherry, E. S. LUTTRELL (*Mycologia*, 32 (1940), No. 4, pp. 530-536, figs. 9).—The author studied the development of a fungus infecting the twigs of *Prunus serrulata* near Durham, N. C., describing it as *Catenophora pruni* n. gen. and sp., in the Melanconiaceae.

Tree therapeutics, E. G. REX (*Natl. Shade Tree Conf. Proc.*, 15 (1939), pp. 4-11).—A general discussion of the control of systemic diseases of trees, especially maples and elms, with an analysis of the problems of the pathologist with respect to tree diseases.

Virus diseases of forest and shade trees, R. K. BEATTIE (U. S. D. A.). (*Natl. Shade Tree Conf. Proc.*, 15 (1939), pp. 12-21, figs. 3).—General considerations, including pertinent data on spike disease of sandal, witches'-broom of locust, and phloem necrosis of elm, are presented.

Sphaeropsis canker and dieback of shade trees, R. P. MARSHALL (U. S. D. A. et al.). (*Natl. Shade Tree Conf. Proc.*, 15 (1939), pp. 65-69).—The author reviews the genus *Sphaeropsis* and the four species *malorum*, *ulmicola*, *quercina*, and *ellisii*, common causes of canker and dieback on shade trees. They are said to be controllable by sanitation and improved tree vigor, such procedures in large trees being facilitated by technical practices, especially climbing and improved methods of fertilizing developed by commercial workers.

Two diseases of Gleditsia caused by a species of Thyronectria, E. V. SEELER, JR. (*Jour. Arnold Arboretum*, 21 (1940), No. 3, pp. 405-427, pls. 4).—Two tree diseases were found to be due to the American fungus *T. austro-americanana*

n. comb., one a wilt of *G. japonica* and the other a canker of *G. triacanthos*. The speedy killing of trees of *G. japonica* leads to the belief that were the fungus introduced to Japan, where it is not native, it might cause the decimation of this tree there. Collections of the fungus have indicated its distribution from Nebraska to Massachusetts and southward to the Gulf States. Therefore, it is to be expected that the canker disease will be reported elsewhere, now that it has been recognized. The symptoms of the two diseases, successful inoculation tests, and the cultural characters and life history of the causal fungus are reported upon in detail. There are 19 references.

Ustilina vulgaris decay in sugar maple and other hardwoods, W. A. CAMPBELL and R. W. DAVIDSON. (U. S. D. A. et al.). (*Jour. Forestry*, 38 (1940), No. 6, pp. 474-477, fig. 1).—During the summer of 1938, a number of sugar maple (*Acer saccharum*) sprouts over 50 yr. old on the Green Mountain National Forest, Vt., were dissected for butt rot as a guide to treating sprout maples during stand improvement. Among the associated fungi was an ascomycete, *U. vulgaris*, which was also common on beech (*Fagus grandifolia*) and red maple (*A. rubrum*). This apparent prevalence of *U. vulgaris*, together with previous reports of its parasitism on other hosts, made desirable a detailed analysis of its occurrence on sugar maple.

Studies on the ink-spot disease of poplar, R. POMERLEAU (*Canad. Jour. Res.*, 18 (1940), No. 5, Sect. C, pp. 199-214, pl. 1, figs. 3).—This leaf disease, due to *Sclerotinia bifrons* (E. S. R., 82, p. 789) was studied during a severe outbreak (1935-37). The fungus was found to hibernate on the ground in the sclerotial stage, and during spring the apothecia are produced thereon. Leaf infection is induced by ascospores ejected from the apothecia, and after 2-3 weeks of incubation reddish areas appear on the leaves. New sclerotia are formed in the lesions in June and are ready to fall about July 15. Epidemic development of the disease is favored by a fairly large number of sclerotia on the ground, the occurrence of a dense stand of young poplars, and low temperature and high humidity before and at the time of foliation. During an outbreak a considerable number of trees in the sapling stage are killed and others are affected by an intense defoliation. These effects are noticeable only in thickets of pure population of aspen, which usually represent the first stage of natural reforestation in Quebec.

A preliminary report on a fungus disease of the field bindweed, *Convolvulus arvensis*, W. M. BEVER and C. I. SEELY. (Idaho Expt. Sta. coop. U. S. D. A. (*Phytopathology*, 30 (1940), No. 9, pp. 774-779 figs. 3).—A fungus attacking *C. arvensis* was observed in the Palouse area of Idaho and Washington, particularly on northern slopes. Successful inoculations and reisolations have been made. Field symptoms of the disease are characterized by initial infections appearing in or towards the center of a bindweed patch and spreading more or less in all directions with the spread of the weed. Infected individuals gradually die out so that the centers of the patches eventually become bare and surrounded by a ring of healthy, green plants, giving the entire patch a "doughnut" appearance. Lesions appear on any point of the stem that may be in close proximity to the soil. Plants repeatedly killed back become very weak and appear as though suffering from depleted carbohydrate reserves. Under greenhouse conditions on artificially inoculated seedlings, the lesions are formed at the crown. The attacked plants eventually wilt and occasionally the leaves turn yellow before actual death of the plant. The fungus has been tentatively identified as *Rhodospora* sp. Evidence indicates the fungus to be soil-borne.

Opuscula miscellanea nematologica, VI-VIII, G. STEINER. (U. S. D. A.). (*Helminthol. Soc. Wash. Proc.*, 4 (1937), No. 2, pp. 48-52, figs. 2; 5 (1938), No. 1, pp. 35-40, figs. 3; 7 (1940), No. 1, pp. 54-62, figs. 5).—Continuing this series (E. S. R., 77, p. 808), the following are included:

In part 6 the author discusses the status of the nematode *Aphelenchoides coffeae* n. comb. (= *Aphelenchus coffeae*); the occurrence of the bud and leaf nematode *Aphelenchoides fragariae* on the peony and oriental poppy in the United States; and notes on *Eucephalobus teres* observed on a narcissus bulb in Virginia, including a more complete description of the species.

Part 7 comprises (1) observations on nematodes associated with Irish potatoes grown in South Carolina, including, among others, *Zeldia odontoccephala* n. sp., and *Acrobeloides enoplus* n. sp.; (2) on *Criconemoides sphaerocephalum* A. L. Taylor, 1936, living on cotton roots in the United States; and (3) on sporozoan parasites of nematodes, reporting some observations made on the material discussed in (1).

In part 8 the possible harmful effect of soil-nematode invasions on cuttings to be rooted is noted, with examples; *Chiloplacus trilineatus* n. sp. from diseased snapdragon cuttings and a new grass nematode *Anguina australis* n. sp. are described; and notes are given on measurements and morphology of *Aphelenchoides limberi*, discovered in 1938 on a dahlia tuber from Germany and in 1939 in elm roots from California.

Plant-parasitic and free-living nematodes in Hawaii, J. M. OLIVEIRA. (Hawaii. Pineapple Prod. Expt. Sta.). (*Bernice P. Bishop Mus. Occas. Papers*, 15 (1940), No. 29, pp. 361-373).—Approximately 84 species in 60 genera are listed, with 54 literature citations.

ECONOMIC ZOOLOGY—ENTOMOLOGY

The status of wildlife in the United States, K. PITTMAN ET AL. (U. S. Senate, 76 Cong., 3. Sess., Rpt. 1203 (1940), pp. [2]+457, pls. 74, figs. 8).—The first and main part of this volume consists of a report by the Special Committee on the Conservation of Wildlife Resources, which includes a list of publications of the U. S. D. A. Bureau of Biological Survey, and of other publications relating to the subject. Appended to the committee's wildlife report are special reports relating to the subject from the U. S. Bureau of Fisheries (pp. 241-245), U. S. D. A. Forest Service by H. L. Shantz and J. H. Hatton (pp. 247-346), U. S. National Park Service by V. H. Cahalane, C. C. Presnall, and D. B. Beard (pp. 347-380), U. S. D. A. Soil Conservation Service (pp. 381-399), Civilian Conservation Corps by J. J. McEntee (pp. 401-407), U. S. Bureau of Reclamation by J. C. Page (pp. 409-417), Office of Indian Affairs by J. Herrick (pp. 419-423), U. S. Grazing Service by R. H. Rutledge (pp. 425-436), U. S. D. A. Agricultural Adjustment Administration by R. M. Evans (pp. 437-441), and U. S. D. A. Bureau of Agricultural Economics, Land Classification Section, by W. M. Rudolph (pp. 443-446).

Insects of the forest floor available as food for game animals, W. M. KULASH. (Mass. State Col.). (*Jour. Forestry*, 38 (1940), No. 7, pp. 554-557).—Field work conducted by the author in conjunction with a wildlife and timber management study in Massachusetts has shown the forest floor to be a suitable environment for many species of insects and spiders, some of which serve as food for game animals.

American mammals: Their lives, habits, and economic relations, W. J. HAMILTON, JR. (New York and London: McGraw-Hill Book Co., 1939, pp. XII+434, figs. [93]).—This volume, dealing with North American mammals, is presented in 18 chapters, each of which includes a bibliography.

The land mammals of Nova Scotia, R. W. SMITH (*Amer. Midland Nat.*, 24 (1940), No. 1, pp. 213-241, fig. 1).—Presented with a list of 45 references to the literature.

Effect of ditching for mosquito control on the muskrat population of a Delaware tidewater marsh, L. A. STEARNS, D. MACCREARY, and F. C. DAIGH (*Delaware Sta. Bul.* 225 (1940), pp. 55, figs. 24).—Following an introduction and brief discussion of mosquito control work in Delaware, the importance of the muskrat industry in the State, the selection and a description of the experimental marsh area, experimental procedure, and the effect of ditching in 1936-38 on (1) mosquito breeding, (2) height of water table, (3) character of vegetative cover, and (4) distribution of muskrat population are dealt with, and the continuance of the investigation is considered. Initiated by the station in 1932 at the request of resort interests, some 2,199 miles of ditches have been dug on an area estimated at 44,468 acres. This amounts to 44.7 percent of such land in the State and represents about 65 percent of the marshes which are serious mosquito-breeding areas. Much of the marshland bordering the Delaware River and Bay is adapted by nature to support a sizeable muskrat population, and for years a large proportion of the cash income of farmers in that part of the State has been derived from the sale of muskrat hides and meat. The total annual catch in the State approximates 150,000 hides, of which about 61 percent is derived from New Castle County, 14 percent from Kent County, and 25 percent from Sussex County. The total annual income to Delaware trappers from the sale of hides has ranged from as low as approximately \$50,000 to as high as approximately \$500,000. The average for the 20-yr. period, season of 1919-20 to that of 1938-39, inclusive, was slightly over \$200,000.

During the years 1936-39, inclusive, the effect of ditching for mosquito control upon muskrat life was determined by population and other studies on drained and undrained marsh, the experimental area comprising approximately 23 acres. "The recorded data show very definitely that when a muskrat marsh, such as this, is effectively ditched for mosquito control there is a rapid lowering of the water table, which within a short time is sufficient to effect a radical change in the existing vegetation. The plants, particularly *Scirpus olneyi* and *Spartina cynosuroides*, upon which the muskrats feed and which are utilized by them in house construction are soon replaced by others (*Hibiscus oculiroseus*, *Kosteletzkya virginica*, *Solidago sempervirens*, *Bidens trichosperma* var. *tenuiloba* and *Aster novi-belgii*) practically worthless for such purposes. This results in migration of muskrats from areas so treated to those which meet better their water and plant requirements. Observations over a period of years (1932-1939) indicate that productive muskrat marshes in Delaware are, generally speaking, relatively unimportant from the standpoint of mosquito breeding. Nevertheless, when such marshes are so located that mosquitoes originating therein cause appreciable discomfort in, and retard the development of, resort and other communities and when this consideration obviously more than offsets that of the income derived locally from the muskrat industry, such areas should be brought under control by ditching or other means. The marshlands of New Castle County from Delaware City to Smyrna are particularly valuable, however, with respect to muskrattng. Furthermore, while the mosquitoes produced therein undoubtedly cause considerable annoyance to the scattered rural population throughout that section, trap records show that there is little or no migration to the towns located to the west. On the contrary, flight data emphasize a substantial eastward movement correlated with prevailing winds from the southwest during the months [of] May to September, inclusive. Control operations in that part of the State are certainly unwarranted except in the case of possible limited areas of heavy breeding.

"Although the results of the experimental work treated in this bulletin permit but one conclusion, namely, that effective ditching of a productive muskrat marsh for mosquito control is definitely injurious, no attempt is made to generalize on the basis of the recorded data."

Life history and ecology of the white-throated wood rat (*Neotoma albigula albigula* Hartley) in relation to grazing in Arizona, C. T. VORHIES and W. P. TAYLOR (*Arizona Sta. Tech. Bul.* 86 (1940), pp. [2]+453-529, figs. 15).—Active investigations of the ecology and economic status of *N. albigula albigula*, conducted, because of its abundance on great areas of grazing range in Arizona, by both authors working together and separately from 1932 to 1935, inclusive, and by Vorhies alone from 1935 to 1938, inclusive, are reported. The field work was carried out chiefly in southern Arizona, centering on the Santa Rita Experimental Range of more than 50,000 acres about 35 miles south of Tucson, with some comparative studies on the Jornada Experimental Range in southern New Mexico. Collections and observations were made by Taylor in southern California and Texas and by Vorhies in northern Arizona on the Kaibab Plateau and in the Chuska Mountains. This subspecies ranges from near sea level to an altitude of about 8,200 ft. Analyses of 360 stomachs (30 per month for a year) show that cactus constitutes 44.17 percent of all its food and mesquite 29.8 percent. Grass furnishes but 4.79 percent of the total food and is not a principal item at any time, and animal matter, chiefly insects in great variety, furnishes only 0.28 percent. Quantities of succulents (cactus, etc.) eaten may amount to from 25 to 43 percent of body weight of the wood rat in a 24-hr. period, but dry weight food consumption is on the order of 5 percent of body weight. It stores food but in a somewhat erratic manner. Stores may be negligible in quantity or large in amount.

"The population of [*N. albigula*] *albigula* on the Santa Rita Range is estimated at 4.78 per acre or a total of 242,862. No definite fluctuations in numbers have been noted. Economically, the wood rat may be rated as (1) harmful, in consuming grass, as a nuisance about habitations, damaging range forage or cultivated plants, disseminating cactus, and harboring blood-sucking insects; (2) neutral, in food habits, its principal foods being not only abundant but even overabundant on some ranges; or (3) beneficial, as an aid to planting, in aeration and fertilization of the soil, as a food supply for man and valuable fur animals, or as a pet. Increase of the white-throated wood rat appears to be an effect rather than a cause of overgrazing—an 'animal weed.' Its principal foods are the cactus and mesquite which ranchmen are actually being paid to remove in some areas; hence, it cannot consistently be rated as injurious. Large-scale control is not needed and is undesirable. Local control, to eliminate the nuisance about habitations and get rid of assassin bugs, is a simple matter of a few snap traps."

A list of 32 references to the literature is included.

Observations on the incidence of some nematode parasites of the common rabbit (*Oryctolagus cuniculus*), W. M. R. EVANS (*Parasitology*, 32 (1940), No. 1, pp. 67-77, figs. 5).—Examinations made during the period November 1936 to February 1937 of 80 rabbits and from August 1937 to July 1938 of 446 additional rabbits for the presence of nematodes resulted in the finding of *Graphidium strigosum*, *Passalurus ambiguus*, and *Trichostrongylus retortaeformis*. The incidence of these nematodes is reported and their seasonal incidence discussed, with special reference to its ecological implication. "Evidence of host and age resistance is also demonstrated in infections with *G. strigosum*, *P. ambiguus*, and *T. retortaeformis*. The proportion of the sexes in *G. strigosum* was found to be constant during both periods. The percentage of males in

1936-37 was 45.6 and 45.96 in 1937-38. In *P. ambiguus*, however, the proportion of the sexes varied to a large extent."

Observations upon some common cestode parasites of the wild rabbit (*Oryctolagus cuniculus*), W. M. R. EVANS (*Parasitology*, 32 (1940), No. 1, pp. 78-90, figs. 6).—Examination of 96 and 446 rabbits, respectively, during the period indicated in the work above noted for cestode parasites, the rabbits being taken from the same area, resulted in the finding of the following species: *Cittotaenia denticulata*, *C. pectinata*, *Coenuurus serialis*, *Cysticercus pisiformis*, and two species of *Hymenolepis*. The span of life of both *Cittotaenia pectinata* and *C. denticulata* is found to be not greater than 10 mo., and evidence is given to show that the intermediate host of *C. denticulata* is available between April and December and that of *C. pectinata* from August to April.

Life histories of North American cuckoos, goatsuckers, hummingbirds, and their allies: Orders Psittaciformes, Cuculiformes, Trogoniformes, Coraciiformes, Caprimulgiformes, and Micropodiiformes, A. C. BENT (*U. S. Natl. Mus. Bul.* 176 (1940), pp. VIII+506, pls. 73).—This is the thirteenth in a series of bulletins (E. S. R., 81, p. 805) on the life histories of North American birds, in the preparation of which many workers, recognized in the introduction, have contributed material.

Starling attacks upon warble-infested cattle in the Great Plains area, A. L. GOODRICH, JR. (Kans. State Col.). (*Jour. Kans. Ent. Soc.*, 13 (1940), No. 2, pp. 33-40).—This contribution, with its list of 22 references to the literature, is said to have been prepared in an effort to present a record of the attacks of starlings upon cattle, of which only incomplete accounts have been published.

An annotated list of the arthropods found in the burrows of the Florida gopher tortoise (*Gopherus polyphemus* (Daudin)), F. N. YOUNG and C. C. GOFF. (Fla. Expt. Sta.). (*Fla. Ent.*, 22 (1939), No. 4, pp. 53-62).

On some worms of the genera *Trichostrongylus* Looss, 1905, and *Cooperia* Ransom, 1907, in South India, M. A. NARAYAN RAO (*Indian Vet. Jour.*, 16 (1940), No. 5, pp. 306-311, pls. 2, figs. 10).

[Work in economic zoology and entomology by the Alabama Station] (*Alabama Sta. Rpt.* 1938, pp. 8, 9, 26-29).—The work of the year briefly reported upon (E. S. R., 81, p. 65) includes the tarnished plant bug and the pea aphid as factors in reducing seed yields of vetches, by H. R. Albrecht; the vegetable weevil, by J. M. Robinson; the relative efficiency of rotenone-containing insecticides in the control of vegetable insects, by F. S. Arant; control of citrus insects with oil emulsions, by L. L. English; fish production in farm ponds, by H. S. Swingle and E. V. Smith; and food crops for game birds, by A. M. Pearson.

[Work in economic zoology and entomology by the Arizona Station] (*Arizona Sta. Rpt.* 1939, pp. 63, 66).—The work of the year (E. S. R., 82, p. 216) briefly referred to includes a study of the seasonal utilization and forage requirements of range vegetation by rodents; and the aphid *Monellia costalis* affecting the pecan.

[Economic insects and rodents of the orchard and their control] (*Conn. Pomol. Soc. Proc.*, 48 (1938), pp. 81-92, 174-186, figs. 5).—Contributions relating to insect and rodent pests of the orchard and their control presented at Hartford, Conn., in December 1938 include the following: Important Insects of the Apple Orchard and Methods of Control, by P. Garman (pp. 81-87) (Conn. [New Haven] Expt. Sta.); and The Relation of Parasites to the Control of the Oriental Fruit Moth, by H. W. Allen (pp. 88-92), and Report on Rodent Control Work in Connecticut—Mouse Investigation and Control, by R. Isaac and H. Merrill (pp. 174-186) (both U. S. D. A.).

[Contributions on rodent and insect control in the orchard] (*Md. State Hort. Soc. Proc.*, 42 (1940), pp. 16-35).—Contributions presented at Hagerstown, Md., in January 1940 include A More Effective Method of Orchard Mouse Control, by H. J. Spencer (pp. 16-18); Should We Use Dinitro or Tar Oil for Dormant Spray? by W. S. Hough (pp. 18-21) (Va. Expt. Sta.); and Résumé of New Developments in Japanese Beetle Retardation Work in Maryland for 1939, by G. S. Langford (pp. 22-27), and The Codling Moth Situation, by E. N. Cory, H. S. McConnell, and C. Graham (pp. 27-35) (both Univ. Md.).

An introduction to entomology, J. H. COMSTOCK (*Ithaca, N. Y.: Comstock Pub. Co.*, 1940, 9. ed., rev., pp. XIX+1064, pl. 1, figs. 1228).—A revised edition of this work (E. S. R., 77, p. 810) which includes a 20-page list of references.

The microbiology of insects, with special reference to the biologic relationships between bacteria and insects, E. A. STEINHAUS. (Ohio State Univ.). (*Bact. Rev.*, 4 (1940), No. 1, pp. 17-57).—This review, under the headings of extracellular flora of insects, role of micro-organisms in insect nutrition, intracellular flora of insects, and other biologic relationships between micro-organisms and insects, is presented with a 10-page list of references to the literature.

Insect biochemistry, R. CRAIG and W. M. HOSKINS. (Univ. Calif.). (In *Annual Review of Biochemistry*, IX, edited by J. M. LUCK and J. H. C. SMITH. Stanford University, Calif.: Ann. Rev., Inc., 1940, vol. 9, pp. 617-640).—This review is presented with a list of 117 references to the literature cited.

Entomological systematics examined as a practical problem, J. SMART (In *The New Systematics*, edited by J. HUXLEY. Oxford: Clarendon Press, 1940, pp. 475-492).

Supplementary list of common names of insects approved by the American Association of Economic Entomologists (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 708, 709).—A list is given of the common names and of the scientific names of 32 insects to be added to those previously adopted (E. S. R., 82, p. 70).

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 646, 647, 647-649, 699-705, figs. 3).—The contributions presented (E. S. R., 83, p. 652) are: Effect of Wheat Harvesting Machinery on Insect Control, by T. H. Parks (pp. 646, 647) (Ohio State Univ.); Effect of Idle Land Upon Grasshopper Populations, by F. G. Butcher (pp. 647-649) (N. Dak. Agr. Col.); The Blueberry Bud Mite [*Eriophyes vaccinii*], a New Pest, by B. B. Fulton (p. 699) (N. C. Expt. Sta.); The Titratable Acidities and pH Values of Cryolite Insecticides, by R. H. Carter (p. 699), Effects of Phenothiazine on Chicken Lice [the Chicken Head Louse, the Chicken Body Louse, the Shaft Louse *Menopon gallinae* (L.), and the Fluff Louse], by H. E. Parish (p. 700), and Fire Ants [*Solenopsis xyloni* MacCook] Causing Damage to Telephone Equipment, by C. Eagleson (p. 700) (all U. S. D. A.); Light Trap for Counting or Collecting Leafhoppers on Lettuce Plants, by T. C. Watkins (p. 701) (Cornell Univ.); Distribution and Hosts of Some Fleas of Economic Importance [the Cat Flea, Dog Flea, Human Flea, Oriental Rat Flea, and the Sticktight Flea], by H. L. Trembley and F. C. Bishopp (pp. 701-703) (U. S. D. A.); Dichlorethyl Ether as a Means of Control for Pear Thrips, by S. C. Jones (p. 703) (Oreg. Sta.); *Cyclocephala immaculata* Oliv. as a Test Insect, by P. O. Ritcher (p. 704) (Ky. Sta.); and An Agromyzid Fly [*Agromyza caerulea* Mall.] Infesting Sweetpotato Seed in Puerto Rico, by W. K. Bailey and H. K. Plank (pp. 704, 705) (P. R. Sta.).

[Work in economic entomology by the Georgia Station] (*Georgia Sta. Rpt.* 1940, pp. 48, 58-64, fig. 1).—The work of the year (E. S. R., 82, p. 792) reported upon includes control of the sheep tick and the sheep louse *Trichodectes ovis*, the cowpea curculio, tomato fruitworm, southern corn rootworm, a mite

(possibly *Paratetranychus ununguis* Jac.) on water oaks and willow oaks, the velvetbean caterpillar on peanut plants, and a study of the effect of the abnormally cold winter on insect life.

[Contributions on economic insects and their control] (Kans. State Hort. Soc. Bien. Rpt., 45 (1938-39), pp. 29-48, 169-196, 239-242).—Among the contributions presented are the following: Lead Arsenate Combinations and Nicotine Combinations as Control Measures for the Codling Moth During the Season of 1938 (pp. 29-37) and Control of American Strawberry Leafroller *Ancylis comptana fragariae* Walsh and Riley During the Season of 1938 (pp. 39-46), both by P. G. Lamerson and R. L. Parker (Kans. Expt. Sta.); Some Entomological Problems, by H. B. Hungerford (pp. 47, 48); Some Insects Causing Injury to Shade Trees in 1939—Red Cedar Scale *Cryptaspidotus shasta* (Coleman), by G. A. Dean (pp. 169-172); Lead Arsenate Combinations and Basic Copper Arsenate as Control Measures for the Codling Moth During the Season of 1939 (pp. 173-179) and Control of the American Strawberry Leafroller During the Season of 1939 (pp. 181-186), both by R. L. Parker and P. G. Lamerson (Kans. Sta.); Codling Moth Studies in Northeastern Kansas and Northwestern Missouri During 1939, by H. Baker (pp. 187-196) (U. S. D. A.); and Insects Which Attack the Redbud [*Cercis canadensis*], by R. L. Parker (pp. 239-242) (Kans. Sta.)

[Work in economic entomology by the Rhode Island Station] (*Rhode Island Sta. Rpt.* [1939], pp. 20, 24, 41).—Brief reference is made (E. S. R., 81, p. 808) to control work with root maggots on cauliflower and early cabbage, green cabbageworms, flea beetles on tomato plants, bean beetle, webworms and cutworms on velvet bentgrass, and ants in golf greens and lawns.

The history of the Riker mount, S. F. BAILEY. (Univ. Calif.) (*Ent. News*, 51 (1940), No. 4, pp. 91-94).

Further tests with concentrated mixtures for aerial spraying, S. F. POTTS and R. R. WHITTEN. (U. S. D. A.) (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 676-681, figs. 2).—Further work (E. S. R., 82, p. 71) was conducted with the view to determining (1) whether certain concentrated spray mixtures can be successfully applied from the air and (2) the comparative merits of various spreading agents, adhesives, arsenicals, and substitutes for arsenicals when applied in concentrates. Twenty-two mixtures were applied to woodland plats by an autogiro. Fresh foliage from most of the plats was then fed to fourth- and fifth-instar larvae of the orange-striped oak worm. The arsenical sprays were found more toxic than were the organic sprays after longer periods of exposure. "The toxic principles of derris, derris extract, nicotine sulfate, free nicotine, and quebracho-fixed nicotine remained on the foliage in effective quantities after 2 to 3 weeks' exposure. With the exception of lime-sulfur, none of the mixtures caused any injury to wild black cherry foliage. Non-drying oils and spreaders reduced adherence, but drying oils increased adherence. Mixtures containing a drying oil, such as fish oil, gave a heavy deposit and good adherence after 4 in. of rainfall. Two-tenths of a pound of fish oil per pound of arsenical gave sufficient adherence for most conditions. Certain spreaders increased the atomization, width of swath, and spreading qualities of the mixtures. They facilitated the mixing of the materials and made possible a considerable reduction in the amount of water required to make a fluid mixture. One and one-half lb. of water per pound of lead arsenate was sufficient for good results when a spreader was added."

Certain new coal tar insecticides, W. C. FERGUSON. (Ohio State Univ.) (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 596-600).—Description is given of new materials derived from low-temperature tar which have shown insecticidal

value against certain insects. "Five-tenths percent and 1 percent heavy oil dusts, 1 percent and 6 percent brown solution dusts, and 10 percent copper pitchate dust proved to be as effective against the larvae of [the] Mexican bean beetle as 0.75 percent rotenone dust and cryolite dust. It was indicated that 1 percent heavy oil dust, 10 percent copper pitchate dust, and 10 percent pitch acid dust gave as good control of potato leafhopper on bean at Columbus, Ohio, as did pyrethrum-sulfur dust."

Low temperature tar oil in orchard sprays, W. C. FERGUSON and D. M. DELONG. (Ohio State Univ.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 600-610, figs. 6).—In an effort to evaluate low-temperature tar oil as a tree spray oil, field and laboratory tests were conducted in 1938 and 1939. Such tar oil differs from high-temperature coal tar oil chiefly in its higher percentage of tar acids (of high boiling range) and of paraffins, and its lower percentage of aromatics. It was found that as an ovicide against apple aphids "tree spray oil from low-temperature tar is as effective as is a tree spray oil from high-temperature tar, both used at 2.5-percent concentration. In one instance a 1.5 percent low-temperature tar oil spray gave adequate control against these pests. The addition of petroleum oil to tar oils in usual proportions does not affect their value as aphid ovicides. A 4.5 percent low-temperature tar oil spray shows equally as good control in the field against the eggs of European red mite as a 2 percent Dowspray Dormant. In this spray, the stock emulsion of which was compounded with lignin by means of the colloid mill and contained 2.5 percent low-temperature tar oil plus 2 percent petroleum oil, it is apparent that the tar oil when used in this proportion depresses or counteracts the toxic effect of the petroleum oil against the red mite eggs. When a spray containing 3.24 percent low-temperature tar oil plus 2.16 percent petroleum oil was used (5.4 percent total), good control of the mite was obtained. Thus it seems that a small addition of low-temperature tar oil depresses the effect of the petroleum oil, but a larger addition of the tar oil adds some potency of its own against the European red mite. A 1.7 percent low-temperature tar oil plus 2 percent Diamond Paraffin oil spray gave the most economical mite control of all the sprays tested, but it is questionable whether a sufficient factor of safety is present to assure good control all of the time. Against the egg stage of oystershell scale a 4.5 percent low-temperature tree spray oil proved to be significantly better than a high-temperature tar oil spray of the same concentration. Other sprays giving good control, with no significant difference between them, were 'Tar-O-Wash' containing 2.8 percent high-temperature tar oil and 3.5 percent petroleum oil, a low-temperature oil-Diamond Paraffin oil of the same concentration as Tar-O-Wash, and a low-temperature tar oil-Diamond Paraffin oil combination 4.0-0.5.

"When applied in the dormant or delayed dormant stages to apple trees, low-temperature tree spray oils, when properly emulsified and applied, showed little or no injury to the buds or foliage. In fact, the oil in most cases showed superior lateral bud development of the treated trees over those which were untreated. There was no injury to either the Hale or Elberta peach varieties by the low-temperature tar oils. . . .

"Preliminary results of plate-oil deposit studies conducted in the laboratory indicate that a 1-1.5-100 bordeaux combination is sufficient emulsifier to give a safe, fairly slow-breaking emulsion containing 2.5 percent low-temperature tree spray oil. Photographs accompanying this paper show at a glance the oil deposit obtained from the various tank-mixed sprays."

Phytotoxic properties of undiluted low-boiling petroleum oil distillates, T. C. ALLEN and T. L. CARPENTER. (Wis. Expt. Sta.). (*Jour. Econ. Ent.*, 33

(1940), No. 4, pp. 591-596, fig. 1).—In the work reported, use was made of a method devised whereby a constant and known amount of undiluted, low-boiling petroleum oil distillates could be applied to plant foliage in the field. "Under similar refinement, results indicate that distillates of Midcontinent base crudes were slightly more toxic to plant foliage than paraffin base crudes. Such distillates, however, derived from Midcontinent crudes caused relatively little injury to plants when treated with 130 lb. of fuming sulfuric acid per barrel of oil. Distillates derived from Pennsylvania crudes caused relatively little injury to plants when treated with 100 lb. of fuming sulfuric acid per barrel of oil. Under the conditions of this experiment, fractions having a kinematic viscosity of approximately 1.7 centistokes proved least toxic."

Relative susceptibility of the ootheca and adult female of the German cockroach to liquid household insecticides, B. M. PARKER and F. L. CAMPBELL. (Ohio State Univ.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 610-614). In the work reported, kerosene sprays containing extracts of pyrethrum gave a high kill of adult female German cockroaches when applied by the settling mist method at certain concentrations and dosages. Under this treatment the majority of the insects dropped their oothecae prematurely. "It was concluded that when a high kill of females is obtained by pyrethrum sprays, the females are more susceptible to this insecticide than are their oothecae. With the possible exception of the large nymphs, the ootheca is the most resistant stage of the German cockroach to pyrethrum sprays. The effect of the pyrethrins on females and their oothecae was compared with that of other toxicants. At an unusually high concentration normal butyl carbitol thiocyanate gave about the same percent mortality of females and oothecae as did the pyrethrins. However, this thiocyanate did not cause the females to drop their oothecae, although its paralytic effect was greater than that of the pyrethrins. It was concluded that this thiocyanate had some insecticidal value against the oothecae at the concentration used, but that the females were more susceptible than their oothecae. At the concentrations used, cresylic acid was comparable to the thiocyanate and rotenone to the pyrethrins. Neither substance caused the females to drop their oothecae and neither caused marked mortality among the females or their oothecae."

The effect of alkaline dust diluents on toxicity of rotenone-bearing roots as determined by tests with houseflies, T. C. ALLEN and J. W. BROOKS. (Wis. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 12, pp. 839-845).—Determination of the pH value of a number of insecticidal dust diluents has shown these materials to vary in H-ion potential from 4.23 to 12.50. Representative samples of these dusting materials, which varied widely in H-ion potential, were mixed with rotenone-bearing plants and placed in damp storage in the absence of light for a period of 7 days. Kerosene extracts prepared from these dust mixtures were tested against houseflies. Rotenone-bearing dusts prepared from highly alkaline diluents showed considerable loss in toxicity, while acid samples kept under identical conditions retained their toxicity to the housefly. Dry or unmoistened alkaline and acid samples remained unchanged in this respect. Addition of sulfur to the alkaline dust mixtures prevented deterioration of the rotenone-bearing material under the conditions of this experiment.

Avoiding obvious residue from nicotine-bentonite sprays, C. G. VINSON and S. A. McCORRY. (Mo. Expt. Sta.). (*Science*, 92 (1940), No. 2378, p. 79).—In reporting further (*E. S. R.*, 80, p. 224), sprays consisting of combinations of Black Leaf 40 and dry bentonite are said to leave no visible residue on fruit or foliage. They gave results that compare very favorably with the standard lead arsenate spray.

Spray residues as affecting the processor, I. D. CARDIFF (*Cong. Rec.*, 86 (1940), No. 124, pp. 13447-13449).—In the course of this discussion, the author considers the origin of the spray residue problem; lead, arsenic, and fluorine in nature; physiological effects of lead, arsenic, and fluorine; lead and arsenic in medicine, legal aspects, etc.

Tests of insecticides for certain cotton insects during 1939, J. C. GAINES. (Tex. Expt. Sta. and U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 684-688).—Tests conducted at the station in 1939 to determine the comparative effectiveness against the bollworm and bollweevil of a specially prepared calcium arsenate, a commercial calcium arsenate, and a synthetic cryolite are reported. An infestation of the rapid plant bug that developed on one of the plats made it possible to obtain some information on the action of the arsenicals on this pest also. "The special calcium arsenate, containing large particles and a high percentage of water-soluble arsenic pentoxide, gave a significantly better control of the rapid plant bug than the commercial calcium arsenate. This poison gave a higher control of the bollweevil and a higher yield than the commercial calcium arsenate, but the differences were not found to be significant. Calcium arsenate gave significantly better control of weevils than cryolite, but this year under dry weather conditions which caused excessive shedding this difference did not affect the yields. In a preliminary test sulfur-calcium arsenate mixture (2 to 1) applied at the rate of 15 lb. per acre gave 89-, 39-, and 61-percent control of the flea hopper, rapid plant bug, and bollweevil, respectively."

Vegetable insect pests in Hong Kong, I, II, K. CHAN (*Hong Kong Nat.*, 9 (1939), No. 4, pp. 199-202, figs. 2; 10 (1940), No. 2, pp. 98-101, figs. 7).—Part 1 reports upon the cabbage worm *Pieris canidia* Sparrm, one of the most destructive pests in Hong Kong market gardens; part 2, upon the diamondback moth, of great importance as a pest of cultivated crucifers.

[Contributions on fruit insects and their control] (*Amer. Pomol. Soc. Proc.*, 55 (1940), pp. 25-31, 82-85, 184-201).—Included in the contributions presented at Worcester, Mass., in January 1940 are the following: Scope and Method of the Lead Arsenate Spray Residue Health Investigation, by W. C. Dreessen (pp. 25-31); Orchard Insect Pests in 1939, by W. D. Whitcomb and A. I. Bourne (pp. 82-85); and a round table discussion of insects and control methods by W. H. Thies et al (pp. 184-201).

Survey of fruit insect pests in Massachusetts in 1938, W. D. WHITCOMB and A. I. BOURNE (*Mass. Fruit Growers' Assoc. Rpt.*, 45 (1939), pp. 28-32).

Fall clean up of citrus insects, J. R. WATSON. (Fla. Expt. Sta.). (*Fla. Grower*, 48 (1940), No. 9, p. 15).

Certain sucking insects causing injury to rose, F. F. SMITH. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 658-662, figs. 3).—In observations of 44 insects as vectors of mosaic and streak disease of the rose, several species not usually recognized as attacking roses were found to feed or to breed on this host for an extended period. Injuries, including yellowing and necrosis by the yellow-headed leafhopper and the potato leafhopper, stippling by the apple leafhopper, *Erythroneura* sp., and the white apple leafhopper, speckling by *Myzus porosus*, and general dwarfing by aphids and mealybugs, are described. Differential characters of stippling and of fecal deposits are given for identifying the injuries caused by the several species of *Empoasca*, *Erythroneura*, and *Typhlocyba*.

Additions to annotated lists of insects reared from elm bark and wood, C. H. HOFFMANN. (U. S. D. A.). (*Bul. Brooklyn Ent. Soc.*, 35 (1940), No. 2, pp. 54-63).—These additions to the earlier annotated lists by Pechuman and Kaston (E. S. R., 78, p. 660; 79, p. 359) are arranged by order and family.

The principles of fumigation of insect pests in stored produce, A. B. P. PAGE and O. F. LUBATTI (*London: Dept. Sci. and Indus. Res., 1940, pp. [3]+28, figs. 7*).

Lures and traps to control clothes moths and carpet beetles, H. F. WILSON. (Univ. Wis.). (*Jour. Econ. Ent., 33 (1940), No. 4, pp. 651-653*).—The observations conducted demonstrated that clothes moths and carpet beetles can be lured by bait materials and that fairly heavy infestations can be reduced beneficially. A series of experiments show that large numbers of adult clothes moths can be caught on baited fly rolls and that carpet beetle and clothes moth larvae can be lured into baited traps laid on the floor. It was also found that clothes moths were attracted to such traps and laid eggs on the cloth pads contained in the traps.

Insect activity at a light trap during various periods of the night, R. E. HUTCHINS (*Jour. Econ. Ent., 33 (1940), No. 4, pp. 654-657, figs. 4*).—The observations reported have shown that there is a constant shifting in the abundance or activity of insects at a light trap during the night. Thus, a group or species may become extremely active for a brief period, then suddenly disappear. In nearly every case the abundance of male Lepidoptera at the trap increased considerably until 1 a. m. and then decreased, while female abundance remained nearly constant. The period of night between 1 and 3 a. m. appeared to be the turning point in the locality under observation for the activity of nearly all the major insect groups.

Notes on Chaetoanaphothrips orchidii (Moulton) found attacking citrus fruit in Florida, W. L. THOMPSON. (Fla. Expt. Sta.). (*Fla. Ent., 22 (1939), No. 4, pp. 65-67*).—These notes relate to a thrips, *C. orchidii*, found in 1937 to have been the cause of surface markings on mature grapefruit grown near Cocoa, Brevard County, Fla. A similar injury to oranges in California, as reported by Boyce and Mabry (*E. S. R., 78, p. 819*), and to grapefruit in Honduras is said to have been caused by the greenhouse thrips. Thus far commercial damage has been observed in only a limited number of groves, and in each case no sulfur or only a minimum number of sulfur sprays had been applied during the spring and summer. "In one portion of a commercial grove an unsprayed check plat had thrips injury on 57 percent of the fruit hanging singly and 70 percent of the fruit hanging in clusters. Sulfur sprays applied for rust mite control are apparently a factor in keeping the thrips population at a minimum. In various experimental plats receiving sulfur sprays there was less marked fruit than in the unsprayed checks, although none of the sprays were applied for thrips control. In one preliminary experiment for thrips control on grapefruit the thrips population was decreased 84 percent with 1.5 percent lime-sulfur solution supplemented with 6 lb. of wettable sulfur per 100 gal."

A synopsis of the Hemiptera-Heteroptera of America north of Mexico, J. R. DE LA TORRE-BUENO (*Ent. Amer., n. ser., 19 (1939), Nos. 3, pp. 141-206; 4, pp. 207-304, figs. 17*).

Additions and corrections to "A synopsis of the Hemiptera-Heteroptera of America north of Mexico," part 1, J. R. DE LA TORRE-BUENO (*Bul. Brooklyn Ent. Soc., 35 (1940), No. 2, pp. 51-53*).—Additions and corrections to the work noted above are presented.

The effect of fertilizers on chinch bug resistance in sorghums, R. G. DAHMS and F. A. FENTON. (U. S. D. A. and Okla. A. and M. Col.). (*Jour. Econ. Ent., 33 (1940), No. 4, pp. 688-692, figs. 4*).—In pot and field experiments at Lawton, Okla., in continuation of earlier studies (*E. S. R., 76, p. 506*) with Atlas sorgo, Dwarf Yellow milo, and Finney milo sorghums, their resistance to chinch bug attack was consistently decreased by sodium nitrate, and in the

majority of cases increased by superphosphate, applied to the soil in which the plants were grown. Results in pot experiments were variable, the resistance of Atlas sorgo being in most cases apparently somewhat decreased and that of Dwarf Yellow milo somewhat increased.

The 1939 green bug outbreak in Oklahoma, F. A. FENTON and E. H. FISHER (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 628-634, figs. 6).—A severe outbreak of the green bug in northeastern Oklahoma in the spring of 1939 resulted in an estimated loss of over half a million dollars to small grain crops. Winter barley was more severely damaged than winter wheat, and the greatest damage was inflicted on spring oats. There is said to be some evidence of comparative resistance of some oats varieties to green bug damage. Fall-planted barley, oats, and wheat were much more severely damaged following grain sorghums in a rotation than following soybeans, corn, or wheat. "In all fields studied, the parasite *Lysiphlebus testaceipes* did not occur in sufficient abundance to check the green bug until after the infestation had declined to a low point or until the grains had already been damaged beyond recovery. The most important predator was *Hippodamia convergens*, the larvae of which were abundant at the peak of the green bug infestation."

Differential susceptibility of corn hybrids to *Aphis maidis*, E. V. WALTER and A. M. BRUNSON. (U. S. D. A. and Ind. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 623-628, fig. 1).—In observations made during the summer of 1939 on the abundance of corn leaf aphids on 225 inbred and 486 hybrid strains of corn grown on a farm of the Indiana Station, consistent differences between inbred lines in behavior toward aphid attack were indicated. These ranged from the extreme susceptibility of 38-11 and 4-8 with 100 percent of the plants infested to the practical immunity of 2 strains with no infestation. The severity of infestation and the parts of the corn plant attacked also varied with the inbred, the lower part of the tassels being the most favored point of attack, and the ear shoots, silks, and upper leaves of the more susceptible varieties also being infested. Individual inbreds differed greatly in prepotency in transmitting susceptibility or resistance to their hybrids. In general hybrids were less heavily infested than the parental inbreds, although combinations involving 1 inbred strain provided a notable exception. No plant character or group of characters was found to be consistently correlated with aphid susceptibility.

Control of the pea aphid in eastern Virginia in 1939, H. G. WALKER and L. D. ANDERSON. (Va. Truck Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 620-623).—Experiments conducted in the spring of 1939, when a very severe outbreak of the pea aphid occurred on canning peas on the Eastern Shore at about the time the first pods were beginning to set, are reported. "Vaporized nicotine and a 4 percent nicotine-copper-lime dust gave higher initial kills of pea aphids than did derris-talc dusts containing 1 percent rotenone, but the derris dusts had more residual effect than did the nicotine materials. Derris-talc dusts containing 1 and 3 percent Vatsol OS [sodium salt of an alkyl naphthalene sulfonic acid, practically 100 percent pure] were not significantly different from each other, but both were more effective than a similar dust that did not contain a wetting agent. Peas treated with each of these materials produced highly significant increases in yield over the untreated check plats. In commercial control work by pea growers, vaporized nicotine gave uniformly good control of the pea aphid, whereas derris dusts were reported as giving good results in some instances and poor results in others. An atomized oil containing rotenone and nicotine gave high kills of the aphids hit, but due to the poor coverage obtained failed to give entirely satisfactory results."

The species of *Aphidius* (Aphidiinae: Braconidae) as parasites of aphids in South Africa, G. C. ULLYETT (*Union So. Africa Dept. Agr. and Forestry, Sci. Bul.* 178 (1938), pp. 28, figs. 9).—Braconid parasites of the genus *Aphidius*, which attack aphids in South Africa, are dealt with, part 1 (pp. 6–14) relating to their morphology, part 2 (pp. 13–16) to bionomics and biology, and part 3 (pp. 16–27) to the value of *Aphidius* in the complex.

A survey of the pineapple mealybug in Puerto Rico and preliminary studies on its control, H. K. PLANK and M. R. SMITH. (Coop. U. S. D. A.) (*Jour. Agr. Univ. Puerto Rico [Univ. Sta.]*, 24 (1940), No. 2, pp. 49–76, figs. 6).—A field survey of conditions in four main pineapple-growing districts of Puerto Rico revealed a pineapple mealybug infestation of 87.1 percent of pineapple plants ranging from 9 mo. to about 2 yr. of age. Infestation in individual fields varied from 66.7 to 100 percent of the plants examined, and about as many plants were found infested on the inside of the fields as along the edges. "All parts of the pineapple plant were seen infested, roots, leaves, and fruits, as well as the stem. Wherever heavily infested plants were found they were usually stunted, chlorotic, and often wilted, and the fruits were much reduced in size. Under conditions of severe infestation the normal yield has been estimated to be reduced by 36 percent. Including the pineapple, 25 species of host plants of the mealybug have been recorded in Puerto Rico. Evidence obtained showed that the mealybug was widely distributed in the parts of the island where examinations were made, and that certain grasses and weeds in a pineapple field or near the edges can harbor the mealybug and act as reservoirs from which the pineapples will later be infested.

"The pineapple mealybug was seldom found unattended by ants. Sixteen species of ants were found associated with this insect, all but 2 of these being observed attending the mealybug on pineapple plants. The fire ant, the most important species, was found in this association on over 43 percent of the infested plants on which ants were present. Three species of ants were frequently seen carrying young mealybugs about in the fields. The greater frequency with which ants were found attending mealybugs on pineapple plants on the edges of the fields, as compared with that on the inside, indicated a definite relation of the surrounding vegetation to the ant distribution within the field itself. That ants do spread the mealybug from infested to uninfested plants was shown experimentally. The larvae of 2 small moths, 1 a tineid and the other a pyralid, and the larvae of a small cecidomyiid fly, all found living in large groups of mealybugs, were thought to be predators of this pest. Two hymenopterous parasites have been recently introduced, but only 1 has as yet become established in pineapple fields of the island.

"In experiments with methods to clean planting stock of mealybugs, submersion of pineapple slips in water for 96 hr. under the conditions described resulted in a 99.13-percent kill of the mealybugs but also killed over half the plants. Submersion for 72 hr. produced 92.04-percent control but so injured 15.5 percent of the plants that they later died, and among those that survived an average of 5 living mealybugs were found on each infested slip. Treating the slips in a closed room with moisture-saturated air at 46° C. (about 115° F.) for 6 hr. seemed to produce the most satisfactory results; 97.93 percent of the mealybugs were killed by this treatment, and although 10.5 percent of the slips still contained living mealybugs, the number averaged only 1 mealybug per slip. None of the planting stock was lost, and instead of injuring the slips this treatment seemed to stimulate their later growth."

On the nature and origin of the diapause in *Platyedra gossypiella* Saund., F. A. SQUIRE (*Bul. Ent. Res.*, 31 (1940), No. 1, pp. 1–6, fig. 1).—Report is made

of a study in Trinidad of the condition termed diapause (including hibernation, estivation, and diapause manifestations), characterized by a marked depression of metabolism and quiescence, of which the "remote causes as suggested by observation are cold, heat, drought and (or) certain nutritional peculiarities such as richness or dryness of food. These factors may act singly or in combination, with different factors dominant in different cases." It is concluded that all the remote causes of diapause may be reduced in physiological terms to an unfavorable free water balance. In the case of the pink bollworm, nutrition is the dominant factor causing this moisture deficiency, for, as is shown, the larvae are subject more and more, as the crop advances, to food that is both drier and richer in oil.

Effect of the mechanical husker in corn borer control, L. L. HUBER. (Ohio Expt. Sta.) (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 643, 644).—It is stated that there is no evidence that the use of the mechanical husker has directly or indirectly played a leading role in increasing corn borer population, and that there can be no entomological objection to its use.

The bean pod borers in Puerto Rico, L. B. SCOTT. (U. S. D. A.). (*Jour. Agr. Univ. Puerto Rico [Univ. Sta.]*, 24 (1940), No. 2, pp. 35-47, figs. 2).—A study of three species of pod borers, namely, *Maruca testulalis* (Geyer), the lima bean pod borer, and the Caribbean pod borer, found commonly in 1935-36 infesting wild and cultivated legumes in all parts of Puerto Rico, is reported. The first two mentioned were equally numerous, but *M. testulalis*, due to its confining its attacks almost entirely to cultivated plants, was by far the most important economically. The Caribbean pod borer was the least abundant, and although found largely in cultivated plants, was much less destructive than either of the other two. In addition to various legume crops, the three borers attacked several wild legumes, particularly *Crotalaria incana*, one of the island's commonest crotalarias, and *Canavalia maritima*, commonly called the bay bean. Some wild legumes, such as the wild lima bean (*Phaseolus lunatus*) and one of the commonest crotalarias (*C. retusa*), appeared to be highly resistant, if not immune, to attack. Experiments conducted at Yauco, Isabela, and Mayaguez indicated that the pod borers could be successfully controlled by two 25-lb.-per-acre applications of dust containing 80 percent of natural cryolite. Similar applications of pyrethrum dust were moderately effective, but the cost of the material was prohibitive. Dusts and sprays containing rotenone failed to provide satisfactory control. Observation of various varieties and types of lima beans indicated that the small-seeded lima bean, particularly the variety Carolina, was highly resistant to pod borer attack.

A list of the butterflies of Michigan, S. MOORE (*Mich. Univ., Mus. Zool. Occas. Papers*, No. 411 (1939), pp. 23, fig. 1).—This list, based upon all previously published records and examinations of collections, lists 124 species as known from the State. Dates, localities, and collection are included.

An outbreak of the velvetbean caterpillar in Alabama, with data on control, F. E. GUYTON. (Ala. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 635-639, fig. 1).—An extensive outbreak of the velvetbean caterpillar in peanut fields in 1939 led to the control work here reported, the details of which are given in two tables. "Lead arsenate, applied in dust form at the rates of 8 and 10 lb. per acre, gave an average of 91-percent control of the velvetbean caterpillar on peanuts. It caused no burning of leaves. Calcium arsenate dust, applied at the rates of 8 and 10 lb. per acre, gave an average of 89-percent control but caused burning of peanut foliage in almost every instance. Timbo dusts containing 0.5 percent and 1 percent rotenone were in-

effective as controls for the velvetbean caterpillar. Neither lead nor calcium arsenate gave effective control when mixed with more than an equal part of a diluent. Peanut was the principal host plant of the velvetbean caterpillar in Alabama in 1939. Soybeans, velvetbeans, and kudzu were also severely damaged in certain sections of the State. The maximum kill from the arsenicals used in this experiment occurred 3 to 4 days after exposure. Data obtained were not satisfactory for determining the effect of complete defoliation of the plants on yield of peanuts."

The biology of a tachinid parasite, *Sturmia rhodesiensis* sp. n., of the cotton boll worm *Heliothis armigera* Hubn. in Southern Rhodesia, E. PARRY JONES (*Brit. So. Africa Co. Pub. 7 (1938), pp. 11-34, pls. 4*).—A report of studies of a new tachinid parasite, here described as *S. rhodesiensis* n. sp. (= *S. halli* Curran 1939),¹ which was found at Mazoe and is one of the most important of the dipterous enemies of the bollworm. Though at first confused with *S. munroi* Curran, an examination of the terminalia revealed a distinct difference. "*S. rhodesiensis* is one of the first of the tachinid species to emerge in the spring, i. e., at the end of August and during September. Several generations are passed through during the summer, but the species overwinters in the pupal stage. The duration of the overwintering puparia varies from 99 to 175 days. The percentage parasitism of the bollworm has been determined during the citrus [fruit] infestation in September and October and during the last summer generation of the host in April and May for the year 1934 to 1938. The parasitism for these two periods varies from 14.7 to 24.8 percent and from 3 to 4.8 percent, respectively. In both periods *S. rhodesiensis* has been found to be one of the most active of the tachinid species attacking the bollworm. No other host of the species has been recorded so far."

Insect cultures inbred for 200 generations, D. F. MILLER. (Ohio State Univ.). (*Science, 92 (1940), No. 2381, pp. 147, 148*).—Report is made of the laboratory rearing of the blowflies *Lucilia sericata* and *Phormia regina* through approximately 200 generations in the course of 10 yr. These inbred blowflies are said to have lost nothing in vigor and to be well adapted to laboratory rearing and uses. After experimentation in which many foods were tested, the procedure adopted consisted of feeding the adults on lean beef, which was essential to egg development, and brick sugar. Fresh tap water was supplied at all times. The maggots were fed fresh hamburger. It is said that no other food was used over a period of 8 yr.

Methods of destroying blowfly larvae and pupae in carcasses and in soil, A. L. BRODY and E. F. KNIPLING. (U. S. D. A.). (*Jour. Econ. Ent., 33 (1940), No. 4, pp. 662-665*).—The results of tests of chemical, mechanical, and burning methods, conducted at Valdosta, Ga., with a view to determining the most effective means of destroying the screwworm and other blowfly larvae in carcasses and soil, are reported. Sodium cyanide at the rate of 1 oz. in from ½ to 2 gal. of water was found to kill all the larvae and pupae in the soil and at the rate of ½ oz. in from 1 to 2 gal. of water was over 98 percent effective in preliminary tests on 1-sq. yd. plats. "In tests on larger plats, sodium cyanide in concentrations of ½ and ¼ oz. per gallon of water applied at the rate of 2 gal. per square yard killed all larvae in carcasses and in the soil on which the carcasses had laid, while ⅛ oz. per gallon of water at the same rate killed 98 percent of the larvae and pupae in the soil. Carbon disulfide emulsion (¼ pt. of equal parts of carbon disulfide and sulfonated castor oil in 2 gal. of water) destroyed all larvae and pupae in soil when applied at the rate of 2 gal. per square yard. Pounding the soil seemed to be effective on improved

¹ Amer. Mus. Novitates, No. 1022 (1939), pp. 5.

pasture sod but relatively ineffective on rough woodland pastures." It was found that in carcasses and soil the screwworm may be destroyed with a prickly pear burner using gasoline or kerosene. Top burning of the carcasses and soil and burning by the trench method, followed by spreading the fire over the soil, was more effective than trench burning of the carcasses with wood, which was the least effective. It is pointed out that the fire should be spread over an area extending at least 3 ft. from the carcass in all directions. Burning carcasses and heating the soil on which they have laid, if conducted with thoroughness, will kill blowflies that are present in the carcass and soil.

The toxicity of phenothiazine and certain related compounds to young screwworms, R. C. BUSHLAND. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 666-669).—In laboratory tests conducted with a view to determining the toxicity of phenothiazine and a number of related organic compounds to young screwworm larvae, the following were found to be toxic at concentrations of 0.67 percent or less: "Acridine, *p*-dibenzodioxin, dibenzothiophene, dibenzyl, 5,10-dihydroacridine, 9,10-dihydroanthracene, diphenyl, diphenylamine, diphenylene oxide, diphenylmethane, diphenyl sulfoxide, phenazine, phenothiazine, phenothioxin, phenoxazine, phenyl ether, and phenyl sulfide. Compounds found to be nontoxic at a concentration of 0.67 percent were anthracene, carbazole, diphenyl sulfone, phenothiazine sulfoxide, and thianthrene." A discussion of the relationship between molecular structure and toxicity to screwworm larvae is included. It is apparent that any alteration of the molecule in these compounds may influence toxicity.

The toxicity of some organic compounds to young screwworms, R. C. BUSHLAND. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 669-676).—In continuation of the work above noted, laboratory tests were made of 551 organic compounds with a view to determining their efficiency in the field in protecting wounds against screwworm infestation. Of these, listed according to minimum lethal concentration and relative toxicity with regard to phenothiazine and rotenone, "284 showed little or no toxicity at a concentration of 0.67 percent, 190 killed all larvae at concentrations of 0.17 to 0.67 percent, and 77 compounds, considered to be of outstanding toxicity, were lethal at a concentration of 0.1 percent or less. Of these highly toxic compounds, 10 were less toxic than rotenone, 25 were equal in toxicity to rotenone (minimum lethal concentration 0.05 to 0.08 percent), 31 were equal in toxicity to phenothiazine (minimum lethal concentration 0.03 to 0.05 percent), and 11 were more toxic than phenothiazine (minimum lethal concentration 0.03 percent or less). The 11 compounds found to exceed phenothiazine in toxicity were: Cinchonine, *m*-dinitrobenzene, 2,6-dinitro-4-chlorophenol, 3,5-dinitro-*o*-cresol, 2,4-dinitro-6-cyclohexylphenol, methylphenylnitrosoamine, *o*-nitroanisole, *p*-nitroanisole, *p*-nitrobenzotrile, *p*-nitrophenetole, and *p*-nitrophenylacetoneitrile. Although these studies have revealed no basis from which the toxicity of a prospective larvicide can be definitely predicted, it is evident that some groups show more promise than do others. For example, of 158 nitro compounds 36 were outstandingly toxic, while of 51 compounds containing a primary amino group only 1 showed outstanding toxicity. Of the compounds comprising quinoline and 16 of its derivatives, all were toxic to the screwworms and 12 of them outstandingly so."

Sheep maggot-fly problem: New Zealand survey, 1937-38, D. MILLER (*New Zeal. Jour. Sci. and Technol.*, 21 (1939), No. 4A, pp. 240A-244A, fig. 1).—A report is made upon maggots from struck sheep received from various parts of New Zealand and flies reared therefrom. The results are analyzed so far as the limited data allow from the points of view of (1) causes of strike, (2)

species of flies concerned, and (3) the apparent zones in which the 2 primary flies (*Calliphora laemica* and *Lucilia sericata*) dominate. Of the 14,843 flies reared during the observations, *C. laemica* composed 49 percent, *L. sericata* 46.27, *Chrysomya rufifacies* 1.4, the false stablefly 1.36 and *Calliphora quadrimaculata* 1.2 percent, with 7 species representing less than 1 percent each.

Dipterous larvae and wound treatment, A. D. IMMS (*Nature [London]*, 144 (1939), No. 3646, pp. 516, 517).—A brief summary of the present status of knowledge of the subject as known to the author.

The mosquitoes of Arkansas, S. J. CARPENTER (*Little Rock, Ark.: State Bd. Health, 1939*, pp. [4]+89, figs. [32]).—Following a brief introduction, the habits of mosquitoes, methods and technic employed, structures commonly used in determination of species, seasonal occurrence of the different species met with in Arkansas, a key to adult female mosquitoes, and a key to the larvae of Arkansas mosquitoes are presented and descriptions given of 42 species occurring in the State, including 5 of *Anopheles*, 7 *Culex*, 15 *Aedes*, 9 *Psorophora*, 2 *Theobaldia*, and 1 each of *Mansonia*, *Orthopodomyia*, *Uranotaenia*, and *Megarrhinus*. The work concludes with a discussion of methods of mosquito control by natural factors and artificial measures, a report of studies of flight range of the common malaria mosquito, and a list of 48 references to the literature.

Viability of *Aedes aegypti* eggs, J. H. LE VAN (*Pub. Health Rpts. [U. S.]*, 55 (1940), No. 20, p. 900).—In an experiment conducted, it was shown to be possible for yellow-fever mosquito eggs to remain viable in the vicinity of Miami, Fla., for at least 1 yr. It is pointed out that no freezing weather occurred during the experimental period.

The biology and control of wireworms: A review of the literature, C. A. THOMAS (*Pennsylvania Sta. Bul. 392 (1940)*, pp. [2]+90).—This review, presented with a 13-page list of references to the literature, deals with the subject as follows: Biology, life history, and ecology (pp. 2–15); environment (pp. 15–29); biological control of wireworms (pp. 29–37); insecticides used against elaterid larvae (pp. 37–53); attractants and repellents (pp. 54–60); planting practices (pp. 60–64); cultivation practices (pp. 64–70); crop rotation (pp. 70–76); and miscellaneous control methods (pp. 76, 77).

Effects of substitute crops and rotations on wireworm control, W. C. NETTLES. (Clemson Agr. Col.). (*Jour. Econ. Ent.*, 33 (1940) No. 4, pp. 644–646).—It is concluded that substitute crops will unquestionably aid in the solution of the wireworm control problem. Rotations are considered of outstanding importance.

Arsenicals for controlling white grubs in strawberries, T. W. KERR, JR. (Cornell Univ.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 693–698, fig. 1).—The results of control work with the *Phyllophaga* spp. in newly set strawberries in Erie and Steuben Counties, N. Y., are reported, the details being given in table and chart form. "It was found that the application of certain sand and arsenical mixtures, at planting time, to the roots of strawberry variety Premier 1938 and 1939 resulted in a greater percent survival of plants than when the plants were not treated. In the 1938 investigations, where second-year grubs were abundant and where normal moisture conditions existed, 97.5 percent of the plants survived when treated with lead arsenate and sand, 1–20, while the mean percent survival of the plants in six check rows was 55.2. . . . Zinc arsenite, zinc arsenate, and calcium arsenate and sand mixtures were found to be extremely injurious to the strawberries. Arsenic-free ground glass and an aqueous mixture of calomel and gum arabic were both found to be ineffective in preventing white grub injury to strawberry roots. . . . Analyses of the strawberry fruit picked from plants treated with lead arsenate or magnesium arsenate and sand

mixtures indicate that there is no increase, either in lead or arsenic, over the amount normally present in strawberries."

The cranberry rootworm as an apple pest, S. W. HARMAN (*New York State Sta. Bul.* 692 (1940), pp. 11, figs. 4).—Widely distributed over the United States and primarily a pest of the cranberry, the adult of the cranberry rootworm has for many years attracted attention in western New York, particularly in Wayne County, through its attack upon the apple. In 1928 a grower reported damage through mutilation of his Ben Davis crop to the extent of 70 percent. Fruit injured is unfit for the general market and can only be utilized for canning or evaporated stock. Tests conducted over a 2-yr. period in apple orchards have shown two sprays of lead arsenate, the first applied when the beetles first appeared in the orchard, followed by a second in about 10 days, to provide adequate protection. Usually the first cover spray for the codling moth is applied by the third week in June and is thought to be of considerable value in preventing the rootworm from becoming a common pest in apple orchards. In plantings where it is causing damage, the mid-June spray should be timed with special reference to the emergence of the beetles. The studies have indicated that it prefers a light, sandy soil in uncultivated orchards. The beetle was found to be a general feeder on orchard vegetation.

New baits for the control of the alfalfa snout beetle (*Brachyrhinus ligustici* (L.)), C. G. LINCOLN and C. E. PALM. (Cornell Univ.): (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 639-643, figs. 8).—In reporting further upon the control of this pest (E. S. R., 83, p. 663), it is stated that, while raisin-shorts-sodium fluosilicate bait still remains the best to use for its control, substitute baits have been found to be nearly comparable in efficiency. "Considering cost, ease of spreading, and availability of materials, corncob, sugar, soybean flour, [and] sodium fluosilicate bait can be recommended for the control of this insect. Bran-sugar-soybean flour-sodium fluosilicate bait compares favorably with the corncob bait, except for the fact that it is more difficult to mix and to spread in the wind."

Boll weevil control with calcium arsenates containing different percentages of water-soluble arsenic pentoxide, R. C. GAINES. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 682-684).—In work in South Carolina, Florida, Mississippi, Louisiana, and Texas, calcium arsenates containing low, intermediate, and high percentages of water-soluble arsenic pentoxide by the New York method were tested against the bollweevil in eight localities in 1938 and five localities in 1939. The average infestation during the 2 yr. in the plats treated with a low percentage was 18.9 percent, intermediate 17.6, high 17.2, and untreated checks 34.7 percent. The average yield in $\frac{1}{60}$ -acre plats treated with low was 24.1 lb. per plat, intermediate 23.2 lb., high 23.3 lb., and untreated checks 19.6 lb.

Special report of North American infestation of *Hypera brunneipennis* on Yuma Reclamation Project, Arizona and California, J. C. HAMLIN (*Calif. Dept. Agr. Spec. Pub.* 174 (1939), pp. 22-25).—Report is made of an investigation of conditions surrounding the *H. brunneipennis* infestation noted by Wehrle (E. S. R., 83, p. 93) in the Yuma area conducted during the last few days of April. Included is a discussion of possible host plant relations and extent of infestation.

Some observations on habits and characteristics of *Hypera brunneipennis* in Yuma County, Arizona, J. L. E. LAUDERDALE (*Calif. Dept. Agr. Spec. Pub.* 174 (1939), pp. 89-91).

Studies of serious bee losses of last few years being made, G. F. KNOWLTON. (Coop. U. S. D. A.). (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 3, pp. 1,

11).—Reference is made to the progress of an investigation commenced in 1939, in which year unusually severe bee losses occurred in Utah. Although arsenical poisoning was suspected, but few samples of bees collected up to June 27, 1940, and analyzed, showed unusual amounts of arsenic. Repeated experimental tests with various grasshopper bait combinations spread near a large apiary in Weber County during August and to mid-September of 1939 indicated that the bees seldom were attracted to such baits during the period under investigation. Similar tests conducted in Cache County during June and July 1940 attracted few honeybees. Observations in tomato fields indicate that honeybees are not particularly attracted to blossoming tomato plants. While the period June 15 to July 15, 1939, was a period of heavy bee loss in Utah, only a few beekeepers reported unusual losses during this period of 1940.

The effect of color of hive covers upon the temperature within the hive, A. V. MITCHENER (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 649, 650).—It is concluded that "hive covers with galvanized metal tops should be painted with at least two coats of a good quality white paint to aid in reducing the temperature within the hives on hot days. Aluminum paint absorbs much more of the heat from the sun than white paint and should not be used with the idea of keeping the hives cool. Unpainted hive covers having galvanized tops absorb practically as much heat as do those painted black."

A review of the parasitic wasps of the ichneumonid genus *Exenterus* Hartig, R. A. CUSHMAN (*U. S. Dept. Agr., Misc. Pub.* 354 (1940), pp. 15, fig. 1).—The need for knowledge of the *Exenterus* parasites of the larvae of pine-feeding sawflies (subfamily Diprioninae), 3 species of which sawflies have recently become established in North America, led to the review here presented. Several exotic species of the genus have been released in eastern Canada and New England, of which *E. marginatorius* (F.), sometimes misidentified as *E. adspersus* (Htg.), has become established. Four species are described as new, namely, *E. flavissimus*, *E. pini*, and *E. tsugae* from North America and *E. vellicatus* from Czechoslovakia and Germany. A key to the separation of the 15 species, 8 of which are North American and 7 exotic, is included.

A study of some factors affecting the efficiency of *Encarsia formosa* Gahan, an aphelinid parasite of the greenhouse white fly *Trialeurodes vaporariorum* (Westw.), H. E. MILLIRON (*Michigan Sta. Tech. Bul.* 173 (1940), pp. 23, figs. 10).—Report is made of studies extending over a period of more than a year, conducted with a view to ascertaining the relative value of the aphelinid parasite *E. formosa* as a factor in the control of the whitefly in Michigan greenhouses. Parasitism of 91 percent of the whitefly on fuchsia and 86 percent on tomato was the greatest control observed during the course of experiments conducted. The highest percentage of parasitism of the whitefly on the majority of plants was reached under nearly constant temperatures of 75°–79° F. and 50–70 percent relative humidity. Widely fluctuating temperatures between 57°–81° gave somewhat higher percentages. The parasite, however, accomplished very little control at temperatures of 64° or below, because at such temperatures it was sluggish. The data and observations here recorded show that if the percentage of parasitism is any indication of the optimum conditions of the parasite, the optimum temperature is lower than 30° C. (86° F.). "Of the physical environmental factors affecting the efficiency of the parasite, temperatures seems to be the most important. Other factors which appear to play an important part are humidity and light. The effect of such physical factors as character of the host plant is expressed by the degree of pubescence and the amount of excretion of both plant and whitefly larvae. . . . In other words, the degree of parasitism is affected by the pubescence of the host plant and by

the excretions of host plant and whitefly larvae. The parasite does not appear to restrict its oviposition activity entirely to the fourth instar. It has been observed attacking the second and third as well. Oviposition is, however, normally confined to the fourth instar. Even in an environment that seems most ideal for the parasite, and despite the fact that each generation is composed of 100 percent females in most cases (thelytoky), the biotic potential of the parasite is apparently unequal to that of its host, especially during heavy infestations. Where a variety of plants are grown together, therefore, it seems unlikely that complete control can be rendered by the parasite alone under normal greenhouse conditions. But, under favorable conditions and a large parasite population, *E. formosa* definitely checks the rapid increase of its host."

A list is given of 47 references to the literature.

Importation, rearing, and colonization of parasites of the oriental fruit moth, H. W. ALLEN, J. K. HOLLOWAY, and G. J. HAEUSSLER (*U. S. Dept. Agr. Cir. 561* (1940), pp. 62, figs. 15).—An account is given of the work of the Bureau of Entomology and Plant Quarantine from 1929 to 1935, inclusive, during which period a search was made for beneficial parasites of the oriental fruit moth in Europe, Australia, Japan, and Chosen (Korea). Seven beneficial species found in Europe, 2 of the 10 species found in Australia, and 17 of about 65 species found in Japan and Chosen were successfully imported and liberations made in the United States. Parasites secured directly from importations were supplemented by those propagated at the receiving station in New Jersey and by liberations of several indigenous species, including *Macrocentrus ancylivorus*. One thousand and ninety-three separate liberations were made. These were well distributed throughout the infested area from Massachusetts to Michigan and southward to Georgia and Arkansas. Special attention is given to the technic of importing to prevent entry of undesirable species, to propagation and rearing at the receiving station, and to methods of shipping the adult parasites to insure delivery of vigorous stock at the liberation points, frequently several hundreds of miles from the place where the parasites were reared.

DN dusts on hops for control of the red spider, H. E. MORRISON and D. C. MOTE. (Oreg. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 4, pp. 614-619).—Following a historical review covering the common red spider as a hop pest, the results of control work conducted continuously from 1938 are reported. Preliminary tests in the field in 1938 favored the use of the proprietary 1 percent DN dust (dinitro-*o*-cyclohexylphenol). In experiments with this dust in 1939 very high kills were obtained from mechanical dilutions at concentrations "of 1, 0.75, 0.50, 0.25, 0.125, 0.0625, and 0.03125 percent. Tale, hydrated lime, bentonite, diatomaceous earth, Loro, rotenone, pyrethrum, and nicotine sulfate were found compatible with the proprietary 1 percent DN dust, but did not contribute to added toxicity. DN dusts were found safe on the foliage of 10 hop varieties, but caused severe injury to 2 Russian varieties (Serebrianka and Skorospelka). Mechanically diluted DN dusts were found safe on 4 varieties of beans. Promising results have been obtained in the development of suitable commercial means of contacting red spiders on the under surfaces of hop foliage."

ANIMAL PRODUCTION

[Livestock investigations in Alabama] (*Alabama Sta. Rpt. 1938, pp. 11-14, 17*).—Progress results (E. S. R., 81, p. 84) are briefly presented for the following lines of investigation: The value of peanut hay for wintering breeding cows and for fattening steers, kudzu as a grazing crop for beef cattle, shelter v. no shelter for fattening steers, returns secured from rough untillable land in the form of beef produced, and the transmission of factors related to the economical

production of swine, all by J. C. Grimes; the detection of infertile eggs previous to incubation, by D. F. King; and the value of kudzu and other summer green feeds for poultry, by G. J. Cottier and King.

[**Investigations with livestock in Arizona**] (*Arizona Sta. Rpt. 1939*, pp. 55-59, 95, 96).—Studies for which results are briefly noted include the nutritional value of range plants, the utilization of grain in hegari silage by beef cattle, the relation between conformation of feeder steers and their feeding and slaughter efficiency, a comparison of rations for laying hens, and the effect of backcrossing and reciprocal crosses on egg production in the offspring.

[**Livestock investigations in Georgia**] (*Georgia Sta. Rpt. 1940*, pp. 37, 39-47, 48-51, fig. 1).—Experiments for which progress results are reported (E. S. R., 82, p. 804) include: The influence of fertilized pastures on the reproductive efficiency of dairy cattle, a comparison of peanut hay v. silage and of peanut meal v. cottonseed meal for fattening cattle, the value of peanuts and vines in cattle fattening rations, the winter feed requirements of the beef cattle breeding herd, the value of supplementary concentrates for young beef cattle and for dairy heifers on summer pasture, sweetpotato meal as a feed for fattening cattle, the effect of length of day on the breeding season of sheep, the use of Hampshire and Southdown rams for improving the lamb- and wool-producing quality of native sheep, the utilization of peanuts and peanut meal for swine feeding, corn v. wheat for hogs, and the influence of pasture fertilization on the growth and development of young mules.

[**Livestock investigations in Mississippi**] (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 8, pp. 3-5, 8, figs. 6).—The results of experiments with livestock are reported in articles entitled A Study of the Influence of Breeding Upon Performance Under Mississippi Conditions—The Production of Beef Calves, by A. E. Cullison; and Green Grass Best for Calves: Codliver Oil a Substitute, by W. C. Cowsert.

Composition and utilization of range vegetation of Sutton and Edwards Counties, G. S. FRAPS and V. L. CORY (*Texas Sta. Bul. 586 (1940)*, pp. 39).—Analyses of 349 samples of range vegetation and a study of the kinds of vegetation eaten by cattle, sheep, and goats indicated that the forage supplied sufficient quantities of lime (calcium). The protein was probably insufficient in the rations of the cattle in February, March, April, and November of the years studied. The protein was probably insufficient in the rations of the sheep and goats only in 1 mo. (November) of the period studied. The phosphoric acid was probably insufficient in the ration of the cattle from September through February, that of the sheep in December 1930, January 1931, and from September to December 1931, and that of the goats was probably deficient from October 1930 through February 1931 and October, November, and December 1931.

The composition of grass at various stages of maturity, and the changes occurring during haymaking, with particular reference to carotene-content, F. E. MOON (*Empire Jour. Expt. Agr.*, 7 (1939), No. 27, pp. 225-234, figs. 2).—A study was made at King's College, Newcastle, of the carotene content and organic constituents in a mixed meadow herbage at approximately 2-week intervals from April to July. The carotene content was depressed by an April drought, then remained about constant until flowering began, when a marked loss occurred. No further decrease during the postflowering period was observed, although dry matter increased during this period. A loss of about 50 percent of the carotene in mown grass occurred during 4 days in the swath under unfavorable weather conditions. Little additional loss occurred during the subsequent 6 days under more favorable curing conditions.

The carotene-contents of some grass and clover species, with a note on pasture weeds, F. E. MOON (*Empire Jour. Expt. Agr.*, 7 (1939), No. 27, pp.

235-243).—Data are reported on the carotene content at various stages of growth of seven grasses and three clovers. In spring the carotene content was closely related to growth activity, while in summer it depended largely on the stage of maturity. During the summer the clovers and also grassland weeds were superior to the grasses as a source of carotene. In the fall carotene content generally increased unless plants were in an advanced stage of maturity or when growth ceased for any reason.

Silage from hay crops: Making it—feeding it, S. T. DEXTER and C. F. HUFFMAN (*Michigan Sta. Cir. 173 (1940)*, pp. 8, figs. 3).—The discussion deals with crops suitable for silage production, stage of maturity for harvesting and desirable moisture content, methods of handling the crop, the use of preservatives, and practical feeding recommendations.

Production, handling, and feeding sorghum silage by use of the trench silo, W. N. McMILLEN, C. H. JAMISON, and W. LANGHAM ([*Oklahoma*] *Panhandle Sta., Panhandle Bul. 66 (1940)*, pp. [2]+11+23, figs. 8).—A practical discussion of the relative merits of silage v. dry feed, sorghum crops suitable for silage production, the location and construction of the trench silo, filling the silo, and feeding recommendations for various classes of livestock.

[**Sixteenth and seventeenth annual reports of the activities of the National Live Stock and Meat Board for the fiscal years 1938-39 and 1939-40**], R. C. POLLOCK (*Natl. Livestock and Meat Bd. Ann. Rpts., 16 (1939)*, pp. 115, figs. 65; 17 (1940), pp. 88, figs. 62).—Included in these reports are progress statements of the cooperative meat investigations being conducted by State experiment stations and the U. S. Department of Agriculture.

A study on the preservation of meats by cold storage, A. VALENZUELA and M. D. SUMULONG (*Philippine Jour. Anim. Indus., 6 (1939)*, No. 6, pp. 459-466).—Data are presented on the chemical composition of beef, Indian buffalo, and carabao meats in the fresh state and after chilled or frozen storage for varying periods. The slight changes in composition and in flavor, aroma, and texture of meats due to cold storage indicated that the nutritive value and palatability of meats were not impaired during 3 months at 38° F. or up to 13 months at from 18° to 22°. Good sanitary precautions during the preparation of meat for storage and humidity control during storage also proved to be important considerations in maintaining meat quality.

Calves from cows compared with calves from heifers, P. GERLAUGH (*Ohio Sta. Bimo. Bul. 205 (1940)*, pp. 123, 124).—A record of the gains made by cows' calves and heifers' calves in two fattening trials, each of 308 days' duration, showed no significant difference in the rate of gain for the two groups.

Hybrid versus open-pollinated corns for fattening steer calves, P. GERLAUGH (*Ohio Sta. Bimo. Bul. 205 (1940)*, pp. 124, 125).—In a feeding trial with steer calves extending over 308 days hybrid corn (mixture of four hybrids) and open-pollinated corn (mixture of four varieties) were compared. The protein concentrate mixture, hay, and silage portions of the ration were identical for the two groups. The slight advantage of the group receiving hybrid corn over the group fed open-pollinated corn both in average rate of gain and in the amount of feed required per unit of gain was not considered significant.

Iron-treated cottonseed meal for steer calves, P. GERLAUGH (*Ohio Sta. Bimo. Bul. 205 (1940)*, pp. 125, 126).—In a feeding trial of 308 days' duration comparing linseed meal, hydraulic cottonseed meal, and hydraulic cottonseed meal plus 2 lb. of ferrous sulfate per hundredweight as protein supplements for fattening steer calves, the rate and economy of gains were practically identical for the three lots, indicating that the addition of iron to cottonseed meal does not enhance its feeding value for this type of animal.

Adding supplement to corn for calves on pasture, P. GERLAUGH (*Ohio Sta. Bimo. Bul.* 205 (1940), pp. 127-130).—In a further report of this series of experiments (E. S. R., 77, p. 525), a summary of the results of these trials to determine the value of adding cottonseed meal to a corn and pasture ration for beef calves indicated that calves receiving the cottonseed meal supplement made average daily gains of 1.79 lb. and required 569 lb. of corn and 56 lb. of cottonseed meal per 100 lb. of gain, while those receiving no supplement gained at the average rate of 1.63 lb. daily and required 649 lb. of corn per 100 lb. of gain. In all trials the calves receiving the supplement were equal or superior to the calves receiving only corn while on pasture.

Coast disease in Western Australia, H. W. BENNETTS (*Jour. Dept. Agr. West. Austral.*, 2. ser., 17 (1940), No. 1, pp. 41-48).—Experimental evidence was obtained to indicate the identity of coast disease of sheep and cattle in Western Australia with that of South Australia (E. S. R., 80, p. 107) and to be due to a dual deficiency of copper and cobalt. The administration of salts of copper and cobalt as a lick, as a drench, or in the drinking water proved highly effective in preventing the onset of this disorder.

Meat qualities in the sheep, with special reference to Scottish breeds and crosses, II, H. PÁLSSON (*Jour. Agr. Sci. [England]*, 30 (1940), No. 1, pp. 1-82, pls. 11, figs. 9).—Continuing this report (E. S. R., 82, p. 523), data are presented on a comparative study of the anatomical composition and characters of the different breeds and crosses previously described. The material for this study was provided by the complete anatomical dissection of 11 wether lambs and 5 yearling wethers selected as representative. In both groups the study confirms the findings resulting from the statistical comparisons based on carcass measurements of the same breeds and crosses at constant weight. Breed differences in the relative development of the different regions of the body and of the major tissues in different joints and in total carcass and also the concept of early and late development as a fundamental factor in meat production are emphasized. The comparison of lambs and yearlings showed that in the total carcass bone had increased least, muscle only slightly more, and fat most during the increase in age from 4.5 to 13 mo. Variations in the number of vertebrae in the different anatomical regions and other anatomical differences are described and illustrated. The relationship of the many factors and principles involved in this study to practical problems in lamb and mutton production are discussed at length.

The merits of Rambouillet sheep, R. F. MILLER (Univ. Calif.). (*South-west. Sheep and Goat Raiser*, 10 (1940), No. 6, pp. 19, 22).—A summary of research previously noted (E. S. R., 75, p. 92).

Studies indicate that trucking sheep from winter to summer range has many advantages over trailing, A. D. SMITH (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 3, p. 7).—Comparative data on liveweight losses sustained by flocks trailed or trucked from winter to summer range showed that both ewes and lambs, particularly the latter, lost considerably more weight under the former method. Later weights indicated that the lambs moved on foot subsequently grew at a slower rate, indicating that trail losses may be permanent.

Fattening lambs on Oregon feedstuffs, D. E. RICHARDS (*Oregon Sta. Bul.* 370 (1940), pp. 24, figs. 3).—The results of trials comparing both roughages and grain feeds of local origin for fattening lambs are reported. Chopped alfalfa hay (second cutting) proved much superior to wild hay, barley hay, or alsike clover straw when each was fed with barley as a concentrate. The addition of carrots to the barley hay and grain ration markedly improved the value of this feed mixture. A roughage composed of one-half chopped alsike straw and one-half chopped alfalfa, while inferior to straight alfalfa, promoted satisfactory

gains and provided a satisfactory method of utilizing the straw. Chopping alfalfa hay proved profitable, reducing the feed requirement per unit of gain and increasing the rate of gain and dressing percentage of lambs as compared with long hay. Pea-vine silage could be used to good advantage, best results being obtained when 1 lb. of chopped alfalfa per head daily was fed as the supplement to the silage and barley ration. Wheat gave somewhat better results than barley which, in turn, was superior to oats as a grain supplement. Grinding grain for lambs was not a profitable practice. Alsike clover screenings, when added to the alfalfa-grain ration, improved the rate of gain. In general, about 200 lb. of alfalfa hay and 100 lb. of grain were required to convert a thin feeder lamb into a good market lamb in about 90 days.

Self-feeding vs. hand-feeding fattening lambs and rations for self-feeding lambs, G. A. BROWN and L. H. BLAKESLEE (*Michigan Sta. Spec. Bul. 303 (1940), pp. 27, figs. 6*).—The results of a series of feeding trials, involving 10 different feeding practices or combinations of feeds with a total of 1,091 feeder lambs, are summarized on the basis of rate and economy of gain over each of three 28-day experimental feeding periods and for the entire 84-day fattening period used in each trial. When alfalfa hay and shelled corn were self-fed v. hand-fed, the rate of gain was similar under the two systems with 44 percent hay and 56 percent corn comprising the ration in the former case and 54 percent hay and 46 percent corn in the latter. With hay priced at \$5, \$7.50, \$10, and \$12.50 per ton self-feeding proved more economical than hand-feeding when corn was worth not more than 42, 56, 71, and 85 ct. per bushel, respectively. Shelled corn and long alfalfa hay gave more economical gains than cracked corn with cut or ground alfalfa, although death losses were somewhat higher on the long hay. Cut hay was generally less satisfactory than ground hay. The use of linseed cake as a supplement to corn and alfalfa increased the rate of gain and decreased the death losses, though not sufficiently to justify its use economically. Free-choice feeding of corn, oats, bran, and linseed cake resulted in relatively more costly gains due to the heavy consumption of the linseed cake. Corn-and-cob meal and alfalfa hay promoted slightly slower gains than shelled corn and alfalfa or a mixture of shelled corn and ground alfalfa (8:2) plus alfalfa hay. Oat hulls had only about one-half the value of ground alfalfa as a bulking agent in the self-fed ration.

Cottonseed meal, hegari, and alfalfa hay for the fattening of lambs, P. E. NEALE (*New Mexico Sta. Bul. 272 (1940), pp. 14, figs. 2*).—A ration of alfalfa hay and hegari grain was compared with ground hegari fodder and hegari grain supplemented with varying amounts of cottonseed meal as rations for fattening lambs. Approximately 20 lambs per lot were fed for 83 days in trial 1 and 98 days in trial 2, with roughage fed ad libitum and approximately 0.95 lb. of concentrates allowed per head daily in all cases. The addition of 0.35–0.5 lb. of cottonseed meal per head daily to the fodder ration gave average gains closely approaching those on the alfalfa ration and at a lower cost per unit of gain than when smaller or larger amounts of cottonseed meal were fed. It is concluded that at least 0.35 lb. of cottonseed meal per head daily should be fed when ground hegari fodder is the only roughage, and that good alfalfa hay without a protein supplement is a better roughage for fattening lambs than hegari fodder supplemented with any amount of cottonseed meal.

Swine production, F. H. REED and H. E. WILSON (*Canada Dept. Agr. Pub. 686 (1940), pp. 56, figs. 23*).—A popular publication dealing with breeds and breeding and the feeding and management of swine under western Canadian conditions. The material is based, in the main, on results of experiments conducted at the Lacombe (Alta.) Station.

Initial trials with dried whey powder in rations for pigs, A. R. CALLAGHAN and V. R. McDONALD (*Jour. Dept. Agr. So. Austral.*, 43 (1940), No. 8, pp. 584-595, fig. 1).—A series of feeding experiments compared the following four rations for bacon pigs: (1) Wheat and skim milk, equal parts, 289 lb.; (2) wheat 373, meat meal 31.5; (3) wheat 363, dried whey 34; and (4) wheat 289, meat meal 24.5, dried whey 27 lb. Average daily gains per pig were 1.64, 1.21, 1.32, and 1.49 lb., and the amounts of dry matter consumed per pound of gain were 2.51, 3.58, 3.23, and 2.95 lb.. It is concluded that the addition of dried whey to wheat-meat meal mixtures will materially improve the efficiency of the ration and go far in providing a satisfactory substitute for skim milk. It appeared that under South Australian conditions the dry matter requirement for growing pigs is substantially lower than that recommended in commonly accepted feeding standards.

The function of nitrate, nitrite, and bacteria in the curing of bacon and hams, J. BROOKS, R. B. HAINES, T. MORAN, and J. PACE (*[Gt. Brit.] Dept. Sci. and Indus. Res., Food Invest., Spec. Rpt.*, 49 (1940), pp. VIII+32, figs. 2).—Based on the results of a series of experiments as described, the conclusion is reached that the characteristic cured flavor of bacon is due primarily to the action of nitrite on the flesh and that a satisfactory flavor can be produced by using only sodium chloride and sodium nitrite in the curing pickle. A satisfactory color and flavor was obtained with a relatively low nitrite content of the order of 10 p. p. m. in the lean tissue. The presence of nitrate or microbial action during curing did not prove essential for the development of bacon flavor. Advantages claimed for the direct use of nitrite in curing bacon included greater control of nitrite content in the finished product; greater latitude in the composition of the tank pickles to permit control of pH and the use of various flavoring ingredients; and a reduction in the microbial population on the surface, making possible a bacon that would keep better.

The use of tomatoes and tomato products in feeding fur animals, S. E. SMITH. (U. S. D. A., Cornell Univ., et al.). (*Amer. Fur Breeder*, 13 (1940), No. 2, pp. 26, 27, fig. 1).—A brief progress report.

A deficiency disease of foxes, R. G. GREEN and C. A. EVANS. (Univ. Minn. et al.). (*Science*, 92 (1940), No. 2381, pp. 154, 155).—A further description of a nutritive disorder, previously reported (E. S. R., 80, p. 386), which commonly occurs among foxes in captivity receiving 10 percent or more of fish in the diet and is apparently due to vitamin B₁ deficiency. Pathologically this disorder is the counterpart of Wernicke's disease or hemorrhagic poliоencephalitis of man.

The effect of controlled culling of chickens on the efficiency of progeny tests, I. M. LERNER and L. W. TAYLOR. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 11, pp. 755-763).—A population of White Leghorn pullets, including at least 50 daughters from each of 12 sires, was used in this study. The production and mortality of the progeny of the different sires over the first laying year are presented. A number of culling systems were applied to these data, including paper culling of 12, 18, 24, 30, and 36 percent of each family at the end of the laying year, and 12, 18, and 24 percent of each family in 3, 4, or 6 controlled cullings during the year. Based on statistical analyses of these data, it is concluded that when annual egg production and livability are the gross desiderata considered paper culling at the end of the year is of questionable value, and that no system of culling investigated gave greater differentiation between matings than the system used in calculating the production index (E. S. R., 80, p. 472). Controlled cullings as used enhanced the possibility of selecting superior sire families but at the same time decreased the precision in eliminating inferior families. Marked economies could be

effected by culling both in savings of feed and in conversion into meat of a large number of birds that would have died during the first laying year.

A statistical study of seasonal variation in the egg production of White Leghorn and Rhode Island Red chickens, R. G. MARTIN (*Philippine Jour. Anim. Indus.*, 7 (1940), No. 1, pp. 45-52, figs. 2).—An analysis of annual egg production records for the above-mentioned breeds over a 9-yr. period gave evidence that egg production followed a definite cycle under Philippine conditions, gradually rising from October to a peak in March and then gradually decreasing to a minimum in August. Maximum production was attained during the dry season, and minimum production during the wet season. A high positive coefficient of correlation was found to exist between annual egg production and that during the wet season, indicating the value of such short-time records for detecting good layers.

Summer management of pullets, D. C. KENNARD and V. D. CHAMBERLIN (*Ohio Sta. Bimo. Bul.* 205 (1940), pp. 119-121, fig. 1).—Practical suggestions are offered, with stress on the importance of adequate space in the brooder house, the value of isolated range for chicks and growing pullets, and the desirability of pasture as a part of the ration for growing birds.

Lability of metabolic processes in laying hens, C. F. WINCHESTER. (Mo. Expt. Sta.). (*Poultry Sci.*, 19 (1940), No. 4, pp. 233, 234, fig. 1).—A partial report of research noted from another source (E. S. R., 83, p. 672).

Seasonal metabolic rhythms in the domestic fowl, C. F. WINCHESTER. (Mo. Expt. Sta.). (*Poultry Sci.*, 19 (1940), No. 4, pp. 239-245, figs. 4).—A further report of research as noted above.

The utilization of food elements by growing chicks.—IX, The nitrogen of urea, C. W. ACKERSON, W. E. HAM, and F. E. MUSSEHL (*Nebraska Sta. Res. Bul.* 120 (1940), pp. 7).—Continuing this series of investigations (E. S. R., 82, p. 664), the effect of substituting a mixture of starch and urea for one-third of the protein concentrates in the basic ration on an equivalent nitrogen basis was determined in a growth and body-analysis experiment with day-old chicks. Chicks receiving urea gained at a slower rate and retained 12 percent less of the total nitrogen ingested than the control chicks. While the gain per gram of nonurea nitrogen fed was slightly greater in the urea-fed lot than in the control lot, it appeared that urea nitrogen was not utilized by chicks up to 6 weeks of age.

The ability of citrulline to replace arginine in the diet of the chick, A. A. KLOSE and H. J. ALMQUIST. (Univ. Calif.). (*Jour. Biol. Chem.*, 135 (1940), No. 1, pp. 153-155).—Continuing this line of investigation (E. S. R., 80, p. 89), the authors found that the addition of 1 percent arginine hydrochloride or 1 percent citrulline (prepared from ornithine) to a basal diet containing 20 percent casein promoted much more rapid gains in young chicks than were obtained on the basal diet alone or on the basal plus 1 percent ornithine. Citrulline was fully equal to arginine in this respect.

The complex nature of the alcohol precipitate factor required by the chick, A. E. SCHUMACHER, G. F. HEUSER, and L. C. NORRIS. (Cornell Univ.). (*Jour. Biol. Chem.*, 135 (1940), No. 1, pp. 313-320, fig. 1).—In a further report of these investigations (E. S. R., 82, p. 667), evidence is presented to indicate the requirement of the chick for two growth factors distinct from other factors now recognized as essential in chick nutrition. These two factors were found to be present in large amounts in dried yeast. Both were extracted with 0.24 N hydrochloric acid solution and separated by alcohol precipitation upon adjustment of the pH. One fraction, designated as factor R, was soluble in acid alcohol, while the other, factor S, was precipitated in this solution. Factor R was further purified by neutralization of the acid alcohol filtrate to give a neutral alcohol

precipitate. Either fraction, when added to the basal diet, stimulated more growth than was obtained on the unsupplemented diet but less than was obtained on a combination of the two factors in the diet. The possible identity of one of these factors and factor U of Stokstad and Manning (E. S. R., 80, p. 814) is suggested.

The effect of differing mash levels of alfalfa leaf meal in enhancing hatchability (*Rhode Island Sta. Rpt.* [1939], pp. 53, 54).—A further progress report (E. S. R., 81, p. 827).

A breed difference in the manganese requirement of laying hens, W. V. GOLDING, P. J. SCHAIBLE, and J. A. DAVIDSON. (Mich. Expt. Sta.). (*Poultry Sci.*, 19 (1940), No. 4, pp. 263-269, fig. 1).—In an experiment of 8 months' duration, two pens of White Leghorn pullets receiving the same basal ration but containing 9 and 50 p. p. m. of manganese, respectively, laid at 33- and 39-percent levels, with eggs having hatchabilities of 74.6 and 75.9 percent, respectively. No chondrodystrophy occurred in chicks from either group. In a second trial involving both White Leghorn and Barred Rock layers, the hatchability of Barred Rock eggs on each of two low-manganese basal rations was 59.7 and 58.7 percent as compared with hatchabilities of 81.3 and 81.6 percent when manganese supplement was added. As in the first trial, White Leghorns on the low-manganese diet produced eggs of approximately 75 percent hatchability, and the addition of manganese supplement improved hatchability but slightly. Chondrodystrophy was almost entirely confined to the Barred Rocks on the unsupplemented ration. It appeared that Barred Rocks were definitely more sensitive to a lack of manganese than the White Leghorns, and further that a manganese supplement to practical laying and breeding rations was desirable in the case of the former breed.

The influence of elemental sulphur upon chick growth and bone ash, O. E. GOFF and C. W. UPP. (La. Expt. Sta.). (*Poultry Sci.*, 19 (1940), No. 4, pp. 270-280, fig. 1).—Continuing the studies on the effects of sulfur in the chick diet (see p. 106), seven trials were conducted in which various levels and sources of sulfur were included in the diet along with supplements of cod-liver oil, molasses, and charcoal. The addition of 0.25 percent cod-liver oil (400 or more A. O. A. C. units of vitamin D) to rations containing from 0.5 to 5 percent commercial flour sulfur failed to promote normal bone calcification and growth in chicks to 8 weeks of age when confined in the absence of sunlight. Increasing the cod-liver oil to 0.5 percent from 8 to 12 weeks improved the rate of growth and generally prevented leg weakness, although bone ash values were below normal. In the presence of 0.5 percent cod-liver oil, greater gains were consistently obtained with 5 percent than with 2 percent or no commercial flour sulfur in the ration. However, with micronized sulfur or flowers of sulfur, better gains were obtained at 2- than at 5-percent levels. When over 4 percent sulfur was fed, best gains were obtained with the commercial flour sulfur, followed in order by 325-mesh sulfur, micronized sulfur, and flowers of sulfur, while at lower levels of intake results were similar except that flowers of sulfur gave greater gains than the micronized product. The addition of molasses or charcoal to the rations containing sulfur generally reduced the rate of growth, suggesting that the various sulfurs may not be compatible with these ingredients in chick rations.

Some observations on feeding dyes to laying chickens, C. A. DENTON. (U. S. D. A.). (*Poultry Sci.*, 19 (1940), No. 4, pp. 281-285).—Twenty-four dyes, including 9 water-soluble and 15 alcohol-soluble ones, were administered to laying pullets after egg yolk color had been depleted on a low pigment ration. The dyes were fed in capsules generally at the rate of 20 mg. per bird daily. All of the water-soluble and 8 of the alcohol-soluble dyes failed to be deposited in any part of the egg, while 7 of the alcohol-soluble ones were deposited in the yolk with varying

degrees of intensity. Color appeared in the yolk from 2 to 3 days after first feeding of the dyes, and in most cases yolk color diminished rapidly after dye feeding was discontinued. One dye, Hexyl Blue, stained all abdominal and external fat, and color was imparted to the egg yolk for an extended period after feeding was discontinued, indicating that this particular dye was withdrawn from body-fat depots and deposited in the yolk.

Some factors affecting variations in egg shell quality, L. A. WILHELM. (Wash. Expt. Sta.). (*Poultry Sci.*, 19 (1940), No. 4, pp. 246-253, figs. 3).—Data were recorded on the egg weight, dry weight of shell, percentage of shell, and shell thickness of eggs produced by an experimental flock of 40 White Leghorn pullets over a complete laying year (13 28-day periods). No significant difference was found to exist in egg weight or shell thickness between hens laying more than or less than 200 eggs during the year, indicating that shell thickness and rate of production are independent of each other. Also, there was only a slight decrease in shell thickness between the first and last egg laid in clutches of 1, 2, 3, or 4 eggs. A definite seasonal variation in shell thickness was definitely correlated with temperature, maximum thickness occurring in winter and minimum in midsummer. Shell thickness was significantly correlated with dry weight of shell and percentage of shell and was not independent of egg weight.

Percentage shell as a function of shell thickness, egg volume, and egg shape, V. S. ASMUNDSON and G. A. BAKER. (Univ. Calif.). (*Poultry Sci.*, 19 (1940), No. 4, pp. 227-232, figs. 3).—Data are presented on the weight and length-breadth index of whole eggs, the density of egg and of shell, and the weight and thickness of shell for eggs of ring-necked and silver pheasants, chickens, and turkeys. Ring-necked pheasant eggs had thinner shells than chicken eggs, which in turn were thinner shelled than the turkey or silver pheasant eggs. Analysis of the data indicated that at a constant shell thickness the shape of the egg had a negligible effect on the percentage of shell, although it decreased slightly with increasing relative breadth of the egg. However, the percentage of shell decreased significantly as volume or size of the egg increased. Within a species it was found that shell thickness had three times as great an effect in the opposite direction as the same relative change in volume on the relative change in shell percentage.

Dysfunction of the biliary system and hemorrhages in the gizzard of the chicken, A. I. LANSING and D. MILLER. (U. S. D. A.). (*Poultry Sci.*, 19 (1940), No. 4, pp. 258-262).—The results of 4 separate experiments are summarized. In a test with adult fowls the hepatic and cystic bile ducts were ligated in 4 birds and only the cystic duct in 3 others. From 5 to 21 days after this operation examinations revealed the presence of newly developed hemorrhages in the gizzards of 6 of the 7 birds. Examination of the bile system and gizzards of 85 1- and 2-day-old chicks showed considerable variation in the size of the gall bladders, and in 63 cases in which the cystic ducts contained no bile the severity of gizzard hemorrhages and erosions of their gizzards was much higher than in the 22 birds in which bile was present in the ducts, suggesting a relationship between gizzard hemorrhages and failure of the bile to pass from the gall bladder. Cholecystographic examinations of from 1- to 6-day-old and 3-week-old chicks tended to confirm this finding. A study of the effect of various feedstuffs on the biliary system revealed that when feed was withheld from chicks for 2 days the gall bladders were filled with dark-green bile and the ducts were generally emptied, as was the case when birds received singular feedstuffs, as casein, corn oil, or cornstarch for 7 days. Chicks receiving a normal diet for 4 days or more generally had flaccid gall bladders containing clear pale-green bile and the ducts contained bile.

Turkey production in Missouri, T. W. NOLAND (*Missouri Poultry Sta. Bul.* 41 [1940], pp. 17, figs. 8).—A practical handbook on the management of the turkey breeding flock, the production and incubation of eggs, the feeding and management of growing turkeys, and common turkey diseases.

DAIRY FARMING—DAIRYING

List of sires proved in dairy herd improvement associations, 1940 (*U. S. Dept. Agr., Misc. Pub. 393* (1940), pp. 240).—The present publication, which is the fourth list of the series (E. S. R., 82, p. 95), contains the names and summarized records of 3,183 sires whose records have been tabulated recently.

The value of sodium metaphosphate in detergent mixtures in the cleaning of milking machines, W. L. MALLMANN and C. S. BRYAN. (*Mich. Expt. Sta.*). (*Jour. Dairy Sci.*, 23 (1940), No. 7, pp. 621-627).—Surveys of milk supplies from producers using milking machines gave evidence of relatively high average bacteria counts, particularly where field inspection was inadequate. In controlled experiments in which normal machine cleaning methods were compared with cleaning with a detergent containing 20 percent sodium metaphosphate, the latter method prevented the formation of milkstone on both metal and rubber parts of the machine, while the control machines were heavily coated with milkstone. Milk of lower bacteria count was produced with the machines free from such deposits.

Contamination of milk from internal and external sources, L. W. JONES (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 3, pp. 8, 9, fig. 1).—A general discussion, indicating that contamination can practically be eliminated by keeping the cow clean, using a narrow-topped pail, sterilizing equipment, and adequate cooling.

Cooling milk at the farm, with special reference to modern electric milk coolers, J. E. NICHOLAS. (*Pa. State Col.*) (*Milk Plant Mo.*, 29 (1940), No. 7, pp. 23-27, figs. 8).—Data are presented on the rate of cooling of milk at different levels in a 10-gal. can when the can is submerged in the cooling medium. These data emphasize the importance of submerging the can below the milk level and of low temperature and agitation of the cooling medium to insure rapid and uniform cooling of the milk. The cooling of milk over a 50° F. range was accomplished in an electric milk cooler with an expenditure of energy of only slightly more than 1 kw.-hr. per 10-gal. can.

Old and new bacteriological analyses, E. G. HASTINGS. (*Univ. Wis.*), (*Amer. Milk Rev.*, 2 (1940), No. 4, pp. 82, 83, 88).—A critical comparison of the old and new standard methods for milk analysis in which the value of the newly adopted method is questioned.

Lipolysis in raw milk: Influence of homogenization temperature, I. A. GOULD. (*Mich. State Col.*). (*Indus. and Engin. Chem.*, 32 (1940), No. 6, pp. 876, 877, fig. 1).—Mixed herd samples of raw milk were heated to temperatures of 70°, 105°, 115°, 125°, 135°, and 145° F., then homogenized at 1,500-lb. pressure and cooled to 40°. Subsamples were then prepared, one of which was immediately pasteurized to prevent further lipolysis, the other held for 72 hr. and then pasteurized. Titration of purified fat samples from the various lots of milk for free fatty acids gave evidence that the heated samples underwent lipolysis in every case, with maximum fat splitting occurring within the temperature range from 105° to 125°. Samples homogenized at 70° showed only slight fat splitting, and temperatures of from 135° to 145° inhibited but did not entirely prevent lipolysis accelerated by homogenization.

A review of oxidation in milk and milk products as related to flavor, W. C. BROWN and L. M. THURSTON. (W. Va. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 7, pp. 629-685).—A comprehensive review with 412 references to the literature.

Oxidized flavor in milk.—II, The relation of oxidation-reduction potentials to its development, A. M. SWANSON and H. H. SOMMER. (Univ. Wis.). (*Jour. Dairy Sci.*, 23 (1940), No. 7, pp. 597-614, figs. 8).—Continuing these investigations (E. S. R., 83, p. 392), studies were conducted on the effect of various catalysts and antioxidants on the oxidation-reduction potential and flavor of pasteurized milks. The addition of copper to whole milk, skim milk, or cream was followed by a marked increase in oxidation-reduction potential and a subsequent development of oxidized flavor, the intensity of this flavor being greater in cream than in whole or skim milk. Approximately 10 times as much ferrous iron as copper was required to produce the same intensity of off-flavor in milk, and the presence of the iron caused oxidation-reduction potential to decrease. Ferric iron in milk caused a slow increase in oxidation-reduction potential but induced little or no oxidized flavor. Either crystalline ascorbic acid or crystalline *d*-isoascorbic acid when added to milk lowered the oxidation-reduction potential. The former inhibited the development of oxidized flavor, but the latter had little effect in this respect. Also passing electric current through the milk lowered the oxidation-reduction potential but failed to inhibit oxidized flavor. It is concluded that the Eh of the medium did not accelerate or inhibit the development of this off-flavor.

The relation of metals and their alloys to the flavor of milk, C. L. ROADHOUSE. (Univ. Calif.). (*Amer. Milk Rev.*, 2 (1940), No. 5, pp. 106, 107).—A summary of research previously noted (E. S. R., 83, p. 393).

Cream neutralization, N. E. FABRICIUS. (Iowa State Col.). (*Amer. Butter Rev.*, 2 (1940), No. 6, pp. 202-204, fig. 1).—A comprehensive discussion of the purposes of and proper procedures for this operation in buttermaking.

The relationship between the melting time of butterfat and its melting point, W. D. GALLUP and A. H. KUHLMAN. (Okla. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 7, pp. 593-595, fig. 1).—Employing the method previously described (E. S. R., 78, p. 151), further data have been obtained which confirm the previous finding that the melting time of butterfat is roughly proportional to its melting point. By means of a curve the melting time of butterfat samples may be closely approximated from melting point determinations.

The effects of various feeds on the milk fat constants and on the flavor and texture of butter, F. H. HERZER, J. S. MOORE, and W. C. COWSERT (*Mississippi Sta. Tech. Bul.* 25 (1939), pp. 62, figs. 8).—The results of a series of experiments extending over a number of years and involving the use of many feeding stuffs are summarized. A preliminary comparison of the physical and chemical characteristics of butter originating in Mississippi and in Minnesota showed the melting point and the heat resistance of Mississippi butter to be consistently higher than that of Minnesota butter. The refractive index and the Reichert-Meissl and iodine numbers of Mississippi butter did not follow the decided seasonal trends of the Minnesota butter. Trials involving comparisons of alfalfa hay with Johnson grass, Bermuda grass, soybean, lespedeza, and Sudan grass hays showed no significant trends in the effect of these dry roughages on the quality of butter. Silage had a beneficial effect on butter texture, with corn silage and sorghum silage exerting similar effects. The inclusion of cottonseed hulls in the ration quickly increased the melting point and produced a hard gummy butter. Cottonseed meal and cottonseed oil in the ration raised the melting point, refractive index, and iodine number, and increased the firm-

ness and gumminess of the butter. Both products decreased the Reichert-Meissl number, particularly the latter. Extracted cottonseed meal did not increase the melting point or iodine number and, while increasing firmness, did not increase the gumminess of the butter. Soybean meal in combination with cottonseed meal largely counteracted the hard texture typical of butter produced under cottonseed meal feeding. The resulting butter was superior to that produced when either protein concentrate was fed singly. Cured sweetpotatoes in the ration gave a butter of high Reichert-Meissl number and low iodine number, a very firm texture, and pleasing flavor. Dried sweetpotato pulp gave a butter of low iodine number and a firm, hard dry texture. The predominance of the Jersey breed is considered a contributing factor to the firm butter typical of the area. It is pointed out that firmer butter, to a moderate degree, is desirable to the South in plant processing, in shipping, and on the consumer's table during the warm months.

The incubation test as an indication of the keeping quality of butter, H. B. NAYLOR and E. S. GUTHRIE ([*New York*] *Cornell Sta. Bul.* 739 (1940), pp. 19).—Butters obtained from 10 churnings of sweet cream made under carefully controlled sanitary conditions in the laboratory and from 28 commercial churnings in 4 different creameries were subjected to the incubation test in an attempt to predict keeping quality. Both unsalted and salted samples were obtained from each churning. Flavor score, pH, and total and caseolytic bacterial counts were determined on both the salted and unsalted butters when fresh, after 7-14 days' incubation at 60° F., after 2-5 months' storage at 0°, and after 10 days at 60° following the cold storage. The tests proved fairly reliable in indicating the keeping quality of the sweet cream butters prepared in the laboratory. Unsalted and mildly salted butters had similar keeping qualities. Very little loss in flavor score occurred during any of the incubation periods. The pH of the salted sweet cream butter averaged somewhat lower than that of the unsalted lots, while in both lots pH remained practically constant throughout the observation period. The test was also fairly reliable in predicting keeping quality of the commercial butters, although some exceptions occurred. Loss in flavor score was accompanied by a decrease in pH during the incubation period for all samples of unsalted butter. The pH of the salted samples remained quite constant. It appeared that proteolytic Gram-negative rod types of bacteria were largely responsible for the deterioration of unsalted butters.

Factors affecting the quality of Limburger cheese made from pasteurized milk, M. W. YALE (*New York State Sta. Tech. Bul.* 253 (1940), pp. 28, figs. 5).—Following the method of manufacture commonly used for producing Limburger cheese from raw milk, experimental cheeses were made in July, August, and October from 10 lots of milk ranging in bacterial count from 400,000 to 90,000,000 per cubic centimeter. Forty lots of cheese comprising 172 1-lb. loaves were made from the raw milk or milk which had been heated to 145° F. for 0, 10, 15, 20, or 30 min. The cheeses were analyzed and graded for quality after suitable ripening periods. Either partial or complete pasteurization improved the quality of cheeses made from poor quality milk in July and August, but not the quality of cheeses made in October from better quality milk. Holding at pasteurization temperature for 30 min. gave as good results as any of the shorter holding periods. Cheese from pasteurized milk was generally milder in flavor than raw milk cheese. A more pronounced flavor usually occurred in pasteurized milk cheese when no starter was used. The grade of the cheese was sometimes, though not always, improved by the addition of from 0.05 to 0.1 percent of lactic starter. It is concluded that pasteurization of milk for the manufacture of Limburger cheese results in a product of uniformly good quality when the proper manufacturing method is followed.

Effect of heat and pH on the inactivation of rennin in whey, E. B. STRUBLE and P. F. SHARP. (Cornell Univ.). (*Jour. Dairy Sci.*, 23 (1940), No. 7, pp. 587-591, fig. 1).—Samples of clarified whey were treated with hydrochloric acid or sodium hydroxide to give a pH range from below 1.0 to 7.0. Commercial rennet extract was added to the whey samples which were then heated to temperatures of 120°, 130°, 145°, and 158° F. for 2, 6, 10, and 14 min. After heating and cooling, all samples were adjusted to pH 6.0-6.5, after which the milk-coagulating power of the whey was determined. The zone of maximum stability of the milk-coagulating power of the rennet when heated to 120° or above centered at pH 4.0. The pH inactivation curves were nearly symmetrical both above and below pH 4.0. Alterations of one pH unit included approximately the complete inactivation effect. It appeared that normal amounts of rennet can be inactivated by holding at 50° C. (122° F.) for 14 min. at pH 6.8 to 7.0.

Homogenization, C. D. DAHLE and C. M. MOSS. (Pa. Expt. Sta. et al.). (*Ice Cream Trade Jour.*, 36 (1940), No. 6, pp. 18, 19, 63-65, figs. 4).—Two rotary-type and one joint-valve, pressure-type homogenizers were compared for the homogenization of ice cream mixes. Pressures of 750 lb. on the rotary-type machines and 2,000 lb. on the standard-type machines gave very similar results with reference to size of fat globules in the homogenized mix, the time required to obtain 90-percent overrun in freezing, and the texture score of the frozen product. The temperature rise of the product during homogenization varied as follows: Pressure machine (2,000 lb.), 5° F.; rotary No. 1 (750 lb.), 7°; and rotary No. 2 (750 lb.), 25°.

A comparative evaluation of an ice cream supply as it reaches the consumer, L. K. CROWE and P. A. DOWNS. (Nebr. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 7, pp. 615-620).—Samples of vanilla ice cream representative of 19 different plants were purchased on the open market in consumer-size packages and examined for weight, overrun, chemical composition, bacteria count, and flavor and body score. Reasons for the difference in price level, which ranged from 15 to 30 ct. per pint, were not apparent on the basis of these criteria. Only slight differences in average composition and score were evident for groups of samples averaging 15, 20, and 25 ct. per pint in cost. The average net weight was lowest for the 15-ct. lot and highest for the 25-ct. lot, but the quantities of total solids or calories purchased per unit cost favored the low-price samples. Calories per unit cost were materially greater in fountain-dipped packages than in the factory-filled cartons. It is suggested that studies of this nature carried out at intervals of 6 mo. or 1 yr. would tend to bring to the consumer a more uniform product and establish a sound basis for differences in price per unit quantity.

VETERINARY MEDICINE

American veterinary history, I-IV, B. W. BIERER ([Baltimore]: Author, [1940], vols. 1-4, pp. [129]).—This history of veterinary medicine in America is presented in four parts, each of which includes a list of references to the literature, a total of 374.

Handbook of histological and cytological technique, R. R. and S. H. BENSLEY (*Chicago: Univ. Chicago Press* [1938], pp. VIII+167).—The first part of this work, consisting of 5 chapters (pp. 1-30), deals with technics for the study of fresh tissues and the second part, consisting of 16 chapters (pp. 31-158), with technics for the study of fixed tissues. A list of 20 references to the literature and an index are included.

Clinical parasitology, C. F. CRAIG and E. C. FAUST (*Philadelphia: Lea & Febiger*, 1940, 2. ed., rev., pp. 772, figs. 244).—A thoroughly revised and enlarged edition.

Notes on the preparation of papers for publication in the *Journal of Hygiene and in Parasitology*, G. H. F. NUTTALL (*Parasitology*, 32 (1940), No. 1, pp. 1-7).

[Work in animal pathology by the Arizona Station] (*Arizona Sta. Rpt. 1939*, pp. 96, 97).—The work of the year (E. S. R., 82, p. 249) briefly referred to includes bacteriological studies on infectious keratitis in cattle and goats, plants poisonous to range livestock, the use of sodium iodide injections in the treatment of actinomycosis, derris root solution for control of common cattle grub larvae in cattle, and control of death losses in young calves brought in from ranges and placed on alfalfa pastures by the feeding of dry hay.

[Work with animal diseases by the Rhode Island Station] (*Rhode Island Sta. Rpt. [1939]*, pp. 54-56).—The work reported upon (E. S. R., 81, p. 834) includes infectious coryza, infectious bronchitis, and autopsy examinations of fowl and swine.

[Contributions on animal pathology and parasitology] (*Onderstepoort Jour. Vet. Sci. and Anim. Indus.*, 12 (1939), No. 2, pp. 279-318, 335-366, figs. 12).—Contributions presented (E. S. R., 82, p. 817) include the following: The Use of Saponin Spore Vaccine for Inoculation Against Anthrax in South Africa, by M. Sterne, E. M. Robinson, and J. Nicol (pp. 279-302); Observations on the Life-History of *Bunostomum trigonocephalum*, a Hookworm of Sheep and Goats, by R. J. Ortlepp (pp. 305-318); and Recent Investigations Into the Toxicity of Known and Unknown Poisonous Plants in the Union of South Africa, IX, by S. J. van der Walt and D. G. Steyn (pp. 335-366) (E. S. R., 80, p. 540).

Livestock poisoning by oat hay and other plants containing nitrate, W. B. BRADLEY, H. F. EPPSON, and O. A. BEATH (*Wyoming Sta. Bul. 241* (1940), pp. 20, figs. 2).—The many cases of poisoning in Wyoming during the past 5 yr. resulting from the ingestion of oat hay and straw, largely by cattle, led to the work here reported. High concentrations of potassium nitrate (saltpeter) were found to be the cause of the poisonous properties sometimes shown by oat hay and straw. "After the ingestion of one-fourth of a gram or more of saltpeter per pound of body weight, cattle develop sufficient methemoglobinemia to cause their death. This methemoglobinemia is probably produced by nitrite which is formed from the nitrate in the gastrointestinal tract. It has been found that sheep and horses may also be poisoned by forages containing high concentrations of nitrate, although practically all reported losses have been of cattle. Methylene blue in doses of 2 gm. per 500 lb. of animal injected intravenously, immediately counteracts the effect of this ingested nitrate by converting the methemoglobin into normally functioning hemoglobin. Other plants such as wheat, barley, sorghums, corn, and weeds may sometimes contain enough nitrate to be poisonous. The concentration of nitrate in the soil is one factor which determines the amount of nitrate in the plants. Whether this is the only factor is not known."

Nutlets of *Amsinckia intermedia* toxic to swine, horses, and cattle, E. C. McCULLOCH. (Wash. Expt. Sta.). (*Madroño*, 5 (1940), No. 6, pp. 202, 203).—Wheat screenings containing nutlets of *A. intermedia*, a plant which grows abundantly in grain fields in certain semiarid regions of Washington, Oregon, and Idaho, proved toxic to nine pigs, three horses, and one of three calves to which they were fed. Hepatic cirrhosis developed, the parenchymal cells of the liver being destroyed and replaced by connective tissue. In cattle and swine the condition is known locally as hard liver, in horses as walking disease because of their tendency to wander aimlessly. As a result of its toxic effect in certain limited regions, the raising of swine and horses has been largely abandoned. It is probable that sublethal poisoning is much more widespread, occurring in those areas where the species is only moderately abundant.

Studies in chronic selenosis, M. I. SMITH, R. D. LILLIE, E. F. STOHLMAN, and B. B. WESTFALL (*U. S. Pub. Health Serv., Natl. Inst. Health Bul. 174 (1940)*, pp. V+49, pls. 3, figs. 6).—The several parts of this report deal with the chronic toxicity of naturally occurring food selenium, gastric acidity in chronic selenium poisoning, liver function and bile pigments in experimental chronic selenium poisoning, and selenium in the hair as an index of the extent of its deposition in the tissues in chronic poisoning.

A simple method for preparing antigenic substances from the typhoid bacillus, J. W. PALMER and T. D. GERLOUGH (*Science, 92 (1940)*, No. 2381, pp. 155, 156).—The authors applied to pneumococci and to dried typhoid bacilli (*Eberthella typhosa*) a method of extraction with concentrated phenol which dissolved associated proteins and left capsular polysaccharides in the residue. The polysaccharides soluble in phenol were similarly purified by fractional precipitation from phenol solutions by alcohol or glacial acetic acid. Applied to typhoid organisms this method yielded a substance, probably still crude in nature, which was highly antigenic in mice. The details of the method are given. The antigens obtained were found to be toxic.

The treatment of certain experimental anaerobic infections with sulfapyridine and with immune sera, and the problem of synergic action, D. W. HENDERSON and P. A. GORER (*Jour. Hyg. [London], 40 (1940)*, No. 3, pp. 345-364).—In experiments with sulfapyridine administered against anaerobic infections, it was found to be an efficient prophylactic or therapeutic agent for use against intradermal infection with the strain of *Vibrio septique* that was selected for the test, whereas in intramuscular infection it is unreliable and saves only a relatively small proportion of animals. The strain of *Clostridium welchii* (type A) selected for test is not insusceptible to the action of this drug. "A significant degree of protection against intradermal infection may be obtained, however, only when a prophylactic dose of the drug is given. The drug is apparently without action against intramuscular infection with this strain. Under the particular experimental conditions sulfanilamide is much less effective than sulfapyridine against infection with either *V. septique* or *C. welchii*. There is no evidence that sulfapyridine given per os neutralizes the toxins of *V. septique* or *C. welchii* injected intravenously. It is possible to control infection with *V. septique* by antitoxin or antibacterial serum given at a time when sulfapyridine is of little use. *C. welchii* antitoxin has a marked therapeutic effect in infection with this strain of the organism, but sulfapyridine given only after infection is apparently without action on the course of the disease. In intradermal infection with *V. septique* the combined action of sulfapyridine and antitoxin or of sulfapyridine and antibacterial serum effects a saving in life much greater than would be expected if a mere summation effect was in question. A similar effect was observed in intramuscular infection provided the administration of the drug was sufficiently prolonged. No such synergic effect is produced by the combined action of antitoxic and antibacterial serum. In *C. welchii* infection the combined action of antitoxin and sulfapyridine produces a noticeable synergic effect, but the evidence on this point is less clearly defined. The pathogenesis of infection with spore-bearing anaerobes is discussed in relation to prophylaxis or therapy with chemotherapeutic agents, antitoxin, antibacterial serum, and combinations of such."

Anthelmintic activity of fresh pineapple juice, J. BERGER and C. F. ASENJO. (Univ. Wis.). (*Science, 90 (1939)*, No. 2335, pp. 299, 300).—Living specimens of *Ascaris lumbricoides* and *Macracanthorhynchus hirudinaceus*, obtained from hog's intestines, were incubated at a temperature of from 35° to 40° C. with

pineapple juice freshly squeezed from a Cuban pineapple. At the end of 24 hr. both parasites were completely digested, while controls incubated in heat-inactivated pineapple juice and in saline solution were very lively and active. The results obtained indicate that the juice possesses enzymatic activity similar in nature to that of some *Ficus* latexes, and therefore there is some scientific basis for its use as an anthelmintic. Reference is made to the findings of B. H. Robbins,² A. J. Walti,³ and others that the enzyme ficin which they obtained from some of these latexes was the active agent responsible for the digestion of the parasites.

Anthelmintic inactivity of fresh pineapple juice in vivo, E. KUITUNEN-EKBAUM (*Science*, 91 (1940), No. 2358, pp. 240, 241).—The author reports upon observations which have failed to support the findings of Berger and Asenjo, as above noted, that fresh pineapple juice may be of value as an anthelmintic.

Anthelmintic activity of crystalline papain, J. BERGER and C. F. ASENJO. (Univ. Wis.). (*Science*, 91 (1940), No. 2364, pp. 387, 388).—In continuing the studies noted above, the authors found a commercial preparation of papain (Merck) to possess strong worm-digesting activity. "A 0.7-percent solution of dried preparation of M/18 phosphate-phthalate buffer pH 5 digested *Ascaris lumbricoides* (obtained from hog intestines) almost completely in 17 hr., while a 0.07-percent solution also showed some activity. Since this preparation had been on hand several years, a fresh sample was analyzed and found to have approximately the same activity. *Macracanthorhynchus hirudinaceus* (from hog intestine) was not digested by a 0.7-percent solution of either of these papain preparations, but was digested by fresh pineapple juice."

The bacteria-free culture of a nematode parasite, R. W. GLASER (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 3, pp. 512-514).—An account is given of a method by which a bacteria-free culture of a nematode parasite may be obtained. Since by this method the parasitic nematode can be "grown on both liquid and solid media free from bacteria, it will be possible to study its nutritional and other requirements and to test the effects of various vitamins and hormones."

Diplogynia americana, a new species of cestode (Hymenolephidiidae) from the eastern little green heron (*Butorides virescens virescens* (Linn.)), O. W. OLSEN. (Minn. Expt. Sta.). (*Amer. Micros. Soc. Trans.*, 59 (1940), No. 2, pp. 183-186, figs. 6).

Strains in Giardia ondatrae Travis 1939, P. C. WATERS, A. R. FIENE, and E. R. BECKER. (Iowa Expt. Sta.). (*Amer. Micros. Soc. Trans.*, 59 (1940), No. 2, pp. 160-162, fig. 1).—A study of *G. ondatrae* of the small intestine of the muskrat (*Ondatra zibethica*) revealed strains with significant size differences but practically identical contours.

A pathogenic agent of the genus Rickettsia found in Haemaphysalis bispinosa Neumann from a deer in Cochinchina (Cochinchina) [trans title], J. MESNARD and C. TOUMANOFF (*Compt. Rend. Acad. Sci. [Paris]*, 210 (1940), No. 10, pp. 378-380).—The authors report upon a species of *Rickettsia*, pathogenic for the guinea pig, that was isolated from *H. bispinosa* taken from a deer (*Cervus (Rusa) unicolor* Cuv.) in Cochinchina.

Biochemical and serological studies of microorganisms of the Salmonella cholerae-suis group, D. W. BRUNER and P. R. EDWARDS (*Kentucky Sta. Bul.* 404 (1940), pp. 289-303).—Studies of the *S. choleraesuis* (*S. suipestifer*) group of pathogenic bacteria have shown the *kunzendorf* variety to be the predominant type among these bacilli in the United States, *S. choleraesuis*, which for-

² Jour. Biol. Chem., 87 (1930), No. 2, pp. 251-257, fig. 1.

³ Jour. Biol. Chem., 119 (1937), No. 1, p. CI.

merly predominated, now being found only occasionally. "By the use of the Wassén technic, it was possible to isolate specific components from all the *kunzendorf* strains examined. Three cultures of the *kunzendorf* type were found to occur naturally in the diphasic state. *S. typhisuis*, *S. typhisuis* var. *voldagsen*, and *S. paratyphi* C were not found among cultures isolated in the United States. Biochemical tests were of great value in identifying the bacilli. The failure of the cultures to ferment arabinose, trehalose, and inositol served to distinguish them from other *Salmonella* types. Micro-organisms of the *S. choleraesuis* group were found not only in hogs but in man, foxes, cattle, dogs, chickens, and canaries. In addition to the *S. choleraesuis* group, numerous other *Salmonella* types occur in hogs."

Benefits of eradicating Bang's disease, J. R. MOHLER, A. E. WIGHT, and E. LASH (*U. S. Dept. Agr., Misc. Pub. 384* (1940), pp. [1]+18, figs. 6).—The status of Bang's disease eradication and the benefits to be derived are outlined in this publication.

Studies with *Clostridium chauvoei* (blackleg) aggressin, I. LIVE (*Jour. Immunol.*, 39 (1940), No. 2, pp. 137-162).—Natural aggressin, culture filtrate, and sonic extract of *C. chauvoei*, the strictly anaerobic, spore-forming organism causing the highly infectious blackleg disease of young cattle and sheep, reduced phagocytosis in vitro when present in the phagocytic mixtures. "By allowing the aggressin to act upon serum and upon leucocytes, it was shown that the inhibition of phagocytosis was due to fixation of opsonins and not to a direct action upon the leucocytes. The agglutinative titers of two antisera were diminished when the different dilutions of the sera were mixed with equal quantities of aggressin, filtrate or extract and incubated for 1 hr. prior to setting up the test. Three pairs of rabbits were immunized by intravenous injection of washed suspensions of live organisms, formalin-killed organisms, and culture filtrate, respectively. The antisera thus produced were used in complement-fixation and precipitative tests, and they all gave positive reactions with culture filtrates, natural aggressin, and extracts of *C. chauvoei*. The fact that suspensions of washed organisms free of by-products of growth, and particularly suspensions of washed formalin-killed organisms, stimulated the production of antibodies which reacted with antigen in aggressin and filtrate proves that the latter contain soluble material derived from disintegration of the bacterial cells."

A list of 50 references to the literature is included.

Serological studies with black-leg aggressin, I. LIVE (*Jour. Bact.*, 39 (1940), No. 6, pp. 753, 754).—This is an abstract of a contribution on serological studies with blackleg aggressin, which included phagocytosis, agglutination, complement-fixation, and precipitation tests, that were undertaken to determine whether the immunizing potency of blackleg aggressins could be ascertained in vitro. It was found by phagocytosis experiments that the aggressins had an inhibitory influence which was due to antiopsonic action and not to direct effect upon the leucocytes. "The reduction in phagocytosis was proportional to the quantity of aggressin used. The action of aggressin upon an immune serum did not impair the agglutinating property of the serum. Complement-fixation and precipitation tests demonstrated that the quantity of autolyzed bacterial substance present in an aggressin could be determined by the use of antisera produced in response to injections of washed live, as well as formalin-killed, suspensions of *Clostridium chauvoei* and of aggressin. Injections of a filtrate of sonically disintegrated *C. chauvoei* into guinea pigs protected the animals against subsequent infection. These findings, coupled with the fact that killed bacterial cells, free of any aggressin, are known to immunize effi-

ciently against blackleg, would strongly suggest that the autolysates of the organisms present in blackleg aggressins are responsible for the immunizing quality of the latter. Thus, the concentration of dissolved bacterial substance in blackleg aggressins could be evaluated by means of the complement-fixation and precipitin tests."

[Internal parasites of sheep] (*Georgia Sta. Rpt. 1940, p. 47*).—Reference is again made (E. S. R., 82, p. 822) to the station work on important parasites of sheep, including the stomach worm (*Haemonchus contortus*), the nodular worm (*Oesophagostomum columbianum*), and tapeworms, and means of control.

Effect of phenothiazine on the development of roundworm larvae in the feces, D. A. SHORB and R. T. HABERMANN. (U. S. D. A.). (*Vet. Med.*, 35 (1940), No. 8, pp. 454-457).—The administration of phenothiazine in gelatin capsules to one sheep at the rate of 7 gm. per day for 3 days and to two other sheep at the rate of 0.5 gm. per day in the feed for 7 and 9 days, respectively, completely inhibited the development of nematode larvae, with the exception of *Strongyloides papillosus*, in cultures made from the feces of these animals. "This inhibition of larval development was manifested in the culture made from the feces 48 hr. after the administration of the first dose of phenothiazine and continued for 48 hr. after the last dose had been given. The number of *Strongyloides* larvae was reduced. When administered at the rate of 0.25 gm. per day in the feed, phenothiazine failed to inhibit larval development. Phenothiazine mixed thoroughly with sheep feces containing *Haemonchus contortus* eggs only, at the rate of 1 percent by weight, inhibited the development of all larvae. When mixed with feces in amounts of less than 1 percent, larval development was retarded."

Primary encephalomyelitis in goats associated with *Listerella* infection, L. S. KING (*Amer. Jour. Pathol.*, 16 (1940), No. 4, pp. 467-478, pls. 3).—In a series of nine goats spontaneous encephalitis associated with *Listeria* (*Listerella*) infection (see E. S. R., 83, p. 541) was observed. "Pathologically the lesions were essentially restricted to the brain stem, especially the medulla and spinal cord. Peripheral nerves and ganglia were inconstantly affected. There was an associated meningitis. The primary parenchymal lesion is a circumscribed focal collection of mononuclear cells (with or without an admixture of a few neutrophilic leucocytes) in close relation to a blood vessel. The infection is very fulminating. Diffuse tissue infiltration may supervene, sometimes with the formation of small abscesses, but these are secondary and late phenomena. The blood vessels show marked degenerative changes, coupled with cellular infiltration of the walls and adventitia. Bacteria can frequently be demonstrated histologically in the parenchymal lesions. Nerve cells may be destroyed, but there is relatively little tissue necrosis."

Data on experimental transmission and pathogenesis are briefly discussed. The similarity to rickettsial encephalitis and cerebral toxoplasmosis is pointed out. A list of 31 references to the literature is included.

Production and immunological studies on toxic substances produced by streptococci isolated from equine encephalomyelitis, G. T. KENSLEE. (Purdue Univ.). (*Jour. Bact.*, 39 (1940), No. 5, p. 631).—Streptococci isolated from the brain of horses having fatal infections of equine encephalomyelitis were capable of producing toxic substances when grown in vitro on a suitable medium. "These substances were found to be filtrable and were titratable on white mice and 12-day-old chick embryos. Their toxic action could be counteracted by either formalin or specific immune serum, as shown by in vivo tests. Filtrates containing these toxic substances when formalinized and used as antigens induced the development of a degree of immunity in an inbred strain of

white mice which agreed favorably with that induced by chick embryo vaccine. Immunity was determined by the intracranial injection of varying minimum lethal doses of the western strain of equine encephalomyelitis virus." Strains of streptococci isolated from poliomyelitis could likewise produce toxic substances when cultivated in vitro. These were similar to those produced by equine encephalomyelitis streptococci, and were rendered atoxic by the use of specific immune or antistreptococcus poliomyelitis serum.

The effect of hookworm infestation on the coagulation time of dogs' blood, M. GREENSAFT and R. SPENCER (*Vet. Med.*, 35 (1940), No. 8, pp. 462, 463).—In the course of study of 30 stray dogs collected at random, it was found that 36.6 percent were infested with hookworms. The average coagulation time of the infested dogs was 44 percent longer than the average of the noninfested dogs.

Fleas as acceptable intermediate hosts of the dog heartworm *Dirofilaria immitis*, W. A. SUMMERS (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 3, pp. 448-450).—The dog flea, the cat flea, and the human flea, collected from dogs harboring *D. immitis*, have been found by the author to be naturally infected with the microfilarial and larval stages of this parasite. "The female fleas seemed much more susceptible to the infection than the males. All three species of fleas have been experimentally infected, and in all three the extra-mammalian phase of the life cycle has been completed. The time required for this development in fleas was 120 hr. in warm weather and 216 hr. in cold weather. This phase of the life cycle was more rapidly achieved in fleas than in mosquitoes. It appears that both biologically and epidemiologically fleas are more suitable intermediate hosts of *D. immitis* than had been previously supposed."

Coccidiosis of domesticated animals and fowls, J. L. WEST. (Ala. Polytech. Inst.). (*Jour. Amer. Vet. Med. Assoc.*, 96 (1940), No. 758, pp. 603-606).

The effect of *Eimeria tenella* (coccidia) upon the blood sugar of the chicken, I. PRATT. (Univ. Idaho). (*Amer. Micros. Soc. Trans.*, 59 (1940), No. 1, pp. 31-37).—In studies of *E. tenella* in Idaho, a severe coccidiosis caused a marked rise in the blood sugar of the chicken by the sixth day after infection. "Starving the chickens for 19 hr. before making the determinations caused the blood sugar level to be lower than that in chickens on feed, but did not prevent the marked rise during acute coccidiosis. Withdrawal of large quantities of blood from the hearts of normal, uninfected chickens caused their blood sugars to increase approximately the same amount as did coccidiosis in other chickens. Starvation of uninfected chickens for 72 hr. did not cause a marked rise in blood sugar. The loss of blood from the cecal pouches of the chicken during the acute stage of coccidiosis probably caused the marked increase in blood sugar at that time."

Effect of four grades of sulphur upon artificially produced coccidiosis: Preliminary report, O. E. GOFF and C. W. UPP. (La. Expt. Sta.). (*Poultry Sci.*, 19 (1940), No. 3, pp. 180-186).—The authors outline a technic for the preparation and evaluation of cultures of coccidia. The data obtained indicate that "each of the four grades of sulfur tested, namely, flowers of sulfur, commercial flour sulfur, 325-mesh sulfur, and micronized sulfur, has value in preventing coccidiosis mortality. No accurate evaluation of the protective value of each sulfur grade was made, but data indicate that of the ground crude sulfurs, the finer the grind the greater the effectiveness. Commercial flour sulfur retarded growth less than other grades of sulfur and gave the least protection from coccidiosis. The addition of poultry charcoal in the amount of 5 percent to rations containing 5 percent sulfur apparently enhanced the pro-

tective value of the rations. Regardless of the grade or amount of sulfur fed, chicks inoculated with coccidia produced oocysts which were viable, would sporulate, and produce clinical evidence of the disease. The use of elemental sulfur in the prevention of coccidiosis remains in the experimental stage, and recommendations for its use are not presented."

Immunity to fowlpox studied by means of skin grafts on chorioallantois of chick embryo, E. W. GOODPASTURE and K. ANDERSON (*Arch. Pathol.*, 30 (1940), No. 1, pp. 212-225, figs. 2).—Experiments reported conclusively proved that "the epithelial cells of skin from chickens with acquired immunity to fowl pox, and completely resistant to infection by cutaneous inoculation while a part of the immunized host, become quite susceptible to infection by this virus after being grafted onto the chorioallantoic membranes of chick embryos. If such grafts, as well as grafts from normal chickens, were regrafted on muscle of immune chickens and inoculated, no infection took place. Normal skin, on the other hand, when regrafted on the muscle of normal chickens was quite susceptible to infection by inoculation. These experiments therefore gave no indication that acquired immunity was inherent in the epithelial cells themselves, but pointed rather to humoral or local factors in other tissues as the cause of the acquired resistance of the normally susceptible epithelium."

Transmissible fowl leukosis: A review of the literature, C. OLSON, JR. (*Massachusetts Sta. Bul.* 370 (1940), pp. 48).—This review, brought together with a list of 240 references to the literature, deals with the subject under the following headings: Historical aspects, types of transmissible fowl leukosis (erythroblastic leucosis and granuloblastic leucosis), types of disease sometimes classified as "fowl leukoses" (lymphocytoma, myelocytoma, and fowl paralysis), incidence of fowl leukosis, transmission of fowl leukosis, the transmissible agent, immunity, treatment, and attempts to produce leukosis without the use of the specific agent. A synopsis in table form of the various transmissible strains of fowl leukosis agent reported by investigators, which includes the author, reference, and year described, strain, number of serial passages, and type of disease produced, is included.

Fowl pox and laryngotracheitis vaccination, G. KERNOHAN (*Nulaid News*, 18 (1940), No. 4, pp. 8, 9, 16).

Twentieth annual report on eradication of pullorum disease in Massachusetts, H. VAN ROEKEL ET AL. (*Massachusetts Sta. Control Ser. Bul.* 103 (1940), pp. 13).—The annual report for the season 1939-40 (E. S. R., 82, p. 110) on pullorum disease eradication reveals a marked increase over the preceding year in the number of tests made, also increases in the number of tested fowl flocks and turkeys. In 6 of the 12 counties no reactors were detected in the flocks tested, emphasizing definite progress in eradicating the disease and establishing and maintaining pullorum-free flocks in the State.

Further studies on the pathogenicity of *Trichomonas gallinae* for baby chicks, N. D. LEVINE and C. A. BRANDLY. (Univ. Ill.). *Poultry Sci.*, 19 (1940), No. 3, pp. 205-209, figs. 2).—The authors report upon further studies (E. S. R., 81, p. 718; 82, p. 542) of a disease of the upper digestive tract characterized by dry, caseous multiple foci on the mucous membranes of the crop and esophagus that is caused by *T. gallinae*. "Experiments in the transmission of the disease to baby chicks by the feeding of the trichomonads from culture showed that most of the chicks utilized did not become infected, but that scarification of the esophagus before feeding allowed some chicks of a resistant lot to become infected. A marked difference was noted in susceptibility of chicks from different sources. Chicks from one source were readily infected, while those from two other sources were very refractory to infection.

The results of this study indicate that chickens are relatively resistant to upper digestive tract trichomoniasis, but that individual differences in resistance and concomitant diseases may allow the protozoa to set up a pathologic condition."

Poultry diseases in the Southern States, M. W. EMMEL. (Fla. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 96 (1940), No. 758, pp. 600-602).

AGRICULTURAL ENGINEERING

[**Agricultural engineering investigations by the Arizona Station**] (*Arizona Sta. Rpt. 1939*, pp. 42-44, 45, 46).—This report notes ground-water studies in the Cortaro-Marana district, the Eloy pumping district, the upper Santa Cruz Valley, the Queen Creek ground-water basin, and the Little Chino Valley, and a summary of a report of a committee appointed by the Governor to study and report on ground-water law.

Stock-water developments: Wells, springs, and ponds, C. L. HAMILTON and H. G. JEPSON (*U. S. Dept. Agr., Farmers' Bul. 1859* (1940), pp. II+70, figs. 44).—It is pointed out that although it is quite commonly believed that improved livestock-watering facilities are required only in range areas in the arid and semiarid States, many sections of the more humid States have inadequate watering facilities on farm pastures. Recent periods of drought have revealed these deficiencies. Pasture water supplies that may be well located and have served satisfactorily for several years often go dry during or immediately following repeated dry periods. The development of necessary pasture and range watering facilities aids indirectly in the establishment of beneficial soil and water conservation practices in both range and agricultural areas. With proper development and distribution of water supplies, grazing can be restricted on overgrazed, eroded, or depleted range land and the livestock systematically rotated over other areas according to their grazing capacity. In farming areas adequate water supplies in pastures will encourage more uniform grazing, facilitate pasture-improvement practices, and retard erosion damage. They may also enable profitable utilization for pasture of soil-conserving crops and of erodible or steep areas unfit for producing cultivated crops.

This publication takes up, among other topics, planning stock-water developments, wells, troughs and tanks, springs, reservoir inflow, excavated reservoirs, impounding reservoirs, and protection and maintenance. The impounding dams dealt with are of the earth-fill type for small reservoirs. Natural and artificially made vegetated spillways and mechanical spillways for such reservoirs are also described and illustrated.

Influences of vegetation and watershed treatments on run-off, silting, and stream flow.—A progress report of research (*U. S. Dept. Agr., Misc. Pub. 397* (1940), pp. 80, figs. 26).—Prepared by the Forest Service and the Soil Conservation Service, an introductory section on soil, vegetation, and water flow describes the hydrologic cycle and related phenomena. The investigational data are detailed under the further heads factors affecting infiltration, influences of vegetation on water behavior, consequences of change in vegetal cover, run-off and erosion control by cropping practices and mechanical measures, and current research in water conservation, with numerous subtopics.

Lining irrigation canals to save water, O. W. ISRAELSEN (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 3, pp. 5, 11, figs. 2).—Considering the welfare of all the people in an irrigated valley or State, the lining of irrigation canals is valuable (1) for saving of water for use in irrigation, (2) for reduction

of the cost of drainage of irrigated land, and (3) for conservation of soil productivity. To the stockholders of a mutual irrigation company, however, the lining is valuable only to the extent that it saves water for the use of the stockholder irrigators. The drainage systems are usually not under the management or control of the irrigation company, and, therefore, the reduction of drainage costs does not directly influence the canal company officials. Likewise the lands that need protection against waterlogging and alkali concentration are frequently far removed from the canals that sustain seepage losses. At present the cost of lining must be justified largely, if not entirely, on the basis of the value of the water saved. The author analyzes the costs and savings involved in lining canals with cement concrete and reduces his results to a formula for estimating the justifiable cost per square foot of lining.

Dynamic properties of soils as applied to the elements of implement design: Development of reduced-friction surfaces and materials for experimental plows, F. A. KUMMER. (Coop. Miss. Expt. Sta.). (*Alabama Sta. Rpt. 1938, pp. 7, 8*).—Comparative field tests on two types of bottom plows having, respectively, impregnated wooden surfaces and standard steel moldboards revealed that the impregnated wooden surfaces produced considerably better scouring than the steel moldboards. Tests of sliding friction between soil and wood or metal surfaces showed that under the same conditions considerably less force was required (in some cases 50 percent less) to move the impregnated wooden sliders over the soil than was required to pull the steel sliders.

Repairing farm machinery, I. G. MORRISON (*Danville, Ill.: Interstate, 1940, pp. [16]+181, figs. [133]*).—The author has assembled instructions and methods for repair of some of the more generally representative farm machines. The book is designed primarily to be of use in the training of teachers of vocational agriculture, as a reference book for students in this field, and as a manual for farmers in farm-machinery repair. The repairing of mowers and of grain binders is dealt with in much detail, attention being called to the fact that many of the jobs on the mowing machine are applicable to other farm machines, especially to the cutting mechanism of binders and combines. Less detailed instructions for the repair and adjustment of the walking plow, wheeled plow, disk harrow, spike-tooth harrow, spring-tooth harrow, cultivator, corn planter, grain drill, side-delivery rake, and corn binder are given, together with a short section on the painting of farm machinery.

A lamp-type electric pig brooder, F. E. PRICE, A. W. OLIVER, and I. BRANTON (*Oregon Sta. Cir. 135 (1940), pp. 4, figs. 4*).—The device described is made in the form of a right-angled triangle to fit into a corner of the pen, the two short sides being 3 ft. in length. The framework is of 2- by 4-in. material and is supported by three 12-in. legs of the same, placed in the angles. The top, or hover, is of 0.25-in. or 0.5-in. plywood and has a centrally placed circular opening, 12 in. in diameter, over which is set a sheet-metal reflector cone carrying a rubber-covered socket and a 100- or 150-w. electric-light bulb. The use of rubber-covered shop extension cord is considered necessary to safety. The reflector opening is to be framed, on the under side of the hover, with 2- by 2-in. pieces, and a protective covering of 0.5-in. mesh hardware cloth is to be attached to this frame. The brooder is to be protected from the brood sow by two 2- by 12-in. planks set one above the other to form a 2-ft. wall resting on the long side of the triangle and attached to the side walls of the pen.

The use of this equipment reduced losses during cold weather.

AGRICULTURAL ECONOMICS

Investigations in agricultural economics by the Georgia Station, 1939-40. (Coop. U. S. D. A.). (*Georgia Sta. Rpt. 1940*, pp. 6-8).—Data are included as to the types of farms, net cash returns per farm, relative labor requirements and net cash returns per acre for cotton and peppers, and the relative labor requirements for oats and corn and as to the percentages of cotton of different grades and staple lengths of the 1938 and 1939 crops in the State and in different areas of the State.

[**Investigations in agricultural economics**] (*Ohio Sta. Bimo. Bul. 205 (1940)*, pp. 122, 123, 144).—Under the heading of Relative Cost of Hay-Crop Silage and Corn Silage, by F. L. Morison, a table is included based on a study of 120 farms in 1939, showing by operations a respective cost per acre prior to harvest of alfalfa, soybeans, and corn for silage of \$9.15, \$13.31, and \$17.54 and of harvesting \$10.96, \$16.03, and \$10.69. The table of index numbers of production, price, and income, by J. I. Falconer (*E. S. R.*, 83, p. 835) is brought down through April 1940.

[**Investigations in agricultural economics by the Rhode Island Station, 1939**] (*Rhode Island Sta. Rpt. [1939]*, pp. 4-8).—In addition to results previously noted, some findings are included regarding (1) the relative prices, 1931-39, of locally grown and Maine No. 1 Green Mountain potatoes in Providence and of Green Mountain No. 1 potatoes in Providence and Boston, and the possibilities of increasing local production, (2) the profitableness of feeding different amounts of roughage and concentrates to dairy cows and of growing more roughage, and (3) shipments of canned milk into the State, sources of the milk supply of the State, average daily sales of different groups of distributors, and the changes in total population and in percentages in different age groups.

[**Papers on agricultural economics**] (*Ohio Veg. and Potato Growers Assoc. Proc.*, 25 (1940), pp. 25-52, 142, 144-148, 150, 152).—Included are the following papers presented at the twenty-fifth annual meeting of the Ohio Vegetable and Potato Growers Association: The Northeast Vegetable and Potato Council, by R. A. Porter (pp. 25-32); A Program for Improving the Marketing of Ohio Produce, by P. R. Taylor (pp. 32-44) (U. S. D. A.); and Are Retail Prices Reliable Guides to Quality? (pp. 44-52) and Factors of Grade Affecting the Marketability of Ohio Potatoes (pp. 142, 144-148, 150, 152), both by C. W. Hauck (Ohio Expt. Sta.).

Annals of International Confederation of Agriculture [trans. title] (*Ann. Conféd. Internatl. Agr.*, 20 (1938), pp. 316).—Included in addition to the proceedings of the general meeting at Praha (Prague), July 7-10, 1938, and the meetings of the special commissions on cooperation in agriculture and on questions on agricultural labor, and a description of the composition of the confederation are the following papers: The Viewpoint of Agriculture Upon the Possibility of Obtaining Reduction of Obstacles to International Trade, by E. Laur (pp. 111-119); Agricultural Insurance as One of the Fields of the Confederation, by W. Beinzger (pp. 120-151); The Fields of the Confederation in Domestic and Foreign Trade. (a) in Plant Products, by L. Feierabend (pp. 152-160), and (b) in Animal Products, by K. Langenheim (pp. 161-180); Conclusions of the First Session of the Permanent Agricultural Commission, by G. Mullie (pp. 181-191); The Accessions of Agricultural Workers in the Working and Ownership of Land, by F. Angelini (pp. 192-207); and The Problems of Unemployment and Poverty of Agricultural Labor, by A. Borel (pp. 208-283).

Farm credit in Hempstead County, E. E. SPARLIN (*Arkansas Sta. Bul. 399 (1940)*, pp. 24, fig. 1).—The county was selected as representative of the coastal plain of southwestern Arkansas. Records for 1938 as to land inventory, crops, livestock, equipment, cash income, expenditures, and the amount, source, delinquency, and cost of credit used were obtained by interviews with 103 small owners, 11 plantation owners, and 56 tenants selected at random and from bank officials and county records. An analysis is made by groups—tenants, small owners, and plantation owners—of production credit, long-term credit, including trends, and the effect of high ratio of indebtedness on farm plans and operation.

The numbers using short-term credit and the average amounts used were small owners 64 and \$159, plantation owners 2 and \$638, and tenants 43 and \$152. The percentages of the number of loans obtained from different sources were local banks 21.2, merchants 17.8, production credit association 18.7, individuals 11, landlords 7.6, U. S. D. A. Farm Security Administration 11, and other sources 12.7. The costs, including all charges, were landlords 16 percent, local banks 15.5, production credit association 10.4, individuals 9.4, and others 9.8 percent. The averages by tenure were small owners 10.4 percent, plantation owners 5, and tenants 15.3 percent. The average costs decreased from 13.5 and 13.7 percent for the gross-cash-income groups \$250 or less and \$251–\$500 to 7.5 and 5 percent for those of \$2,001–\$5,000 and \$5,001 and over. The average percentages of loans delinquent December 31, 1938, by sources of credit were local banks 4, production credit association 4.5, merchants 38.1, Farm Security Administration 84.6, and others 27, averaging 26.3 percent. Long-term credit was used by 39.8 percent of the small owners, 27.3 of the plantation owners, and 17.9 percent of the tenants. Of the total amount of such credit the Federal Land Bank furnished 47.8 percent, individuals 29.1, local banks 4.1, Land Bank Commissioner 7.3, Farm Security Administration 6.6, insurance companies 2.6, and other sources 2.5 percent. Small owners and tenants with heavy indebtedness devoted a larger share of their farm enterprises to cotton and depended more upon one crop for cash income than did those with lower indebtedness.

Farm credit in Ashley County, E. E. SPARLIN (*Arkansas Sta. Bul. 400 (1940)*, pp. 16, fig. 1).—This study of Ashley County, representative of the southeastern part of the State, is similar to the study noted above. It is based upon farm records for 1938 from 104 small owners, 12 plantation owners, and 41 tenants.

Sixty-nine small owners, 10 plantation owners, and 35 tenants used short-term credit, the average size of the loans being \$165, \$3,271, and \$181, respectively. Of the total amount, 58.6 percent was furnished by local banks, 18.5 by merchants, 9.3 by production credit association, 6.2 by landlords, 4.5 by individuals, 2.2 by the U. S. D. A. Farm Security Administration, and 0.7 percent by others. The average costs were 12.8 percent for small owners, 8.4 for plantation owners, and 17.6 percent for tenants. The two lower gross-cash-income groups paid approximately 15 percent and the \$5,000 and over group 7.4 percent. On December 31, 1938, 30.9 percent of the loans were delinquent. The percentages for different sources of credit were: Production credit association 15.4, local banks 24.5, merchants 35.3, Farm Security Administration 62.5, and others 34.4. Long-term credit was used by 39.4 percent of the small owners, 58.3 of the plantation owners, and 12.2 percent of the tenants. The Federal Land Bank furnished 66.6 percent of the funds, local banks 15, Land Bank Commissioner 6.7, individuals 4.3, Farm Security Administration 3, insurance companies 1.3, and other sources 3.1 percent.

Factors affecting success of farm loans: A study of lending experience in seven counties in east-central Illinois, 1917–1933, J. ACKERMAN and L. J. NORTON (*Illinois Sta. Bul. 468 (1940)*, pp. 457–527, figs. 6).—This bulletin

is based on the history and applications and appraisal reports for 827 first-mortgage loans made between 1917 and 1933, a survey of 66 of the borrowers, personal observations and interviews regarding 103 of the borrowers on foreclosed farms, land-use records for 1935 for 338 of the farms, financial records for 92 owner-operated farms, etc. An analysis is made of the following factors in their relation to success of loans: Quality of land, date of loan, loan ratio, topography, transportation facilities, farm organization, and personal qualities of borrowers, and of the causes of foreclosure and influence of debt burdens on land use and farm organization. Some of the findings were: On April 1, 1936, 14 percent of the loans had been paid. The principal and interest payments had been met on 52 percent, extensions had been granted on 17 percent, 4 percent were delinquent, and 13 percent had been foreclosed or the land transferred voluntarily to the lender, extensions had been granted on 17 of the loans were on farms with good soils, intermediate, and inferior soils, respectively. Loans averaged 36 percent of their appraised value where the loans had been paid and 43 percent where foreclosures had been made. On the farms acquired by lenders the percentages on different soils and net loss per \$1,000 loaned were, good soils 21 and \$16.10, intermediate soils 35 and \$45.99, and inferior soils 44 and \$106.29. The net losses on farms appraised at from \$50 to \$99 per acre were \$92 per \$1,000 loaned and on farms appraised at from \$150 to \$199, \$145. The percentage of foreclosure and losses were highest on loans made before 1925.

Net loss on foreclosed farms was \$3 per \$1,000 where the loan ratio to appraised value was from 20 to 29 percent and \$57 where it was over 40 percent. On good soils the medium-sized farms were the best risks; on inferior soils small farms were the best. The percentage of foreclosures was highest on farms with a high proportion of the land in crops. The most important factors given by the individuals acquainted with the situation on 103 farms acquired by the lenders were personal, such as poor management, extravagance, laziness, failure to control erosion, too much equipment, etc., for 47 farms; accidental, such as death, ill health, etc., for 29; and capital—too heavy indebtedness, speculation, low incomes, etc.—for 27. The information obtained from land use and financial records of owner-operated farms showed that on delinquent and foreclosed farms the percentage of land in crops was higher and that of soil-depleting crops was approximately 6 percent higher, while the successful loans were on farms on which the proportion of land in rotation pasture was higher, there was no relationship between loan ratio and percentage of cropland in soil-depleting crops, and there was a slight tendency for the farms with high loan ratios to have a high percentage of total land in crops.

"Fair value" and the deficiency judgment, J. L. TIERNEY (*Jour. Land and Pub. Util. Econ.*, 16 (1940), No. 2, pp. 181-195).—This is a discussion of the legislation and court decisions.

Uncollected property taxes in Montana, R. R. RENNE and O. H. BROWNLEE (*Montana Sta. Bul.* 382 (1940), pp. 39, figs. 21).—An analysis is made of the amount, growth, causes, and means of reducing Montana property tax delinquency, with special emphasis on rural property.

Total unpaid taxes on June 30, 1939, amounted to nearly \$27,000,000, or 8.2 percent of the total taxable valuation of the State, and was twice as large as in 1930 and four times as large as in 1920. Approximately \$18,398,000 of unpaid taxes were outstanding against property carried on the current tax rolls, being equivalent to a 56-mill levy on the total assessed taxable valuation of the State. About 4½ million acres of land were subject to tax deed (delinquent 5 yr. or more), and an equal amount was already owned by counties.

The acreage was equal to 17 percent of the total taxable area. The county-owned acreage increased over 85 percent from that in 1925. Uncollected taxes on farm real estate on June 30, 1939, was 40 percent greater than those on all property. Delinquency was greatest in the more arid agricultural counties in the eastern half of the State. Methods suggested to reduce future delinquency are reduction of governmental costs through improved administrative efficiency and organization and the adapting of governmental services to community needs and resources, broadening the tax base, requiring local government units to build up cash reserves in years of good income, assessment of lands on a true productivity basis, and increase of farm income by better prices of farm products and improved land use and farm management practices.

Rural tax delinquency study of the State of Oregon, W. H. DREESSEN (*Oregon Sta. Bul. 371 (1940), pp. 21, figs. 2*).—Included are the results of four surveys made to determine the relationships between (1) size of farms and tax delinquency existing on the tax rolls from 1928 to 1932 in the summer of 1934 in eight counties, (2) delinquency and land types in six counties of the Willamette Valley, (3) delinquency and land use in Umatilla and Morrow Counties, and (4) delinquency and wheat yields in the five major wheat-producing counties—Umatilla, Morrow, Gilliam, Wasco, and Sherman. The history of rural tax delinquency studies in the State, the Oregon taxation laws, the recent changes in the laws, and the effects of the changes are discussed.

The size-of-farms study showed no significant correlation between size and tax delinquency, and that in each county there is one size group with a shorter average period of delinquency. In the Willamette Valley the average period of delinquency was shorter on lands adapted to intensive crops, general farming, and hay, grain, and seed production than on lands classified as adapted to pasture, general farming, and extensive farming. In Morrow County there was practically no variation in the degree of delinquency between different land-use areas. In Umatilla County the period of delinquency was 47 percent longer for timberlands and 24 percent longer on sage lands than for wheatlands; that on the better grazing lands was practically the same as for timberlands. In Umatilla County the average periods of delinquency were longer on the poorer yielding wheatlands and shorter on the better yielding lands. In the other wheat counties practically no correlation was found.

Land tenure in Arkansas.—II, Change in labor organization on cotton farms, J. G. McNEELY and G. T. BARTON. (Coop. U. S. D. A.). (*Arkansas Sta. Bul. 397 (1940), pp. 26, fig. 1*).—This is the second bulletin in the series (E. S. R., 82, p. 836). Data regarding total farms and cropland and cotton acreages and production by tenure and individual operating units during the period 1932–38 were obtained from A. A. A. records for all farms having more than the average amount of cropland and operated continuously by the farm operator in Chicot, Mississippi, and Pulaski Counties in the delta area, Independence and Pope Counties in the hilly upland area, and Clark in the coastal plain area. The areas and characteristics of the farms and labor organizations are described. An analysis is made of the changes in the farm labor organization during recent years, of the factors associated with the changes, and the changes in crop acreage on renter and sharecropper farms. A random sample was also selected for a special survey on crop acreages by tenure, numbers of tenants and wage earners, changes in mechanical equipment, and other factors relating to methods and systems of farming and labor organization.

From 1932 to 1938 the average number of resident families per 10,000 acres of cropland declined 20 percent in Chicot, 14 in Mississippi, 12 in Pulaski, 7 in Clark, 25 in Pope, and 19 percent in Independence Counties. In the

delta counties there was considerable shift from share renters and sharecroppers to wage laborers. In the coastal plain county sharecroppers replaced share renters as the predominating group, and wage families remained unimportant. The number of share renters and sharecroppers declined in the hilly upland counties. The percentage of cotton worked by wage hands increased, while that worked by share renters and croppers decreased in all counties. The cotton production control programs caused sharp declines in the cotton acreages in all counties, the reduction in the counties surveyed being over 40 percent from 1932 to 1938. Corn replaced cotton in the delta and coastal plain counties and pasture and feed crops, other than corn, in the hilly upland counties, and the labor requirements were substantially reduced. Number of tractors per 10,000 acres of land increased from 10.5 to 17.3 in Chicot County, from 12.5 to 29.6 in Mississippi, and from 16.8 to 24.3 in Pulaski County. Smaller increase took place in the coastal plain and hilly upland counties. The average cotton acreage per share renter declined from 25 to 13 and that for sharecroppers from 15 to 10 acres in the delta counties. In the coastal plain county the declines were from 19 to 11 and from 17 to 12 acres, respectively. Corn acreage per family increased only slightly for all tenure groups, and the acreage for other crops remained unimportant.

Some economic aspects of western range-land conservation, M. H. SAUNDERSON. (U. S. D. A.). (*Jour. Land and Pub. Util. Econ.*, 16 (1940), No. 2, pp. 222-226).—Some methods of conserving range lands are discussed.

An economic study of land utilization in Kent County, Delaware, R. O. BAUSMAN (*Delaware Sta. Bul.* 224 (1940), pp. 99, figs. 30, map 1).—The climate, soils, markets, and methods used in measuring land classes are described, and the trends in production of important crops and the numbers and different kinds of livestock and livestock products are discussed. The lands are divided into four classes—I, poorest grade, chiefly timber, brush, and marshland, 36.6 percent; II, largely open untillable land, 5.1 percent; III, poorest land suited to cropping, 28.8 percent; and IV, the best grade of cropland, 29.5 percent. The use of lands, soils, size and condition of buildings, crop yields, income, size of farm business, use of labor, social aspects—age, birthplace, former residence, education, farming experience, etc., of farmers, size of families, and occupation of mature children—roads, electric power and telephone service, etc., on different land classes are discussed. Some of the findings are as follows: The number of farms has decreased 8 percent since 1910 and the number of acres in farms 13.2 percent since 1900. Close relations were found between land classes and agricultural practices and reasonably close relationships between land classes and general soil types and size and condition of farm buildings. In land classes II, III, and IV the averages per farm were crop yield indexes 69, 96, and 107; labor incomes —\$225, —\$92, and +\$78; capital in real estate \$2,088, \$3,854, and \$6,528; productive man-work units 224, 343, and 468; and animal units 4.8, 10.8, and 14.1, respectively. As the lands increased in grade for agricultural use, the age of farmers decreased, the percentage of farmers from nonagricultural vocations decreased, percentage of children leaving school at the end of the eighth grade decreased, the proportion of sons taking up farming increased, and the percentage of roads hard-surfaced increased. Hard-surface roads increased the value of farm real estate per acre \$3.72, 11.9 percent, in land class III and \$6.48, 14.4 percent, in class IV.

Farm performance in north central South Dakota, 1930-1939, M. MEYERS (*South Dakota Sta. Bul.* 343 (1940), pp. 55, figs. 32).—The physical and social characteristics of the area, its importance in wheat production, and

the factors affecting wheat growing in the area are described. The data in from 29 to 165, total 658, farm reports each year, 1930-39, were analyzed to show the organization and performance of the farms. Comparisons were made of the 10 highest and 10 lowest income farms, 1932-39, to determine the factors influencing financial return.

The average annual operator's labor earnings (farm labor income plus value of farm products used minus value of unpaid family labor) ranged from -\$2,240 in 1934 to \$1,700 in 1936, averaging -\$408 for the 10 yr. 1930-39. For the years 1932-39 the yearly operator's earnings ranged from -\$1,001 to \$2,063, averaging \$320 on the higher income, and from -\$3,018 to \$602, averaging -\$1,118 on the low income farms. The high income farms were considerably larger, had larger cropped acreages, more productive animal units per acre, more equipment per acre, smaller percentage of investment in real estate and larger percentage in working capital, higher crop yields, higher livestock productive efficiency, handled more crop acres and animal units per man, and carried larger reserves of grain, roughage, and cash.

Rural zoning for Missouri? V. HURLBURT. (*U. S. D. A.*). (*Jour. Land and Pub. Util. Econ.*, 16 (1940), No. 2, pp. 151-158).—This is a discussion of rural zoning, using Missouri as an example.

Regulation or development for the Missouri Ozarks, C. H. HAMMAR. (*Univ. Mo.*). (*Jour. Land and Pub. Util. Econ.*, 16 (1940), No. 2, pp. 159-167, fig. 1).—This is a discussion of the preceding paper. Other technics for solving the land-use problems of the Ozarks are outlined.

Land utilization in China: A critique of methodology, C. Y. HSIANG. (*Univ. Wis.*). (*Jour. Land and Pub. Util. Econ.* 16 (1940), No. 2, pp. 226-229).—Criticisms are made of the methodology used in the study previously noted (*E. S. R.*, 80, p. 120).

Efficient management of sheep ranches in southwestern Utah paid dividends in 1939, D. A. BROADBENT (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 3, pp. 6, 7).—An analysis of the records of a group of ranches operating over 250 head of ewes revealed marked differences between the extremes. Profits per breeding ewe were 2.77 and 22 ct., percentage of lamb crop at marketing time 84 and 64, weight per lamb at market 74 and 62 lb., pounds of wool per fleece 9.3 and 8.4, percentage death loss of stock sheep 6.7 and 11.6 and of lambs 5 and 12.6 for the 15 most profitable and 15 least profitable ranches, respectively. The possibility of increasing rate of production and decreasing death losses without significantly increasing the per unit cost of production is emphasized.

An economic study of commercial poultry farming in Florida, F. W. BRUMLEY (*Fla. Univ. Agr. Ext. Bul.* 105 (1940), pp. 95, figs. 3).—Records were obtained from 20 to 104, total 261, farms each year, 1926 to 1931-32. Analyses chiefly for the years 1926 to 1928-29 were made of the size; receipts; expenditures; labor income and factors affecting it; and the costs and returns in producing eggs, raising pullets, and incubating chicks and the factors affecting each.

Labor incomes averaged \$965 in 1926, \$48 in 1927-28, and \$694 in 1928-29, and in addition the farm privileges averaged \$400 in 1927-28 and \$459 in 1928-29. Fifty percent of the farms made labor incomes of more than \$1,000 in 1926, 7 percent in 1927-28, and 31 percent in 1928-29. Size of business, eggs per hen, labor and capital efficiency, and type of business were important factors affecting labor income.

Milk distribution as a public utility, W. P. MORTENSON (*Chicago: Univ. Chicago Press*, [1940], pp. XVIII+221, figs. 2).—This volume is based on research work of the Wisconsin Experiment Station. It includes chapters on history

and background of fluid-milk regulation (pp. 3-12), characteristics of public utilities and comparison with the fluid-milk business (pp. 13-19), general survey of costs of milk distribution (pp. 23-31), analysis of operating costs and the possible savings through unification (pp. 32-89), profits (pp. 90-104), legal aspects of milk control (pp. 107-136), public ownership and public control (pp. 137-146), methods and difficulties of public utility control of milk distribution (pp. 149-169), what groups would gain under a unified distribution system (pp. 173-181), and conclusions and outlook (pp. 182-185). Appendixes include data on division of costs of milk distribution, supplementary information on delivery, and the effect of price upon the consumption of fresh and evaporated milk.

Factors affecting costs of milk production in southeastern Louisiana, J. N. EFFERSON and F. MERRICK (*Louisiana Sta. Bul. 321 (1940), pp. 8*).—Analysis is made of data for the crop year 1937-38 for 68 farms in Tangipahoa Parish. The average cost of production per 100 lb. of milk was \$2.18, varying from \$1.28 to \$4.29. Average net returns per farm varied as follows: Farms (24) with an average of 11 cows \$117, farms (23) with 34 cows \$553; with average production per cow of 2,331 lb. (20 farms) —\$28, with 4,487 lb. (23 farms) \$453; farms (21) receiving an average of \$1.94 per 100 lb. of milk —\$20, those receiving \$2.36, \$344; and —\$77 for the 20 farms with 44 percent of the total income from dairying and \$596 for the 24 farms with 80 percent of the income from dairying.

Twenty-five years of Illinois crop costs, 1913-1937, R. H. WILCOX and H. C. M. CASE (*Illinois Sta. Bul. 467 (1940), pp. 357-455, figs. 17*).—This bulletin summarizes crop-cost data in farm accounts kept by selected groups of cooperating farmers. The objectives, selection of cooperators, location and size of farms, and the methods of compiling and analyzing the data are discussed. The important factors influencing crop costs and the variations of costs between areas, years, and farms are discussed. An analysis is made of the trends in efficiency in production, labor requirements, changes in acreages of different crops, use made of time saved, and changes in the character of farm expenses. An appendix shows the year-by-year changes in costs of production.

Yearly operating expenses in the production of a composite acre (rotation two fields of corn and one each of oats and wheat) varied from \$18.30 in 1919 to \$7.80 in 1933; those for wheat declined from \$17.16 in 1914-15 to \$8.70 in 1935-36; those for corn were \$11.61 in 1913-15 and \$11.22 in 1935-37; those for oats \$7.27 and \$8.34, respectively; and those for soybeans \$17.08 in 1922-24 and \$9.11 in 1935-37. Yield increases per acre were wheat 4 bu., corn 15, oats 13, and soybeans 10 bu. The man labor requirements decreased from 18.5 to 9.6 hr. for corn, from 19.4 to 4.9 for wheat, and from 13.4 to 4.2 hr. for soybeans. That for oats declined approximately 40 percent. Due to the use of tractors, the decreases in horse-hours per acre were for corn from 43.6 to 14, wheat 34.6-5.1, and soybeans 29.1-2.6. The average number of hours of tractor work in 1936-38 for corn was 3.6, wheat 2, oats 1.3, and soybeans 2.4. Total costs of production per acre, including land charges and size of crop, were for corn in 1913, \$18.49 and 35 bu. and in 1937, \$18.19 and 61 bu.; wheat \$26.59 and 23.4 bu. in 1914 and \$14.01 and 27.2 bu. in 1936; oats \$14.20 and 31 bu. in 1913 and \$14.30 and 37 bu. in 1936; and soybeans \$29.04 and 15 bu. in 1922 and \$17.48 and 26 bu. in 1937. The net cost per bushel of soybeans was \$1.46 in 1922 and 68 ct. in 1937. Direct cash outlay in producing corn in 1913-15 was 14.1 percent and cash reserve for depreciation 4.3 percent of the total costs, and in 1935-37 28.3 and 8 percent, respectively.

Cost of curing white Burley tobacco with artificial heat, G. B. BYERS (*Kentucky Sta. Bul. 406 (1940), pp. 333-351*).—Data were obtained for 63 farms in 1938 and 32 farms in 1939 on which Burley tobacco was cured with artificial heat and on 22 farms in 1938 where the tobacco was air-cured. An analysis is made of fuel, labor, equipment, and housing requirements and costs. "The total cost of curing and drying with artificial heat averaged \$7.69 per acre, or 49 ct. per day for each acre, in 1938. Charcoal briquets and labor cost \$7.28 per acre, or 56 ct. per day for each acre of tobacco cured and dried in 1938. In 1939 the cost was \$3.83 per acre, or 53 ct. per day for each acre cured."

The composition of gross farm income since the Civil War, F. STRAUSS. (Coop. U. S. D. A.). (*Natl. Bur. Econ. Res. [New York] Bul. 78 (1940), pp. 24, figs. 10*).—The changes in the composition of total farm income and that from the domestic market and from farm exports are discussed. The total gross farm income ranged from \$2,554,000,000 to \$2,373,000,000 for the years 1869-73 and from \$6,233,000,000 to \$9,131,000,000 for the years 1934-37, of which 83.4 and 91.6 percent were from domestic markets in the respective periods.

The percentages of the total gross farm income in the periods 1869-83 and 1934-37 were for all staple foodstuffs 16 and 10, wheat 11.2 and 5.7, hogs 20.3 and 12.3, cattle 9.5 and 9.7, calves 0.3 and 1.6, sheep and lambs 0.5 and 1.2, all meat animals 30.6 and 24.8, cotton 12.6 and 8.8, cotton and cottonseed 12.6 and 10.4, tobacco 1.4 and 3.3, fruits 1.9 and 4.9, dairy products 10.2 and 15.9, chickens 2.3 and 4.2, eggs 2.5 and 7.5, and all other 22.5 and 19. The percentages of the gross income from the domestic market were wheat 10.2 and 5.7, all meat animals 35.2 and 26.4, cotton 4.3 and 5.1, tobacco 0.4 and 2.4, fruits 1.8 and 4.2, dairy products 12 and 17.4, and chickens and eggs 5.8 and 12.8. The percentage contribution of different products to total agricultural exports were wheat 27.8 and 5.2, corn 6 and 2, pork and pork products 13.1 and 4.2, cattle and beef products 6.2 and 0.5, cotton 35.1 and 46, tobacco 2.9 and 17.7, fruits 0.4 and 10.8, and all other 8.5 and 13.6.

Variations in farm income and family living in Robertson County, J. H. BON DURANT and M. M. THARP (*Kentucky Sta. Bul. 405 (1940), pp. 305-331, figs. 2*).—The data were obtained from 152 farmers in the central and northern areas of the county for the year 1935 and from 61 of the same farmers for the year 1937.

The total receipts were \$735 per farm in 1935 and \$1,284 in 1937. The receipts from tobacco were \$515 higher in 1937, due to higher yields and prices and larger acreage. Labor incomes per farm averaged \$17 in 1935 and \$451 in 1937, and, in addition, the value of use of dwelling, fuel, and food produced and used amounted to \$347 and \$313 in the respective years. Size of business, tobacco yields, and net livestock receipts per productive animal unit were the principal factors affecting the variations in labor income in the same year. Farms large enough to develop a system of farming requiring from 300 to 500 productive man-work units produced the most satisfactory incomes.

Thirty years of farm prices and production in Kentucky, A. J. BROWN and D. G. CARD (*Kentucky Sta. Bul. 403 (1940), pp. 189-287, figs. 30*).—This compilation of available statistics includes tables and charts showing the monthly prices and relatives of prices for major and minor crops, livestock, and livestock products; the acreage, production, price, and farm value of crops; the number and value of livestock on farms; the index numbers, 1912-39, of estimated value of real estate; and the condition of pastures by months.

World wheat survey and outlook, January 1940, V. P. TIMOSHENKO and H. WORKING (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 16 (1940), No. 5*,

pp. [2]+205-242, figs. 8).—Continuing the series (E. S. R., 82, p. 410), wheat prices in North America were strongly influenced during September-November 1939 by the selling policy of the Argentine grain board, which raised its selling prices only moderately following the outbreak of war and sold freely, favored by the fact that ocean freights from Argentina advanced no more than from North America. Canadian prices declined persistently under this competition, and in the United States prices responded only moderately to the sensational deterioration of prospects for winter wheat there. Severe crop damage in Argentina and a change in Argentine selling policy, however, contributed to sharp advances from late November to mid-December. At Antwerp, price increases during December were extreme, reflecting great further increases in ocean freights. International trade in wheat, curtailed in September and October, has since been larger than last year.

Farm storage and marketing of rough rice in Arkansas, O. J. HALL (*Arkansas Sta. Bul.* 395 (1940), pp. 23, figs. 3).—Data for the crop year 1937 were obtained by the survey method for 80 farms in Lonoke, Prairie, and Arkansas Counties, of which 11 had no farm storage. An analysis is made of the types and size of farm facilities, cost of farm and public storage, costs of transportation to farm granaries and public storage or markets, methods of sale and average monthly prices received by farmers 1909-10 to 1937-38, and purchasing power of rough rice 1920-21 to 1936-37.

Of the crop, 57.2 percent was moved from the farms at threshing time. The capacity of farm granaries varied from less than 2,500 to 28,000 bu., averaging 8,166 bu. The average annual depreciation per granary was \$41.46, repairs \$18.30, and interest \$26.48, being 1.2 ct. per bushel of capacity and 4.3 ct. per bushel stored in 1937-38. Public storage averaged 1.61 ct. per bushel for 1 mo. and 4.59 ct. for 6 mo. An average of 184.9 min. per load was used in hauling from the thresher to farm granary and then to market as compared with 141.6 min. where the rice was hauled directly to the market. Contract prices for hauling to market averaged 1.9 ct. from farm granaries and 2 ct. per bushel from threshers. Approximately 37.3 of the farms sold to local mills, 18 to local buyers, 23.3 to cooperative associations, and 0.3 to out-of-State buyers. From 1920-21 to 1936-37, the value of rice increased 7.5 times and decreased 3.2 times after October 15. On an average, the price in November was 105 percent of the October value, 106 in December and January, 110 in June, and 111 percent in July.

Farmers' cooperative marketing and purchasing associations in North Dakota, W. L. ETTESVOLD (*North Dakota Sta. Bul.* 294 (1940), pp. 26, figs. 5).—This bulletin is based on a survey made in cooperation with the Farm Credit Administration of St. Paul, Minn. Most of the information was obtained for the fiscal year 1936-37. Data are presented as to the number of associations of different types, number of members and patrons and volume of business, and the laws affecting organization, time of establishment, financing, and operating results of the associations in the State.

Crops and Markets, [July 1940] (*U. S. Dept. Agr., Crops and Markets*, 17 (1940), No. 7, pp. 129-156, figs. 2).—Included are crop and market reports of the usual types.

RURAL SOCIOLOGY

Standards of value for program planning and building (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1939, pp. [2]+III+132).—These proceedings of the school for Washington staff of the Bureau of Agricultural Economics, held October 17-20, 1939, include papers on backgrounds; the place of government in modern society;

regionalism, nationalism, and internationalism; and problems of social adjustment and administration; and summaries of the discussion groups as follows: Man as a Biological Phenomenon (pp. 1-11), and Culture Patterns and the Social Necessity of Adjustments (pp. 70-82), both by M. A. Graubard; Can Human Nature Be Changed? (pp. 12-18), and Individualism, Democracy, and Social Control (pp. 28-32), both by R. B. Vance; There Ought To Be a Law About It (pp. 19-27), and Democracy and Group Leadership (pp. 83-92), both by E. G. Nourse; Administration in a Democracy (pp. 33-37), and Problems of Centralization and Decentralization in Government and Administration (pp. 57-61), both by L. M. Short; Problems in Continuing a Program of Agricultural Adjustment (pp. 38-47), and A Desirable Foreign Trade Policy for American Agriculture (pp. 62-69), both by J. S. Davis; Culture and Agriculture, by H. Miner (pp. 48-56); and The Relation of the Administrator to the Farmer and the Expert, by K. Young (pp. 93-103).

Relocation of farm families: Selected references on settler relocation, L. O. BERCAW (*U. S. Dept. Agr., Bur. Agr. Econ., Econ. Libr. List 14 (1940), pp. 46*).—This is an annotated list of references which relates to the literature concerning the relocation of farm families, especially isolated and submarginal settlers, in the United States.

Opinions on living in the open country and farming (*Rhode Island Sta. Rpt. [1939], pp. 48-52*).—This study reports the results of the opinions of the heads of 1,100 households concerning the advantages and disadvantages of living where they are, reasons for engaging in nonagricultural occupations, and preference as to a place to live if the heads of families were selecting a new residence.

Migration and social welfare: An approach to the problem of the non-settled person in the community, P. E. RYAN (*New York: Russell Sage Found., 1940, pp. [VII]+114*).—The author develops the social significance of migration in the western world, including chapters on migrations in the building of America, the depression, migration today, the impact of the migrant upon the community, the provision of assistance, proposals and experiments, and the national policy.

Professional migratory farm labor households, C. F. REUSS. (Wash. Expt. Sta.). (*Sociol. and Social Res., 24 (1940), No. 4, pp. 337-344*).—The author concludes that "poverty is the greatest problem for the migratory farm labor family. Its greatest needs are some sort of economic security for slack harvest months and for old age, and some accurate method of directing the family to work opportunities and placing it in jobs when it arrives in the area."

The sugar cane farm: A social study of labor and tenancy, H. HOFFSOMMER. (Coop. U. S. D. A.). (*Louisiana Sta. Bul. 320 (1940), pp. 67, figs. 8*).—“This study [based largely on data derived from 100 sugar farms of 30 acres or over] aims to describe from the social viewpoint the labor and tenancy arrangements on Louisiana sugarcane farms.” The production of cane for sugar is located in the section known as the Sugar Bowl, comprising 20 parishes in the south-central part of the State. Seven percent of the cane operators have more than 70 percent of the total acreage. The sugarcane farm is conducted largely on a labor basis. Of more than 1,000 families (exclusive of owners and special workers) living on the farms studied, 83 percent were resident laborers, 14 percent tenants, and 3 percent sharecroppers. The position of the resident laborer on the sugar farm is analogous to that of the sharecropper on the cotton farm, excepting that the former is paid wages rather than a share of the crop and works on the farm at large rather than on an assigned acreage. A third of the sugar growers had business and occupational

interests in addition to growing sugarcane. One of the most important of these interests was in connection with sugar mills, of which there were 8 on the 100 farms studied. More than one-half of the workers on these sugar farms were colored. Among the share tenants, whites predominated with 72 percent, but 60 percent of the resident laborers and 64 percent of the croppers were colored. Labor demand on the sugarcane farm, in general, is about 3 times greater in December, the busiest month, than in July and August, the slackest months. Employment of women, nearly all of whom were colored, was greatest during the harvest season. During November, 22 percent of the total days of labor were contributed by women as compared with 5 percent during August.

One of the most persistent problems in the Sugar Bowl is that of providing sufficient year-round employment to support the labor population in the area. Off-season common labor was paid almost entirely by the day. The bulk of the farms paid \$1, but several paid as low as 75 and 80 ct. and roughly one-third paid 90 ct., which brought the average down to 97 ct. The highest wage reported was \$1.40. The most common day wage for cane cutting for males was \$1.25, with a range of from \$1 to \$2. The average wage for males was \$1.36.

Hours were longest during the cultivating and planting seasons. Roughly one-half of the operators reported days of from 10 to 11 hr., 46 percent from 11 to 12 hr., and the remainder less than 10 hr. Most of the laborers began work between 5 and 6 a. m. and quit between 6 and 7 p. m. All resident laborers conventionally received perquisites of some kind. Of 902 families, 898 received house and garden space, 9 out of 10 received wood, 7 out of 10 a team for hauling it, and 6 out of 10 some kind of farm equipment for working their gardens. One-third of the nonresident laborer families received perquisites, of which roughly three-fourths received them for only the 3-mo. harvest period. The most common perquisites were house or room and board and wood. Resident laborers on 50 of the 74 farms reporting received advances, 45 from their landlords and 5 from their merchants. The degree of responsibility as to the welfare of tenants and laborers varied among operators from scarcely any to almost complete care in sickness and old age. Contributions from operators to laborers and tenants for churches, funerals, and fines tended to be relatively more numerous on the larger farms.

A social and economic survey of Beadle County, South Dakota, B. R. McCLASKEY (*Chicago: Author, 1940, pp. [XI]+260, figs. 8*).—This is a study of the social action in boom and depression years in an agricultural community. The several chapters summarize the history of South Dakota and Beadle County and discuss the population, natural resources, business structure, farming, farm mortgage indebtedness, government, taxation, educational facilities, and social action and control in the county.

School services in rural communities in Washington County, J. L. CHARLTON (*Arkansas Sta. Bul. 398 (1940), pp. 43, figs. 7*).—This study, designed to show the nature and extent of high school participation, suggests the need for the following improvements: "First, public transportation, particularly for the benefit of the weaker districts; second, transportation and high school tuition for pupils from rural districts that do not provide high school facilities; third, enlargement of many of the rural school districts by means of consolidation; and, fourth, financial and operating management for rural schools. The wide discrepancy between the performance of the school system in village or town and in the open country shows that special measures for rural school improvement, considered separately from public school operations in general, must be undertaken if needed improvement is to be expected."

Sickness and medical care among a rural bituminous coal-mining population of Arkansas, I. C. WILSON (*Arkansas Sta. Bul. 394 (1940), pp. 44, figs. 5*).—Continuing this series (E. S. R., 81, p. 447), the 307 families in the Midland community, a typical rural bituminous coal-mining community in Sebastian County with a population of 1,189 persons (all white), were interviewed as to the state of their health, the costs and type of medical service utilized, and their indebtedness for medical care. The people of the community used the services of doctors in adjoining towns from 6 to 8 miles distant from Midland, and in the city of Fort Smith, 22 miles distant, and of dentists in towns from 8 to 10 miles distant and in Fort Smith. There were 4 hospitals available in Fort Smith, 1 tubercular hospital connected with the county farm for dependent persons, and free maternity wards for indigent mothers. There were no graduate nurses living in the community and only 66 graduate nurses in the county. Transportation and communication facilities were very good, only one-fifth of the families living in unimproved roads. Reports from heads of the family showed that 70 percent of the people were in good health, 15 in fair health, and 15 in poor health; that 31 had eye defects, and 2.5 percent had some degree of deafness. The total cost for medical service in this area was \$11,850.05, with an average expenditure of \$38.60 per family and \$9.96 per capita. The physicians' services were utilized by 67.4 percent of the families in this community, dental services by 11.4, chiropractic services by 1, services of medical care associations by 36.5, hospital services other than those of the medical care associations 5.5, oculists' services by 2.9, and midwives' services by 0.3 percent. A study of the families grouped according to income levels showed a close relation between income and state of health, number of illnesses, duration of illness, and type of illness.

Illegitimacy in rural Utah studied by rural sociology department: Offenders found to be mostly non-farmers, J. N. SYMONS (*Farm and Home Sci. [Utah Sta.], 1 (1940), No. 3, pp. 2, 4*).—The author presents the rate of illegitimacy per 1,000 in the United States and in Utah, and discusses the age, residence, vocation, marital status, and mobility of offenders.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

The land-grant colleges, G. A. WORKS and B. MORGAN (*Washington: Govt., 1939, pp. IX+141, figs. 2*).—The legislation regarding financial support to, administration of, and work under the Federal grants for resident instruction, experiment station research, and agricultural extension work, is described. The relationship of separate land-grant colleges and State universities, matching requirement, extension work in home economics, extension and research in Negro land-grant colleges, relationship of extension to regulatory functions, variations in Federal control, uniform allotments to States, clarification of State and Federal relations, additional grants, and the influence of the Land-Grant College Association are discussed.

FOODS—HUMAN NUTRITION

[**Nutrition studies by the Arizona Station**] (*Arizona Sta. Rpt. 1939, pp. 75-81*).—Included in this progress report (E. S. R., 82, p. 275) are summaries of an extension of studies on vitamin A, including, in addition to the work previously noted (E. S. R., 83, p. 561), a comparison of biological and chemical methods for determining the vitamin A value of foods, and a study of dark adaptation in persons with a history of tuberculosis; on fluorine, particularly the fluorine content of foods; and on iron, with emphasis on the total weight of iron in the bodies of rats under different conditions. Brief reports are also given of a study of

the growth of Mexican school children and the effect of sunlight and feed on the vitamin D potency of milk.

[**Food and nutrition studies by the Georgia Station**] (*Georgia Sta. Rpt. 1940, pp. 64-66, 73, 74*).—This progress report includes an extension of earlier work (E. S. R., 82, p. 845) on available calcium to include certain calcium salts; on dark adaptation in school children, with a comparison of results by the biophotometer and vitamin A status as evaluated by the differential leucocyte method proposed by Abbott et al. (E. S. R., 81, p. 873); and on the ascorbic acid content of certain foods, including raw turnip greens and several varieties of tomatoes grown at the main station, the Mountain Substation, and the Coastal Plain Station. Progress is also reported on methods of freezing foods, with a discussion of advantages of the method of freezing before packaging and of problems still awaiting solution.

[**Nutrition studies by the Rhode Island Station**] (*Rhode Island Sta. Rpt. [1939], pp. 46, 47*).—Progress is reported on a continuation of studies on the nutritional status of college women with respect to vitamin C (E. S. R., 81, p. 148) and on vitamin A metabolism in human subjects as determined by a new type of adaptometer named the rhodometer.

[**Modern aspects of soft curd milk**, R. L. MILL (*Farm and Home Sci. [Utah Sta.], 1 (1940), No. 3, p. 9*).—Reference is made to the pioneer work of the station on the distribution of the soft-curd characteristic in dairy cows and to the work in developing the test now in use to determine the softness of the curd of milk, and in relating superior digestibility to the soft-curd character. Natural soft-curd milk, modified milk, processed soft-curd milks prepared by the homogenization process or the base-exchange treatment, evaporated milk, and boiled milk are considered briefly as to softness and digestibility of the curd. It is pointed out that in selecting cows for the production of soft-curd milk care must be taken to select only animals which secrete such milk as a natural characteristic and to exclude animals which are producing soft-curd milk due to udder infection (subclinical mastitis).

[**The quality and vitamin content of green peas when cooked or home-canned**, J. E. RICHARDSON and H. L. MAYFIELD (*Montana Sta. Bul. 381 (1940), pp. 19, fig. 1*).—The location and scope of this study and the methods of vitamin assay employed were similar to those of an earlier study on string beans (E. S. R., 81, p. 741). For the quality tests the Alaska, Laxtonian, Little Marvel, and Pioneer varieties were used and for the vitamin tests only Laxtonian. For all of the varieties 1 qt. of shelled peas weighed approximately 1½ lb. The peas were cooked by boiling for 30 min. in salted water in an uncovered aluminum saucepan and were canned by the steam-pressure cooker method, as recommended in a previous publication (E. S. R., 74, p. 278), and also, for purposes of comparison of spoilage records, by the hot-water bath and oven methods recommended in the same publication for acid foods only. No spoilage occurred in the peas canned by processing in the pressure cooker at a temperature of 240° F. for periods ranging from 30 to 50 min., but on examination 9 percent of the jars processed for only 30 min. showed the presence of viable organisms. Spoilage was extensive in the peas canned by the other two methods even when the processing was continued for long periods of time. In judging the quality of the cooked and canned (pressure cooker) peas, color changes were measured by the Munsell disks according to the technic described by Nickerson (E. S. R., 62, p. 503) and tenderness by the method described by Bonney et al. (E. S. R., 65, p. 190). The characteristic greenish yellow color of canned peas as compared with the green color of freshly cooked peas was found to consist of a change in hue, with very little change in brilliance and chroma. Determinations of pH indicated

that the change was due to increased acidity. In tenderness the canned peas met the Federal requirements for a standard product.

The vitamin A content calculated from growth data using vitamin A reference cod-liver oil for the standard was 4 International Units per gram for raw frozen peas, 8.6 I. U. for the same after boiling 30 min., 9.6 for pressure-canned peas (from the same lot) stored for 6 mo. and reheated 10 min., and 8.1 I. U. per gram for a sample of commercially canned peas stored 6 mo. and reheated for 10 min. The higher values for cooked than raw frozen peas was attributed to the increased digestibility on cooking. Vitamin B₁ values, also obtained by the growth method with vitamin B₁ International standard clay for comparison, in the same order of materials tested, were 1.02, 0.85, 0.82, and 0.82 I. U. per gram, respectively. Vitamin C values were estimated both biologically and chemically. By the former method the vitamin C content of raw frozen peas was 0.25 mg. per gram, home-canned by the pressure-cooker method 0.17 mg., and the same after storage for 6 mo. 0.13 mg. per gram. The average ascorbic acid values, as determined chemically, were raw 0.27 mg. per gram, boiled 30 min. 0.18, home-canned (pressure cooker at 240° for 45 min.) 0.19 mg. per gram for the unheated solids, 0.22 mg. per cubic centimeter for unheated juice, and 0.19 mg. per gram for peas and juice reheated together. The same canned peas showed no appreciable loss in vitamin C after storage for 8 and 12 mo. A sample of commercially canned peas had a considerably lower content. On the basis of the vitamin data, the authors conclude that an average serving of 70 gm. of cooked frozen peas or reheated peas canned at home under the above conditions would furnish about 600 I. U. of vitamin A, 60 I. U. of vitamin B₁, and 13 mg. of vitamin C.

Apple and cherry juice: Promising new outlets for Utah's fruit crops, F. M. COE (*Farm and Home Sci. [Utah Sta.], 1 (1940), No. 3, pp. 1, 10, figs. 2*).—Methods adapted to home and farm use for the preparation and preservation of clarified cherry and apple juices are noted briefly. The rack and cloth type of press is recommended. The cherries, after washing, grading, and soaking, are crushed and heated to 150° F. for pressing, the heat treatment serving to coagulate the pectin and thus permit of satisfactory clarification by filtering (after settling) in a home-made cloth-bag filter. Cold pressed juice, although better as to flavor, is less satisfactory as to color, and requires heating and treatment with pectinal enzyme before filtering. For apples cold pressing of the fresh fruit is recommended, the strained juice being treated with pectinal enzyme and after 5 hr. or more filtered with a cloth-bag filter with the use of Hyflo Supercel filter aid.

For preservation the juices are pasteurized by the holding or flash method and then sealed to exclude air. Glass containers or enamel cans may be used. Where freezing storage is available cherry and apple juices may be kept for long periods frozen at temperatures of 10° or lower.

The Montmorency cherry is the standard juice cherry, although blends of Montmorency, English Morello, and Black Tartarian are satisfactory. For beverage purposes the cherry juice is diluted, a sugar sirup being a satisfactory diluent for the sour juices. The Jonathan apple is recommended for an apple cider of rich body and full flavor, the Jonathan cider being satisfactory used alone or blended with juice from milder, sweeter apples which are too flat to use alone. The White Pearmain and Wealthy apples give good tart sweet ciders.

The chemical composition of foods, R. A. McCANCE and E. M. WIDDOWSON (*[Gt. Brit.] Med. Res. Council, Spec. Rpt. Ser. No. 235 (1940), pp. 150*).—These extensive tables present data on the proximate constituents and calorie value and on the mineral constituents and acid-base balance of a great number of fresh,

dried, canned, and cooked foods. Notes on technic and some individual findings are given in the text, together with certain explanations of terms and conventions. In addition to the main tables, supplementary tables are included giving data on "available" (nonphytic acid) phosphorus, and on "available" (ionizable) iron in foods.

The analyses in the several tables were obtained over a period of 14 yr. in the course of work by McCance and associates at King's College Hospital, London. Some of the data have been published earlier, but many are here given for the first time. The values given for the composition of cooked dishes containing several ingredients do not represent analyses, however, but calculations based on the composition of the ingredients and the change in weight (determined) on cooking. The recipes for these cooked dishes are given.

Foods and public health, J. E. FULLER (*Massachusetts Sta. Bul.* 373 (1940), pp. 16).—This bulletin gives practical information about food-borne diseases classified as diseases spread by milk, including tuberculosis, typhoid fever, scarlet fever, septic sore throat, and undulant fever; food poisoning, including ptomaine poisoning, *Salmonella* food poisoning and food poisoning from staphylococcus and other bacteria; botulism; and trichinosis. Preventive or protective measures for each group are discussed, and a list of 26 literature references is given.

Food consumption in urban Puerto Rico [trans. title], S. DÍAZ PACHECO (*Puerto Rico Univ. Sta. Bul.* 52 (1940), *Span. ed.*, pp. 29, figs. 6; *Eng. abs.*, pp. 28, 29).—This report presents the results of a food consumption study based on 1,901 family schedules taken in 22 cities and towns in Puerto Rico. These families, representing about 14 per cent of the total population of these districts, averaged 6.2 persons per family with an average annual income of \$734. The results were compared with those from a similar study in San Juan (*E. S. R.*, 81, p. 308).

One-fourth of the families in the 22 cities and towns bought 49 qt. or less of fresh milk per person per year, 30 percent bought from 50 to 99 qt., and 36 percent 100 qt. or over; 31 percent of the families consumed 99 eggs per person during the year, 32 percent from 100 to 249, and 21 percent 250 or over; only 18 percent of all families consumed over 61 lb. of beef per person during the year, 22 percent bought from 31 to 60, and 47 percent 30 lb. or less; plantains, tomatoes, sweetpotatoes, and yautias were also included in this analysis. With increase in income and also apparently with better education of the housewife the consumption of meats, fish, eggs, cheese, greens, tomatoes, plantains, and bread increased.

Distribution of foods in urban Puerto Rico [trans. title], S. DÍAZ PACHECO (*Puerto Rico Univ. Sta. Bul.* 53 (1940), *Span. ed.*, pp. 17, fig. 1; *Eng. abs.*, pp. 15-17).—The results of the distribution phase of the food consumption study noted above are given in the present report. In this the families are classified into income groups, the cities and towns into population groups, and within these groups an indication is given as to the importance of various distribution agencies. Street vendors, retail markets, small general stores, and special stores are the distribution agencies considered, and the food commodities are classified as minor crops, fresh beef and pork, chickens, fresh fish, fresh milk, eggs, and grocery goods.

The metabolism of carbohydrate and protein during prolonged fasting, W. H. CHAMBERS, J. P. CHANDLER, and S. B. BARKER. (Cornell Univ.). (*Jour. Biol. Chem.*, 131 (1939), No. 1, pp. 95-109).—In this study 11 adult mongrel dogs weighing between 9 and 22 kg. were observed during a prolonged fast with free access to water. Quantitative collection of the urine was begun at the intermediate stage of inanition after the dogs had lost 25-30 percent of

their original weights. The urine was analyzed to determine the excretion of total nitrogen, ketone bodies, creatinine, and creatine. Respiratory metabolism was determined at frequent intervals in the Lusk calorimeter. As the weight loss increased to about 50 percent, 7 of the 11 dogs exhibited the characteristic premortal rise in nitrogen metabolism. In these, designated as the "high-nitrogen" group, there was approximately a threefold increase in nitrogen excretion, a rise in the basal respiratory quotient to about 0.81, about a tenfold rise in creatinuria, and a definite fall in the ketone body excretion. These changes indicated a shift from the oxidation of stored fat as the source of energy, as characterizes the intermediate period, to oxidation of body protein in the premortal period.

In the 4 dogs designated as the "low-nitrogen" group, this characteristic shift was not observed, for the group maintained the low level of nitrogen excretion and high ketonuria, with basal respiratory quotients of about 0.73, and showed only about a five-fold increase in creatine excretion. Dogs of this latter group fasted for a much longer period before attaining the 50 percent loss in weight; this difference and the basal heat production of the animals suggested a greater store of fat in the low-nitrogen group. Moreover, with this group fat ingestion produced no effect on nitrogen excretion, whereas it exerted a marked nitrogen sparing effect in the high-nitrogen group. After fat ingestion, the metabolism of both groups resembled that of the intermediate fasting stage. The response to a glucose test meal was the same in both high- and low-nitrogen groups, the response being a rise in respiratory quotient to about 0.89, a fall in ketonuria, and small excretion of sugar, thus indicating partial restoration of the ability to oxidize glucose in this fourth phase of fasting metabolism. After the ingestion of meat normal respiratory metabolism and specific dynamic action were observed, although the ketonuria was increased.

The availability for growth of N-methyltryptophane administered as its acetyl derivative. W. G. GORDON, W. M. CAHILL, and R. W. JACKSON. (Cornell Univ. et al.). (*Jour. Biol. Chem.*, 131 (1939), No. 1, pp. 189-196, fig. 1).—Previous work having shown that *l*-tryptophan or, in lieu of preformed tryptophan, acetyl-*l*-tryptophan or *dl*-N-methyltryptophan, would support growth, the *l*-isomer of acetyl-N-methyltryptophan was tested. It was reasoned that if appreciable hydrolysis of this isomer occurred, then the resulting *l*-N-methyltryptophan should cause definite increase in the growth of test animals. Accordingly, male albino rats of about 100 gm. body weight were placed on a basal diet deficient in tryptophan but otherwise satisfactory. After the individual growth responses were established (about 6 weeks), the acetyl derivative to be tested was incorporated in the basal diet and fed for 4 weeks. Each animal served as its own control in subsequent periods when the basal diet was fed with or without a growth-promoting supplement of *l*-N-methyltryptophan. The diets were fed at libitum, the supplement in the control experiments being given at a level of 53.4 or 106.8 mg. per 100 gm. of basal diet, the lower level having been established as the minimum to produce unmistakable growth response; the supplement of acetyl-*l*-N-methyltryptophan was fed on an equivalent basis. In one experiment the test supplement was injected, as was also the control supplement, which in this case was the more soluble *dl*-N-methylamino acid.

From the individual growth curves and consumption records obtained in these experiments, it was apparent that the acetyl-*l*-N-methyltryptophan was not utilized for growth in the rats ingesting a diet deficient in tryptophan. Apparently, therefore, the substitution of the methyl group for the amide hydrogen of acetyl-*l*-tryptophan prevents its hydrolytic cleavage in the body.

The influence of diet on the endogenous production of citric acid, A. H. SMITH and C. E. MEYER (*Jour. Biol. Chem.*, 131 (1939), No. 1, pp. 45-55).—The experiments described were undertaken to obtain more definite information as to which of the major foodstuffs may give rise to urinary citric acid. Rats weighing about 200 gm. were placed in individual metabolism cages and given one of four diets, the citric acid content of 3-day urine samples being then determined for a number of successive periods. The diets were represented by a standard ration containing amounts of carbohydrate, fat, and protein commonly used in adequate basic diets, and three other rations containing, respectively, an exaggerated quantity of protein (72.6 percent of purified lactalbumin), carbohydrate (58.6 percent dextrin), or fat (70.5 percent Crisco). The intakes of citric acid from the various diets were uniform and small, amounting at the most to no more than 6.0 mg. per rat per 3-day period.

In the first experiment involving three rats on each diet over four consecutive 3-day metabolism periods, citric acid production (calculated as urinary minus ingested citric acid) averaged 2.7 mg., 0.7, 13.3, and 10.7 mg. per rat per 3 days on the standard, protein, carbohydrate, and fat diets, respectively. In a second experiment of six metabolism periods, using other groups of rats, the corresponding averages were 21.9 mg., 3.9, 54.0, and 37.8 mg. per rat per 3 days. The greater excretion in the second experiment is attributable to the well-known effect of alkali on citric acid excretion, for in this experiment a different lot of lactalbumin with a higher alkaline value was used. Although rats on the same diet varied in their citric acid production and there was some overlapping between groups, still it was evident as indicated by the averages obtained that there were distinct differences between the different diets. These findings were confirmed in other experiments, using the original groups of test animals but interchanging the diets.

These studies give evidence, therefore, that the white rat has the ability to synthesize citric acid, and that diets containing the major portion of the energy either in the form of carbohydrate or fat favor the formation of citric acid more than those composed chiefly of protein.

Mineral metabolism, growth, and symptomatology of rats on a diet extremely deficient in phosphorus, H. G. DAY and E. V. MCCOLLUM (*Jour. Biol. Chem.*, 130 (1939), No. 1, pp. 269-283).—Observations were made on 66 young rats as to the symptomatological and histopathological changes occurring upon a diet extremely deficient in phosphorus. Mineral balance studies were conducted on 7 rats, 3 of which were maintained on the phosphorus-deficient diet and 4 on the diet modified by the addition of adequate phosphate; of these 4, 1 was permitted to eat ad libitum while the other 3 were maintained as paired feeding controls. The present paper is concerned with the gross effects of the deficiency and with its progressive effects on the metabolism of Ca, Mg, Na, K, Cl, and N. The diet was composed of purified materials and contained only 0.017 percent of phosphorus but adequate amounts of other nutrients.

The young rats on the phosphorus-deficient diet grew slowly for 5-6 weeks, then declined, and died 2-3 weeks later. Extreme rarefaction of the skeleton quickly occurred, accompanied by progressive disability in walking, standing, and breathing. As observed in 2 rats in extreme deficiency, restoration of phosphorus to the diet brought about marked recovery. The metabolism of Na, K, and Mg appeared to be unaffected by the phosphorus deficiency, and the results on chlorides were equivocal. Nitrogen retention was positive for 5 weeks and then became negative as the animals began to lose weight. The changes in P and Ca metabolism were striking. There was a great loss of Ca, this loss being precipitous during the first 2 weeks; there was also loss of P, though

this was much less than the Ca loss. Apparently the P was withdrawn from the bones to be transferred to the soft tissues, where it was used with N for their growth. With rapid depletion of the P, however, there was no longer any growth of these tissues and the negative N balance ensued. With the mobilization of P from the bones, the Ca was released and this and Ca absorbed from the diet had to be excreted. The loss of Ca was principally through the urine, but most of the excreted P was in the feces. The results are discussed with relation to the conclusion of Schneider and Steenbock (E. S. R., 81, p. 884) that vitamin D induces P deposition in bone in preference to soft tissues when the dietary provides little P.

The sulphur content of foods, M. MASTERS and R. A. McCANCE (*Biochem. Jour.*, 33 (1939), No. 8, pp. 1304-1312).—Sulfur, expressed as milligrams per 100 gm. or per 100 cc. of fresh material (edible portion), is reported for about 300 foodstuffs of plant and animal origin, including fresh, dried, and canned fruits; fresh and cooked vegetables; cereals and starch products; dairy products; sweetmeats, jams, etc.; beverages, including a number of commercial (English) products and several beers; condiments; fats; sausages and meat and fish pastes; fresh and cooked meats; meat organs; fresh, cooked, smoked, and canned fish; and shellfish. For nearly all of the fruits, vegetables, and nuts, the determinations were made on the dried mixed samples analyzed for other constituents by McCance et al.⁴ A number of the food materials, notably cereals, were analyzed concurrently for other constituents by McCance and Widdowson (noted on p. 123). These publications may be consulted for data on other constituents, including moisture and nitrogen, for information on preparation and sampling of materials, and for scientific nomenclature. A few vegetables which it was thought might contain volatile or potentially volatile sulfur compounds were obtained as fresh samples and analyzed in the wet state. Flesh foods analyzed in this state were obtained as fresh samples, and moisture, sulfur, and nitrogen were determined. For scientific nomenclature of these foods, reference should be made to the study of McCance and Shipp.⁵ The results of the sulfur determinations are compared very briefly with those of other workers, and the N : S ratio is given some consideration.

Sulfur was determined in most cases by a hydrogenation method, although destructive oxidation of the organic matter with a nitric-perchloric acid mixture, followed by a gravimetric estimation of the resulting sulfates as BaSO₄, was used in some cases, particularly for the analysis of undried material. These methods are described in the study noted on page 8.

Body needs of iron given by legumes, leafy vegetables, O. SHEETS (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 8, pp. 1, 2).—This brief report, presented in popular form, outlines studies conducted to determine the suitability of green leafy vegetables and legumes as sources of iron for hemoglobin formation. The legumes—cowpeas, butter beans, pinto beans, and soybeans—gave better hemoglobin gains than the greens—mustard, collards, turnip tops, spinach, and lettuce. This was due in part, it was determined, to the adequate amounts of copper furnished by the legumes and in part to the greater availability of their iron, which was 90 percent available to the body as compared with 60-65 percent in the greens.

Influence of age upon the requirement of vitamin A, J. T. IRVING and M. B. RICHARDS (*Nature [London]*, 144 (1939), No. 3656, pp. 908, 909).—Groups of litter mate rats were put on the authors, vitamin A-free diet (E. S. R., 82, p.

⁴ [Gt. Brit.] Med. Res. Council, Spec. Rpt. Ser. No. 213 (1936), pp. 107, figs. 26.

⁵ [Gt. Brit.] Med. Res. Council, Spec. Rpt. Ser. No. 187 (1933), pp. 146, figs. 36.

423) at weaning (23 days) and given doses of vitamin A varying from $\frac{1}{3}$ to 3 International Units daily. At the end of stated periods the rats were killed and their teeth examined for color and histological changes, the degree of which was assessed by an arbitrary scale. The negative controls showed the first abnormal signs after 30 days on the diet, these progressing with time. The longest survival on the vitamin A-free diet was 66 days. At this time the teeth of the negative controls were quite white, those receiving $\frac{1}{3}$ and $\frac{2}{3}$ I. U. of vitamin A a pale yellow, and those receiving 3 I. U. almost normal. As the experiment proceeded, the teeth of the rats on the higher doses faded progressively. After 105 days, the teeth of those on 1 and 1.5 I. U. of vitamin A were quite white, at 135 days those on 2 I. U. were completely colorless, and at 180 days those on 3 I. U. showed only a faint yellow tinge.

Slight histological changes were seen in the teeth of the animals receiving $\frac{1}{3}$ and $\frac{2}{3}$ I. U. and examined after 49 and 66 days, the others being normal. In a group killed at 52 days the teeth showed changes up to an intake of 2 I. U. daily. At 119 and 148 days the animals receiving 1 I. U. daily showed marked changes and in those killed after 180 days the teeth were not entirely normal even on 3 I. U.

The post-mortem findings checked closely with the color and histological changes. Of the animals killed up to 66 days, the negative controls showed the usual pathological changes such as keratosis of the stomach. Those on 1 or more I. U. of vitamin A per day were quite free of pathological change. In those killed after 52 days all showed some slight abnormality except the one receiving 3 I. U. All of the animals continued longer on the experiment had keratosis of the stomach, decreasing in severity with increased dosage of vitamin A.

These results are thought to furnish definite proof that the requirement of the animal for vitamin A increases with age. This is thought to be in line with the suggestion of Guilbert and Hart (E. S. R., 74, p. 527) that the requirements of vitamin A are a function of body weight.

A study of diet in relation to health: Dark adaptation as an index of adequate vitamin A intake, II, III, A. M. THOMSON, H. D. GRIFFITH, J. R. MUTCH, D. M. LUBBOCK, E. C. OWEN, and G. LOGARAS (*Brit. Jour. Ophthalmol.*, 23 (1939), Nos. 7, pp. 461-478, figs. 6; 11, pp. 697-723, figs. 7).—These two papers continue a series, the first paper⁶ of which reported a preliminary study of a modification of the Edmund and Clemmesen method of assessing degrees of dark adaptation by measuring the power of distinction with a series of test letters ranging from black to nearly white over a wide light range.

II. *A new photometer for measuring rate of dark adaptation.*—The new adaptometer described, with technic for its use and discussion of its reliability, uses a single black test letter only (E or U) with a more sensitive type of light control and with measurements of light threshold only, involving no estimation of power of distinction between grays. A distinctive feature of the method is the use of a bleaching apparatus which consists of a metal bowl 2 ft. in diameter and 18 in. deep, lined with plaster of paris. The subject's head is supported on a chin rest on the lower edge of the bowl, and above his head is a "pearl" electric globe controlled by a variable resistance to give a steady light. The intensity of illumination of the surface of the bowl, as measured by a visually corrected photoelectric cell, has a value of 93 footcandles at the point directly opposite the eye position, diminishing to 88 footcandles 60° from the center. After preliminary dark adaptation, the subject undergoes a 4-min. bleaching period. In the opinion of

⁶ A study of diet in relation to health: Dark adaptation as an index of adequate vitamin A intake.—Technique and preliminary results, J. R. Mutch and H. D. Griffith. *Brit. Med. Jour.*, No. 4002 (1937), pp. 565-570, figs. 9.

the authors, many of the inconsistencies reported in the use of dark adaptation methods are due to incomplete bleaching. Data are reported in proof of this point.

After the bleaching the test proper begins. This consists essentially in varying the intensity of the light by the use of a diaphragm with holes of graded size and recording the time taken before the subject sees the test letter and indicates its direction. In evaluating results obtained with the test, both the extent of illumination required as determined by the size of the aperture and the time required are taken into consideration.

III. *The relation of diet to rate and extent of dark adaptation.*—This paper reports the application of the Rowett adaptometer described in the preceding paper to the assessment of dark adaptation in various groups, the determination of standards of dark adaptation from data obtained on normal subjects known to be receiving ample vitamin A, the rates of dark adaptation in children on different diets, and the effect of vitamin A administration in individual cases. The results obtained in the above tests and the reported observations of others are compared. Various sources of error and factors affecting the tests are discussed, and the following conclusions are drawn:

"It would appear from our results that neither rate of dark adaptation nor light threshold of the fully dark adapted eye has necessarily a close correlation with intake of vitamin A in the diet. Considerable variation may occur in one individual and between individuals on the same diet. Clinical observations and experiments in vitamin A deficiency have shown that vitamin A and dark adaptation are related. But it seems that in certain cases at any rate the speed and extent of cure of hemeralopia by vitamin A concentrates are subject to considerable variation. The majority of workers believe that the study of dark adaptation can be used as a test for vitamin A deficiency, but until differences in technic and interpretation of results have been resolved, it is impossible to be certain how far their recorded observations represent physiological facts."

An extensive bibliography is appended.

Vitamin A deficiency: Its prevalence and importance as shown by a new test, L. B. PETT (*Jour. Lab. and Clin. Med.*, 25 (1939), No. 2, pp. 149-160, figs. 4).—The rapid test described, with photograph and working diagram of the apparatus employed, depends on the recovery time after looking at a bright light, the test object being a rectangle or bar of dim light which is seen vertically or horizontally. Following a 30-sec. exposure to bright light during which the subject looks at a black spot marking the position where the bar of dim light will appear later, the bright light is turned off, and the subject says "up" or "across," indicating the direction of the bar at the moment when it becomes visible. A recovery time of 11 or more seconds is considered to indicate deficiency in vitamin A. Normality with respect to vitamin A is ascribed to anyone who does not show a change in recovery time after a single 50,000 International Units dose of vitamin A and who has no evidence of vitamin deficiency.

"Proof of the test's relation to vitamin A has been given by (1) a report of experimentally induced vitamin A deficiency, correlating the test with other signs; (2) the prolonged recovery times observed in people with liver disease (cirrhosis or diabetes) or on special diets whereby they either do not receive the vitamin or do not convert it from carotenoids; (3) the recovery on treatment with vitamin A of some 200 cases classed as deficient; and (4) subjective improvement in many such cases. The effects on the test of sex, age, color of eyes, myopia, hyperopia, astigmatism, wearing of spectacles, and fatigue are negligible, since great accuracy is not demanded. The size of pupil, disparity of vision of the two eyes, and diseases might have an effect."

Of the 1,600 or more people examined, 52 percent were found deficient in vitamin A by the criteria employed, the highest percentage in any group, 64 percent, being among single men from 20 to 35 yr. of age on relief. In a comparison of 393 normal and 360 deficient subjects, higher percentages of the deficient than of the normal subjects were found to be suffering from various conditions, including night blindness, eyestrain and photophobia, dry conjunctiva, dry skin, dry nasal mucosa, scanty saliva, and frequency and duration of colds.

Photometric measurements on visual adaptation in normal adults on diets deficient in vitamin A, L. F. STEFFENS, H. L. BAIR, and C. SHEARD (*Mayo Found. Med. Ed. and Res., Proc. Staff Mtgs. Mayo Clinic, 14 (1939), No. 44, pp. 698-704, figs. 3*).—For the apparatus described two adjoining lightproof rooms were used. In one were placed the person being tested, the small light with red filter which served as the fixation target, and the area which on illumination acted as the source of retinal stimulus. In the other room were placed a bench with sliding head carrying a small lamp which on being moved toward the subject caused an increase in the intensity of light falling on the retinal stimulus target. The threshold intensities in micromillilamberts were determined by suitable calibration. In the use of the apparatus the subject's right eye was light-adapted for 3 min. by looking at the screen uniformly illuminated with a light of 160 footcandle intensity. The adapting light was then turned off, the subject looked at the fixation light, and the operator moved the light source slowly toward the subject until the light on the target was seen. The time elapsing from the beginning of the dark adaptation period, the position of the light source on the optical bench, and the value of the light transmitted by the filter used were recorded.

Three subjects on a diet with adequate provision for protein, calcium, phosphorus, iron, and vitamins other than A and with the A intake restricted to from 100 to 300 International Units daily were tested at intervals during periods of 44, 160, and 190 days, respectively. Determinations of the light sensitivity were made at intervals of $\frac{1}{2}$ –2 min., with alternate readings for the macular and paramacular (10° above macula) regions. The readings were continued after the resumption of an ordinary diet supplemented with 80,000 units of vitamin A. In the two subjects who remained longest on the deficient diet the light thresholds of both regions were increased by only 0.5 logarithmic unit in 3 mo., a change considered insufficient to warrant concluding that there was any evidence of vitamin A deficiency. This was further borne out by a tendency of the light threshold to decrease gradually to the normal level at the beginning of the experiment and to be practically unaffected by subsequent increases in vitamin A intake. Comparable and in some cases almost identical values were obtained with the biophotometer.

Microscopic examination of sections of the skin of one of the subjects showed that after 190 days changes characteristic of the late stages of avitaminosis appeared. These are described as "hyperkeratosis, keratotic plugging of the hair follicles, atrophy of the sebaceous glands, and perivascular infiltration in the upper cutis." A repetition of the test 17 days after treatment with vitamin A showed restoration to normal conditions except for keratotic plugs in the hair follicles. As the skin changes antedated appreciable changes in light sensitivity, the authors suggest the possibility that "normal values of light sensitivity may be maintained over considerable periods of time through the utilization of carotene and vitamin A previously deposited in the skin and fatty tissues, and that the minimal requirements of these substances for proper visual function may be much less than has heretofore been believed."

Thyroxine and hypervitaminosis-A, C. A. BAUMANN and T. MOORE (*Biochem. Jour.*, 33 (1939), No. 10, pp. 1639-1644, fig. 1).—The conflicting literature on the question of the interrelationship of vitamin A and thyroxine is reviewed briefly, and new experimental evidence on rats is reported, indicating that when both vitamin A and thyroxine are administered in doses so large as to be toxic but not rapidly fatal, no interrelation could be established.

The effect of large doses of thyroxine was first studied in 1-year-old stock female rats which had high reserves of vitamin A at the beginning of the experiment. The animals were divided into four groups which received, respectively, a low vitamin A diet plus an excess of vitamin A (8 mg. daily), the same plus 0.6 mg. of thyroxine injected subcutaneously 3 times a week, the basal diet alone, and the basal diet plus thyroxine. All animals receiving either thyroxine or excess of vitamin A or both showed decreased food intake and loss of weight, greater for the animals receiving both supplements than one alone. The decreased food intake by the animals receiving thyroxine was followed after 10 days by a sudden increase, which was not duplicated by the animals receiving only the basal diet alone or with vitamin A. The animals receiving thyroxine alone or vitamin A alone survived the 6 weeks of the experiment. All those receiving vitamin A and thyroxine died between the fourteenth and nineteenth days.

A second series of similar tests was run on young rats 4 weeks of age at the beginning of the experiment, with similar results.

Keratoconus experimentally produced in the rat by vitamin A deficiency, J. R. MUTCH and M. B. RICHARDS (*Brit. Jour. Ophthalmol.*, 23 (1939), No. 6, pp. 381-387, fig. 1).—Keratoconus is defined as a condition of the eye in which the central portion of the cornea bulges forward in the form of a cone without any sign of inflammatory symptoms. In the study reported, it was produced in rats in which acute xerophthalmia had developed on a vitamin A-deficient diet and allowed to progress until the cornea showed a central haziness, at which time the animals were given concentrated doses of vitamin A. The stage at which the vitamin A was administered determined whether or not the keratoconus followed. When the vitamin was given too early the eyes cleared up rapidly, leaving no apparent abnormality, while if treatment was delayed too long the eye perforated. "In cases where keratoconus developed the sequence of the symptoms was as follows: By the second day following the administration of vitamin A the discharge had become much less, the eyes were partly open, and the cornea showed a central protrusion. This protrusion increased and came to a point. It took on an average 10 days for the cone to reach a maximum size." In most cases the cornea regained its normal shape after a few weeks dosing with vitamin A, although corneal nebulae and myopia remained as permanent defects.

Studies of the vitamin B complex: Further studies of vitamin B₆ deficiency, W. D. SALMON (*Alabama Sta. Rpt.* 1938, p. 16).—In this progress report (*E. S. R.*, 81, p. 140) the effectiveness of various substances in the cure of vitamin B₆ deficiency is noted.

Observations on the vitamin B₁ excretion of four healthy subjects living on different Indian diets, R. C. GUHA and B. AHMAD (*Indian Jour. Med. Res.*, 27 (1939), No. 2, pp. 465-469).—The urinary excretion of vitamin B₁ by four healthy subjects on diets typical of different sections of India was determined by the rat growth method on Lloyd's reagent adsorbates of the urine prepared by the method of Harris and Leong (*E. S. R.*, 76, p. 425). The daily output of vitamin B₁ of these subjects on their customary diets ranged from 84 to 228 μ g. (28-96 International Units), which represented from 5.9 to 19 percent of the estimated intake. When the vitamin B₁ content of the diets was decreased without lowering the calorie content by replacing home-pounded and half-milled rice by polished

rice and atta by white flour, both the total and the percentage outputs of vitamin B₁ were decreased. Three of the subjects then returned to their original diets and were given supplements of vitamin B₁ in the form of a clay adsorbate of rice polish furnishing 600–1,200 μ g. of vitamin B₁. Four days were required for one of the subjects and 3 for another to reach approximately the initial level of excretion. The third subject, tested only on the second day, had not reached the initial level at that time.

Attention is called to the agreement of the results in this study with the observations of Harris and Leong except that the daily output was higher in the present study than of normal subjects in the Cambridge study. "The amount of vitamin B₁ excreted in the urine depends upon the dietary intake and the previous dietary history of the subject. It represents, however, a small percentage of the total intake. When the intake is low, the percentage excretion is lower than that on a high vitamin intake. This might be a physiological adjustment on the part of the organism to conserve the stores in the face of a declining supply."

Processing and thiamin, A. ARNOLD and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Food Res.*, 4 (1939), No. 6, pp. 547–553, figs. 3).—The thiamin content of certain meats and meat products processed in 1-lb. tins was determined by the chick assay procedure (E. S. R., 79, p. 672), with unprocessed vacuum-dried samples as controls. The control sample of beef kidney contained 5 International Units or 15 γ of thiamin per gram, dry basis, and the sample processed for 2 hr. at 115.6° C. only 3 γ . Corresponding values for beef lung tissue were 6 γ and less than 1.5 γ , and beef spleen 6 γ and 1.7 γ per gram, respectively. Hog muscle contained 20 γ of thiamin per gram in the vacuum-dried sample and less than 4 γ after processing for 1 hr. 50 min. at 121° C. A meat product containing a small amount of cereal grains furnished 5 γ of thiamin per gram in the control sample, and 2 γ , 1.7 γ , 1.5 γ , and less than 1 γ per gram after processing 1 hr. at 240° F., 1 hr. 30 min. at 240°, 2 hr. at 240°, and 1 hr. 50 min. at 250°, respectively. The results show that processing under the conditions followed is very destructive of thiamin, and that increase in temperature is somewhat more destructive than increase in time.

The utilization of certain sulfur-containing compounds for growth purposes, W. C. ROSE and E. E. RICE. (Univ. Ill.). (*Jour. Biol. Chem.*, 130 (1939), No. 1, pp. 305–323, figs. 4).—Four compounds, *dl*-homocystine, *dl*-homocysteine, the thiolactone of *dl*-homocysteine hydrochloride, and *l*-cysteine hydrochloride, prepared by methods described, were tested for their growth-promoting effects in young rats. The compounds were fed, respectively, as supplements to a basic diet in which the nitrogenous portion of the food was furnished in the form of a mixture of highly purified amino acids; the mixture excluded both cystine and methionine and likewise the nonessential (to the rat) acids norleucine, hydroxyglutamic acid, and citrulline. For control purposes, like experiments were conducted with cystine and methionine as the respective supplements, the latter compound promoting rapid growth, the former permitting a decline in weight. The diet contained in all cases an adequate supply of minerals and vitamins, the vitamin B factors being furnished in two different forms in successive experiments.

The *l*-cysteine hydrochloride failed to improve the nutritive quality of the basic diet, permitting a decline in weight at a rate comparable to that which occurred when cystine was furnished in the absence of methionine. The effects of homocystine, homocysteine, and the thiolactone of homocysteine hydrochloride were found to depend on the nature of the vitamin B supplement. When the B factors were supplied in the form of tikitiki and milk concentrate, either of the three amino acids permitted growth, although at distinctly subnormal rates as evidenced by the growth curves and weight data presented.

Bare maintenance or even loss of weight occurred with either of the three amino acids when the vitamin B factors were supplied as the crystalline vitamins plus ryzamin-B, the form adopted by Du Vigneaud et al. in the study noted below. It is considered, therefore, that the ability of the organism to synthesize methionine out of the compounds in question is facilitated to a greater extent by one type of vitamin B supplement than by the other.

A relationship between the nature of the vitamin B complex supplement and the ability of homocystine to replace methionine in the diet, V. DU VIGNEAUD, H. M. DYER, and M. W. KIES. (Cornell Univ. et al.). (*Jour. Biol. Chem.*, 130 (1939), No. 1, pp. 325-340, figs. 2).—This investigation, an outgrowth of a study to determine the mechanism of conversion of methionine and homocystine into cystine in the animal body, was undertaken when it became evident that the nature of the vitamin B supplement might influence the ability of homocystine to substitute for methionine.

In growth studies with young rats, homocystine as a dietary supplement or homocysteine injected subcutaneously was administered to animals on a basic diet in which the nitrogenous constituents were supplied by an amino acid mixture (20.4 parts) devoid of methionine and cystine and almost identical with the one used by Rose et al. in the study noted above; dextrin 27.6, sucrose 15.0, lard 26.0, cod-liver oil 5.0, agar 2, and salt mixture 4 parts completed the diet. The vitamin B factors were supplied by a daily supplement per rat of 0.02 mg. of crystalline thiamin chloride, 0.02 mg. of riboflavin, and 0.02 mg. of nicotinic acid, with 25 mg. of ryzamin-B (an aqueous acetone extract of rice polishings) as a source of the other B factors. With this regime neither the homocystine nor the homocysteine was capable of supporting growth of the animals; at autopsy they showed fatty infiltration of the liver. With the same basal diet but with the vitamin B factors supplied by tikitiki and milk vitamin concentrate (as used by Rose et al.), homocystine was found to support growth. Apparently, therefore, some factor (or factors) was present in the tikitiki and milk vitamin concentrate, but lacking or present in insufficient amounts in the mixture of purified vitamins and ryzamin-B, which made possible the utilization of homocystine by animals on a methionine-deficient diet.

Studies on the metabolism of pyruvic acid in normal and vitamin B₁-deficient states, IV-VI (*Biochem. Jour.*, 33 (1939), No. 10, pp. 1525-1537, fig. 1; pp. 1538-1543, figs. 2; pp. 1544-1548).—In continuation of the series noted previously (E. S. R., 83, p. 133), three papers are presented.

IV. The accumulation of pyruvic acid and other carbonyl compounds in beriberi and the effect of vitamin B₁. B. S. Platt and G. D. Lu.—Data are reported on the quantities of bisulfite-binding substances (B. B. S.), particularly pyruvic acid, in the blood, cerebrospinal fluid, and urine of adult subjects, most of whom were in various stages of vitamin B₁ deficiency. For purposes of comparison some observations were also made on apparently healthy persons and on B₁-deficient subjects, including some cases of fulminating beriberi, following the administration of vitamin B₁. A few samples of human milk from normal Chinese and British women and from Chinese women in a state of subacute vitamin B₁ deficiency were analyzed for pyruvate.

A group of 60 subjects classified with respect to beriberi as resting or cured gave blood pyruvic acid values ranging from 0.4 to 0.75 mg. per 100 gm.; of 12 after adequate dosage of vitamin B₁, 3 gave cerebrospinal pyruvic acid values less than 0.4, 6 between 0.4 and 0.55, and 3 between 0.70 and 0.75 mg. per 100 gm. In an earlier study blood B. B. S. values (calculated as pyruvic acid) for 23 apparently healthy Chinese subjects ranged from 2.22 to 4.8 mg. per 100 gm., with a mean of 3.27 and standard deviation of 0.70. In comparison with

these figures pyruvic acid blood values in subacute beriberi ranged from 0.17 to 1.93, with a mean of 0.93 mg. per 100 gm., and B. B. S. from 2.7 to 7.3, with a mean of 4.5; pyruvic acid in cerebrospinal fluid from 0.41 to 1.32, with a mean of 0.72, and B. B. S. from 1.8 to 4.2, with a mean of 2.81 mg. per 100 gm. The number of cases in the four groups were 84, 65, 30, and 25, respectively. In acute beriberi the values were all much higher, the means for the four items being 2.72, 10.1, 1.69, and 3.7 mg. per 100 gm., respectively. Data for 4 cases of fulminating beriberi, cured by vitamin B₁ in amounts ranging from 40 to 5 mg., were obtained at intervals during recovery. Initial blood pyruvic acid values ranged roughly from 3 to 5 mg. per 100 gm. and were reduced to from 1 to 2 mg. per 100 gm. 5 hr. after treatment. In 3 of the 4 cases there was a lag of 3 or 4 hr. before a sudden fall. Pyruvic acid values for human milk ranged from 0.1 to 0.24, with a mean of 0.16 mg. per 100 gm. for 8 normal Chinese women, from 0.12 to 0.26, with a mean of 0.18 mg. per 100 gm. for 3 normal British women, and from 0.34 to 0.53, with a mean of 0.41 mg. per 100 gm. for 5 Chinese women in a state of subacute vitamin B₁ deficiency.

In discussing these findings the possibility is recognized that pyruvate accumulation is specific for vitamin B₁ deficiency only insofar as there is a derangement in intermediate carbohydrate metabolism. Concerning the fact that the increases in B. B. S. are greater than can be accounted for by the increase in pyruvic acid, three possibilities are suggested. "They may be products of deranged metabolism due solely to insufficient amounts of vitamin B₁; they may be derived from pyruvic acid or, thirdly, they may be the products of some associated deficiency or other metabolic error."

V. *The effect of exercise on blood pyruvate in vitamin B₁ deficiency in man*, G. D. Lu and B. S. Platt.—The exercise in this study consisted either of sitting up and lying down in bed without assistance 20 times in a 45-sec. interval, or climbing 100 steps 5 times in from 8 to 10 min. Blood was taken for analysis at rest, immediately after exercise, and at the end of ½ hour's rest following the exercise. The subjects thus tested included 13 patients cured of beriberi, 2 of whom were tested twice, and 5 subacute cases tested before and after treatment with vitamin B₁ by intravenous injection. In the cured cases the pyruvic acid values for the most part showed an increase immediately after the exercise, but dropped back to approximately the original levels ½ hr. later. Following treatment with vitamin B₁, light exercise did not consistently increase the blood pyruvate levels, and such B. B. S. value increases as were noted disappeared by the end of the ½ hr. period. They showed no consistent change. Detailed accounts of 2 typical examples of acute beriberi showing effects of vitamin B₁ injections on blood pyruvic acid, and B. B. S. values before and after light and heavy exercise, are also reported, with similar data on normal and cured subjects. These indicate that when the changes of blood pyruvate are inconsiderable, marked increases accompanied by clinical symptoms resembling those of fulminating beriberi may follow heavy work, but that still heavier work may be tolerated by subjects not deficient in vitamin B₁ and without appreciable increases in blood pyruvate values. B. B. S. values were increased when the blood pyruvate was markedly increased, but to an extent that could not be accounted for solely by increase in pyruvic acid. Increase in pyruvic acid excretion after exercise was also noted.

It is considered probable that increased muscular work is only one of a number of factors capable of increasing the requirement for or deficiency of vitamin B₁ through their contribution to the increase in metabolic activities in which this vitamin is involved. It is suggested that exercise may be used to reveal latent vitamin B₁ deficiencies, but that exercise tests may be limited by the subject's inability to engage in heavy effort. "In view of this it is suggested that a modifi-

cation might be based on the determination of blood changes following a measured amount of work in a limb in which venous return is obstructed. In view of the possible association of fatigue, vitamin B₁ deficiency, and exercise this test might well be combined with observations of the development of sensations of pain in the exercised limb."

VI. *The fate of injected pyruvate in the normal rabbit*, G. D. Lu and D. M. Needham.—Rabbits were loaded with definite amounts of pyruvate by intravenous injections lasting for from 1 to 2 min., and blood samples were taken for analysis of total reducing sugar, fermentable sugars, nonglucose substances, pyruvic acid, and lactic acid before and immediately after the injection and 8, 20, and 30 min. later. The injection of small doses, 150 and 200 mg., of pyruvic acid gave rise to a temporary increase in nonglucose substances and lactic acid, followed by a more marked increase in the fermentable sugars as the nonglucose-reducing substances returned to resting levels. Analyses of lactate and pyruvate changes in the muscles and blood of rabbits after injections of 340 and 550 mg. of pyruvate are also reported. Only from 2 to 3 percent of the total injected pyruvate was retained by the muscles. In 30 percent of the cases significant lactate increase occurred in the muscles and in all cases a lactate increase in the blood. In samples from 2 rabbits a possible change in various phosphate fractions was sought but not found.

These findings are thought to suggest that the ability to rebuild carbohydrate from lactate and pyruvate is "one of the factors in the organism limiting the efficiency of pyruvate removal. The well-known decrease of glycogen content in the tissues, the similar small increase of pyruvate accompanied by a much larger increase of lactate in the blood, and the delayed removal of these after exercise in avitaminous animals appear to indicate that vitamin B₁ may play an important role in the anabolism as well as the catabolism of glycogen."

Vitamin C content of vegetables.—XII, **Broccoli, cauliflower, endive, cantaloup, parsnips, New Zealand spinach, kohlrabi, lettuce, and kale**, K. WHEELER, D. K. TRESSLER, and C. G. KING (N. Y. State Expt. Sta. et al.). (*Food Res.*, 4 (1939), No. 6, pp. 593-604).—The vitamin C content was determined by titration, and checked for most of the samples by biological assay. For the cauliflower, broccoli, endive, lettuce, parsley, and New Zealand spinach a mixture of 5 percent sulfuric acid and 2 percent metaphosphoric acid was used in the extraction; for cantaloups and parsnips an 8 percent acetic acid and 2 percent metaphosphoric acid mixture, and for kale an 8 percent trichloroacetic acid and 2 percent metaphosphoric acid mixture. The vegetables were tested fresh from the field and after storage at different temperatures for different lengths of time. The effect of variety, portion of the plant, and maturity was also tested with some of the samples.

The average ascorbic acid values of the edible portion of the freshly harvested vegetable are given as parsley 2 mg. per gram, broccoli 1.3, kale 1.3, cauliflower 0.9, kohlrabi 0.65, New Zealand spinach 0.45, parsnip 0.40, cantaloup 0.35, lettuce 0.15, and endive 0.14 mg. per gram. Varietal differences were slight for the four varieties of broccoli, cauliflower, and endive tested. The five varieties of lettuce tested and their ascorbic acid content were California Iceberg 0.10, Mignonette 0.11, White Boston 0.13, Salamander 0.14, and Black Seeded Simpson 0.21 mg. per gram; and the six varieties of cantaloup Bender Surprise 0.23, New Wonderful 0.24, Cooper Sweetheart 0.25, Aristocrat 0.37, Golden Marvel 0.38, and Honey Rock 0.48 mg. per gram. Broccoli had a higher ascorbic acid content in September than in July, with averages of 1.64 and 1.19 mg. per gram, respectively, and at the same season a higher content in the blossoms than in the stems (July values 1.46 and 1.09 mg. per 100 gm., respectively).

Cauliflower blossoms were also richer in ascorbic acid than the stems, with values of 1.03 and 0.90, respectively, for the July samples. When held at room temperature in the summer, broccoli, cauliflower, endive, kale, lettuce, and New Zealand spinach lost ascorbic acid rapidly. Refrigeration effectively retarded the losses for broccoli, cauliflower, and endive, but not so effectively for lettuce and kale. The ascorbic acid content of parsnips kept in a pit during the winter at temperatures slightly above freezing decreased from 0.400 mg. per gram in November to 0.149 mg. in March. The losses were still greater at a higher temperature, 44.6° F., and the parsnips were also in a much poorer condition.

The concentration of vitamin C in the blood during and after pregnancy, A. SADOVSKY, D. WEBER, and E. WERTHEIMER (*Jour. Lab. and Clin. Med.*, 25 (1939), No. 2, pp. 120-131).—The first part of this report deals with the theoretical aspects of vitamin C metabolism and behavior in the blood and urine and the second with results of vitamin C determinations in the blood of women (nonpregnant, pregnant, and post-partum). In the opinion of the authors "the surest method of determining an actual vitamin deficiency in contradistinction to a mere reserve deficiency is provided by assaying the concentration of vitamin C in the blood." A concentration of 0.78 mg. percent is considered normal, although this must be raised to 1.4 mg. percent before excretion can occur, the latter concentration being the threshold saturation level. The validity of values for blood obtained by indophenol titration according to the Farmer and Abt method was shown by the practically complete reduction of reducing properties of blood serum and plasma by the action of a cucumber juice extract which catalyzes the oxidation of ascorbic acid. The stability of the vitamin in blood samples was tested, with the conclusion that it is greatest at neutral or weakly alkaline pH and least at pH 5. No method of inhibiting the residual autoxidation could be found, although deproteinization by metaphosphoric acid is recommended as inhibiting the action for several hours.

The average vitamin C concentration in the blood of 322 women was found to be 1.01 mg. percent. Of these subjects, 207 pregnant women gave an average value of 1.09 mg. percent, 62 post-partum 0.79, and 47 nonpregnant 0.98 mg. percent. Insignificant differences were found in the vitamin C content of the blood of pregnant women with teeth in good, medium, or bad condition, and the concentration of calcium and phosphorus was likewise found to be independent of the condition of the teeth. In 43 pregnant women suffering from gingivitis, the vitamin C content of the blood was normal, averaging 1.18 mg. percent, and in 7 with gingivitis complicated with caries slightly below normal, averaging 0.9 mg. percent.

The concentration of vitamin C in human milk during the first 9 days after confinement was determined in a total of 147 tests for 62 women. Values rose from an average of 2.63 mg. percent on the first day to 5.52 mg. percent on the eighth day, with calculated daily totals of 2.44 and 27.0 mg., respectively. There appeared to be no definite correlation between the vitamin C content of the milk and the blood of the same subject or between the age of the mother, number of children born previously, and weight of the new-born infant and the concentration of vitamin C in milk and blood. An arrangement of the blood values by month showed markedly higher values during the citrus season.

Some effects on guinea pigs of feeding vitamin C intermittently, M. T. HARMAN and A. MILLER. (*Kans. Expt. Sta.*). (*Kans. Acad. Sci. Trans.*, 42 (1939), pp. 445-449).—In continuation of studies noted previously (E. S. R., 80, p. 429), the effects of intermittent vitamin C feeding either as ascorbic acid or greens on the pathological changes in jaw bones, cheek teeth, and incisors of guinea pigs, as well as their general nutritive condition and incidence and

severity of scurvy, were observed in 47 guinea pigs, male and female and of different ages, with the conclusion that for normal growth and best physiological conditions a liberal amount of vitamin C should be included in the diet regularly, but that animals can be deprived of vitamin C for a short time and still live. On resumption of vitamin C, some animals seem to recover fully while others do not. Individual differences in the degree of resistance to the lack of vitamin C were apparent in the animals studied, suggesting that "the degree of resistance to an attack of scurvy is an individual factor," and that "although there is a chance for recovery from a pronounced case of scurvy produced by a limited amount of vitamin C, there is probably a greater chance for death."

Influence of fever therapy on blood levels and urinary excretion of ascorbic acid. K. DAUM, K. BOYD, and W. D. PAUL (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 1, pp. 129-132).—In a group of seven patients receiving fever therapy electrically induced and with temperatures of 105°-106° F. maintained for 2-5 hr. during the treatment at 1- to 3-day intervals, analyses for ascorbic acid of blood samples drawn before and after the heat therapy and during the intervening days and of repeated 24-hr. urines showed consistent decreases in the blood and urine ascorbic acid values, with two exceptions in the urine values following the treatment. Comparison was also made of blood and urine values following a test dose of 500 mg. (700 for one subject) in five normal subjects, five pathological subjects (cardiac (two), obesity, tuberculosis, and arthritis), and five of the fever therapy cases. The blood levels in the three groups showed similar variation, but the normal subjects excreted from 17 to 40 per cent of the ingested dose and the pathological and fever therapy subjects from 2 to 5 percent (with one exception in the fever therapy cases of 14 percent). It is concluded that the decreased excretion in the urine, as found in this study and as reported for infectious cases with fever, is due to the increased temperature rather than to an invading organism.

Studies in mineral metabolism with the aid of artificial radio-active isotopes.—III, The influence of vitamin D on the phosphorus metabolism of rachitic rats, W. E. COHN and D. M. GREENBERG. (Univ. Calif. et al.). (*Jour. Biol. Chem.*, 130 (1939), No. 2, pp. 625-634).—Groups of rachitic rats were separated into uniform subgroups of three animals each. After 3 hr. of fasting, one subgroup received an oral dose of 0.1 cc. of viosterol (10,000 U. S. P. XI units per gram); 1 hr. later all animals received an oral (stomach tube) or an intraperitoneal dose of a solution of Na_2HPO_4 (0.25-1.0 cc. containing 0.5-2.2 mg. P) containing from 2,000 to 5,000 units of radioactive P. The rats, then placed in individual cages having urine-feces separators, were permitted food after 1 hr. and were killed with chloroform after an interval of 64-80 hr. Samples of muscle (from hind leg) and bone (femur and tibia) were taken and these, as well as the remaining carcass, urine, and feces, were analyzed for radioactive phosphorus (P^{32}) and total phosphorus (P^{31}). In certain bone samples these phosphorus determinations were made separately on the lipid (alcohol-ether extract), organic (KOH-glycerol extract of fat-free bone), and inorganic (ash of extracted bone) portions. From the various analyses the excretion and the net absorption of P^{32} , the retention of P^{32} by the muscle, and the distribution of the absorbed P^{32} in the bone were calculated for animals with and without vitamin D treatment. The results are expressed as percentage of the amount of radioactive phosphorus injected or absorbed.

The values obtained indicated that the net absorption of phosphates by rachitic rats was increased by only 10-15 percent by vitamin D; this small increase in net absorption was due to increased absorption from and decreased

reexcretion into the gut. The urinary phosphorus excretion was so low in the rachitic rats that no effect of the vitamin D administration could be demonstrated. The vitamin D appeared to cause a slight drop in the uptake of absorbed phosphorus by the muscle. In the case of bone the vitamin D caused a 25-50 percent increase in the inorganic phosphorus uptake, apparently at the expense of the most recently ingested phosphorus, but produced little increase in the organic phosphorus. In this organic portion, however, the $P^{32} : P^{31}$ ratio was raised by vitamin D, the ratio being higher than in muscle or total viscera and as high as in urine. Apparently, therefore, the exchange of phosphorus between blood and the organic matter of bone was more rapid in muscle and preceded in time the deposition of inorganic P^{32} in the bone. On the basis of this indirect evidence it is considered that the vitamin D acts to aid the conversion of organic to inorganic phosphorus, and that the transfer of phosphorus from the blood to the organic fraction of bone is independent of vitamin D.

A comparison of cereal and non-cereal diets in the production of rickets, J. H. JONES (*Jour. Nutr.*, 18 (1939), No. 5, pp. 507-516).—In this study rolled oats, wheat, and yellow corn were compared with each other and with noncereal diets in their ability to promote calcification in the rat. The cereals and the dextrinized cornstarch and the cane sugar used in the several diets were incorporated at a 70- or 75-percent level as supplements to a basal mixture previously described (*E. S. R.*, 81, p. 879) and consisting of alcohol-extracted fibrin, carotene, and a salt mixture complete except for calcium and phosphorus, which were variables. The diets were fed in several series of experiments to rats taken at about 25 days of age and observed for evidences of rachitogenic action of the diets; daily food consumption and weight gains were observed and serum calcium and phosphorus and femur ash were determined.

In the first experiments when the calcium of the diet was high (CaCO_3 3 percent) and the phosphorus low (0.36, 0.31, 0.26, 0.09, and 0.09 percent in the oats, wheat, corn, dextrin, and sucrose diets, respectively), the rolled oats and wheat produced more calcification than did corn or either of the noncereal diets. When the CaCO_3 was reduced to 1 percent there was an increase in calcification on all of the cereal diets but not on the dextrin and sucrose diets. Similar results were obtained when the CaCO_3 was omitted entirely, although the difference in calcification between the cereal and noncereal diets was less.

Without the addition of CaCO_3 the diets contained from 0.05 to 0.08 percent of calcium; at this low level, with calcium the limiting factor, an addition of phosphorus (0.5 percent) produced no detectable difference in the calcification produced on any of the diets. In none of the experiments was evidence obtained to support the view that cereal grains contain a specific anticalcifying factor.

Studies on experimental rickets in rats.—III, The behavior and fate of the cartilage remnants in the rachitic metaphysis, G. S. DODDS and H. C. CAMERON. (*W. Va. Expt. Sta.*). (*Amer. Jour. Pathol.*, 15 (1939), No. 6, pp. 723-740, pls. 2, figs. 2).—Earlier studies in this series dealt with structural modifications of the epiphyseal cartilages in the tibia and other bones and with the healing process in the head of the tibia and other bones (*E. S. R.*, 81, p. 747). The present study is concerned with the behavior and fate of the cartilage remnants, as observed in experimental rats, during active rickets and during the healing process. The changes observed are described in detail and illustrated with photomicrographs and drawings. In the rachitic metaphysis there was observed (1) an osteoid envelopment of cartilage, considerable osteoid being deposited on the surfaces of the cartilage remnants, and (2) an osteoid infiltra-

tion of cartilage in which osteoid was deposited in the opened lacunae near the surface of the cartilage remnants by the osteoblasts from the adjacent bone marrow. These two changes affected the surface cells of the cartilage trabeculae, and the two types of tissue were direct products of the marrow.

The third change, observed in the deeper cells of the cartilage remnants, involved mitotic division of the cartilage cells and metaplasia into an osteocytelike form. In the unopened lacunae about these cells and as a product of their activity there was deposited an uncalcified osteoid matrix. During this internal reorganization process the matrix of the cartilage was not changed. It persisted to become calcified during the healing of rickets and to serve as a base for the deposition of bone in the formation of the trabeculae of the restored bone.

Antihemorrhagic activity of simple compounds, M. TISHLER and W. L. SAMPSON (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 9, pp. 2563, 2564).—The activity of 2-methyl-1,4-naphthoquinone was reinvestigated (its minimum dose was not determined in the previous study by Fieser et al. (*E. S. R.*, 83, p. 15)) by an assay method noted briefly. From the results of the assay on over 120 chicks, using levels of 0.5 γ –1.0 γ , it is concluded that this compound has an antihemorrhagic activity of the same order as that reported for vitamin K₁ by Thayer et al. (*E. S. R.*, 82, p. 89). This confirms the findings of Ansbacher and Fernholz (*E. S. R.*, 83, p. 14). The activities of the 2-ethyl-, and 2-*n*-propylnaphthoquinones and of the 2,3- or 2,6- or 2,7-dimethyl-1,4-naphthoquinones were found to be less than that of the 2-methyl naphthoquinone.

Alimentary K-avitaminosis in rats, H. DAM and J. GLAVIND (*Ztschr. Vitaminforsch.*, 9 (1939), No. 1–2, pp. 71–74; *Ger., Fr. abs.*, p. 74).—The production of K avitaminosis in rats by dietary means is reported. It is stated, however, that rats show no constant behavior in this regard, and that the symptoms may be very marked in some rats, while others remain unattacked even after a very considerable time. In this study K avitaminosis was produced within 15–80 days in 7 out of 15 rats by feeding them an artificial diet without vitamin K. Of the affected animals, only 3 showed hemorrhages, 2 dying from this cause. Seven of the animals not showing hemorrhages had normal coagulation, while 4 of them had a very marked reduction of their prothrombin. Intravenous injection of an emulsion of vitamin K concentrate, administered to 3 of the 4 rats which showed abnormal coagulation, effected a rapid cure of the disease.

TEXTILES AND CLOTHING

Problems in fur fiber research, T. M. PLITT (*Amer. Fur Breeder*, 13 (1940), No. 2, pp. 14, 15, figs. 4).—A brief discussion with illustrations of methods developed in the Bureau of Biological Survey, U. S. Department of the Interior, for studying the structure of individual hairs in the pelts of fur-bearing animals.

Type of fur fibers, T. M. PLITT and J. I. HARDY. (U. S. D. A. et al.). (*Amer. Fur Breeder*, 13 (1940), No. 2, p. 29).—A further discussion on the relation of fiber structure to fur quality, with a description of mounting technics for the microscopic study of fur fibers.

Technical evaluation of textile finishing treatments: Flexibility and drape as measurable properties of fabric, L. J. WINN and E. R. SCHWARZ (*Textile Res.*, 10 (1939), No. 1, pp. 5–16, figs. 6).—A technical and detailed presentation of a study noted essentially from another source (*E. S. R.*, 83, p. 860).

HOME MANAGEMENT AND EQUIPMENT

House planning ideas of Oregon rural women, M. WILSON and L. WELLS (*Oregon Sta. Bul.* 369 (1940), pp. 28, fig. 1).—On the basis of replies from Ore-

gon homemakers to a questionnaire covering opinions as to the desirability of various features of a dwelling, the preferences are summarized of farm and other homemakers in the State for the major features of the dwelling, together with descriptions of 16 house plans to meet the various preferences recorded. Of the 450 homemakers who cooperated in the study, 60 percent lived on farms and 40 percent lived in villages, suburban districts, and on acreages. The households of the farm homemakers averaged 4.1 persons and of the others 3.9. There were children under 19 yr. of age at home in 75 percent and of preschool age in 30 percent of the homes.

One-story and two-story houses were about equally favored considering the State as a whole, with slight differences in favor of two-story houses west of the Cascades and one story east of the Cascades. Four out of five women voted for a basement regardless of the number of stories preferred, but with various suggested uses. Living room dimensions satisfying the largest portion of the women were 15 by 20 ft. and bedrooms 12 by 14 ft. Dining rooms were desired by most of the women, but five out of six wanted kitchens large enough to serve family meals comfortably on occasion. Only one in eight favored a combination dining-living room. Out-of-door dining areas were popular both for family meals and for serving meals to crews of farm help. At least one bedroom on the first floor was specified by 99 percent of the women and a second one by many with young children. It is suggested that this should be planned as a multipurpose room. A fireplace in the living room was regarded as desirable, even when not needed as an extra source of heat, by more than 75 percent of the women. A large fabric rug for the living room was favored by more than one-third of the farm women and more than one-half of the others, with linoleum receiving almost one-third of the farm votes but very few of the others. For the dining room linoleum covering the entire floor or a large linoleum rug was favored by three-fourths of the farm women and three-fifths of the others.

Electric light for the farmstead (*U. S. Dept. Agr., Farmers' Bul. 1838 (1940), pp. 61, figs. 43*).—This publication presents information on good lighting practices to serve as a guide in planning installation of lighting fixtures and the necessary wiring. Detailed consideration is given to the essentials of good lighting, types of lighting, fixtures, portable lamps and bulbs; remodeling old lighting installations and equipment; yard lighting; lighting farm buildings with reference to natural and artificial lights and wiring; and planning of lighting for farm buildings, with recommendations based on observations and records as to adequate lighting for meeting the special needs in the various buildings.

The publication is well illustrated, and descriptive material is adequately supplemented by diagrams. In planning installation it is suggested that the activities to be carried on in each room be analyzed and grouped according to requirements for general or local lighting; that general lighting, with switch control if possible, be furnished for each room, hall, and stairway; that local lighting with wall brackets or portable lamps be provided for group activities, for working, and for reading and sewing (such provision being adjustable within given expenditure limits); that similar procedures be followed in planning for outdoor paths and farm buildings; that adequate sizes of light bulbs (as recommended) be used; and that wiring be of adequate size to carry the expected load.

A set of utensils for the farm kitchen, M. WILSON and H. E. McCULLOUGH (*Oregon Sta. Cir. 134 (1940), pp. 31, figs. 5*).—Among the sources of information used in preparing this list of minimum essentials in utensils (nonelectric) for western Oregon farm kitchens were laboratory tests, information from farm homemakers, and recommendations in the literature. Following a brief description

of the procedure used in the selection of articles for the list and a discussion of general considerations, sections are devoted to materials used in utensils, with their suitability for different purposes and advantages and disadvantages over other materials; storage of kitchen utensils, with considerations in planning and types of storage facilities; and points in buying and care of utensils for different purposes. The recommended set of utensils is tabulated by function, with points to be considered in selection, uses, and estimated frequency of use. As a definite buying guide a classified list of these utensils is given, with the cost at retail prices in Corvallis or Portland of the different groups included.

Study of kinds and maintenance of floor finishes best suited for household use (*Rhode Island Sta. Rpt.* [1939], pp. 47, 48).—This progress report (E. S. R., 81, p. 887) describes briefly the technic for evaluating film-forming wood finishes with an accelerated wear testing machine developed at the station.

Use of cold storage lockers rapidly expanding in Utah (*Farm and Home Sci.* [*Utah Sta.*], (1940), No. 3, p. 12, fig. 1).—This article presents a very brief survey as to the distribution and capacity of the 31 plants in operation in Utah; the growth of the storage locker system in the State; the chilling, cutting and processing, sharp freezing, and freezer storage services rendered by individual plants; and the advantages and problems of freezer locker storage.

MISCELLANEOUS

Forty-ninth Annual Report [of Alabama Station], 1938, M. J. FUNCHES ET AL. (*Alabama Sta. Rpt.* 1938, pp. 29).—The experimental work reported is for the most part referred to elsewhere in this issue.

Fiftieth Annual Report [of Arizona Station], 1939, P. S. BURGESS ET AL. (*Arizona Sta. Rpt.* 1939, pp. 102, figs. 26).—This includes an account entitled Fifty Years of Achievement by the Arizona Agricultural Experiment Station (pp. 3-29), the pioneering years being discussed by R. H. Forbes, the middle years by J. J. Thornber, and the final decade by Burgess. The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fifty-second Annual Report [of Georgia Station, 1940], H. P. STUCKEY (*Georgia Sta. Rpt.* 1940, pp. 93, figs. 15).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fifty-second Annual Report [of Rhode Island Station, 1939], B. E. GILBERT (*Rhode Island Sta. Rpt.* [1939], pp. 61+[1]).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Mississippi Farm Research, [August 1940] (*Miss. Farm Res.* [*Mississippi Sta.*], 3 (1940), No. 8, pp. 8, figs. 8).—In addition to articles noted elsewhere in this issue, this number contains Soil Conservation Not a New Problem, But of Increasing Acuteness, by C. Dorman (pp. 1, 8), and Federal Inspection Cream and Butter Requires Farm Care, by F. H. Herzer (pp. 1, 7).

Analytical index and list of publications of the Virginia Agricultural Experiment Station, 1888-1938, A. P. CUNNINGHAM, J. D. OBENSHAIN, and L. R. CAGLE (*Virginia Sta.*, 1938, pp. 118).

Public ownership versus State purchasing: The case of printing, E. E. SPARLIN. (Univ. Ark.). (*Jour. Polit. Econ.*, 48 (1940), No. 2, pp. 211-221).—Arguments are presented in favor of "a combination of the public plant and contract systems."

NOTES

Georgia University and Station.—F. W. Peikert has resigned as associate professor of agricultural engineering of the university to accept a similar position in the Texas College and Station, and has been succeeded by J. L. Shepherd. Other appointments include Joseph W. Kelly as associate professor in poultry and James B. Cooper and D. T. Sullivan as instructors in poultry and horticulture, respectively.

The station observed the sixth annual Dahlia Field Day October 13, 1940, when over 2,000 visitors inspected the blooms of more than 100 new varieties of dahlias being tested for growth in Georgia. Roots for the test were contributed by 22 dahlia producers throughout the United States.

New Hampshire University and Station.—Dr. Ormond R. Butler, since 1912 professor of botany and botanist, died October 24, 1940, aged 63 years.

Dr. Butler was a native of Australia, coming to the United States in 1895 and receiving the diploma of the Institut Nationale Agricole of Lausanne, Switzerland, in the same year. Subsequently he received from the University of California the B. S. and M. S. degrees and from Cornell University the Ph. D. degree in 1910. Prior to coming to New Hampshire, he had been associated with the horticultural and botanical work of the Universities of California and Wisconsin.

In the words of a recent statement issued by the station, "in his chosen field Dr. Butler was one of the world authorities on copper compounds in relation to control of fungus diseases. His published papers on copper fungicides are widely known throughout the world and are classics. Because of the relation of copper sprays to certain plant diseases, Dr. Butler gave special attention to the control of apple diseases and the relation of control measures to the production of fruit and to the control of potato diseases. He was the moving spirit in building up the growing of seed potatoes in New Hampshire and in the present advanced practice of potato seed certification."

Cornell University and Station.—Dr. Benjamin D. Wilson, associated with the agronomic work of the College of Agriculture since 1917 and professor of soil technology and soil chemist since 1934, died September 5, 1940, following an automobile accident in Ohio. He was a native of Kentucky, receiving the B. S. and M. S. degrees from the University of Kentucky in 1909 and 1914 and the Ph. D. degree from Cornell in 1917. He was assistant chemist in the Kentucky Station from 1909 to 1914.

Drs. Gordon H. Ellis and Karl C. Hamner have been added to the faculty of the College of Agriculture and the Federal Regional Soil and Nutrition Laboratory, the former as biochemist in the laboratory and assistant professor of biochemistry and nutrition and the latter in charge of plant investigations in the laboratory and assistant professor of plant physiology.

New York State Station.—Fred E. Gladwin, chief of research (pomology) since 1936, died November 16, 1940, at the age of 63 years. A native of New York and a graduate of the University of Rochester in 1904, he was appointed a special agent of the station in 1909 and placed in charge of the newly established Vineyard Laboratory at Fredonia. His subsequent service was with this laboratory, and he became exceptionally well-informed on all matters pertaining to grape growing.

Ralph R. Jenkins, associated with the chemical research of the station since 1930 (since 1936 on the quick freezing of fruits and vegetables), died October 9, 1940, in his thirty-eighth year. He was a native of Massachusetts and had received the B. S. and M. S. degrees from the University of New Hampshire.

The recent death is also noted of Dr. Edward C. Worden, assistant chemist in 1896-97 and subsequently in chemical work in New Jersey.

Dr. W. I. Zimmerman has been appointed assistant in research (chemistry) vice Ralph Colmer, resigned.

Vermont University.—Dr. Guy W. Bailey, comptroller since 1917, acting president in 1919, and president since 1920, died October 22, 1940, at the age of 64 years. He was a native of Vermont, graduating from the university in 1900, and receiving the LL. D. degree from the university, Middlebury College, and Norwich University, and was associated with many Vermont undertakings. A recent statement in *School and Society* notes that "his administration of the university was marked by the most extensive building program in its history, as well as by substantial increases in enrollment and the provision of new scholarship and endowment funds."

U. S. D. A. Library.—On November 15, 1940, Claribel R. Barnett and Emma B. Hawks, librarian and assistant librarian, respectively, retired, terminating a service beginning in 1895 and which in the words of an appreciative memorandum by Secretary of Agriculture Claude R. Wickard has been "responsible for the leadership and development of what is today truly one of the world's great libraries in the field of agriculture." Ralph R. Shaw, chief librarian of the Gary (Ind.) Public Library, has been appointed librarian, and Mary G. Lacy, librarian of the Bureau of Agricultural Economics, assistant librarian.

The librarian has been given general supervision and coordination of library work in the Department. A library advisory committee has also been established, consisting of the Director of Research as chairman, the Director of Extension Work, the Director of Information, and the Chief of the Bureau of Agricultural Economics, together with a rotating membership of the Chiefs of three bureaus to be designated by the chairman of the committee.

Association of Official Agricultural Chemists.—This association held its fifty-sixth annual meeting in Washington, D. C., from October 28 to 30, 1940, with a registration of over 500. The address of the president, Dr. W. W. Skinner, dealt mainly with the history and development of the association and called attention to its broadening field and dependence on new methods in which physical and biological measurements play an increasing part. Officers for the ensuing year were elected as follows: President, L. B. Broughton; vice president, J. W. Sale; secretary-treasurer, W. W. Skinner; and as an additional member of the executive committee, G. H. Marsh.

Association of American Feed Control Officials, Incorporated.—The thirty-second annual convention of this association was held in Washington, D. C., on October 31 and November 1, 1940, with representatives of 30 States and several agencies of the Federal Government in attendance. The address of the president, J. F. King, discussed ways of improving the work of the association and the promotion of greater uniformity in reporting results by the various States. Among the special papers was one by R. M. Bethke of the Ohio Experiment Station entitled Protein, Fat, and Fibre. Officers for the ensuing year were elected as follows: President, J. B. Smith; vice president, P. B. Curtis; secretary-treasurer, L. E. Bopst, College Park, Md; and additional member of the executive committee, H. H. Hanson.

Association of Land-Grant Colleges and Universities.—In addition to the general officers enumerated on page 5, the following section officers were elected

at the Chicago meeting of November 11-13, 1940: Agriculture, T. R. Bryant of Kentucky, chairman, A. L. Deering of Maine, vice chairman, and L. E. Call of Kansas, secretary; engineering, H. B. Dirks of Michigan, chairman, and B. R. Van Leer of North Carolina, secretary; home economics, Margaret S. Fedde of Nebraska, chairman, and Florence Harrison of Missouri, secretary; and graduate work, C. W. Hungerford of Idaho, chairman, and W. C. Russell of New Jersey, secretary. Within the section of agriculture, the subsection of experiment station work elected M. F. Miller of Missouri, chairman, and C. R. Orton of West Virginia, secretary; the subsection of resident teaching, E. L. Anthony of Michigan, chairman, and H. H. Hume of Florida, secretary; and the subsection of extension work, J. E. Carrigan of Vermont, chairman, and P. E. Miller of Minnesota, secretary.

The committee on experiment station organization and policy was reorganized and enlarged to provide representation for the four quarters of the Nation. The new members added for agriculture are J. A. Hill of Wyoming and M. J. Funchess of Alabama, while for home economics Esther L. Batchelder of Rhode Island, Margaret S. Fedde of Nebraska, Agnes F. Morgan of California, and Statie E. Erikson of Kentucky (reappointment) were named for terms of 4, 3, 2, and 1 year, respectively, and Sybil L. Smith and Louise Stanley of the U. S. Department of Agriculture were given the status of members *ex officio*.

Other committee changes included the appointment of C. S. Boucher of Nebraska and J. A. Burruss of Virginia to the committee on college organization and policy, vice F. D. Farrell of Kansas and H. C. Byrd of Maryland. On the committee on instruction in agriculture, L. E. Jackson of South Dakota and P. W. Chapman of Georgia, succeeded H. H. Kildee of Iowa and V. C. Freeman of Indiana, and on that on instruction in engineering, Gibb Gilchrist of Texas succeeded P. H. Hammond of Pennsylvania. Pearl S. Greene of Maine and Florence Harrison of Missouri were succeeded on the committee on instruction in home economics by Mildred T. Tate of Virginia and Laura W. Drummond of Pennsylvania; J. C. Taylor of Montana, C. E. Brehm of Tennessee, and Venia M. Kellar of Maryland on extension organization and policy, by William Peterson of Utah, E. E. Scholl of Oklahoma, and Marion Butters of New Jersey; G. D. Humphrey of Mississippi and A. C. Willard of Illinois on military organization and policy by J. W. Fulbright of Arkansas and F. L. Eversull of North Dakota; and E. B. Norris of Virginia on engineering experiment stations by H. P. Hammond of Pennsylvania. In the special committees, H. J. C. Umberger of Kansas was succeeded on the radio committee by J. F. Cunningham of Ohio; L. N. Duncan of Alabama on land-grant institutions for Negroes by R. F. Poole of South Carolina; C. A. Lory of Colorado, C. E. Friley of Iowa, and C. W. Creel of Nevada on relationships by J. R. Hutcheson of Virginia, R. E. Buchanan of Iowa, and L. R. Simons of New York; R. G. Bressler of Rhode Island on rural youth by E. H. White of Mississippi; and C. A. Lory of Colorado on preservation of phosphate deposits by R. M. Green of Colorado. On the joint committee on projects and correlation of research Noble Clark of Wisconsin succeeded V. R. Gardner of Michigan, and on that on publication of research, C. B. Hutchison of California replaced C. E. Ladd of New York. No change was made in the committee on training for Government service or the joint committee on accrediting, and the committee on the engineering experiment station bill was discontinued. H. L. Bevis of Ohio became a representative to the American Council of Education, vice J. J. Tigert of Florida.

VOL. 84.

FEBRUARY 1941

No. 2

RESEARCH AT THE 1940 CONVENTION OF THE ASSOCIATION OF LAND-GRANT COLLEGES AND UNIVERSITIES

In an organization as complex as the Association of Land-Grant Colleges and Universities, the emphasis given to a specific interest is bound to fluctuate more or less from year to year. There is therefore no special significance to be attached to the statement that the 1940 convention was not outstanding in its relations to research. In the three general sessions, there was one address from this standpoint, that by Dr. L. W. Wallace, director of engineering and research for the Crane Company, on *The Human Factor in Industrial Research*. The joint session of the three subsections of agriculture was given up entirely to other matters, and this was largely true of the programs of the sections of engineering, graduate work, and home economics. On the other hand, there was a joint session of the subsections of resident teaching and experiment stations on the topic *The Protection of College and Station Workers From Too Many Outside Demands*, and there was of course the usual extensive consideration in the experiment station subsection, which had two convention sessions and a day of preconvention meetings. Attention was also accorded research aspects in the panel discussion of the subsection of resident teaching, led by Mr. R. W. Trullinger, Assistant Chief of the Office of Experiment Stations, and entitled *Training for Public Service in the Field of Agriculture*, and the reports at a luncheon of the home economics section on current research at the land-grant colleges by Miss Sybil L. Smith of the Office of Experiment Stations and at the Bureau of Home Economics by Dr. Louise Stanley, Chief of that Bureau. Reference has already been made in the account of the convention in the January issue (*E. S. R.*, 84, p. 1) to the emphasis laid on research developments in home economics by Miss Lita Bane in the general sessions and by the section of home economics in its discussion of *National Nutrition in the Defense Program*.

The address of Dr. Wallace maintained that although research is being handicapped by its perversion abroad to destructive purposes, it is still indispensable to progress. His discussion was largely from the standpoint of industry, in which field the isolated effort of individuals is becoming increasingly less important than group organization

and cooperation. He criticized the tendency in educational institutions when preparing research workers to devote too much time to technical processes at the expense of developing fundamental principles and analytical judgment, and urged that all possible encouragement be given to students with intellectual honesty, an exploring urge, and tenacity of purpose.

Another paper of general application, although confined in its treatment to the State experiment stations, was that of Director F. J. Sievers of Massachusetts on *Some Essentials and Nonessentials in Agricultural Research*. Prominent among the qualifications for a research staff was placed the need of a vivid imagination expressed in such ways as "a keen sense of humor, a flexibility in mental make-up readily adaptable to new and changing conditions, a power of discrimination between the important and unimportant, and a knowledge of research limitations as regards personal, technical, and laboratory equipment." Another essential enumerated was personal courage, which he felt to be even more important today than ever before. There is, he maintained, "more demand today for intelligent and unbiased opinion than there is for the fundamental research upon which such opinions should be based. If our experiment stations, as public services, are to contribute to the solution of the several prominent sociological and economic problems confronting this country, our people must develop and express the courage to assume some leadership in putting plans into operation." He also argued for the development on the part of directors of a sympathetic as well as an informed leadership, since "the answer to problems involving human relationships needs to depend upon more than mere scientific soundness."

The discussion of the protection of workers from undue outside demands was developed as to the instruction staff by Director L. E. Call of Kansas and as to the station personnel by Assistant Director Noble Clark of Wisconsin. Both speakers conceded the desirability of some outside activities, and Director Clark stressed particularly the need for such contacts in the case of research people active in an applied field like agriculture. He saw in the increasing demands an implied vote of confidence in research and an indication that it is "winning its place in the sun of public confidence." Nevertheless he felt that dissipation of funds and time should be avoided, since research is "as socially necessary as competing activities." "I believe," he said, "that the citizens of the United States owe much more of their present security, comfort, and convenience to the results obtained by research workers in our agricultural experiment stations and universities than to the achievements of any similar number of citizens or any organization, public or private, which has received comparable financial support. Having station workers drop their research to take on other

kinds of assignments is, therefore, mighty hard to justify as in the public interest." Particularly he deprecated the impairment of energies by undue demands for committee service and administrative duties, as well as for too much teaching, close supervision of graduate students, or excessive extension or action appeals. On the other hand he advocated a larger share by station workers in the planning of programs in which they will eventually participate.

Coordinated Regional Research on Marketing Problems was discussed by Director E. C. Johnson of Washington. He pointed out that for such commodities as apples "the great magnitude of the marketing problems in terms of geography and their similarity for contiguous areas of commercial production are the principal reasons why the possibilities of coordinated regional marketing research should be carefully considered." In his opinion, "the need for cooperative research will be determined largely by the similarity of the marketing processes for one or more products produced in adjacent States or by the similarity of one or more marketing services for the products of two or more States." Although cooperative research has its limitations, previous experience indicates that under appropriate conditions it yields results which are better than those possible for any one agency operating independently.

Another practical problem was analyzed very thoroughly by Director H. J. Reed of Indiana. This was the economy and feasibility of carrying on research on land not owned by the stations. Director Reed pointed out that some land must inevitably be owned, especially that in locations where permanence is essential and there are substantial investments in buildings. Nevertheless ownership involves substantial initial expense, removes property from the tax rolls, provides only a single area which may not always be widely representative, and ties up capital in holdings which may be expensive to maintain and difficult to dispose of if their usefulness becomes impaired. Under certain conditions, therefore, he saw definite advantages in other forms of tenure.

The familiar subject of experiment station publications and mailing lists was assigned to Director Fred Griffie of Maine and discussed by him on the basis of a questionnaire from which 51 replies were available. Perhaps the most striking finding was that of the diversity of practice. No fewer than 23 types of publications were reported, and in some stations as high as 6 separate series. Bulletins are issued by all stations, but they vary widely as to scope and treatment. Four stations now maintain a "research" bulletin series, 13 a "technical," and 1 a "memoir" series; 27 print and 13 mimeograph circulars; 20 still include research findings in annual reports; and 8 are issuing periodicals. Similar diversity prevails as to size of edition and plan

of distribution, although the method of issuing announcements and sending publications upon request is steadily increasing. Director Griffie argued for more standardization in series and the provision of a reasonably large and accessible edition, since the cost of publication is but a fraction of the total expenditure on a research project.

The customary reports of committees were presented to the experiment station subsection, although that of the committee on experiment station organization and policy was made and discussed in part in a preconvention session and to that extent was not available to the general public. The committee itself was enlarged to insure full regional representation in both agriculture and home economics.

The report of the committee on projects and correlation of research as submitted by its chairman, Director S. B. Doten of Nevada, called attention to the possibilities of increasing informal cooperation among research workers. The relationship of the experiment stations to land-use planning was regarded as still incompletely defined, but the committee reported that "it is recognized that insofar as it is practicable, the assembling, with the help of all subject-matter divisions, of needed information on specific problem areas or on problems coming within a land-use planning unit is a function and responsibility of the experiment stations." The appointment of a special committee of station directors to work with the Office of Experiment Stations in more completely formulating station policy in correlating their activities with the land-use planning movement was recommended. A supplementary statement on the current status of cooperative research undertakings indicated that in 1940 "State extension, research, and special planning agencies in every State were participating in this movement, which had reached a stage of organization where the research needs of the land-planning programs were becoming apparent in terms of specific problems for study."

The report of the joint committee on publication of research was given by Director S. W. Fletcher of Pennsylvania. During the year ended October 31, 1940, the number of manuscripts received for publication in the *Journal of Agricultural Research* totaled 133, of which 73 were from the Federal Department of Agriculture, 59 from the stations, and 1 cooperative.

In addition to the items scheduled on the program, a number of other matters received consideration by the section. One of these was the relation of research to the defense requirements of the Nation along nutritional lines. This topic was discussed by Dr. M. L. Wilson, U. S. D. A. Director of Extension, who pointed out the need from this standpoint of additional nutritional inventories of families and special groups and of studies on the causes underlying food habits and the decline in many areas of food production on farms.

Another matter, presented in connection with the report of the committee on experiment station organization and policy, was that of inter-American relationships. The work of the Federal committee on cooperation in agricultural education (E. S. R., 83, p. 289) was summarized by its chairman, Assistant Dean Knowles Ryerson of California, with special mention of such phases as exchange professorships and fellowships, the accrediting of institutions, the development of courses, and the preparation of publications in Spanish and Portuguese, and the status of the proposed Tropical Research Institute and the American Society of Agricultural Sciences. The field and outlook of this society was further discussed by Director J. A. B. Nolla of the Puerto Rico University Experiment Station and others, and announcement was made of special rates to members of affiliated societies.

Thus the convention had before it a wide range of questions more or less directly related to research, and also what is perhaps of even greater importance, a reasonable amount of time available for their consideration. It afforded an excellent opportunity for enlightenment on current issues and for a clarification of views and policies. Its specific reaction toward research matters was both constructive and stimulating.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

Chemistry forms background for most agricultural research (*Farm Res. [New York State Sta.]*, 6 (1940), No. 4, pp. 4, 6).—The essential service of the chemistry division to the work of other divisions of the station and the direct service of chemical research in the solution of agricultural problems are pointed out, and both fields of the chemical work are briefly discussed, with illustrative instances.

Biochemistry and agrostological problems, A. G. NORMAN. (Iowa State Col.). (*Chron. Bot.*, 6 (1940), No. 2, p. 30).—A review of recent advances.

[Chemical investigations by the Indiana Station]. (Partly coop. U. S. D. A.). (*Indiana Sta. Rpt. 1939*, pp. 9, 10, 12, 24-29, 30, 31, figs. 3).—This report notes briefly numerous results of soybean constituents research; factors affecting the canning quality of pumpkins; and seasonal changes occurring in composition of various parts of Winesap apple tree, together with work on a chemical study of quality of inbred lines of sweet corn, by D. M. Doty and J. R. Roach; the photoelectric spectrophotometer, carotenoid pigments, and micro melting point apparatus, all by F. P. Zscheile and J. W. White; photoelectric photometer, by Zscheile, C. L. Shrewsbury, and H. R. Kraybill; chlorophyll pigments and photosynthesis, by Zscheile, C. L. Comar, and L. F. Green; determination of carotene added to butterfat, by Shrewsbury, Kraybill, and Zscheile; separation of glycerides of soybean oil, by A. W. Kleinsmith, Kraybill, and M. H. Thornton; preparation of sterols from soybean oil, by Kraybill, Thornton, and K. E. Eldridge; nonfat constituents of soybean oil, by Thornton and Kraybill; carbohydrates of the soybean, by E. D. Walter; and variation in composition of different fractions of peppermint oil obtained during the distillation, by L. J. Swift.

The quantitative chemical determination of carotenoids and vitamin A in serum [trans. title], H. WILLSTAEDT and T. K. WITH (*Ztschr. Vitaminforsch.*, 9 (1939), No. 3, pp. 212-223; *Fr., Eng. abs.*, pp. 222, 223).—The different methods for determination of serum carotenoids and vitamin A are discussed, and a slightly modified method applicable to hemolyzed or nonhemolyzed samples is presented. The alkali-treated serum is extracted with alcohol and finally with ether, and the residue from the ether extract is taken up in benzene and used for the determinations. The vitamin A is determined by the Carr-Price reaction, and the blue values for this as well as the yellow values for the carotenoids are determined by the step photometer and referred to standard calibration curves. Upon all the sera adsorption analysis of the carotenoids is performed, this being of help in determining the correction factor for the carotenoids in the Carr-Price reaction. Protocols are presented showing for the 15 cases studied a total carotenoid content varying from 0 γ to 145 γ per 100 cc.; corrected values for vitamin A (E 61/E 43=0.15) varied in 6 cases from 66 to 743 International Units per 100 cc. Lycopene was not found in any of the sera tested.

A method for determining ascorbic acid [trans. title], L. ROSENTHALER (*Ztschr. Vitaminforsch.*, 9 (1939), No. 4, pp. 342-344; *Fr. Eng. abs.*, p. 344).—The method as described (in detail) is applied to a dilute (0.1 N) hydrochloric acid solution of pure ascorbic acid. It involves the reduction of mercuric to mercurous chloride, with iodometric determination of the latter compound.

Riboflavin content of yeasts determined photometrically and biologically, A. E. SCHUMACHER and G. F. HEUSER. (Cornell Univ.). (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 4, pp. 203, 204).—By the photometric method described, the riboflavin is determined in a 5 percent hydrochloric acid extract of yeast; the extract is adjusted to pH 3.5-4.0 to give a clear solution, reduced with sodium hydrosulfite to destroy irreversibly reducible interfering pigments, and finally shaken with air to reoxidize the riboflavin. The clear filtrate thus prepared is used for the photometric determination of riboflavin, the photometer used and the method followed being the same as those described by Sullivan and Norris (*E. S. R.*, 83, p. 152). The formula used for the calculation to micrograms of riboflavin per gram is presented.

The chick and hen bio-assays used involved feeding of the test yeast to birds on a basal diet low in riboflavin but otherwise complete, and comparing the response with that obtained in positive control groups receiving graded amounts of a previously standardized dry skim milk. The data presented show that there is good agreement of results of riboflavin determinations by the photometric method, that these results agree well with chick and hen bio-assays, and that the different samples of yeasts vary widely in their riboflavin content; various primary yeasts, for example, contained from 34.2 to 78.2 μg . per gram.

Values obtained by the above procedures were not, however, in good agreement with rat assay values (reported from the laboratory supplying the yeasts) determined by the regular Bourquin-Sherman procedure for vitamin G. No single conversion factor could be employed to convert Bourquin-Sherman units to micrograms of riboflavin, although in general residual yeasts gave a conversion factor of approximately 2.0 μg of riboflavin per Bourquin-Sherman unit, while primary grown yeasts gave a conversion factor of approximately 1.3 μg .

The colorimetric microdetermination of copper [trans. title], I. NUMATA and D. MATSUKAWA (*Jour. Biochem.*, 30 (1939), No. 3, pp. 395-399).—Details as to reagents and the various steps in the determination are presented for this method, employing the dithizone reaction and the Pulfrich photometer for color comparison.

Methods for estimating the iron and copper content of butter, G. M. MOIR and E. D. ANDREWS (*New Zeal. Jour. Sci. and Technol.*, 21 (1940), No. 5A, pp. 249A-265A).—New techniques, termed filtration methods, for the extraction and colorimetric estimation of iron and copper in butter are described. A modification of the conventional wet-ashing method for determining copper in butter also is outlined. Good checks were obtained for iron and copper values determined by the different methods. The principal advantages claimed for the filtration method are simplicity of manipulation with a minimum possibility for contamination of the sample.

The neutralisation value of ghee (butter-fat), H. HAWLEY (*Cur. Sci. [India]*, 9 (1940), No. 7, pp. 337-339).—Determination of the neutralization value of butterfat by the described method readily permitted the detection of adulteration by animal fat and also the detection of adulteration with vegetable fats without resort to a sterol acetate test. Typical values for pure butterfat and various adulterated fats are presented.

Exclusion of lead from maple products (*Vermont Sta. Bul.* 463 (1940), pp. 18, 19).—This report notes further studies (E. S. R., 80, p. 153).

The relation between quality and chemical composition of canned sauerkraut, C. S. PEDERSON (*New York State Sta. Bul.* 693 (1940), pp. 15, figs. 11).—The author examined for quality as compared with chemical composition 332 samples of commercial canned sauerkraut obtained from packers throughout the country.

In general, the samples of poorer quality sauerkraut showed some abnormality in chemical composition, many of them containing less than the required 1 percent of acid, or more than 2.5 percent or less than 1.5 percent salt. The better samples of sauerkraut showed a higher average vitamin C content and more constant amounts of acids, salt, and alcohol. The samples of sauerkraut showing high or low percentages of salt were more often soft, while those containing between 1.5 and 2.5 percent were of firm texture.

Comparisons of determinations of the salt content as obtained by titration and by salometer readings showed that the salometer is not suitable for measuring the salt content of sauerkraut.

The making of candied fruits a practical home industry, F. A. LEE (*Farm Res. [New York State Sta.]*, 6 (1940), No. 4, p. 7, figs. 2).—The candying process, it is noted, involves the gradual building up of the sugar concentration of the fruit by daily additions of sugar to the sirup in which the fruit is immersed. To give a glaceed surface when the fruit is dried (after about a week in the sirup) about one-eighth (or more) of the sugar used is supplied as corn sirup. Fruits for candying are picked firm ripe. Napoleon or Bing varieties for cherries, Reine Claude, Coulon, and Italian Prune for plums and Elberta peaches are suggested as firm varieties that give satisfactory results.

Adequate cleaning methods in food plants costly but essential, W. G. WALTER and G. J. HUCKER (*Farm Res. [New York State Sta.]*, 6 (1940), No. 4, pp. 1, 12, fig. 1).—This is a more or less popular discussion of various methods of cleaning and sterilizing equipment and containers used in handling and packaging. It is pointed out that adequate cleaning and sterilizing methods are necessary to the farmer who sells food products at a roadside stand as well as to the large-scale packer or bottler.

AGRICULTURAL METEOROLOGY

An automatic weather station, H. DIAMOND and W. S. HINMAN, JR. (*Jour. Res. Natl. Bur. Standards [U. S.]*, 25 (1940), No. 2, pp. 133-148, pls. 8, figs. 6).—An important contribution of radio to the collection of weather data lies in the possibility of utilizing completely automatic stations at isolated locations, whereby information on the meteorological factors of interest is automatically transmitted at predetermined intervals. The authors detail a method for the remote indication by radio of measurements of barometric pressure, air temperature, relative humidity, wind direction and velocity, rainfall, and other meteorological factors. This method retains the operating principles of the audio-modulation type radiosonde, but, because of the use of much lower audio frequencies, affords important simplifications in the transmitting and receiving equipment. An experimental installation is described, and measurements for a 30-day period are analyzed.

An improved radio soude and its performance, H. DIAMOND, W. S. HINMAN, JR., F. W. DUNMORE, and E. G. LAPHAM (*Jour. Res. Natl. Bur. Standards [U. S.]*, 25 (1940), No. 3, pp. 327-367, pls. 4, figs. 30).—This describes improvements in component elements of the radiosonde system noted above and discusses per-

formance. The major improvement is in measuring relative humidity. The modified apparatus is shown capable of measuring barometric pressure to an accuracy of 5 mb., temperature to 0.75° C., and relative humidity to 5 percent.

Monthly Weather Review [May-June 1940] (*U. S. Mo. Weather Rev.*, 68 (1940), Nos. 5, pp. 125-156, pls. 12, figs. 6; 6, pp. 157-180, pls. 12, figs. 13).—In addition to the usual detailed summaries of meteorological and climatological data, including observations on aerology, weather on the Atlantic and Pacific Oceans, and rivers and floods; solar radiation and sunspot data; and other information, these numbers contain the following articles:

No. 5.—Sounding-Balloon Observations at Omaha, Nebr., During the International Months July 1938 and April 1939, by L. F. Hafer (pp. 125-129); and The First Century of Meteorological Data in America, by R. H. Brown (pp. 130-133).

No. 6.—An 80-Year Temperature Record [at Marengo, Ill.], by C. J. Root (pp. 157, 158); and Relation of Recent Glacier Retreats to Prevailing Temperatures, by J. B. Kincer (pp. 158-160).

The air and its mysteries, C. M. BOTLEY (*London: G. Bell & Sons, 1938, pp. XV+296, pls. [17], figs. 23*).—This semipopular book deals descriptively with meteorology, recording the methods and results of observation and experiment by which the knowledge of the subject has been advanced and principles established for practical service and intellectual expansion. A foreword is by R. A. Gregory.

Synoptic conditions accompanying tornadoes in the United States during 1884, S. S. GAIGEROV (*Amer. Met. Soc. Bul.*, 21 (1940), No. 6, pp. 229-236).—The conclusions drawn from this study are that the overwhelming majority of tornadoes originate in maritime tropical air, most of them are observed in the warm sector of the cyclones, and over half of them are at a distance of $\pm 250-350$ km. before the cold front. About 5 percent also occur before the warm front, and they appear most frequently to occur above the frontal surfaces and within the tropical air mass. Tornadoes are apparently not observed outside the region of the cyclone, and their tracks most frequently trail the isobars, occasionally deviating to the right. The tornado tracks are most frequently parallel to the cyclone-center tracks. In the maritime tropical air, in the vicinity of its source region the tornadoes are usually far removed from the fronts in the warm sectors of the cyclones over the midsouthern and southeastern United States. In the places where the tropical air has least relative humidity, the tornadoes arise near the fronts or immediately on them. A translation of the regions of tornado activity northward in summer and southward in winter takes place with the seasonal shifts on the polar-front zone.

Researches on temperature changes from day to day and solar constant variations, H. ARCTOWSKI (*Amer. Met. Soc. Bul.*, 21 (1940), No. 6, pp. 257-261, figs. 7).—A review and general discussion.

A comparison of upper soil temperatures and shelter temperatures, W. C. JACOBS. (U. S. D. A.). (*Amer. Met. Soc. Bul.*, 21 (1940), No. 5, pp. 181-183, fig. 1).—A minimum thermometer and soil thermograph were set up at the El Centro, Calif., fruit-frost temperature survey station for the purpose of comparing the upper soil temperatures with those measured at the same time in a standard fruit-region shelter with thermometer about 5 ft. from the ground. Preliminary results indicated that the minimum soil temperature at ± 3 -mm. depth averaged slightly higher than the shelter minimum but varied considerably with clouds and wind, and that the soil maximum departed widely from the shelter maximum but the departures were highly irregular.

Evaporation-loss per month from two drainage areas, D. LLOYD (*Roy. Met. Soc. [London], Quart. Jour., 66 (1940), No. 285, pp. 181-193, figs. 2*).—"Monthly data of the apparent loss by evaporation, etc., of moisture from Vyrnwy and Rivington drainage areas are examined in relation to the rainfall and the temperature. After discussing the subject matter, the association and the degree of association are determined on the hypothesis that variations in evaporation loss can be associated with the variations in rainfall and temperature in a joint functional manner. The regressions have been computed together with the formal evaluation of the significance of the statistics. The results show that, when the temperature is constant, the evaporation loss is proportional to the rainfall; when the rainfall has a given value, the loss increases in relation to the temperature; while the loss is reduced according to the previous rainfall. There is similarity in the relations at Vyrnwy and Rivington."

Hydrologic studies: Compilation of rainfall and run-off from the watersheds of the Texas Agricultural Experiment Station, Substation No. 7, Spur, Texas, 1928-38, B. C. LANGLEY and D. L. BIDWELL. (Coop. Tex. Expt. Sta.). (*U. S. Dept. Agr., Soil Conserv. Serv., 1940, SCS-TP-35, pp. [239], figs. [129]*).

Indirect flood damages, L. O. BERCAW (*U. S. Dept. Agr., Bur. Agr. Econ., Econ. Libr. List 13 (1940), pp. 16*).—An annotated list of 41 references.

Normals for the climate of Montevideo, 1883-1938 [trans. title], L. MORANDI (*Rev. Facult. Agron. [Montevideo], No. 20 (1940), pp. 9-22, fig. 1*).—Data are included on temperature, atmospheric pressure, humidity, rainfall, evaporation, cloudiness, wind, hail, and electrical manifestations.

White settlers in the Tropics, A. G. PRICE (*Amer. Geog. Soc. Spec. Pub. 23 (1939), pp. XIII+311, pls. 20, figs. 31*).—As stated by H. S. Hotchkiss in the foreword, "While others have dealt with particular aspects of the problem and with specific regions, no one before, I think, has attempted as comprehensive a synthesis as has Dr. Price. . . . The book . . . derives its outstanding value from the author's broad outlook," covering as it does the historical, economic, social, administrative, medical, climatic, geological, and geographical phases of the general subject. Part 1 considers the nature and history of the problem of white settlement in the Tropics. Part 2 presents regional studies of white settlements in the trade-wind margins (Queensland and Florida), trade-wind islands of the West Indies, arid and wet-dry tropics in Australia, tropical plateaus (Costa Rica, South America, and Africa), and Americans in Panama. Part 3 takes up some factors governing white settlement in the Tropics, including racial problems, some environmental factors, acclimatization and health (climatological, statistical, pathological, psychological, and physiological studies), diet and exercise, and administrative and economic problems. Appendixes by R. G. Stone consider some results of modern physiological research in relation to acclimatization in the Tropics, comfort zones and acclimatization, a note on cooling power, and additional references on physiology and acclimatization in the Tropics. A section (pp. 241-271) is devoted to notes and literature references on the 18 individual chapters, and an author-subject index is provided.

SOILS—FERTILIZERS

[Soil and fertilizer investigations by the Indiana Station] (*Indiana Sta. Rpt. 1939, pp. 48, 64*).—Work on diagnosing plant-nutrient deficiencies by means of plant-tissue tests, by G. D. Scarseth, and the influence of fertilizers on microorganisms responsible for the fixation of nitrogen, by J. L. Roberts, is briefly noted.

A rapid-action soil tube jack, R. B. ALLYN. (U. S. D. A. and Oreg. Expt. Sta.). (*Soil Sci.*, 50 (1940), No. 1, pp. 49-51, fig. 1).—This jack has a fulcrum block sliding on an upright of $\frac{3}{4}$ in. cold-rolled steel shafting set in a steel base plate, the fulcrum block being made to grip the upright at any point by lightly squeezing together a 9- by $\frac{1}{2}$ -in. control lever and the upright, thereby tipping the $\frac{1\frac{1}{2}}$ -in. opening through the block against the $\frac{3}{4}$ -in. vertical shaft which passes through it. A fully dimensioned working drawing accompanies the description.

Determination of soil structure by microscopical investigation, G. C. REDLICH (*Soil Sci.*, 50 (1940), No. 1, pp. 3-13, pl. 1, figs. 3).—The author describes a modification of the Kubiěna section method (E. S. R., 80, p. 157) for the microscopic study of soil structure, a special soil tube being used for the sampling, and presents also a numerical expression of the relation between microscopically observable pore space and solid material. The use of the expression

$$\frac{\text{percentage of pore space} \times 100}{\text{percentage of crumbs larger than } 1,600\mu}$$

as a "soil quotient" is proposed. It is noted, however, that "the choice of the denominator is arbitrary, as evidence regarding the optimal crumb size for plant growth is not yet available." Microscopic observation was carried out by means of a polarizing microscope with the use of a 6 \times eyepiece fitted with a micrometer scale and a "No. 3" objective of N. A. 0.25 [the No. 3 objective of the maker named by the author is a 16-mm. achromatic, 10 \times]. In the polarized light and as seen through a gypsum plate, clay appears dark, crystals show interference colors, and the pore spaces, which are filled with the resinous material used in the Kubiěna preparation method, appear violet. Clay and sand can therefore be readily distinguished from pores. Photographs taken at a still lower magnification (about 5 \times) accompany the paper.

Lysimeter studies.—IV, Movement of anions through the profile of a Gray-Brown Podzolic soil, J. S. JOFFE. (N. J. Expt. Stas.). (*Soil Sci.*, 50 (1940), No. 1, pp. 57-63, fig. 1).—This paper presents summary data on the composition of the anions of leachings collected during 7 yr. from lysimeters of the funnel type (E. S. R., 69, p. 635). The author points out that of the data presented only those on the A horizon can be considered to be quantitative, since the movement of the water through the A horizon is vertical but through the B only partly so. "The rate of movement of water varies with the soil horizon, being faster through the A horizon because of the lighter texture and the more open structure. The heavier texture and more compact constitution of the B horizon will therefore cause water to accumulate at the junction of the A and B horizons. Under such circumstances the water begins to move horizontally along the B horizon, through which only a portion of it filters, most of it dropping through by way of channels," such as cracks produced by the drying out of the soil, root paths, and passageways and borings of earthworms, rodents, and other animals.

The results indicate that not much nitrogen is lost by leaching from the soil body under forest cover. Although data concerning cultivated soils obtained by means of funnel-type lysimeters are lacking, the author considers that more undoubtedly is lost from such soils than from forest soils. Of sulfur, the data indicate that relatively small quantities, as compared with those of other anionic elements, are leached out. Little or no loss of phosphorus was found. In forest soils "the roots pick up enough to satisfy the needs of the flora, and the dead organic matter returns a similar quantity of phosphorus." The movement of chlorine and silicon compounds through the A and B horizons was also measured.

The laws of soil colloidal behavior.—XXII, The thermal stability of acidoids and basoids, A. HOVDEN, L. WIKLANDER, and S. MATTSOn (*Soil Sci.*, 50 (1940), No. 1, pp. 65-76, figs. 12).—A further study of this series (E. S. R.,

83, p. 23) indicates that thermal stability of soil acidoids and basoids seems to place them in the following order: Free humus acidoids < sesquioxide-bound humus acidoids < sesquioxide-basoids < silicic acidoids. As a result of destruction of the humus acidoids by heating for 6 hr. to 275° C., the exchange reactions of the soil become an expression of the mineral acidoid:basoid activity ratio and serve to characterize the soil type.

[Soil Survey Reports, 1932, 1933, and 1934 Series] (*U. S. Dept. Agr., Bur. Plant Indus. [Soil Survey Rpts.], Ser. 1932, No. 40, pp. 53, pl. 1, figs. 2, map 1; 1933, Nos. 33, pp. 29, pls. 2, figs. 2, map 1; 34, pp. 41, figs. 2, map 1; 1934, Nos. 21, pp. 40, pls. 4, figs. 2, map 1; 22, pp. 52, figs. 2, map 1*).—Except as indicated below, these surveys were made in cooperation with the respective State experiment stations: 1932, No. 40, Jennings County, Ind., H. P. Ulrich et al.; 1933, Nos. 33, the middle Yellowstone Valley area, Mont., W. DeYoung et al., and 34, Audubon County, Iowa, T. H. Benton and W. J. Geib; and 1934, Nos. 21, Zavala County, Tex., H. M. Smith et al., and 22, Ulster County, N. Y., A. T. Sweet and W. Secor ([N. Y.] Cornell).

De Witt County soils, G. D. and L. H. SMITH (*Illinois Sta. Soil Rpt. 67 (1940), pp. 28, figs. 12, maps 2*).—This survey adds 254,450 acres to the total area covered by the State soil survey (*E. S. R., 82, p. 154*).

Analyses of United States soils.—I, North Atlantic States, J. G. LIPMAN, J. S. JOFFE, and A. B. CONYBEARE (*New Jersey Stas., 1940, pp. [91]*).—This first section of an intended compilation of the available soil-analysis data for the country as a whole comprises the compilations for the North Atlantic States—Maine, New Hampshire, Vermont, Connecticut, Massachusetts, Rhode Island, New York, New Jersey, and Pennsylvania. Data for topsoils, subsoils, and the individual horizons of the soil profile are separately given when available. A brief discussion of the data, the methods used in determining them, and their value as an inventory of plant-food resources precedes the tabulated material.

Soil profiles in relation to the recession and extinction of Michigan lakes, J. O. VEATCH. (*Mich. Expt. Sta.*). (*Soil Sci., 50 (1940), No. 2, pp. 103-113, pls. 2, figs. 4*).—The author has made a study of the soil profiles of lakes and of former lake beds with a view to using the resulting information in the formulation of a theory of lake extinction and related phenomena. Some probable mechanisms of lake extinction are discussed and illustrated in diagrammatic drawings, including a series of soil profiles from water surface over bottom ooze and gray sand to a dry-sand profile, and five possible modes of recession and extinction.

Recent advances in soil microbiology, H. NICOL (*Chron. Bot., 6 (1940), No. 2, pp. 32, 33*).—A review.

Influence of microorganisms on soil aggregation and erosion, J. P. MARTIN and S. A. WAKSMAN. (*N. J. Expt. Stas.*). (*Soil Sci., 50 (1940), No. 1, pp. 29-47*).—A sand-bentonite mixture, a sand-clay mixture, a clay loam, and a sandy loam were treated with various carbohydrates and plant residues, together with both pure and mixed cultures of decomposing organisms. The action of micro-organisms was found to result in a marked binding and aggregation of the soil particles. The extent of the binding depended on the organisms concerned and the nature of the organic material added. The effect of these materials depended on their nature and the rapidity of their decomposition. The more rapidly a plant material decomposed, the greater was its binding action upon the finer soil particles. The effect of lime in bringing about an aggregation of the soil constituents appeared to be associated largely with its effect upon the action of the organic materials.

Two procedures, designated, respectively, as the pipette and slope methods, were used to determine the extent to which the added organic matter and its decomposition products had affected the erodibility and the aggregation of the soil particles. The pipette method consisted essentially in suspending 50 gm. of soil in 250 cc. of water under fixed experimental conditions and drawing off 50 cc. from 5 in. below the surface of the suspension, evaporating the water, and weighing the ignited residue. In the slope method, 50-gm. portions of the material were uniformly spread in the center of a small chute (14.5 by 4.5 in.) placed at a 5.5-percent slope. The material was moistened with 50 cc. of water from a pipette, and 450 cc. of water siphoned from a liter flask was allowed to run over the mixture in approximately 2 min. Then 200-cc. aliquots containing the washed out particles were evaporated to dryness in weighed evaporating dishes, ignited, and weighed. The weight of the small particles washed from 50-gm. portions of the original mixture was taken as unbound material, and final calculation was made on 50 gm. of dry material.

The nature of the catalyst causing the hydrolysis of urea in soils, J. P. CONRAD. (Univ. Calif.). (*Soil Sci.*, 50 (1940), No. 2, pp. 119-134, figs. 4).—The antiseptics toluene and chloroform had little, if any, inhibiting action on the hydrolysis of urea in the soils studied. Carbon disulfide and 50 percent alcohol likewise allowed considerable hydrolysis to take place. The natural soil catalytic activity was inactivated or greatly reduced by preheating the moistened soil to 85° C.; by pretreating the soil with the known urease inhibitors HgCl₂, hydroquinone, and catechol; and by predigesting the soil with the proteolytic enzyme trypsin, known to destroy the activity of the protein urease in a very short time. Neither the natural activity nor that of added laboratory jackbean urease could be eluted from the soil by any of the substances commonly used for that purpose. The laboratory urease was moderately adsorbed from solution by preheated Yolo fine sandy loam in various types of procedure. The natural soil activity was found much more resistant to decomposition than that of added laboratory urease. It is suggested that if the activity of the soil is due to an enzyme, urease, it must be associated with some other material which gives it some protection against decomposition, and that a lignoprotein might satisfy such requirements.

Peat and its uses, S. A. WAKSMAN (*New Jersey Stat. Bul.* 681 (1940), pp. 11, figs. 7).—Following a brief statement of the nature and mode of formation of peats, the author describes as the principal forms moss or highmoor peat, sedge and reed peat, forest peat, and sedimentary peat (peat soil, humus, or compost). Of these four forms the three last named are available from large acreages in New Jersey. The preparation of these for marketing and the use of peats as horticultural soils and for soil improvement and other purposes when taken up and marketed are outlined. Cost of drainage and the present excess of agricultural produce are given as the main reasons preventing the wholesale development of the peat bogs for farming purposes. They are considered capable of development into soils among the richest and most valuable in the State.

Relation of pH to phosphate solubility in Colorado soils, R. GARDNER and O. J. KELLEY. (Colo. Expt. Sta.). (*Soil Sci.*, 50 (1940), No. 2, pp. 91-102, figs. 2).—Samples of 12 soils were adjusted to the desired pH values by treating 4 gm. of each soil with 40 cc. of a solution containing suitable proportions of sulfuric acid and potassium carbonate. Colored solutions were treated with bromine, but no other treatment to destroy organic matter was used. The pH values were determined by means of a glass electrode.

It was found that solubility reaches a minimum near the neutral point, that the solubility in the pH range corresponding to the probable range at field

moisture appears to be closely related to plant available phosphorus, that the solubility in the slightly acid range is closely correlated with solubility in the highly alkaline range for soils of similar composition, and that the solubility in the probable range of pH at field moisture is correlated with the degree of colloid saturation as estimated by methods similar to that of Burd and Murphy (E. S. R., 81, p. 482). As practical applications of such data, it is noted that they can serve to indicate whether crops will respond to fertilizer on the soils studied, to indicate the general type of extractants suitable for quick tests of phosphate availability, and possibly as a means of estimating the quantity of phosphate from fertilizer applications which will be adsorbed by the soil in a form not readily available to plants.

Studies on organic phosphorus compounds in soil: Isolation of inositol, R. K. YOSHIDA. (Hawaii Expt. Sta.). (*Soil Sci.*, 50 (1940), No. 2, pp. 81-89, pl. 1).—The author isolated crystalline inositol from the organic phosphorus compounds obtained from soils, showing the presence of inositol phosphates in the soils studied. An ash-free organic-phosphorus product isolated from soil was resistant to decomposition and gave inositol and phosphoric acid on hydrolysis, and the phosphorus and nitrogen contents of this substance suggest the ammonium salt of inositol monophosphate. Quantitative estimations of inositol liberated by hydrolysis showed that inositol-phosphate compounds account for only a part of the total soil organic phosphorus. No evidence of nucleic acid compounds could be found in any of the soils investigated.

Accumulation of zinc on soil under long-persistent vegetation, P. L. HIBBARD. (Univ. Calif.). (*Soil Sci.*, 50 (1940), No. 1, pp. 53-55).—The author reports zinc determinations at several successive depths in soil under redwood, pine, and oak trees, the zinc content being shown to decrease sharply with increasing depth. When powdered leaf material from the trees named was placed on soil columns and leached with distilled water for some days, none of the zinc extracted from the leaves passed through the soil into the percolate, although the leaf extract itself contained 19%, 22%, and 33% in the leachings from 100 gm. of the leaf material from redwood, pine, and oak, respectively.

Pasture improvement (*Vermont Sta. Bul.* 463 (1940), p. 14).—Borax (20 lb. per acre) gave some response in the production and maintenance of native white clover in permanent pastures on a light textured soil where generous amounts of lime had been applied.

Commercial fertilizers: Pastures and plant food, L. S. WALKER, E. F. BOYCE, and H. J. CANNON (*Vermont Sta. Bul.* 464 (1940), pp. 31).—This 1940 fertilizer inspection report shows the use of a steadily increasing proportion of non-acid-forming fertilizers. The percentages on non-acid-forming mixtures on the basis of total tonnage sold were, from 1936 to 1940, inclusive, 17.7, 20.1, 21.8, 26.1, and 33.3.

An added section discusses the problems of pasture conservation and improvement. It is pointed out that it is often cheaper to feed cows from the fertilizer bag (through pasture treatment) than directly from the grain bag. Nitrogen, phosphate, potassium, and liming are separately taken up, with brief indications of desirable practice with respect to each.

AGRICULTURAL BOTANY

A manual of aquatic plants, N. C. FASSETT (*New York and London: McGraw-Hill Book Co.*, 1940, pp. VII+382, figs. [226]).—Defining an aquatic plant as a plant that may, under normal conditions, germinate and grow with at least its base in the water and is large enough to be seen with the naked eye, the author has

aimed to make possible the identification of aquatic plants in sterile as well as in flowering or fruiting condition. The region covered is from Minnesota to Missouri and eastward to the Gulf of St. Lawrence and Virginia. Part 1 (pp. 3-35) presents a general key, and part 2 (pp. 36-341) descriptive treatment. Appendixes include uses of aquatic plants by birds and mammals, an animal index with bibliography, the relation of plants to fish with bibliography, and a glossary. An index to subjects and illustrations is provided.

Alphabetical catalog of the common and scientific names of the plants of Peru, F. L. HERRERA [y GARMENDIA] (*Catalogo alfabetico de los nombres vulgares y cientificos de plantas que existen en el Peru*. Lima, Peru: Univ. Mayor San Marcos, 1939, pp. VII+363).—A historical résumé of botanical explorations in Peru, followed by an alphabetical list of the common names of Peruvian plants with their Latin binomial synonyms.

History of the nomenclature of *Acer saccharophorum* Koch (*A. saccharum* Marsh.) from 1753 [trans. title], J. ROUSSEAU (*Nat. Canad.*, 67 (1940), No. 6-7, pp. 161-200, figs. 5).

A descriptive study of varietal forms in *Buxus*, T. H. ALPHIN (*Amer. Jour. Bot.*, 27 (1940), No. 6, pp. 349-357, figs. 3).—Using measurements of box-wood plants and leaves in the form of ratios, viz, height of plant in terms of its diameter and length of leaf in terms of width, it was found that applications of these mathematical relationships to 31 forms, including 4 species, serve as a simple and accurate expression of the differences among varieties and species of the genus.

An extension of the range of *Rynchospora macrostachya*, O. M. NEAL, JR. (Mich. State Col.). (*Rhodora*, 42 (1940), No. 499, p. 276).—York County, Maine, is added to the range.

Brazilian species of *Theobroma* from the systematic and distributional standpoints [trans. title], A. DUCKE (*Rodriguésia*, 4 (1940), No. 13, pp. 265-281, pls. 7; *Eng. abs.*, pp. 274-276).—The genus is indigenous in tropical America from the Amazon region to southern Mexico, nine species having been found in Brazil. A key to and descriptions of these species are given. The seeds of all the species are said to yield chocolate, but only *T. cacao* is cultivated for that purpose in Brazil.

Ecologic notes on the violets of Alachua County, Florida, W. A. MURRILL. (Fla. Expt. Sta.). (*Ecology*, 21 (1940), No. 2, pp. 282-284).

A preliminary report on the comparative ages of some important East African trees in relation to their habitats, P. E. GLOVER (*So. African Jour. Sci.*, 36 (1939), pp. 316-327, fig. 1).—After presenting general information on the region covered, the author describes the mbuga, semi-mbuga, subclimax, and climax successional types, and discusses the causes of secondary succession and the ages of a number of trees cut down according to the numbers of their annual growth rings. A possible method of determining the ages of trees by measuring their girth is also outlined, involving formulas for each species.

The mycorrhizal habit in relation to forestry, M. C. RAYNER (*Chron. Bot.*, 6 (1940), No. 1, pp. 12, 13).—A review of recent research.

Studies in range and pasture botany, W. E. LAWRENCE (*Corvallis, Oreg.: OSC Coop. Assoc.*, [1940], pp. [185]).—Mimeographed material for use by college students pursuing studies in range and pasture botany. The scope of the subject matter is broad, with special emphasis on ecological relations and Oregon conditions. Suggestions are also given on bibliographic usages suitable for use in research work and reports. The text includes: Introductory aspects of the range problem, life histories of plants, the life history of forage plants,

the physiological life history of a green plant, vegetation and climatic regions of the United States, plant communities indicating growth conditions, climatic life zones and life areas, life zones in Oregon, grazing range areas of the United States, grazing areas of the United States—the physiographic areas, soils and vegetation, plant formations and associations as indicators of soil series, classification of natural vegetation of the United States, grasslands of North America, plant succession in relation to grazing, plant indicators, vegetation types found in western natural lands as indicators of crop, forest, and grazing value, classification of forage types, the grass plant, life history of a grass, selenium poisoning, tarweed, *Senecio*, greasewood, cocklebur, experiments on nonpoisonous species, preparation of scientific papers, manuals and floras of vascular plants for regions of the United States and Canada, and an index to a few common and scientific names of plants.

The communal nature of the fruiting process in the Acrasieae, K. B. RAPER. (U. S. D. A.). (*Amer. Jour. Bot.*, 27 (1940), No. 6, pp. 436-448, figs. 10).—An invitation paper given before the American Association for the Advancement of Science, December 28, 1939, on this group of Myxomycetes inhabiting dung, forest litter, and soil.

Guide to the Mucorineae (Mucorales), N. A. NAUMOV (*Clés des Mucorinées (Mucorales)*). Paris: Paul Lechevalier, 1939, pp. [1]+137+XXXVII+[1], figs. 82).—This monograph is a translation, by S. Buchet and I. Mouraviev, of the second Russian edition with additional notes by the author and a preface by P. Allorge. The first part gives a general outline of the order Mucorineae, and the other three parts present, respectively, empirical keys to the families and genera, keys to the species, and an alphabetical list of all the names of genera and species with their synonyms, so far as known up to 1933. An appendix and bibliography complete the work.

Micrographic studies of fungus spores [trans. title], F. ROSA-MATO (*An. Prim. Reun. Sul-Amer. Bot.*, 2 (1938), pp. 315-324).—Descriptive tabulations and illustrations of spores of species of 26 genera of Agaricales are presented. There are 21 references.

Identification of fungi of the genus *Aspergillus* isolated in Montevideo [trans. title], J. E. MACKINNON (*An. Prim. Reun. Sul-Amer. Bot.*, 2 (1938), pp. 215-231, pls. 4).—Descriptions are included for 11 species isolated from various substrates, including man and animals.

A new species of the genus *Dendrothele* [trans. title], A. P. VIÉGAS (*Rodriguésia*, 4 (1940), No. 13, pp. 283-287, pls. 3; *Eng. abs.*, p. 286).—*D. alba* n. sp. (Thelephoraceae) is described as occurring on dead limbs of *Moquinia polymorpha*.

Mycological study of a strain of *Monascus ruber* isolated from a tomato catsup [trans. title], P. NEGRONI (*An. Prim. Reun. Sul-Amer. Bot.*, 2 (1938), pp. 243-249, pls. 3).—Data on the morphology and cultural and physiological characters are presented.

Observations on *Amanita muscaria* in Uruguay [trans. title], F. ROSA-MATO (*An. Prim. Reun. Sul-Amer. Bot.*, 2 (1938), pp. 309-314, pls. 6).

Polyperi of Rio Grande do Sul, Brazil [trans. title], R. RICK (*An. Prim. Reun. Sul-Amer. Bot.*, 2 (1938), pp. 271-307).—Descriptions of species and varieties of *Ganoderma*, *Amauroderma*, *Lignosus*, and *Polyporus*, including new taxonomy.

The Polyporaceae of Bahia and bordering States [trans. title], C. TORREND (*An. Prim. Reun. Sul-Amer. Bot.*, 2 (1938), pp. 325-341; *Fr. abs.*, p. 341).—Descriptions are presented of species of nine genera of this fungus family in northern Brazil, with special reference to the State of Bahia.

The genus *Polystictus* in Rio Grande do Sul, Brazil [trans. title], J. RICK (*An. Prim. Reun. Sul-Amer. Bot.*, 2 (1938), pp. 251-270).—Descriptions of species and varieties of this genus of the Polyporaceae are given, including new taxonomy.

Fungistatic properties of the fatty acids and possible biochemical significance, C. HOFFMAN, T. R. SCHWEITZER, and G. DALBY (*Food Res.*, 4 (1939), No. 6, pp. 539-545, figs. 6).—The fungistatic properties of the normal saturated fatty acids containing 1-14 carbon atoms were studied at pH 2-8. Many exhibited remarkable effectiveness in inhibiting mold growth, varying according to the chain length, acid concentration, and pH of the media. A branched chain acid, in general, proved less effective fungistatically than the corresponding straight chain acid. Unsaturation tended to increase the effectiveness. At neutrality, the acids containing 8-12 carbon atoms were the most effective in inhibiting mold growth. This suggested that the nutritional value of these fatty acids should be studied in relationship to certain types of disease, and the theory is advanced that the shorter chain fatty acids may prove important in human dietary.

The harmful effect of direct and alternating currents on plant growth, E. BURSTEIN, L. M. ALIMINOSA, and L. MORIBER (*Electrochem. Soc. Trans.*, 77 (1940), pp. 501-515, figs. 6).—The growth retardation in the anode plants resulting from passage of a D. C. through the entire coleoptile proved greater than that occurring in the cathode plants. This difference is shown to follow a growth trend similar to that obtained by others with potentials either induced or applied. The D. C. retarded the growth of the coleoptile regardless of whether the anode or the cathode was at the tip. Current flow as a complicating factor may account for the discrepancy in results by various workers on the movement of auxin under a potential gradient. Results of tests with D. C. through the tip and through the base of the coleoptiles indicate that the effect of the D. C. is greatest in the apical region. The effect of a D. C. of 1 μ a. passing through the entire coleoptile is entirely due to the action of current on the tip portion. D. C. passing through the tip of the coleoptile is presumed to decrease the supply of growth substances to the basal region. The influence of current on growth is discussed in terms of effect on auxin supply and on the complex protoplasmic system. A. C. retarded growth to a much smaller extent than D. C. The effects of A. C. as compared with D. C. are linked with the different effects on pH, permeability, and electrical charges on cell membranes.

Heat resistance of several spring wheats as shown by laboratory tests, E. A. HELGESON and K. L. BLANCHARD (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 1, pp. 5, 6).—Preliminary tests under controlled conditions with Ceres, Thatcher, Premier, and Hope wheat varieties placed them in this order with respect of high temperature resistance. So far as Ceres, Thatcher, and Hope are concerned these results correspond with field observations on their drought resistance. It is hoped that a standardized method along these lines may be worked out which will speed up the breeding and testing program.

The responses of shoots of mungo bean seedlings growing in solutions of 3-indole-acetic acid, E. W. GROSS (*Amer. Jour. Bot.*, 27 (1940), No. 6, pp. 371-376, figs. 5).—When mungo bean seedlings 24 hr. old were transferred from damp chambers to paper-lined beakers containing serial dilutions of 3-indoleacetic acid and to control beakers of distilled water, all the experimental hypocotyls (except those in 0.001 mg. concentration per liter) 3 days after soaking were reduced in size as compared with the controls. Seven days after soaking all the treated hypocotyls showed a slight gain over controls,

and the epicotyls were also taller. At the 7- and 3-day intervals growth responses were correlated with the amount of growth substance used. When day-by-day measurements were made the results agreed substantially with those of the first two experiments. In addition, it was observed that at the 4-day interval the treated epicotyls, when measured for the first time, were markedly shorter than the controls.

Tests on after-effects of auxin seed treatment, P. S. TANG and S. W. LOO (*Amer. Jour. Bot.*, 27 (1940), No. 6, pp. 385, 386).—White mustard grown from seed first treated for 24 hr. in an aqueous solution of 3-indoleacetic acid (1 mg./l., 10 mg./l., and 100 mg./l.) showed accelerated leaf production in the preflowering period and notable and progressive shortening of that period with the two higher concentrations. For these concentrations the number of leaves at vegetative maturity was also reduced, this effect also being most pronounced for the highest concentration. Mustard, tomato, and rice grown from auxin-treated seed usually came into bloom 3–7 days earlier than untreated controls.

Factors influencing the protoplasmic streaming in the oat coleoptile, R. A. OLSON and H. G. DU BUY. (Univ. Md.). (*Amer. Jour. Bot.*, 27 (1940), No. 6, pp. 392–401, figs. 7).—Developing a more reliable and more readily carried out method of measuring protoplasmic streaming through the use of dark field illumination, an entirely objective photographic recording of the rate was devised, depending on the length of the streak on a film made by a moving particle during a given exposure time. The effect of ethyl ether on protoplasmic streaming was determined. No increase in rate was caused, but marked inhibition was found with the higher concentrations (10 gm./l.–32 gm./l.). No marked increase in rate of streaming by indoleacetic acid at 0.001–10 mg./l. could be found, but above this range inhibition was observed. The effect of 2–4-dinitrophenol on streaming proved to be permanent and toxic at concentrations of 50 and 100 mg./l., with no effect at 1 mg./l. No increase of streaming by methylene blue from 10^{-5} molar to 10^{-2} molar concentration could be shown, but above this range inhibition occurred. KCN inhibited the streaming only 50 percent even in concentrations as high as N/100.

The relation between respiration, protoplasmic streaming, and auxin transport in the Avena coleoptile, using a polarographic microrespirometer, H. G. DU BUY and R. A. OLSON. (Univ. Md.). (*Amer. Jour. Bot.*, 27 (1940), No. 6, pp. 401–413, figs. 15).—"The dropping mercury electrode has been adapted to the measurement of the respiration of a single coleoptile section. There occurs at a definite low oxygen concentration a critical point in the respiration process at which a new and lower rate of respiration persists. This lower rate is about 50 percent of the normal rate. This limiting concentration is lower for old coleoptiles than for young coleoptiles. KCN limits the rate of respiration to the same extent that it limits the rate of streaming. The inhibited rate of respiration is about the same as that which is brought about by low O_2 tension. 2–4-Dinitrophenol inhibits the rate of respiration to the same degree that it limits streaming. Indole-3-acetic acid alone or in the presence of fructose has no effect on respiration except in the higher concentrations (25–100 mg./l.) where it inhibits respiration. KCN limits the transport of auxin to the same degree and in the same concentrations that it limits protoplasmic streaming and respiration. 2–4-Dinitrophenol decreases the transport of auxin to the same extent and in the same concentration that it decreases protoplasmic streaming and respiration."

Studies on *Chlorella vulgaris*.—II, Further evidence that *Chlorella* cells form a growth-inhibiting substance, R. PRATT and J. FONG. (Univ. Calif.). (*Amer. Jour. Bot.*, 27 (1940), No. 6, pp. 431–436, figs. 6).—In continuation

(E. S. R., 83, p. 39) of these studies, multiplication of this green alga in a nutrient solution exposed to continuous light from Mazda lamps and through which a gas mixture composed of 5 percent CO₂ and 95 percent air continuously bubbled was used as a measure of growth. Under these conditions growth was relatively unaffected by changes in total salt concentration of the nutrient solution from 0.01 to 0.1 mole per liter.

"When nutrient media prepared with solutions in which growth had occurred but from which all cells had been removed were inoculated, it was found that growth was inhibited by the presence of filtrate in the medium, that the depression of growth increased as the percentage of filtrate in the medium increased, that for a given concentration of filtrate in the medium the depression of growth varied inversely with the initial density of population, and that the depression of growth increased with the physiological age of the filtrate."

Using this method, evidence is presented that seems to demonstrate clearly that *C. vulgaris* cells produce and liberate into the external solution a substance that tends to retard their growth. This substance may be formed in proportion to the metabolic activity of the cells. Probably the reduced growth rates are manifestations of general metabolic sluggishness.

Improvements in the simplified method for osmotic measurements, C. J. LYON (*Plant Physiol.*, 15 (1940), No. 3, pp. 561, 562).—This note presents certain refinements in the technic of a previously published adaptation by the author of A. Ursprung's simplified method.¹

Effect of soil moisture on growth and transpiration in *Helianthus annuus*, E. V. MARTIN (*Plant Physiol.*, 15 (1940), No. 3, pp. 449-466, figs. 4).—Russian Mammoth sunflowers were grown in containers holding ± 130 lb. of dry soil under conditions of different holarid, using two methods, viz, (1) with the holarid maintained near field capacity by frequent additions of water and with other plants allowed to remove about two-thirds of the available soil moisture before replenishment, and (2) with four groups of plants grown in soil mixed at holarids of ± 11 , 14, 17, and 20 percent of the dry weight of the soil, no water being added at any time thereafter. The wilting coefficient of this soil was 7 percent and the field capacity 18 percent.

In all series, lower holarid resulted in reduced growth. In tests using method (1) water requirement and shoot-root ratio increased with greater available water, but in those using method (2) neither was appreciably altered. Stomata were smaller and more numerous on plants with less available water. The leaves were also thinner, but the palisade:sponge tissue ratio was unchanged, the anatomical changes apparently being due to failure of the cells to expand normally because of reduced turgor. Growth rates were affected by even small differences in holarid, and were affected by reduced holarid long before any effect on stomatal opening or transpiration rate per unit area could be detected. The transpiration rate per unit of leaf surface was usually affected when about two-thirds of the available soil moisture had been removed. The stomatal opening appeared unaffected unless the holarid was reduced sufficiently to lower transpiration. In all cases in which the transpiration rate and stomatal opening were affected, the leaves showed signs of wilting. Rate of increase in leaf area fell off as the soil moisture was reduced, but after watering recovered to a value greater than that of controls. This effect was believed due largely to recovery of turgor. No increase in rate of transpiration per unit area of leaf surface in plants recovered from wilting above that of controls could be detected. There are 19 references.

¹ *Plant Physiol.*, 11 (1936), No. 1, pp. 167-172.

Growing plants without soil, F. S. SCHLENKER and R. S. BELL (*Rhode Island Sta. Misc. Pub.* 7 (1940), pp. [12], figs. 4).—A brief conspectus of the subject.

The assimilation of ammonia nitrogen by the tobacco plant: A preliminary study with isotopic nitrogen, H. B. VICKERY, G. W. PUCHER, B. SCHOENHEIMER, and D. RITTENBERG. (Conn. [New Haven] Expt. Sta. et al.). (*Jour. Biol. Chem.*, 135 (1940), No. 2, pp. 531-539).—"When ammonium chloride that contains nitrogen of atomic weight 15 is administered for a short period to rapidly growing plants, the isotope can be promptly detected in all parts of the tissues. The ammonia absorbed is rapidly assimilated into the nitrogen of amides and amino acids and into the proteins. The concentration of isotope in the nitrogen suggests greatest intensity of assimilation in the roots and least in the leaves; on the other hand, the greatest quantity of isotopic nitrogen was found in the leaves. Much of the chemical change can be accounted for as a result of growth during the experimental period, but the quantity of isotope found in the proteins of the tissues was appreciably in excess of that to be expected from growth alone. This excess is apparently the result of continuous chemical interaction between the nitrogen of the tissue constituents and that of the nutrient. In the course of these reactions isotopic nitrogen is introduced into the proteins. This is held to furnish an example of the normal process of nitrogen assimilation. There is a close and striking analogy to the type of continuous chemical reaction in which the tissue proteins of mature animals in nitrogen equilibrium have already been observed to be concerned."

Growth and differentiation of maize in relation to nitrogen supply, P. R. BURKHOLDER and I. McVEIGH. (Univ. Mo.). (*Amer. Jour. Bot.*, 27 (1940), No. 6, pp. 414-424, figs. 10).—Under varied supplies of nitrogen, 12 inbred lines and 9 hybrids of corn were grown in nutrient sand cultures for 5, 7, or 8 weeks, when observations were made on fresh and dry weights of the shoots and roots, development of apical growing points, growth of parenchyma cells in the stems, and differentiation of vascular tissues. Differential growth of the lines and hybrids was observed particularly in response to the higher N increments. All hybrids exceeded either one or both parental lines in dry matter produced under high-N conditions, though some were little if any better than the more vigorous parent. Apical meristematic regions developed more rapidly in the hybrids and in direct proportion to the amount of N supplied. Considerable differences were noted in rates of development among inbreds and hybrids. Stem diameters and both number and size of the constituent parenchyma cells increased directly with the N supply. Plots of the logarithm of cell size in microns against the logarithm of stem diameter in millimeters yielded straight lines with the slopes differing among the different kinds of corn. The vascular bundles were more numerous and contained larger and better differentiated elements in direct proportion to the stem diameters. Hybrid vigor in crosses superior in their ability to produce dry matter and to differentiate organs was not correlated with greater growth and development of the vascular tissues. Size and differentiation of cells in the xylem and phloem were directly proportional to N supply.

An apparatus for the continuous recording of light intensity in foot-candles (graphic light meter), K. POST and M. W. NIXON. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), p. 278).—An abstract.

An environment-control chamber for study of photosynthesis, respiration, and transpiration of horticultural plants, N. F. CHILDERS and H. W. BRODY. (Ohio State Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 384-390, figs. 3).—Detailed plans are presented of a chamber, used successfully for over a year, in which it was possible to maintain a temperature within 1.5° F. over

a range of 35°–120°, a relative humidity within 1 percent over a range of 0–95 percent, and light from 500 footcandles at floor level to 8,000 near the ceiling. Inside dimensions are 7 by 8 by 8 ft., and the cost of building materials and equipment (excluding the photosynthesis machine) was about \$1,500.

Studies on the chlorophylls and photosynthesis of thermal algae from Yellowstone National Park, California, and Nevada, O. L. INMAN (*Jour. Gen. Physiol.*, 23 (1940), No. 6, pp. 661–666).—Myxophyceae normally growing at 65° C. evolved oxygen on irradiation and gave evidence of retaining the power to carry on photosynthesis at 20°, indicating that extra thermal energy is not essential for photosynthesis at least over a short period of time. Chlorophylls a and b found in several species growing in water at 37°–72° were essentially the same as found in plants the world over. Certain standard chemical and spectroscopic tests for the chlorophylls were used as criteria for these comparisons. The ratio of chlorophyll a and b often varied considerably, but in general chlorophyll a showed an increase over the percentage found in most plants. Green algae (*Chlorella* sp.?) were the only forms found at "The Geysers," Sonoma County, Calif. The temperature of the waters from which collections were made was 49°–66°. Collections from Beowawe, Nev., were from waters at 60°–71°. The algae belonged to the Myxophyceae, and the species were like some of those found in Yellowstone National Park. In some of the calcareous regions of the latter, spectroscopic study of the chlorophylls revealed an unidentified absorption band at 548 m μ .

The reduction of ferric oxalate by isolated chloroplasts, R. HILL and R. SCARISBRICK (*Roy. Soc. [London], Proc., Ser. B*, 129 (1940), No. 855, pp. 238–255, figs. 7).—Isolated chloroplasts of *Stellaria media* showed a progressive fall in activity approaching zero in 3–6 hr. Four strains of the plant were grown which showed differences in chloroplast stability after their removal. The activity of the chloroplasts was measured by two methods described. The Q_{O_2} , measured as rate of oxygen production calculated on the basis of dry weight of leaf taken, was ± 20 ; when measured as rate of methemoglobin reduction, it generally appeared less as the reduction of methemoglobin by ferrous iron was relatively low. The reduction of methemoglobin in presence of ferric potassium oxalate was studied quantitatively from the viewpoint of iron, methemoglobin, and chloroplast concentration. The effect of different light intensities on the ferric oxalate reaction was similar to that of varying light intensity on photosynthesis in whole plants and lay within the range of values noted by different workers. The ferric oxalate reaction was inhibited by urethane. Phenyl urethane inhibited in much smaller concentrations than ethyl urethane. The effective concentrations of urethane were similar to those affecting photosynthesis. It is concluded that the light reaction in plant photosynthesis is the production of the O_2 molecule and is not the reduction of CO_2 .

Starch formation in tobacco plants deficient in potassium, D. DAY (*Plant Physiol.*, 15 (1940), No. 3, pp. 367–375).—Using tobacco plants grown from seedlings in sand culture in complete nutrient solution and in similar solution with potassium phosphate replaced by sodium phosphate, the leaves were cut separately and their fresh and dry weights ascertained, and quantitative determinations of starch were made by the iodine precipitation method of Pucher and Vickery (*E. S. R.*, 79, p. 9). Controls grew normally, with more and larger leaves having greater fresh and dry weights than those without potassium. The proportion of dry matter in the leaves was greater in the controls and decreased from top toward base, i. e., decreased water content was associated with K deficiency. The supply of K was apparently correlated with capacity to store starch, since the maximum amount of starch in the leaves of the controls

in each series was greater than the maximum in plants without K. There are 24 references.

Separation of potassium isotopes in Valonia and Nitella, A. G. JACQUES (*Jour. Gen. Physiol.*, 23 (1940), No. 6, pp. 741-742).—"The ratio of K^{39} : K^{41} appears to be lower in the sap of *Valonia* and *Nitella* than in the environment, indicating that the living cell can separate these isotopes to some extent. Experiments with a mixture of guaiacol and *p*-cresol suggest that a similar separation may occur here, but further experiments are needed."

Action curves with single peaks in Nitella in relation to the movement of potassium, W. J. V. OSTERHOUT and S. E. HILL (*Jour. Gen. Physiol.*, 23 (1940), No. 6, pp. 743-748, figs. 6).—"In *Nitella* the action curve has two peaks, apparently because both protoplasmic surfaces (inner and outer) are sensitive to K^+ . Leaching in distilled water makes the outer surface insensitive to K^+ . We may therefore expect the action curve to have only one peak. This expectation is realized. The action curve thus obtained resembles that of *Chara*, which has an outer protoplasmic surface that is normally insensitive to K^+ . The facts indicate that the movement of K^+ plays an important part in determining the shape of the action curve."

The physiological basis of plant nutrient deficiency symptoms, E. E. DE TURK (*Amer. Fert.*, 93 (1940), No. 5, pp. 8, 22).—An abstract.

Salient features of the method of foliar diagnosis, W. THOMAS and W. B. MACK. (Pa. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 253-260, figs. 5).—"The graphic representation of the three-component system nitrogen, phosphoric acid, and potash, which plays a major role in the physiology of plant nutrition, is described in detail. The relationship of the optimum in the pure science of physiology to the optimum in practical agriculture is discussed in terms of the experimental facts established by the method. The foliar diagnosis values of the known optimum serve as a base of reference for all other modes of nutrition obtained for a particular species. The reciprocal effects, or the action of one element on another, are discussed in relation to their influence on the 'nutrient balance' through displacement of the intensity of nutrition and the N- P_2O_5 - K_2O equilibrium. Conclusions of practical importance are drawn from the facts. The method of foliar diagnosis applied to a particular species in a particular soil in a given year is an incontestable means of control by indicating the direction in which nutritional modifications are required."

Effects of guaiacol and hexylresorcinol in the presence of barium and calcium, W. J. V. OSTERHOUT (*Jour. Gen. Physiol.*, 23 (1940), No. 6, pp. 749-751).—"Guaiacol was applied at two spots on the same cell of *Nitella*. At one spot it was dissolved in 0.01 M NaCl, at the other in 0.01 M $CaCl_2$ or $BaCl_2$. The effect was practically the same in all cases, i. e., a similar change of P. D. [potential difference] in a negative direction involving a more or less complete loss of P. D. (depolarization). When hexylresorcinol was used in place of guaiacol the result was similar. That Ca^{++} and Ba^{++} do not inhibit the effect of these organic depolarizing substances may be due to a lack of penetration of Ca^{++} and Ba^{++} . The organic substances penetrate more rapidly, and their effect is chiefly on the inner protoplasmic surface which is the principal seat of the P. D."

Cation exchange in plant roots in relation to metabolic factors, T. C. BROYER and R. OVERSTREET. (Univ. Calif.). (*Amer. Jour. Bot.*, 27 (1940), No. 6, pp. 425-430, figs. 4).—"In a previous paper (E. S. R., 76, p. 457) results were reported on the general nature of salt accumulation by excised barley roots. In the present contribution, employing radioactive isotopes as indicator ions,

further evidence is given that favorable temperature and aerobic cultural conditions are requisite for continued net inward movement of cations. Ionic exchange movements may occur during periods of and under conditions favorable for active solute accumulation. Observed ionic movements are net values, related in part at least to certain two-directional exchange movements of ions associated with, although not depending directly on, metabolic processes and to a lesser degree to those associated merely with colloidal conditions apart from metabolic influences. Some outward movement of cations may occur from regions more deeply seated than the root surface. Under the experimental conditions, aeration was not directly involved in the exchange movements of cations. Temperature had a small and possibly a variable effect in this respect, in contrast to the large influence of temperature on the accumulation movement against a gradient of electrolyte.

The balance sheet of metabolites for potato discs showing the effect of salts and dissolved oxygen on metabolism at 23° C., F. C. STEWARD, P. R. STOUT, and C. PRESTON. (Univ. Calif. et al.). (*Plant Physiol.*, 15 (1940), No. 3, pp. 409-447, figs. 2).—In this second paper on the biochemistry of salt accumulation by plants (E. S. R., 83, p. 320), a summary is presented of the effects of various salt and oxygen treatments so chosen that they comprise a range of conditions of peculiar interest to the subject. The KNO_3 and $CaBr_2$ treatments, in which anion exceeded cation uptake, increased the bicarbonate concentration and alkalinity of the external solution. In aerated solutions K salts stimulated and Ca salts depressed water absorption in a way not wholly explicable by osmotic phenomena. At O_2 tensions such that respiration was not limited thereby, the respiratory behavior of potato disks was determined by the salts in the external solution. The effect of low O_2 concentrations on respiration was confirmed. All the treatments increased the sugar concentration. The salt and O_2 treatments which stimulated respiration produced a low, residual sugar concentration. The sugar concentration did not regulate the respiration rate.

At a low O_2 concentration at which Br accumulation was depressed, synthesis of protein from amino acid was also limited by O_2 lack. In aerated distilled water protein synthesis occurred, and this was increased by KBr in the external solution but was decreased by $CaBr_2$. Dilute KNO_3 produced the greatest observed effect on protein synthesis. An approximately linear relationship occurred between the protein synthesized and the CO_2 respired. Approximately one-third of the respiration of disks in aerated distilled water was produced independently of N metabolism, and this component of the total respiration was not affected by salts or O_2 concentration. Two-thirds of the respiration of disks in distilled water arose from a component of respiration which was linked to protein synthesis from amino acids, was affected by salts and O_2 concentration, and was involved with the oxidase system. The effects of inorganic ions on respiration paralleled their effects on protein synthesis. The characteristic effects of ions on respiration and synthesis were exerted at O_2 tensions at which their absorption occurred, and the reactions of the ions observed therefore constituted an integral part of the mechanism of salt absorption.

Discrepancies in the balance sheet proved to be due to the transfer of organic substance from the surface of those disks which had been in aerated KBr solution or distilled water to the drying papers used to remove surface water. The surface film removed was formed at the expense of the starch fraction and consisted of a complex rich in uronic acid. It is now believed that losses of Mg are attributable to a similar cause. Volatile organic compounds were produced by potato tissue under the test conditions only in small amounts.

A revised balance sheet embodies corrections for all the above processes and summarizes satisfactorily the principal processes occurring in potato disks under conditions conducive to salt uptake and the effects of salts and O₂ on them at 23°. Amino acids and sugar supply the C for the protein molecule and the extra respiration entailed in its production. In the fixation of nitrate N, C is derived from organic acids. The latter disappear during protein synthesis from amino acids and probably contribute here also to the C framework of the protein molecule. The implication of the data is that all of the energy liberated by respiration is absorbed by the surroundings as heat. The significance of the results relative to current views on respiration and salt uptake is discussed. There are 51 references.

Legumes and legume bacteria (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 221-228).—Abstracts of the following papers are of botanical interest: A Suggested Explanation of the "Inefficiency" of Certain Strains of *Rhizobium* sp., by H. G. Thornton; Mechanism of Symbiotic Nitrogen Fixation by Leguminous Plants, by A. I. Virtanen; The Physiology of Nodule Formation, by K. V. Thimann; Studies on the Mechanism of Symbiotic Nitrogen Fixation, by W. W. Umbreit and P. W. Wilson (Univ. Wis.); Respiration Rates of *Rhizobium*—Their Estimation and Significance, by F. E. Allison and S. R. Hoover (U. S. D. A.); The Lyso-Resistance of *B[acterium] radicicola* [= *Rhizobium leguminosarum*] and Its Practical Importance, by A. Demolon and A. Dunez; Bacteriophage and the Legume Bacteria, by H. Katznelson (N. J. Expt. Stas.); Symbiotic Promiscuity in the Leguminosae, by J. K. Wilson (Cornell Univ.); Bacteria Associated With *Gleditsia triacanthos* L., by L. T. Leonard (U. S. D. A.); and Some Soil Factors in Nitrogen Fixation by Legumes, by W. A. Albrecht (Univ. Mo.).

Carbohydrate supply and legume symbiosis, F. E. ALLISON and C. A. LUDWIG. (U. S. D. A.). (*Chron. Bot.*, 6 (1940), No. 1, pp. 8, 9).—A review of recent research.

The structure of "ineffective" nodules and its influence on nitrogen fixation, H. K. CHEN and H. G. THORNTON (*Roy. Soc. [London], Proc., Ser. B*, 129 (1940), No. 855, pp. 208-229, pls. 2, figs. 8).—The anatomy and cytology of nodules on clover, peas, and soybeans produced by "effective" v. "ineffective" *Rhizobium* strains were studied with special reference to the volume changes in the active infected tissue during the life of the nodule. In clover the mean value of this active bacterial tissue was about three times as great in the effective nodules, due to an arrest in growth of nodules produced by ineffective strains. In all nodules the active bacterial tissue eventually disintegrated, but in effective clover nodules it remained without disintegration about six times as long. In a test of N fixation by clover inoculated with an effective and an ineffective strain, the difference in the amounts of N fixed could be accounted for by the differences in volume and duration of the active bacterial tissue. In peas, nodules produced by an effective strain were nearly twice the length and their bacterial tissue remained without disintegration about twice as long as with an ineffective strain. In soybeans, the mean volume of bacterial tissue was 4.75 times as great in the effective nodules, and the percentage of that volume composed of infected cells was twice as great. In ineffective soybean nodules disintegration of the bacterial tissue began when the plant was about 4 weeks old and was practically complete by the twelfth week, at which time no disintegration could be observed in effective nodules. The difference in amount of N fixed by soybean plants bearing each type of nodule could be accounted for wholly by the factors mentioned. Thus in both clover and soybean nodules the volume and duration of the active infected tissue were the main if not the only factors determining differences in N fixation among the strains studied.

Elements of botanical microtechnique, J. E. SASS (*New York and London: McGraw-Hill Book Co., 1940, pp. IX+222, figs. 33*).—This manual was evolved over a period of years in connection with the teaching of a college course in histological methods. Since it is primarily a training manual rather than a reference work, use is made of a graded series of assignments, beginning with subjects in which orientation is easily visualized, few sectioning difficulties are encountered, and a simple stain is used. The two main parts of the text deal, respectively, with general principles and with specific methods.

Comparative morphology of stamens [trans. title], H. SCHAEPPPI (*Chron. Bot., 6 (1940), No. 1, pp. 4, 5*).—A general discussion.

Contribution to the study of potato pollen [trans. title], E. L. RATERA (*Buenos Aires Univ., Inst. Génét. [Pub.], 1 (1940), No. 4, pp. 19, figs. 12*).—The author presents observations of some varieties of the cultivated potato and related wild species with respect to a method of determining the fertility of the pollen and its quantity, quality, germinability, and morphology.

The relation of internal surface to intercellular space in foliage leaves, F. M. TURRELL. (Calif. Citrus Expt. Sta.). (*Science, 92 (1940), No. 2385, p. 244*).—The coefficients of correlation between the internal-external surface ratio and the volume of intercellular space per sample area are presented for 20 leaves of 4 alfalfa plants and for random samples of leaves of 16 angiosperm species from various parts of the world.

The xylem anatomy, relative water conductivity, and transport of dyes in citrus stems, E. DE VILLIERS (*So. African Jour. Sci., 36 (1939), pp. 291-313, figs. 10*).—Material of rough lemon, sour orange, and grapefruit for the anatomical studies was obtained from trees grown at the University of Pretoria and was compared with material of the same species sent from California. As a result of this study, it is believed possible that differences in anatomy and water conductivity may influence the compatibility of the different species and be of importance in explaining the failure of sour orange as a stock in South Africa. Dyes and salts introduced into one root of citrus may be transported to branches on all sides of the tree. Substances transported in the youngest xylem, however, are mainly found on one side of the tree, in which case the substances may travel around some of the branches without entering them. In the older xylem there is a better tangential distribution of dyes than in the younger. Substances transported in the older xylem may enter all branches. This may be explained by the profuse branching of and irregular course followed by the xylem vessels. There are 18 references.

Proceedings of the local branches of the Society of American Bacteriologists (*Jour. Bact., 40 (1940), No. 2, pp. 326, 327, 331, 332, 333, 334*).—Abstracts of the following papers are of interest to botany: The Physiology of Luminescence and Respiration of Luminous Bacteria, by F. H. Johnson; Production of Citric Acid by *Willia anomala*, by H. C. Murray (Purdue Univ.); Growth of Some Non-Sporulating Anaerobic Bacteria in Synthetic Media and Extracts From Corn Silk, by R. A. West, Jr., K. H. Lewis, and W. E. Miltzer (Univ. Nebr.); Respiration Studies on Resting Cells of *Rhizobium meliloti*, by J. T. Kroulik and P. L. Gainey (Kans. Expt. Sta.); Bacteria as Colloids, by T. M. McCalla (Kans. State Col.); and Studies on Natural Bacteriolysins, by W. R. Miller.

The taxonomy of the genus Bacillus.—I, Modes of spore germination, C. LAMANNA. (Cornell Univ.). (*Jour. Bact., 40 (1940), No. 3, pp. 347-360, pl. 1, figs. 29*).—It is claimed that when the modes of spore germination are clearly defined and separated they have taxonomic value, and that the spore germination of a given type is constant for any one culture and species. The modes thus far found are summarized.

Studies on the thermal sensitivity of marine bacteria, C. E. ZOBELL and J. E. CONN. (Univ. Calif.). (*Jour. Bact.*, 40 (1940), No. 2, pp. 223-238).—Most of the bacteria isolated from the sea grew best at temperatures considerably above their marine environment. Although nearly all multiplied slowly at near zero, true psychrophiles were not found. Many of the marine bacteria proved sensitive to the planting temperature. Only 20 percent survived 40° C. for 10 min., and the respiratory enzymes of some forms were inactivated at 30°. Nutrient agar inoculated with sea water or marine sediments yielded maximum colony counts when incubated at 18°-22° for 1-2 weeks, and very few colonies developed at 30°-37°. There are 26 references.

Heavy carbon as a tracer in bacterial fixation of carbon dioxide, H. G. WOOD, C. H. WERKMAN, A. HEMINGWAY, and A. O. NIER. (Iowa Expt. Sta. and Univ. Minn.). (*Jour. Biol. Chem.*, 135 (1940), No. 2, pp. 789, 790).

A comparison of cobalt and nickel salts with other agents for the detection of hydrogen sulfide in bacterial cultures, W. P. UTERMÖHLEN, JR., and C. E. GEORGI. (Univ. Nebr.). (*Jour. Bact.*, 40 (1940), No. 3, pp. 449-459).—The toxicities of Ni and Co ions for a number of bacteria in broth cultures were determined, and a medium containing proteose peptone, cysteine, glucose, dipotassium phosphate, Ni and Co nitrates, agar, and water was developed which is said to compare well with present established media for detecting H₂S production by bacteria. It was shown that detection (and perhaps production) of H₂S in bacterial cultures varies greatly according to the medium and the indicator used—all factors thus need to be specified. The possible causes of this variation are discussed. There are 16 references.

Inhibiting effect of acetic acid upon micro-organisms in the presence of sodium chloride and sucrose, A. S. LEVINE and C. R. FELLERS. (Mass. Expt. Sta.). (*Jour. Bact.*, 40 (1940), No. 2, pp. 255-269, fig. 1).—Acetic acid inhibited bacterial growth almost exactly in proportion to the amount present. The order of decreasing resistance to acetic acid was *Bacillus cereus*, *Salmonella aertrycke*, *Staphylococcus aureus*, and *Phytomonas phaseoli*. Naturally, *Saccharomyces cerevisiae* and *Aspergillus niger* were inhibited at a higher acid concentration than the bacteria, the yeast being the more resistant of the two. At equivalent pH values the greater toxicity was usually noted with the greater amount of acid. Apart from the indirect effect in altering the pH, the salt and sugar aided the acetic acid but little in its toxic effect on bacteria and yeast, nor did they exert appreciable effects on the minimum percentage of acidity required for total destruction of these organisms. Evidence is presented that the toxic action of acetic acid on micro-organisms is not confined to the pH alone. When *A. niger* was inoculated into a series of flasks of glucose broth containing different concentrations of acetic acid, growth was inhibited at pH 4.1 and at a total acidity of 0.27 percent. Addition of 5 percent salt or 20 percent sucrose did not significantly change these growth limits. Acetic acid in nontoxic amounts promoted the development of *A. niger* by supplying energy. At acetic acid concentrations of 0.1-0.17 percent no inhibition of mold growth resulted from adding 5 percent NaCl. On the other hand adding 20 percent sucrose markedly stimulated growth. Maximum mold growth was obtained in a 20 percent nutrient sucrose solution at pH 4.4 containing 0.16 percent acetic acid.

A photomicrographic study of the rate of growth of some yeasts and bacteria, G. KNAYSIL. (Cornell Univ.). (*Jour. Bact.*, 40 (1940), No. 2, pp. 247-253, figs. 2).—The growth rate in substance of the *Schizosaccharomyces pombe* cell became nil or nearly so at the time of cell division. *Bacillus cereus* cells showed no such correlation in an actively growing culture, although the growth rate fluctuated within the life span of the cell.

The biochemical classification of yeast strains, A. S. SCHULTZ, L. ATKIN, and C. N. FREY (*Jour. Bact.*, 40 (1940), No. 3, pp. 339-346).—Examination of 44 yeast cultures described as strains, varieties, or races of *Saccharomyces cerevisiae* or *S. carlsbergensis* has shown that they may be subdivided into three types on the basis of their vitamin relations.

Yeasts occurring on grapes and in grape products in California, E. M. MRAK and L. S. McCLUNG. (Univ. Calif.). (*Jour. Bact.*, 40 (1940), No. 3, pp. 395-407, fig. 1).—The authors report that 241 cultures of yeasts were isolated from California grapes and grape products, of which 82 were imperfect and 159 ascospore-forming. The species found, including 2 new species of *Torulopsis* and 1 of *Asporomyces*, are discussed. There are 26 references.

GENETICS

Diploidy, polyploidy, and winter hardiness relationships in the flowering plants, W. M. BOWDEN (*Amer. Jour. Bot.*, 27 (1940), No. 6, pp. 357-371, figs. 16).—A scale of relative degree of winter hardiness was constructed for comparing the cold resistance of related species in families ranging from the temperate zone to the Tropics. The data thus far obtained are arranged in an extensive table, showing the author's chromosome number determinations of 100 species and varieties of angiosperms with a comparison of counts already reported in related species. These data were found to indicate that, in nature, genic mutation and inter- and intraspecific hybridization have been more important processes than chromosome doubling. The findings failed to support the theory that polyploids are usually harder than diploids and are therefore better adapted to climatically unfavorable regions.

Polyploidy in relation to chemical analysis, W. J. BONISTEEL (*Jour. Amer. Pharm. Assoc.*, 29 (1940), No. 9, pp. 404-408, figs. 3).—The author calls attention, with many examples, to the function that polyploidy exerts in the chemical constituents of drug plants, a field hitherto largely overlooked. For example, in the genus *Aconitum* toxicity of the plants varies with the chromosome number. Diploids are usually nontoxic, whereas the triploids and tetraploids represent the extremely toxic alkaloids of the genus. Hexaploids are considered nontoxic, and no definite information is available regarding the octoploids. Chemical analysis of *Cinchona* hybrids indicates that a shift from one alkaloid to another may take place in hybridization. The point is stressed that all studies on drug plants should include the cytological problems involved.

Failure of cytokinesis during microsporogenesis in *Zea mays* following heat treatment, G. A. LEBEDEFF. (Cornell Univ.). (*Cytologia*, 10 (1940), No. 4, pp. 434-442, figs. 26).—Failure of cytokinesis in the anthers of corn during premeiotic and meiotic divisions had no evident effect on the course of the nuclear division. Microsporocytes in which the cytoplasm failed to divide developed into multinucleate spores. The size of these spores was roughly proportional to the number of nuclei present.

A study of the inheritance of susceptibility and resistance to apple cedar rust, R. C. MOORE. (Va. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 242-244).—Analysis of 1-yr. records indicated that the factor for resistance or susceptibility is inherited and that there is a segregation of the progenies of crosses into resistant and susceptible types. It appeared that resistance might be dominant over susceptibility. Arkansas Black seemed to behave as a homozygous dominant for resistance, whereas Jonathan and Rome Beauty appeared to be homozygous recessives in their susceptibility. Of the other parent varieties involved in the crosses, Delicious, Ralls Seedling, Winesap,

and Virginia Beauty, even though they are phenotypically resistant, appeared to be heterozygous in resistance or susceptibility to rust. Inheritance of resistance appeared to involve only one genetic factor, although the available data were not large enough to establish it definitely. The degree of susceptibility of parent varieties appeared to manifest itself in the respective progenies.

Some aspects of selection of Merino stock for wool-production under pastoral conditions, J. E. NICHOLS (*Empire Jour. Expt. Agr.*, 8 (1940), No. 29, pp. 34-38).—A fairly steady annual increase in fleece weights with some irregularities in Merino sheep of New South Wales was effected from 1879 to 1934. Marked differences in the production in different regions were attributed to varying effects of environment. The important problem for improvement seems to be selection by progeny performance in the less favorable areas, thus basing selection on adaptation to specific local conditions.

Influence of inbreeding and other factors on litter size in Chester White swine, H. O. HETZER, W. V. LAMBERT, and J. H. ZELLER (*U. S. Dept. Agr. Cir.* 570 (1940), pp. 11, figs. 2).—The records of 362 litters of Chester Whites born over a 17-yr. period with variable degrees of inbreeding showed a downward tendency for litter size at birth, at 28 days, and at 70 days. Although the litter size decreased with inbreeding of the litter, size of the litter increased with age of the dam to about 3.5 years. About 10.7 percent of the variance in the number of pigs at birth, 4.9 percent in the pigs at 28 days, and 6 percent in the variance of the number of pigs weaned was associated with age of the dam. About 60 percent of the variance in litter size was due to causes which could not be determined. Less than 20 percent of the variance at any one age was hereditary. Season of birth, yearly changes in feeding and management, and differences in age of the dam appeared to account for the remaining 20 percent of the variance.

An albino buffalo (*Jour. Hered.*, 31 (1940), No. 8, p. 341).—Notation is made of an albino buffalo herd of 200 head in Alaska.

Albinism in the opossum, D. M. SMITH (*Jour. Hered.*, 31 (1940), No. 8, p. 342, fig. 1).—An albino opossum captured in Oklahoma is described.

Genetic studies on a cavy species cross—*Cavia rufescens* (Lund) and *Cavia porcellus* (Linné), G. v. UBISCH and R. F. MELLO (*Jour. Hered.*, 31 (1940), No. 9, pp. 389-398, figs. 5).—Comparative growth curves up to about 1 yr. of age are presented for wild cavies of Brazil (preá), domestic cavies, and reciprocal F₁ and backcross progeny between them. Natural breeding and artificial insemination were employed to produce some of the crosses. The duration of gestation averaged 67.2 days for tame cavies and from 62 to 65 days for *C. rufescens* and hybrids between the species. An equal distribution of the sexes was found in the purebreds and crosses. Notation was made of the morphology of the skulls and semitransparent spots in the frontal bones of the wild species and hybrids.

A new mutation in the mouse—affecting spinal column and urogenital system, L. C. DUNN, S. GLUECKSOHN-SCHOENHEIMER, and V. BRYSON (*Jour. Hered.*, 31 (1940), No. 8, pp. 343-348, figs. 4).—The dominant mutation in mice which causes short tail and a syndrome of abnormalities in the sacral region and is lethal in the homozygote (*E. S. R.*, 78, p. 768) was found to segregate as a unit but does not affect viability before birth. Matings of short-tailed mice (heterozygotes) produced 159 normals, 368 short tails and tailless, and 153 lethals, essentially a 1:2:1 ratio when eliminating the progeny of one male. The genetic constitution of Bagg inbreds seemed to enhance the expression of the mutation in the heterozygote. The mutant *Sd* was not linked with the short tail gene *T* or caracul *Ca*. There was a heavy mortality after birth in the heterozygotes of 72 percent up to 30 days of age.

Change of the age of puberty in albino rats by selective mating, C. P. STONE and R. G. BARKER (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 1, pp. 48-50, fig. 1).—By 6 generations of selection for early and late breeding from 25 pairs of albino rats, strains were produced in which the average age of puberty of ♂s was 47.56 and of ♀s 42.98 days in the early strain, as contrasted with 61.18 in ♂s and 56.87 days in ♀s in the late line. These results suggest that the change in the age of puberty of rats during the last 30 yr. was probably a matter of selection.

[**Genetic studies with poultry by the Indiana Station**], E. E. SCHNETZLER (*Indiana Sta. Rpt.* 1939, pp. 101, 102, 103, 104, figs. 3).—Strains of hens markedly different in size and egg weights were produced by six generations of selection, and strains of turkeys were found to differ widely in their body weights. Differences in skeletal measurements were not proportionate to body size.

Breeding for egg weight and related characters, M. W. OLSEN and C. W. KNOX. (U. S. D. A.). (*Poultry Sci.*, 19 (1940), No. 4, pp. 254-257).—By selection over a 5-yr. period in Single-Comb White Leghorns, the egg weights showed a progressive increase from an average of 54.7 to 59.7 gm., with the body weights of the birds increasing progressively from about 4 to 4.6 lb. During this period the average age at maturity was decreased. An analysis of the contribution of the sire and dam and of their ancestors indicated the closest association of egg weight in the progeny and the egg weight of the sires' sisters.

A record-breaking "freemartin" (*Jour. Hered.*, 31 (1940), No. 9, p. 398).—Notation is made of a cow born twin with a bull which produced five calves.

Sperm stimulation in the bull through the subcutaneous administration of ascorbic acid, P. H. PHILLIPS, H. A. LARDY, E. E. HEIZER, and I. W. RUPEL. (Wis. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 9, pp. 873-878).—The subcutaneous administration of ascorbic acid to bulls of relatively low potency resulted in increases in the ascorbic acid content of semen from values below 2 mg. per 100 cc. to 6 mg. or more. However, excessive amounts of ascorbic acid in the semen were often associated with an unreliable breeding record. Ascorbic acid was vitally concerned with the physiology of reproduction in bulls, but the exact nature of its role in this capacity was not known.

The effect of route of administration on the multiple activities of testosterone and methyl testosterone in different species, C. W. EMMENS and A. S. PARKES (*Jour. Endocrinol.*, 1 (1939), No. 3, pp. 323-331, fig. 1).—Investigation of the androgenic and gynecogenic activities of testosterone and methyl testosterone administered to capons, rats, and rabbits by inunction, orally, and parenterally showed testosterone to be much less active by mouth in capons and castrated ♂ rats than by subcutaneous injection. Progestational proliferation in rabbits was as actively produced by methyl testosterone by mouth as by injection. The two substances were about equally active in causing uterine growth in spayed rats and immature rabbits, whereas methyl testosterone was more potent as an androgen in rats but less potent in capons.

Relaxation of the pelvic ligaments of the guinea pig induced by progesterone, H. O. HATERIUS and N. W. FUGO (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 1, pp. 155-157).—The administration of progesterone following oestrogen stimulation to ovariectomized ♀s was effective in inducing relaxation of the pelvic ligaments. A separate hormone for the action of relaxin was not necessary (*E. S. R.*, 65, p. 428).

Failure of ovarian hormones to cause mating reactions in spayed guinea pigs with hypothalamic lesions, J. M. BROOKHART, F. L. DEY, and S. W. RANSON (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 1, pp. 61-64).—Since ♀ guinea pigs with hypothalamic lesions failed to mate, although most of them showed normal sexual cycles, a series of 27 young adult ♀ animals were ovariec-

tomized and brought into regular oestrus by oestrone and progesterone administration. After lesions were made in the hypothalamus, treatment with ovarian hormones did not induce oestrus or pro-oestrus. None of the animals would mate. However, slight changes in the location of the injury permitted normal oestrous cycles.

Ovarian transplantations in the house mouse, G. G. ROBERTSON (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 1, pp. 302-304).—Four agouti ♀s, each carrying one ovary from a yellow litter mate and none of its own, produced nine yellow and nine agouti progeny after matings with agouti ♂s. Second litters of eight yellow and three agouti offspring were produced by mating with yellow ♂s. The yellows were heterozygous, and failure to produce young when the grafts were not successful showed the completeness of the removal of the ovaries in these cases. The findings bear out previous findings of Castle and Phillips with guinea pigs (*E. S. R.*, 30, p. 472). Transplantations between different inbred lines were unsuccessful.

The production of ovulation in the rabbit by the intravenous injection of salts of copper and cadmium, C. W. EMMENS (*Jour. Endocrinol.*, 2 (1940), No. 1, pp. 63-69).—Adult does of the heavy breeds were injected intravenously with doses of copper acetate, sulfate, and analine and of cadmium acetate and chloride, which produced ovulation in approximately 15 to 17 hr., as determined by laparotomy. Various salts of barium, cobalt, gold, iron, manganese, nickel, silver, and zinc were ineffective. Ovulation was inhibited by the simultaneous administration of an antiserum produced by rabbits after daily injection with 25 mg. of a pyridine of acetone-desiccated ox pituitary.

Superovulation in rabbits, G. PINCUS (*Anat. Rec.*, 77 (1940), No. 1, pp. 1-8).—Pregnant-mare-serum extracts intravenously administered to prepubertal and pubertal rabbits following priming caused ovulation, but rarely superovulation because of a tendency to induce cyst formation. Pituitary extracts under similar conditions usually produced superovulation. There were induced with an unfractionated extract over 80 ova in 3 different litters. Mating did not influence the number of ova but showed that they were fertilizable. Mating could not be substituted for the ovulating dose.

The uterus masculinus of the rabbit and its reactions to androgens and oestrogens, R. DEANESLY (*Jour. Endocrinol.*, 1 (1939), No. 3, pp. 300-306, pl. 1).—The administration of oestrogen to adult castrated and immature ♂ rabbits was found to stimulate the growth and development of the uterus masculinus in spite of the fact that the epithelium underwent shrinkage unless some form of testosterone was also administered.

Effects of oestrogen and androgen injections on reproductive organs in male rats and mice, R. HARSH, M. D. OVERHOLSER, and L. J. WELLS. (Univ. Mo.). (*Jour. Endocrinol.*, 1 (1939), No. 3, pp. 261-267, pl. 1).—Metaplastic changes in the epithelium of various reproductive organs and penis extrusion of immature and adult ♂ rats and mice resulted from the administration of oestrogen. In the joint administration of oestrogen with testosterone, metaplasia in the prostates was prevented, but the androgen did not prevent all the effects of oestrogen since there was bladder dilatation, penis extrusion, and metaplastic change in the seminal vesicle ducts.

The liver and endogenous androgens, M. W. BURRILL and R. R. GREENE (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 1, pp. 273-276).—Since subcutaneous implantations of testicular tissue into immature rats showed some androgenic effects on the penis and accessories but such effects were not shown when the implants were placed so that there would be venous drainage through the liver, it is concluded that the testicular androgen is inactivated in the liver.

Effect of small doses of testosterone propionate on the testis, H. S. RUBINSTEIN and A. A. KURLAND (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 1, pp. 168, 169).—Androgenic potency of testosterone propionate was demonstrated by significant enlargement of the seminal vesicles of rats injected with 10 γ of testosterone propionate daily for 10 days. The rats were 22 days old at the beginning of the experiment.

Effect of thymectomy at birth on spermatogenesis in the albino rat, J. C. PLAGGE (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 1, pp. 57-60).—Thymectomy of δ rats at birth was found at autopsy at from 33 to 38 days of age to neither retard nor hasten spermatogenesis, hormone production, or testis growth, as compared with the controls.

Inadequacy of the vaginal smear in the rat as an index of ovarian dysfunction caused by diet, S. C. FREED, O. HECHTER, and S. SOSKIN (*Jour. Endocrinol.*, 1 (1939), No. 3, pp. 268-274).—Examination by laparotomy of the uterine response observed during vaginal oestrus of ♀ rats on different diets showed that the completeness of the cycle was significantly affected by a low-protein diet plus 4 percent of ammonium chloride, whereas a relatively complete uterine oestrus was produced on a diet to which 8 percent of baking soda was added. The ovaries of rats with incomplete uterine oestrus seemed normal in size and mature follicles were few or absent after 4 weeks on the experimental diets. As a control to show that the rats on these diets did not lose the capacity to show complete uterine response, ♀ s exhibiting only partial oestrus were castrated and found to show complete oestrus following the administration of oestradiol benzoate. These results led to the conclusion that the ovaries damaged by the diets failed to secrete one or more of the oestrogenic factors the composition of which was necessary for complete oestrous reaction. Vaginal oestrus was not necessarily an indication of complete oestrus.

Influence of age of animal and nature of injected hormone preparation on antihormone production, A. S. GORDON, I. LEVENSTEIN, and H. A. CHARIPPER (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 1, pp. 121-126).—The antigonadotropic hormone production of immature and adult ♀ rats injected daily with Follutein (human pregnancy-urine extract) and Gonadin (pregnant-mare serum) for from 35 to 95 days was compared by injection of immature ♀ s simultaneously but at different sites with one of the hormones and the antihormone from the treated animals. Both mature follicles and corpora lutea were seen in the test animals after 5 days' treatment. The analysis of the results, as determined by the inhibition of increased ovarian weights, showed that adult rats produced more antihormone in response to injections of anterior-pituitary-like preparations than immature ♀ s. Follutein evoked the production of more antihormone than Gonadin.

Method of assay for progesterone based on the inhibition of uterine oestrus, A. J. SZARKA (*Jour. Endocrinol.*, 2 (1940), No. 1, pp. 1-11, figs. 2).—Study was made of the fluid distension of the uterus of ovariectomized adult and intact immature ♀ rats following oestrone administration and the inhibition of this effect resulting from progesterone. In the tests from 1.2 to 1.5 mg. of crystalline progesterone completely inhibited the usual response of the uterus to the administration of 4.8 μg . of oestrone. The potency of the progesterone substance to be tested was determined on a regression line based on the degree of inhibition of uterine oestrus. Laparotomy was performed on the experimental animals 44 hr. after the simultaneous administration of oestrone and progesterone, and the uterine condition was recorded. The test was accurate within \pm 20 percent, using from 18 to 20 test animals with each dose.

On the mechanism of the action of gonadotrophin from pregnancy urine, B. ZONDEK (*Jour. Endocrinol.*, 2 (1940), No. 1, pp. 12-20).—Chorionic gonadotropin administered to immature ♂ rats was rapidly inactivated so that only 5 percent could be recovered in 30 hr. from maceration of the whole animal. Inactivation of oestrogen was effected in the liver, but chorionic gonadotropin was not inactivated following shaking and incubation with macerated liver, spleen, and muscle. Chorionic gonadotropin in its original form and not after transformation into a "hormonoid" acts on the ovarian cell.

Modification of the effectiveness of gonadotrophic extracts, R. DEANESLY (*Jour. Endocrinol.*, 1 (1939), No. 3, pp. 307-322).—The addition of 15 mg. of zinc sulfate to extracts of pig, sheep, and ox pituitaries and administration to immature ♀ rats in divided doses on 5 days augmented the ovarian weights to nearly double those obtained with pituitary extracts alone. Extracts of horse pituitary produced much larger ovaries, but they were not augmented further by the zinc salts. Extracts of pregnant-mare serum and pregnancy-urine extract were not augmented in their effectiveness on ovarian weights by the addition of zinc given on 5 days. Combinations of gonadotropic extracts from different sources in relation to synergistic and antagonistic effects gave variable and somewhat contradictory results.

Effect of heterologous antigonadotropic sera on the course of pregnancy in rats, B. ZONDEK, A. HOCHMAN, and F. SULMAN (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 1, pp. 338-341).—The species specificity of antigonadotropic hormones was brought out in a large number of negative results obtained when the hormones inhibiting the action of antigonadotropic sera from one species did not show a similar effect to that from others. Antigonadotropic sera from goats immunized to human prolactin and prosylan did not interfere in the rat with the normal cycle nor with impregnation, nidation, delivery, and normal breeding.

Further evidence for a mammogenic factor in the rat hypophysis, R. P. REECE and S. L. LEONARD. (*N. J. Expt. Stas.*). (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 1, pp. 200-202).—Castrated sexually immature ♀ rats which received no further treatment and served as controls had mammary glands that were involuted, with a naked duct system. Such rats receiving pituitary implants from adult ♂s and ♀s showed numerous and enlarged end buds in the mammary glands at autopsy 12 days later. The mammary glands of rats receiving pituitaries from ♂s and ♀s previously treated for 10 days were not significantly different from the mammary glands of castrated and hypophysectomized ♀s which received implants of pituitaries from oestrogen-treated ♂s and ♀s. However, the latter group made little gain in body weight. Thus the presence of a hypophyseal factor inducing growth of the mammary glands in hypophysectomized castrated immature ♀ rats was demonstrated, in support of the findings of Lewis, Turner, and Gomez (*E. S. R.*, 82, p. 322).

The influence of estradiol on the social organization of flocks of hens, W. C. ALLEE and N. COLLIAS (*Endocrinology*, 27 (1940), No. 1, pp. 87-94, fig. 1).—The birds in five flocks of White Leghorns were intramuscularly injected daily with oestradiol for periods up to 68 days. Few changes in the social aggressiveness and flock organization were evident from peck tests in contradiction to the effects of testosterone (*E. S. R.*, 82, p. 614).

The effects of oestrone and testosterone and of pituitary extracts on the gonads of hypophysectomized pigeons, J. P. CHU (*Jour. Endocrinol.*, 2 (1940), No. 1, pp. 21-37).—Studies of the effect of hypophysectomy and various pituitary extracts and sex hormones on the reproductive organs of normal and hypophysectomized pigeons showed that both the testes and ovaries undergo

statistically significant involution, but the ovarian weights do not show as great difference between the normal and operated birds as that found in the testes. Regression in the weights of the adrenals and the pancreas was also noted, with little change in the thyroid within 14 days. No mature sperm were seen in birds from 15 to 20 days after hypophysectomy. The ovaries were atrophied and showed absence of follicular proliferation. Ox, sheep, and horse pituitary extracts had a pronounced effect, although not complete, on the prevention of loss in weight of the organs when given before regression. When given after regression these extracts considerably stimulated the ovaries, and the oviduct was large and vascularized. Full spermatogenesis was induced by extracts of horse pituitaries, but loss in body weight and weights of other endocrine organs was not checked. Testosterone administered to normal ♂s had no effect on the endocrines, in general, but the testes regressed as in hypophysectomized birds. Testosterone showed a stimulating effect on the gonads of both sexes following hypophysectomy. Oestrone was not effective in maintaining testicular or ovarian activity under such conditions.

Further studies on the relation of the daily exposure to light to the sexual activation of the male starling (*Sturnus vulgaris*), J. W. BURGER (*Jour. Expt. Zool.*, 84 (1940), No. 3, pp. 351-361, pl. 1).—Continuing these studies (E. S. R., 81, p. 195), the author attempted to determine the precise conditions of sexual activation of the sexually inactive ♂ starling. Two groups were exposed to 12.5 and 13.5 hr., respectively, of light daily in a dark room to find the minimum stimulating day lengths. All birds receiving 13.5 hr. showed sperm in the testes by February 12. Sexual stimulation was not uniformly complete in the birds exposed to 12.5 hr. of lighting, and therefore this exposure was fairly close to the threshold. In some birds, activation was complete.

FIELD CROPS

[Agronomic research in the Southern States] (*Assoc. South. Agr. Workers Proc.*, 41 (1940), pp. 53, 54, 63, 65-70, 71, 72, 74-88, 141-149, 184, 185, 188, 190, 191, 195, 196).—Papers concerned with agronomic problems and presented at the convention of the Association of Southern Agricultural Workers at Birmingham, Ala., February 7-9, 1940, reported in abstract form, included Equipment for Experimental Work in Curing Tobacco, by L. S. O'Bannon (pp. 53, 54), and The Place and Value of Liming in Kentucky, by P. E. Karraker (pp. 74, 75) (both Ky. Expt. Sta.); Legume Coverage Studies in Alabama, by I. F. Reed (p. 63), The Nitrogen, Organic Carbon, and pH of Some Southeastern Coastal Plain Soils as Influenced by Green-Manure Crops, by R. D. Lewis and J. H. Hunter (pp. 68, 69), A Complete Balanced Vegetative Program for Soil Conservation, by R. Y. Bailey (pp. 69, 70), Soil Organic Matter and Nitrogen as Influenced by Green Manure Crop Management on Norfolk Coarse Sand, by N. McKaig, Jr., W. A. Carns, and A. B. Bowen (p. 70), The Effects of Calcium and Magnesium on the Physical Properties of Some Lateritic Soils, by T. C. Peele (p. 77), Adaptation of Several *Trifolium* Species to Different Ecological Environment in the South, by E. A. Hollowell (pp. 82, 83), Use of Hormone Treated Cuttings and Special Type Grafts in Cotton Breeding, by W. H. Jenkins, D. C. Harrell, and J. O. Ware (p. 188), and Storage Tests With Cotton Seed, by D. M. Simpson (pp. 195, 196) (all U. S. D. A.); Returns From the Use of Fertilizers on Southern Crops, by H. R. Smalley (pp. 65, 66); The Elimination of Differences in Investment in the Evaluation of Fertilizer Analyses, by W. B. Andrews (p. 66), Variations in Johnson and Dallis Grass, by H. W. Bennett (pp. 85, 86), and Some Water Relations in Sweetpotato, by W. S.

Anderson (pp. 147, 148) (all Miss. State Col.); Selection of Effective Strains of Legume Bacteria for Leguminous Plants in the South, by L. W. Erdman and J. C. Burton (pp. 66, 67); Time and Rate of Plant Nutrient Absorption by Bright Tobacco, by A. L. Grizzard and H. R. Davies (pp. 67, 68), and Selecting a Microchemical Method of Soil Testing for Use in Virginia, by A. L. Grizzard (pp. 80, 81) (both Va. Sta.); Suitable Crop Patterns for Changing Conditions in Southern Agriculture, by T. B. Hutcheson (pp. 71, 72) (Va. A. and M. Col.); The Effect of Liming on the Absorption of Phosphorus and Nitrogen by Winter Legumes, by C. A. Brewer, Jr., and F. L. Davis (p. 74), The Effects of Wetting, Drying, and Treatments on the Availability of Potassium in Soils, by R. K. Walker and M. B. Sturgis (p. 79), and Effect of Certain Methods of Treating and Planting Cotton Seed in South Louisiana, by H. B. Brown (p. 184) (all La. Sta.); Properties of Calcic, Magnesic, and Dolomitic Materials and Their Divergent Behavior in Soils, by W. H. MacIntire (p. 76) (Univ. Tenn.); The Use of Lime in Balancing Our Southern Agriculture, by H. P. Cooper (pp. 76, 77), Experiments With Electricity in Sweetpotato Plant Production, by J. B. Edmond and G. H. Dunkelberg (pp. 146, 147), and The Influence of Height of Bed on Yield and Shape of Sweet Potatoes, by O. B. Garrison (pp. 148, 149) (all S. C. Sta.); Field Variation as a Factor in Sampling for Rapid Soil Analyses, by E. R. Collins and W. R. Hodgen (pp. 77, 78), and Winter Survival and Yield of Rough and Smooth Awned Segregates in Fall-Sown Barley, by G. K. Middleton and W. H. Chapman (p. 86) (both N. C. Sta.); Rapid Chemical Tests in Georgia (pp. 79, 80), and Chemical and Physical Studies on Soils From the Regional Cotton Wilt Plots (pp. 190, 191), both by L. C. Olson, and Permanent Pastures for the Piedmont Section of Georgia, by O. E. Sell (pp. 86, 87) (all Ga. Sta.); A Comparison of Field Crop Response and the Amount of Phosphorus Removed From Alabama Soils by Chemical and Biological Methods, by G. W. Volk (p. 81), Certain Aspects of Southern Seed Potato Trials, by H. M. Darling (pp. 141, 142), and Recent Results of Research Work on the Culture of Irish Potatoes in the South, by L. M. Ware (pp. 144-146) (all Ala. Sta.); Adaptation of Winter and Summer Legumes in the South, by G. E. Ritchey (pp. 81, 82) (Fla. Sta. and U. S. D. A.); Environmental Factors as Related to Growing Winter Pasture Plants in Florida, by R. E. Blaser (p. 83) (Fla. Sta.); Breeding for Adaptation in Red Clover, by L. Henson (p. 84) (Ky. Sta. and U. S. D. A.); Breeding Forage Grasses for Adaptation to Southern Conditions, by G. W. Burton (pp. 84, 85) (Ga. Coastal Plain Sta. and U. S. D. A.); Grass in Southern Agriculture, by L. R. Neel (pp. 87, 88) (Tenn. Sta.); Recent Refinements in Field Plot Technique in Relation to Irish Potatoes, by H. L. McClurg (p. 141) (U. S. D. A. and La. Sta.); Technic and Methods of Breeding Irish Potatoes in the South, by J. C. Miller (pp. 142, 143) (La. State Univ.); Recent Results of Potato Fertilization Research in the South, by H. H. Zimmerley (pp. 143, 144) (Va. Truck Sta.); and Field Results With Gravity Graded Cotton Seed, by K. S. Chester (p. 185) (Okla. A. and M. Col.).

[**Crop research in Indiana**], R. R. MULVEY, G. P. WALKER, A. T. WIANCKO, G. D. SCARSETH, M. DRAKE, W. W. WORZELLA, G. H. CUTLER, C. E. SKIVER, S. R. MILES, A. M. BRUNSON, F. C. GAYLORD, and J. D. HARTMAN. (Partly coop. U. S. D. A.). (*Indiana Sta. Rpt. 1939*, pp. 11, 13-15, 45-50, 60, 61, 99, 111-115, figs. 2).—Progress results are reported from investigations (E. S. R., 81, p. 638) including breeding work with corn and hybrids, wheat, oats, and soybeans; variety tests with corn varieties and hybrids, sunflowers for silage, and sweet-potatoes; comparison of alfalfa, red clover, and sweetclover as hay crops; mixed seedings of legumes and timothy v. straight clover for the hay crop in the rotation; rotation with wheat after soybeans v. wheat after corn; value

of inoculating soybeans; rate of seeding winter barley; effects of clipping of oats; protection of seed grain from weevil damage by treatment with mercury dust; corn production from late plantings; factors affecting winter hardiness and quality in soft red winter wheat; effects of fertilizer applications, other practices, and leaf rust on yield and quality of winter wheat; increase of potash losses from lawns and golf greens caused by heavy applications of ammonium sulfate; ability of plants to absorb native potash from the soil; magnesium deficiency in soils especially induced by high rates of potash fertilization; plowing under heavy applications of cyanamide for corn; effects of various plant foods upon the wheat plant; effects of green manures on the growth of sweetpotatoes; soil fertility studies involving response of corn, wheat, soybeans, and clover in rotations to fertilizers, lime, and manure; effects of different methods of disposing of cornstalks on soil fertility; a comparison of red clover, alfalfa, and sweetclover in rotations with corn and wheat; a study with a 4-yr. rotation of corn, corn, soybeans, and potatoes to find the need of well-disintegrated deep muck of the nonacid type for lime, phosphorus, and potassium; and experimentation on Crosby silty clay loam to determine effects of lime, manure, and commercial fertilizers on yields of corn, wheat, and mixed hay and on soil fertility.

Depth of plowing and crop yields, A. N. HUME (*South Dakota Sta. Bul.* 344 (1940), pp. 23, figs. 4).—Effects of plowing at differential (4- to 12-in.) depths before planting corn in the 4-yr. rotation corn, winter wheat, oats, and legumes, 1913-37, are presented. Corn increased in total weight as well as bushels per acre directly with deeper plowing to the maximum of 12 in., but it was the only crop showing this trend in total weight. Yields of grain from winter wheat and oats, as well as corn, increased in general with increased depth of plowing for corn. No relation was established between the total weight of legume (clover, sweetclover, or soybeans) seed and hay or seed alone and depth of plowing. Subsoiling did not appear to result in an increase in yields.

Soil conditions in relation to the response from green manure applications, H. J. HARPER. (Okla. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 266-270).—Green manure studies indicated that the nitrogen content of three soil types in central Oklahoma is still adequate for production of maximum yields of cotton under the climatic conditions. The nitrogen content of a Kirkland very fine sandy loam declined from 0.077 percent in 1926 to 0.043 in 1939, and during this period cotton yields were not increased when fall-planted hairy vetch or Austrian Winter peas were plowed under each spring about 3 weeks before cotton planting. Profitable increase in cotton yields evidently will not be obtained on most soils under average climatic conditions in the section when soil nitrogen exceeds 0.05 percent. Increases in wheat yields, it appeared, may be obtained at a higher fertility level than cotton when the cropping system includes a legume.

Calcium in relation to phosphorus utilization by some legumes and nonlegumes, W. A. ALBRECHT and N. C. SMITH. (Mo. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 260-265, figs. 8).—The forage production by red-top, bluegrass, Korean lespedeza (*E. S. R.*, 81, p. 642), and sweetclover pointed to an importance of calcium in the use of phosphorus by these crops. More of the applied phosphorus was recovered in the crop as the degree of saturation of the soil by calcium became greater, more largely because of greater crop yields than because of higher concentration of phosphorus in the forage. Increasing applied phosphorus also served to increase the calcium taken from a constant soil supply and suggested a reciprocal effect by phosphorus on

calcium. Saturation of one-fourth of the soil by calcium increased the phosphorus harvest by 36 percent, while the corresponding increase was only 10 percent when the same total calcium supply served to increase the amount of lime in the entire soil by only one-fourth of that necessary for saturation. When phosphorus was applied with limestone this same effect by lime was evident. Thus liming becomes a matter of feeding calcium to the plant effectively and of aiding it in getting its phosphorus rather than one of modifying H-ion concentration. Degree of saturation of a limited soil area appeared more significant in controlling the efficiency of the calcium recovery by the crop than did the total calcium application throughout the soil. This calcium recovery is also influenced by increased phosphorus in the soil. The total harvest of protein also increased when increased calcium and phosphorus harvests occurred. Increases in calcium utilization by the grasses as redbud, for example, served to lower the silicon concentration and also that of aluminum and iron.

Deterioration of midwestern ranges, J. E. WEAVER and F. W. ALBERTSON. (Univ. Nebr. and Kans. State Col.). (*Ecology*, 21 (1940), No. 2, pp. 216-236, figs. 27).—A survey in the summer of 1939 of 88 ranges representative of grazing lands in western Kansas and Nebraska, southwestern South Dakota, eastern Wyoming and Colorado, and the Oklahoma Panhandle showed that severe drought, overgrazing, burial by dust, and grasshopper damage resulted in great reduction of the cover of range grasses. This portion of the mixed prairie has almost completely lost its upper story of midgrasses on nonsandy lands. Short grasses and sedges have undergone a process of thinning so that only the most vigorous plants remain alive. Many less xeric forbs have practically disappeared, and only six or eight of the most xeric native forbs are regularly represented by much dwarfed and widely spaced individuals. The basal cover of grasses was 21 percent or more in only 16 percent of the ranges; in another 16 percent it ranged between 11 and 20 percent; between 6 and 10 percent in 28 percent; from 2 to 5 percent in another group totaling 16 percent; and the remaining 24 percent presented a cover of 1 percent or less. Extremely poor conditions varied with the better ones throughout. The bare soil during periods with moisture is populated with annual weeds, chief of which is Russian-thistle. Cacti have increased greatly almost everywhere and constitute a serious problem. Because of the low precipitation of 1939, most ranges lost any gains made during favorable periods since 1934.

Cereal crops at the Dickinson Substation, R. W. SMITH. (Coop. U. S. D. A.). (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 1, pp. 15-21).—Variety tests, reported in tables showing annual and average yields over the past 10 yr., indicate as productive cereals Gopher, Iogold, Markton, and Rainbow oats; Trebi, Steigum, Ezond, and Spartan barley; Gehu, Dakota White, and Shota flint, and Falconer semident corn; and Bison flax. Emmer yielded slightly less than the best oats on a comparable basis. Flaxseed yields averaged highest from May 1 and April 20 seedings, with progressive decreases from plantings after May 1.

Soil conditions under which alfalfa responded to boron, B. A. BROWN and A. KING. ([Conn.] Storrs Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 310-313).—Boron deficiency in alfalfa appeared on station plats and on Connecticut farms during the dry summer of 1939. Borax at 20 lb. per acre at time of seeding alfalfa in August 1938 reduced the average prevalence of "yellows" in August 1939 from 25 to 3 percent, increased height by 15 percent, yields by 16 percent, and the boron in the alfalfa leaves from 21 to 62 p. p. m. Manure did not obviate the symptoms significantly but apparently increased the available boron in the soil slightly and the total boron in alfalfa leaves appre-

ciably. More affected plants appeared on heavily limed nonboron plats but fewer where potassium chloride had been applied heavily between 1915 and 1923. Alfalfa did not benefit from adding manganese, copper, or zinc to potash-borax or potash-superphosphate-borax treatments.

Differential growth rates in cotton varieties and their response to seasonal conditions at Greenville, Tex., H. C. McNAMARA, D. R. HOOTON, and D. D. PORTER (*U. S. Dept. Agr., Tech. Bul. 710 (1940), pp. 44, pls. 6, figs. 8*).—Rates of growth and fruiting in six upland cotton varieties, Acala, Lone Star, Rowden, Delfos, Half and Half, and Kekchi, which have widely contrasted characters, were studied, 1931-33. In Lone Star, Kekchi, and Half and Half the number of nodes to first fruiting-branch was influenced significantly by season. The interval in days between appearance of first flowers on successive fruiting-branches was strongly influenced by season, and in one case by variety. The intervals between successive flowers on fruiting branches usually were shortest on branches from the eleventh to the fifteenth nodes, the points of maximum fruiting-branch development, and were longer on the first two fruiting branches as well as the uppermost branches, and were influenced significantly by variety and season. An average of 56 percent of all bolls matured on all varieties were located on the first fruiting-branch nodes. Lone Star was lowest in this respect, with 51.31 percent, and Delfos was high, with 58.97 percent. The second fruiting-branch nodes produced about one-half as many bolls as the first and the third node about one-half as many as the second node. Chances of setting bolls evidently were reduced 50 percent with each successive fruiting-branch node. The varieties that produced the most flowers also matured the largest number of bolls. The medium- to large-bolled varieties matured bolls from 26 to 28 percent of their flowers, and the small-bolled varieties, Delfos and Half and Half, set 39.1 and 42 percent, respectively.

About three-fourths of the total crop of bolls was set within 4 weeks after the first flowers appeared. Delfos set 92 percent of its crop within 4 weeks of the first flower. The boll-shed period was rather uniform, averaging 5.16 days for all varieties. In cotton, plants fruit or defruit (as when demand for water becomes acute in drought) in successive zones, which are described as the fruiting, small-boll shedding, and small-square shedding zones. Each zone extends upward and outward from the base of the plant. Branches on which the most bolls were set showed terminal abortion the oftenest. The mean boll period for all varieties was 43.93 days, and like the boll-shed period might be influenced significantly by variety and season. The boll period on upper and outer fruiting positions usually exceeded those on inner and lower positions. Thickness of carpels in relation to boll period also is discussed.

Pectic substance of cotton fibers in relation to growth, R. L. WHISTLER, A. R. MARTIN, and C. M. CONRAD. (Coop. U. S. D. A.). (*Jour. Res. Natl. Bur. Standards [U. S.], 25 (1940), No. 3, pp. 305-308, fig. 1*).—Determination of the content of pectic substance in fibers of Mexican Big Boll (grown at Raleigh, N. C.) at various stages of growth suggested three distinct stages of development of the fiber. The first, extending to about the eighteenth day, is characterized by a gradual decrease in the content of pectic substance. During the second, which extends from the eighteenth to about the thirty-fifth day, there occurs a rapid decrease in pectic substance. In the final stage, from about the thirty-fifth day to maturity, only a slight decrease is noted in the content of pectic substance.

Potato varieties recently distributed to growers in the United States, F. J. STEVENSON. (U. S. D. A.). (*Amer. Potato Jour., 17 (1940), No. 9, pp. 217-235*).—Adaptations and performances are summarized from information provided by experiment stations from their tests and studies of the Chippewa,

Earlaine, Houma, Katahdin, Mesaba, Nittany Cobbler, Pennigan, Pontiac, Red Warba, Sebago, Sequoia, and Warba potato varieties.

Recent studies on fertilizer applications for Gold Skin sweet potatoes, V. A. TIEDJENS and L. G. SCHERMERHORN. (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 857-859).—The fertilizer was applied in different types of band placement, all or in part after setting plants, in solution, and applied with the phosphorus separate from the nitrogen and potassium salts. The results, preliminary in nature, gave indications that any method of applying fertilizer which places it in close proximity to the roots when the plants are set is not conducive to good yields. Deferred applications of all or part of the fertilizer as side dressings materially increased yields. Using less than 100 lb. of fertilizer in solution produced higher yields than the standard treatment, 1,200 lb. of 2-8-10 under the row 2 weeks before setting plants. Placing only superphosphate, with or without lime under the rows, and adding nitrogen and potassium later produced the largest yield increases.

Potato rotation studies, O. SMITH and E. N. McCUBBIN. (Cornell Univ.). (*Amer. Potato Jour.*, 17 (1940), No. 9, pp. 235-243).—In Steuben and Franklin Counties, N. Y., highest yields of potatoes were obtained in rotations in which potatoes are grown every year and receive commercial fertilizer plus 12 tons of manure per acre. The highest-yielding 2-yr. rotation is potatoes following a 1-yr. sod of clover and timothy grown for green manure, and the lowest include potatoes following dry shell beans or soybeans for hay. In Genesee County yields among any of the rotations did not differ much in 1937 or 1938, while in 1939 the 2-yr. rotations, potatoes after corn for green manure and dry shell beans, respectively, did best. Potatoes in manured rotations in this county did not yield higher than in similar rotations omitting manure. Extremely low yields were obtained in Franklin County where potatoes were grown continuously without treatment, while in Genesee County such rotations yielded as well until 1939 as any others.

Arsenic compounds toxic to rice, E. A. EPPS and M. B. STURGIS. (La. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 215-218).—A study was made of the kinds of arsenic compounds that may be toxic to rice (E. S. R., 75, p. 772), as accumulated in the soil as a result of spraying or dusting for control of insect pests, and of means for correcting the toxicity. Some arsenic compounds in flooded soils are reduced, with consequent increase in soluble arsenic content of the soil and decrease in total arsenic content due to liberation of gaseous compounds of arsenic, e. g., as arsine. Many naturally occurring compounds of arsenic are not attacked by the micro-organisms and do not become more soluble. Sulfur added to soils containing toxic amounts of arsenic decreased the amount of soluble arsenic, as was shown by analysis, by improved crop growth, and by decreasing intake of arsenic by rice. The amount of soluble arsenic present in soil after waterlogging is an index of the degree of arsenic toxicity. When soluble arsenic determined by this means exceeds 0.2 p. p. m., arsenical injury may be expected.

[**Papers at the twentieth annual meeting of the American Soybean Association**] (*Amer. Soybean Assoc. Proc.*, 20 (1940), pp. [1]+84, figs. 9).—Papers presented at the meeting held from August 18-20, 1940, included General Review of the Domestic Soybean Situation, by E. F. Johnson (pp. 7-18); Soybean Oil—Its Current Consumption, by H. W. Galley (pp. 19, 20); Soybean Oil Meal—Its Current Consumption, by J. W. Hayward (pp. 21-23); Importance of Soybeans to American Agriculture (With Some Notes on Soybean Research), by W. L. Burlison (pp. 27-35) (Univ. Ill.); News From the Regional Soybean Laboratory, by R. T. Milner (pp. 36-38) (U. S. D. A. and 12 expt. stas.); What

the Implement Manufacturers Are Doing To Assist the Soybean Grower, by F. A. Wirt (pp. 40-52); Today's Trend in Soybean Production, by J. T. Smith (pp. 53-55); Performance of Early Soybean Varieties in Michigan, by C. R. Megee (pp. 56-58) (Mich. State Col.); The Rise of Edible Soybeans, by J. W. Lloyd (pp. 59-62) (Ill. Sta.); Possibilities of Soybean Milk, by E. A. Ruddiman (pp. 62, 63); The Role of the Soybean in Human Nutrition, by H. W. Miller (pp. 64-71); Soybeans Around the World, by W. J. Morse (pp. 72-74) (U. S. D. A.); Progress of the Soybean Industry in Ohio, by J. W. Bricker (pp. 75-77); and Full Soya in the Soldier's Diet, by H. Weiss (pp. 78, 79).

Crop sequence effects and the results with the sugar beet crop on the Merrill farm of the Lake Shore Sugar Company, Merrill, Mich., J. G. LILL. (Coop. U. S. D. A. et al.). (*Michigan Sta. Quart. Bul.*, 23 (1940), No. 1, pp. 29-32).—During the period 1933-39, with corn as the preceding crop on Brookston loam, sugar beets produced an average of 15,550 marketable roots and an acre yield of 10.295 tons of roots, after beans 14,982 and 10.122, barley 13,400 and 8.934, and after oats 13,325 roots and 8.679 tons. The respective indicated-available sugar production per acre was 2,753, 2,604, 2,340, and 2,292 lb. Acre yields of roots followed closely trends shown by numbers of marketable roots, and indicated-available sugar per acre followed very closely the root yield. The quality of the roots was in the decreasing order after corn, oats, barley, and after beans. Differences were definite but, in general, too slight to influence sugar production much. There were definite indications that crop sequence effects on sugar beets should be considered when a rotation including sugar beets is planned. Certain sequences can entail no important increase in cost of producing sugar beets or may even decrease costs.

Sugarcane, W. E. CROSS (*La caña de azúcar. Buenos Aires Univ., Bibliot. Agron. y Vet.* [Pub.] 2 (1939), pp. XVII+231, pls. 8, figs. 68).—Designed primarily for conditions in Argentina and based extensively on research at the Tucumán Experimental Station and elsewhere, this volume discusses the importance of science to the sugarcane industry, sugarcane and its chemical composition, climate and soils, varieties, cultural methods, diseases and insect pests, harvest, sugar yields, and production costs. A bibliography and index are appended.

Effect of various soil treatments on nitrates, soil moisture, and yield of winter wheat, A. F. BRACKEN. (Utah Expt. Sta.). (*Soil Sci.*, 50 (1940), No. 3, pp. 175-188).—The relationships of yield of winter wheat under dry-farm conditions to amounts of available nitrogen and of soil moisture as influenced by time of plowing and manurial treatments were studied at Nephi, Utah, 1928-33.

Delay in spring plowing for fallow was found to reduce significantly the yield of winter wheat, due to lower moisture supplies and reduced amounts of nitric nitrogen. Yields on soils treated with 5 or 10 tons of manure did not differ much, although they were 16 percent higher than on unmanured land, chiefly because of the greater amounts of nitric nitrogen. Most of the available nitrogen was used by the time wheat began to ripen, but a slight increase was noted later, although moisture supplies remained unchanged. On fallow land, accumulation of nitric nitrogen occurred in late summer and in early fall, even though soil moisture conditions were more favorable earlier. The available nitrogen found at the end of summer in fallow land was largely located the following spring, but at a slightly lower depth. Time of plowing did not influence protein percentage of the wheat, but definite increases resulted from manure. Loss of available nitrogen from the soil slightly exceeded that accounted for by removal of the crop. Water cost of dry matter decreased with earliness of plowing for fallow and with increased manure.

An experiment in pre-harvest sampling of wheat fields, A. J. KING and E. H. JEBE. (Coop. U. S. D. A. et al.). (*Iowa Sta. Res. Bul.* 273 (1940), pp. 621-649).—Route sampling of the wheat crop to estimate and forecast yield per acre was shown in studies in 1938 in crop-reporting districts in eastern North Dakota to be a practical and an efficient method. Stratification by varieties would have resulted in a marked gain in accuracy; about 40 percent fewer fields would have been required to give the same precision. Geographical stratification, however, would have added little to the information in 1938. Variance between fields exceeded that within fields and gain in accuracy would be small with increased sampling per field. Sampling more fields would add more to the information. Regression analysis showed number of heads per sample to be the best indicator of yield, although the height of grain in the sample and average length of heads added some information. Yields determined from the objective sampling study exceeded very slightly current estimates by the U. S. Department of Agriculture.

A comparison of hard red winter and hard red spring wheats: An examination of pertinent opinions and data, R. K. LARMOUR (*Kansas Sta. Bul.* 289 (1940), pp. 57, figs. 5).—A survey of published work (71 titles) of many investigators who have studied both classes of wheat failed to provide consistent support for the view that the hard red spring wheats are superior in baking quality to the hard red winter wheats. When compared on the same protein basis, the two classes are found to be equal in intrinsic baking quality. The higher commercial rating which hard red spring wheats have received seemed attributable to their higher average protein content, greater uniformity, and their long established reputation for high quality. The hard red winter wheat arriving at the eastern seaboard usually has been much below the average of the wheat produced in the Southwest, particularly in protein content, which has created a poorer opinion of the whole class than is warranted. This is especially true of European importers who buy American wheat for blending with weaker sorts. The poorest part of the hard red winter wheat supply thus has tended to establish the reputation and to some extent the price of the whole class.

The long-time commercial evaluation of wheat, the author asserts, must be based on a very broad conception of quality, termed general utility value. This would include baking quality and many other factors, such as uniformity, protein content, specific adaptability, and even personal preferences. Many changes in these factors have occurred since hard winter wheats were first grown in the Southwest and more may be expected in the future.

Nitrates in relation to the toxicity of sodium chlorate, E. A. HELGESON (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 1, pp. 9, 10, fig. 1).—Studies with Fargo clay in connection with research on control of perennial weeds confirmed the findings of Crafts (E. S. R., 81, p. 511) and demonstrated that nitrates also reduce the toxicity of chlorates in this soil. Data are included on growth in height and fresh weight of Thatcher wheat as affected by several rates of sodium chlorate alone and with added nitrogen.

HORTICULTURE

Bi-serial r for horticultural research, J. W. CRIST. (Mich. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 269-271).—The author states that the occurrence of measurements not expressible in cardinal numbers is somewhat frequent in horticultural research and necessitates groupings merely in the form of alternate categories with quantitatively indefinable and undefined limits.

Nevertheless, the degree of correlation with the variables concerned is desirable. The biometrical technic of the so-called biserial r is available for the purpose. The author demonstrates its use with reference to the relationship between the color of apple fruits and their content of total sugar, the data being not actual but assumed. The relation between this measure of correlation and that of the ordinary coefficient of correlation, together with the magnitudes of their errors in the same set of measurements, is briefly discussed.

[**Horticultural studies by the Indiana Station**], O. W. FORD, D. L. JOHNSON, C. E. BAKER, J. A. McCLINTOCK, C. L. BURKHOLDER, J. D. HARTMAN, C. C. STAIR, F. C. GAYLORD, K. I. FAWCETT, J. E. DICKERSON, E. R. HONEYWELL, N. K. ELLIS, R. B. WITHROW, T. M. EASTWOOD, and R. K. SHOWALTER (*Indiana Sta. Rpt. 1939*, pp. 30, 31, 94-99, 100, figs. 5).—The following studies are briefly discussed as to progress: Spray residue removal, the use of sulfamic acid in spray residue removal, orchard soil management, apple stocks, apple spraying, plum and prune varieties, production of tomato seed, grading and fast freezing fruits and vegetables, factors affecting quality of mint oil, factors affecting quality of fresh and canned tomatoes, grading and standardization of peony blooms, production and marketing of muck and sandy soil crops, especially peppermint on muck, use of electric light in the greenhouse, and forcing of Easter lily seedlings.

[**Horticultural studies by the Vermont Station**] (*Vermont Sta. Bul. 463 (1940)*, pp. 20-22, 24-28).—Brief reports are presented on the progress of cytological, breeding, and physiological studies with the violet; factors influencing the set of pear fruits; the development of an effective program for the control of apple scab, codling moth, and other pests of the apple; and fertilizer requirements of the apple.

Problems in vegetable and small fruit production on toxic orchard soils of central Washington, C. L. VINCENT. (Wash. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 680-684).—In plats established in the Wenatchee area on soils from which had recently been removed mature apple trees which in their bearing years had been heavily sprayed with arsenic-containing sprays, it was observed that rye made excellent growth and oats much slower development. Among vegetables, potatoes appeared to be fairly satisfactory for planting on newly reclaimed orchard soils. Tomatoes were stunted badly during the early season but recovered later to produce a crop of green fruits. Legumes, such as peas and beans, appeared most adversely affected by soil toxicity. The longer the period following the removal of the trees, the better was the development of the planted crops.

How the Blue Lake pole bean is grown in the State of Oregon, W. D. ENZIE (*Farm Res. [New York State Sta.]*, 6 (1940), No. 4, pp. 5, 11, fig. 1).—Information is given as to origin, varietal characteristics, fertilizer and cultural practices in Oregon, and potentialities for use in New York State.

Root-top ratio of the bush lima bean as an index of adaptability to ecological conditions, F. S. ANDREWS. (S. C. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 752-758, figs. 2).—Data taken on the young plants of several varieties grown under controlled greenhouse conditions showed pronounced differences in root development and in root : top ratios. Fordhook and McCrea (large-seeded varieties) were characterized by a low root : top ratio, and Henderson (small-seeded) by a high root : top ratio. Baby Fordhook, a cross between Fordhook and Henderson, had a root : top ratio intermediate between those of its parents. An examination of the roots of young plants showed Henderson and Baby Fordhook to form fibrous adventitious roots along the stem below the soil surface. Temperature had a profound influence on root growth with varieties responding differently.

In the field the roots of Henderson were much more extensive and numerous than in Fordhook, suggesting a greater capacity for water absorption and a greater capacity to withstand drought. The broad leaves and large blossoms of Fordhook make possible a greater loss than income of water during dry, hot weather and may account in part for the differences in root development which, in turn, depends on photosynthetic processes.

Fertilizer requirements for lima beans, V. A. TIEDJENS and L. G. SCHERMERHORN. (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 743-746).—The application of hydrated lime to soil which was found to have less than 500 lb. per acre of replaceable Ca increased germination of Fordhook lima beans from 20 percent on the untreated to 80 percent on the limed area. An increase of the Ca in nutrient solutions from 10 to 20 p. p. m. stimulated the normal development and setting of the later flowers. In a series of plats on nutrient-deficient soil it was apparent that several years of fertilizer treatment may be necessary to bring the soil to the state of fertility suitable to the most effective production of lima beans. Of different sources of N used, tankage and calcium nitrate gave the best results on a soil of pH 6.0. Among varieties, Fordhook showed the most striking response to N fertilization, apparently having special need for an abundant supply. The indications were that this variety is generally given inadequate N under field conditions in New Jersey. A favorable C : N ratio was maintained by increasing the available N.

Effect of different environments on head shape in Marion Market cabbage, W. S. FLODY, JR., and J. C. WALKER. (Tex. Expt. Sta., U. S. D. A., and Univ. Wis.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 778-782).—An analysis of measurements taken on plants propagated from the same lots of seed but grown in Madison, Wis., and Weslaco and College Station, Tex., showed definite effects of the environment on the shape of heads, as indicated by length : width ratios. The heads were somewhat flattened in Wisconsin and distinctly elongated in Texas. Apparently, plants selected in a given locality to the point of apparent stability for certain characters may become unstable in these respects when transferred to a different environment. The need of adaptation of new varieties during their course of development to the region where they are to be grown is indicated.

Magnesium deficiency in cauliflower in Delaware County, New York, C. H. DEARBORN. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 773-777, fig. 1).—In studies of the B requirements of cauliflower there was observed a chlorosis distinct from that caused by deficiencies of N, P, K, Ca, or B. The injury was manifested first by a yellow mottling between the veins of the lower leaves. Young leaves rarely exhibited mottling. Field experiments in an area in which a crop of cauliflower had failed from chlorosis showed remarkable results from applications of MgO. As compared with no salable heads from a 130-ft. row for no MgO, there were 53 heads where 620 lb. of MgO was applied per acre. In another trial, even where no chlorosis was evident, significant increases in the number and weight of salable heads were obtained from the use of dolomitic hydrated limes. The field results were confirmed in greenhouse experiments in which soil brought from a deficient region was used.

The effect of large applications of nitrogen on the growth of celery, M. M. PARKER. (Va. Truck Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 697-701, fig. 1).—Golden Plume celery sown in the greenhouse about January 1 and transplanted the first of March to sash frames where the crop was grown to maturity was found to require very large applications of fertilizer to obtain best development. In fact, 2 tons of 6-6-5 material were insufficient to produce

maximum growth and optimum foliage color in plants set 6 by 10 in. in the frames. A supplementary treatment of 300 lb. of N per acre proved more effective and economical than either 100 or 600 lb. when applied in six fractional applications at weekly intervals in solution in the irrigation water.

Preliminary results of fertilizer placement for lettuce in raised irrigated beds, W. A. FRAZIER and W. T. MCGEORGE. (Univ. Ariz.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 702-706).—Compared with broadcasting or drilling prior to making the raised beds, band placement of fertilizers gave highly significant increases in yield. The most effective placement was a single band 1.5 in. toward the furrow side from the seed row and 3 in. deep. This procedure permitted lateral movement of the phosphates underneath the plant row as a result of repeated furrow irrigations and finally developed a wide band well placed for nutrient absorption by the roots. Band placement gave more uniform growth and percentage of cut-outs for the first harvests.

Inoculation studies with the garden pea in California, H. A. JONES and B. L. WADE. (U. S. D. A. and Calif. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 718-724).—In 4-yr. comparisons of garden peas from inoculated and control plats at Davis, the control plats significantly outyielded the inoculated during the first 2 yr., but in the last 2 there was no significant difference. The first 2 yr. the Hundredfold variety was used; the last 2, Laxton Progress and Giant Stride. The first-year yield of green vines was significantly higher in the inoculated than in the control plats. In 3-yr. comparisons of yields of seed and straw, using Laxton Progress and Giant Stride, there was no significant difference between inoculated and control plats, and tests at Manteca for one season using these two varieties showed no significant differences in yield of market peas, dry seed, and straw. Commercial cultures of three to five strains of *Rhizobium leguminosarum* prepared for peas were used each year.

Effect of roasting and scalding pimiento pepper fruits to remove the skins prior to canning on the subsequent germination of the seed, H. L. COCHRAN. (Ga. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), p. 679).—Data recorded over a 2-yr. period showed that fire roasting or oil scalding of pimiento fruits to remove the skins reduced the germination of the seed to the point of 14.1 and 14.6 percent, respectively, as compared with 92.1 percent for seeds taken from freshly harvested fruits. Furthermore, the seedlings from the heat-treated lots were often stunted or showed other abnormalities, such as adhering seed coats, ball heads, or single cotyledons.

Heterosis in summer squash (*Cucurbita pepo*) and the possibilities of producing F_1 hybrid seed for commercial planting, L. C. CURTIS. (Conn. [New Haven] Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 827, 828).—Having observed that the F_1 plants from a cross of two summer squashes produced female blooms 10 days earlier than either parent and were unusually uniform in growth and fruiting, the author took definite records on a succeeding planting. On comparable areas the two parents, Connecticut Straightneck No. 10 and Early Prolific Straightneck and the F_1 progeny produced 27, 25, and 59 fruits yielding 17, 15, and 58 lb. in total weight, respectively.

Improved methods of tomato production in Georgia, H. L. COCHRAN (*Georgia Sta. Bul.* 206 (1940), pp. 34, figs. 20).—In connection with general information as to varieties, plant production, culture, harvesting, marketing, control of pests, etc., there are presented data on the yield of a number of varieties over a period of several years and on the effect of fertilizers on early and weekly yields of the Marglobe variety. Louisiana Pink, Penn State Earliana, and Pritchard were the most productive kinds. An application of 600 lb. per acre

of a 6-8-6 fertilizer not only increased total yields but stimulated early yields of Marglobe, as compared with no-fertilizer treatment.

The Victor tomato, A. F. YEAGER (*Michigan Sta. Quart. Bul.*, 23 (1940), No. 1, pp. 3-6, figs. 3).—Originated from a cross of the Allred × Break O'Day varieties, Victor possesses the determinate growth habit of the Allred and the smoothness of the fruit of Break O'Day. The new variety is described and is recommended for trial as an early market tomato for Michigan.

The use of nutrient solutions in the transplanting water for tomato plants, 1939, E. C. STAIR and J. D. HARTMAN. (Ind. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 913-915).—Records taken on field experiments with two nutrient solutions added to the water placed around the roots of Indiana Baltimore tomato plants at the time of setting in the field showed a slightly significant gain from the treatment in the first picking in one instance and none in the other. When total yields were analyzed, the gains from nutrient starters were of no significance as compared with water alone. At no time during the season was there significant difference in growth to distinguish the plats from one another. Samples collected in early November showed the soil of the field to be very low in available phosphoric acid and K, suggesting that low availability of P, as indicated by rapid soil tests, is not a reliable criterion to the benefits that might be expected from the use of phosphates in the starter solution.

A comparison of nutrient solutions for transplanting tomatoes and for packing southern plants for shipment, C. B. SAYRE. (N. Y. State Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 905-909).—A mixture of two parts of Ammo Phos 11-48 and one part of potash proved as effective as, and more economical than, any other combination of chemicals tested. A mixture of equal parts of mono-K phosphate and diammonium phosphate was also very effective. Nutrient solutions containing N, P, and K were more effective than those lacking any one of these ingredients. The important influence of the starter solutions was in assisting the plant to become established quickly, with earlier maturity as a result. Treatments were particularly useful for southern-grown plants or local plants grown under crowded conditions which resulted in a depleted nutrient condition.

The response of tomatoes to fertilizer ingredients, F. K. CRANDALL and T. E. ODLAND. (R. I. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 923-926).—Investigations in the field and in concrete frames showed that N was the only one of the fertilizer ingredients under test which consistently affected the yields. There was a tendency for plats receiving the high-N fertilizer to produce a greater percentage of fruit of No. 1 grade. Under field conditions, where stable manure, green manure, and fairly liberal applications of mixed fertilizers were used, P rarely limited production, not only in tomatoes but also of other vegetables. The same general situation prevailed with respect to K.

Pruning unstaked tomatoes, L. R. HAWTHORN. (Tex. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 930-934, fig. 1).—That pruning of unstaked tomato plants to either 1 or 2 stems is a profitable practice was indicated in results obtained over a 3-yr. period at Winter Haven, Tex. In terms of marketable fruit harvested per acre during the first 4 pickings, covering a period of about 2 weeks, the average yields for the 3 yr. for unpruned, 1-stem, and 2-stem plants were 580, 2,504, and 2,155 lb., respectively. For the entire season of 11 pickings, the average yields were 12,860, 13,030, and 15,356 lb., respectively. Pruning plants to 2 stems per plant is suggested as an advisable practice.

Fruit thinning the watermelon, A. D. HIBBARD. (Mo. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 825, 826).—None of various methods of thinning watermelons increased the total yield per acre as compared with no treatment, but the largest melons and the greatest number per acre of over 26-lb. size were secured when the fruits were thinned to two per vine. The maximum total yield in pounds per acre was secured where no thinning was done.

Behavior of Malling apple rootstocks in soils of high, medium, and low moisture contents, H. B. TUKEY and K. D. BRASE. (N. Y. State Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 305-310, figs. 2).—Uniform, well-rooted 1-year-old trees planted individually in glazed crocks of 10-l. capacity were supplied with water to simulate (1) dry midsummer, (2) favorable moisture, and (3) excessive moisture conditions. On an oven-dry basis the percentages of moisture were 14.9, 17.3, and 23.1, respectively. In general, growth was greater under high than under low soil moisture conditions. There was noted, however, a variation in the response of different clones. For example, during the period of active growth, Malling VII trees showed yellowing of foliage under high moisture and grew better than any other stock under low moisture. Roots of all stocks were generally of smaller diameter in soil of low moisture and stockier in soil of medium moisture. Roots were shortest in soils of high moisture. The results agreed with field observations, and on the basis of the study the Malling stocks are classified as to moisture requirements.

The comparative performance of several standard apple varieties on certain rootstocks, principally the clones Malling I, II, and XIII, R. H. SUDDS. (W. Va. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 311-318, fig. 1).—At Kearneysville, W. Va., Red Rome on Malling I was very variable as a young orchard tree. Stayman Winesap on Malling I gave uniformly semi-standard trees. Red Rome on Malling XIII at from 7 to 8 yr. was somewhat smaller than standard size. Stayman Winesap on Malling XIII was vigorous but late in beginning fruiting. Malling II tended to dwarf somewhat its combinations with Jonathan, Starking, Staymared, Golden Delicious, York Imperial, and Gallia Beauty. Malling II apparently required a deep, fertile soil.

A comparison of the coefficients of variability of the top weights of York Imperial and Gallia Beauty trees on seedlings and on clonal stocks showed no material difference except that Gallia Beauty on seedlings was significantly more variable than when on T-200. However, when trunk circumferences were compared, trees on seedling roots were considerably more variable. The author concludes that certain environmental factors, such as soil type, may be more potent in determining uniformity than are clonal rootstocks.

Relation of cracking of graft coatings to the stand and growth of apple scions, H. A. CARDINELL. (Mich. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 291-293).—Apple cleftgrafts on which eight melted wax formulas, seven water-emulsified asphalts, and two nondrying plastic materials were tested gave evidence that the plastic materials resulted in poor stand and poor growth of scions and that the average of the asphalt coatings was as good as that of the brush waxes. Based on the stand of scions at the end of one season's growth, the conclusion is reached that there was no relationship between waxes that cracked little or not at all and those that cracked severely or fell off entirely. Apparently, other factors may be more responsible for stand and growth of scions than whether or how severely the union coating cracks.

The relationship between structure, chlorophyll content, and photosynthesis in apple leaves, W. F. PICKETT and A. L. KENWORTHY. (Kans. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 371-373).—York Imperial, Jonathan, and Wealthy trees grown in the greenhouse from January to June 1938 were weighed before planting and at digging time to measure photosynthetic activity

during the period in the beds, and quantitative determinations were made of chlorophyll a plus b. Total leaf area was measured, and leaf samples were collected for studies of the ratios of internally exposed leaf surface. Determinations made of water, ash, total acid-hydrolyzable carbohydrates, and total N following digging showed no material difference between varieties. York Imperial accumulated the least, Jonathan an intermediate, and Wealthy the greatest amount of total dry matter per unit meter of leaf surface. No significant difference was found between varieties in chlorophyll content. The ratios of the amounts of internally exposed surface to external surface were 10.09, 12.6, and 15.31 for York Imperial, Jonathan, and Wealthy, respectively, with a mean difference of 0.68 being significant. The coefficient of correlation between the ratio of the internally exposed surface and photosynthetic activity was +0.7, and between chlorophyll content and photosynthetic activity it was +0.24. The results indicate that the extent of the internally exposed surface was more important than chlorophyll content as a factor partially governing photosynthetic activity.

Thinning the apple crop by spray at blooming.—A preliminary report, V. R. GARDNER, T. A. MERRILL and H. G. PETERING. (Mich. Expt. Sta.) (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 147-149).—Tests made in the spring of 1939 with different concentrations of a large number of spray materials to determine their effectiveness as blossom-killing agents when applied at the full-bloom stage showed dinitrocyclohexylphenol to be the most effective killing agent. At concentrations as low as 0.1 percent, some flowers of Duchess apples were killed, with no apparent injury to the foliage. At concentrations of 1 percent, nearly all flowers were killed, with considerable accompanying foliage injury. At concentrations of from 0.25 to 0.50 percent, large percentages of the flowers were killed, accompanied by some but not serious foliage injury. Addition of a wetting agent so as to provide a concentration of 0.1 percent increased considerably the effectiveness of the spray. Similarly, the addition of a proprietary wax emulsion to provide concentrations of from 1-8 up to 1-24 increased the effectiveness of the spray.

What new apple varieties are doing: A survey of growers, R. WELLINGTON and H. O. BENNETT (*Farm Res. [New York State Sta.]*, 6 (1940), No. 4, pp. 2, 9).—This is a further report (E. S. R., 83, p. 775) on varieties originated by the station or recommended as the result of extended trials.

Physiological studies with McIntosh apples in modified atmosphere cold storage, A. VAN DOREN. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 453-458, figs. 5).—Certain modifications in the storage atmosphere were found to favor the keeping life of McIntosh apples. A reduction in the rate of respiration to a desired minimum occurred in an atmosphere of 5 percent CO₂ and 2 percent O₂ at 40° F. Upon further increment of CO₂, with O₂ at 2 percent, the respiration was further reduced, but evidence of CO₂ injury was noted. At 40°, an atmosphere of 10 percent CO₂ and 11 percent O₂ reduced the rate of respiration, as compared with that in air, less than other atmospheric conditions used. Only control of ventilation was needed to produce a summation of 21 percent of CO₂ and O₂.

Firmness and crispness, as indicated by the pressure test, were greater in fruits with slow rates of respiration. No physiological injury occurred in the fruits stored in an atmosphere of 5 percent CO₂ and 2 percent O₂ at 40°, and this condition produced the longest storage life and the longest period of marketability. A study of the soluble pectin changes indicated that the conversion of protopectin to soluble pectin is retarded in certain modified atmospheres and following the removal of the fruit therefrom.

Some additional effects of waxing apples, R. M. SMOCK. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 448-452, fig. 1).—Continuing the investigation (E. S. R., 76, p. 796), the author reports that coating of Golden Delicious apples with Brytene wax emulsion 489A checked materially the rate of shriveling. At a relative humidity of 60 percent, waxing of Golden Delicious with a dilution of 1:1 resulted in a slightly less weight loss than occurred with no wax at a relative humidity of 95 percent. Heating the emulsion to 90° F. reduced weight loss slightly, apparently by giving a better covering. It was observed that some wax emulsions have a slight retarding effect on the development of scald and bitter pit in Rhode Island Greening, while other waxes had no benefit or actually increased the trouble. The use of proper wax emulsions enhanced the appearance of certain varieties, and certain aromatic varieties, such as McIntosh, were improved in aroma.

The waxing of deciduous fruits, L. L. CLAYPOOL. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 443-447, fig. 1).—During 1938 and 1939 over 600 waxing tests were made on a wide range of fruits, using wax emulsions of different concentrations and holding the fruits for several days after waxing at 45° F. to determine the effects. The principal benefit recorded was in reducing water loss. Benefits were greatest in fruits with thin cuticles, with a possible exception of the apricot. Carnauba wax resulted in a brighter, more attractive finish, but was not as effective as paraffin in controlling water loss when used in like concentrations. With the exception of the apricot, greater amounts of wax could be applied to stone than to pome fruits. Waxing did not overcome decay and, in fact, aggravated decay in some instances. The inclusion of a fungicide, such as borax, was found of doubtful value.

Influence of carbon dioxide in lengthening the life of Bartlett pears, F. W. ALLEN. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 473-478).—Employing various storage atmospheres, modified by manipulating the percentage of CO₂ and O₂, the author found that at any given temperature the keeping life of Bartlett pears may be materially lengthened, as compared to fruits in ordinary storage. A concentration of 10 percent CO₂ was considered the optimum and was particularly effective when the O₂ was reduced to 5 percent. Fruit held in nitrogen without CO₂ and with only 2.5 percent O₂ was delayed in maturity (not as much as where CO₂ was employed) and often developed undesirable flavors.

Texas studies on the cold requirements of peaches, S. H. YARNELL. (Tex. A. and M. Col.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 349-352, figs. 4).—Data taken on greenhouse tests of forty-odd varieties, the budwood of which was obtained from different localities in Texas, showed that the locality where grown had a profound influence on the response of any given variety, rendering it impossible to set a minimum cold requirement for any one variety which will hold universally. For example, in Elberta budwood grown in Winter Haven and in the Wichita Valley, development was more rapid in the southern material. Considering only the hours below 45° F., the author found that Elberta was ready to bloom normally after about 400 hr. at Winter Haven and after about 1,200 hr. in the Wichita area. The data suggest a progressive development of fruit buds toward flowering condition which is conditioned by both "cool" and "warm" temperatures. It was possible, however, to classify varieties according to their needs for low temperature and base practical recommendations as to adaptation.

Relative effect upon peach production of nitrogen derived from certain fertilizer sources, C. A. McCUE (*Delaware Sta. Bul.* 222 (1940), pp. 8, fig. 1).—This is a revision in bulletin form of an earlier-noted paper (E. S. R., 76, p. 335) and points out again that, in general, N derived from inorganic

fertilizers gave better returns than N from organic sources. Leguminous cover crops may provide sufficient N for the trees in the early years, but are not adequate as the trees come into fruiting.

The relative cold resistance of some species of *Prunus* used as stocks, R. L. WINKLEPLECK and J. A. McCLINTOCK. (Purdue Univ. et al.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 324-326).—Under controlled laboratory conditions in which stem and root cuttings of different rootstock materials were subjected to different uniform temperatures, there were observed great differences in the capacity to withstand low temperature. Florida peach (probably Peento) grown from pits exhibited the most serious injury of any of the materials. Elberta seedlings also showed little resistance. Considerable variation was noted in materials grown from southern natural seedlings. Myrobalan plum was more resistant than any of the peach materials except that *P. davidiana* was slightly more hardy than Myrobalan in the top tissue. *P. americana* was the hardiest of all the stocks tested. Marianna plum exhibited marked resistance during the first 2 hr. of the test, but in longer exposure was not equal to *P. americana*. On the whole there was a close correlation in the behavior of the roots and tops of any given material.

Twig growth in mutants of Montmorency cherry, J. W. CRIST. (Mich. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 245-249, figs. 2).—A biometrical analysis of the basic type and rate of vegetative growth in barren Montmorency mutants as compared with this phenomenon in normal, fruit-bearing limbs and trees of the same variety indicated fundamental sameness in the law and type of this growth, but a hereditary difference with respect to rates. The specific rate constant for the mutant form appeared to be lower. This, coupled with a relative deficiency in rate of carbon assimilation, offers a physiological explanation, in part at least, of the failure of barren mutants to form fruit buds and their perpetual barrenness.

Methods of retarding the ripening of strawberries in northern Michigan, R. L. EGGERT (*Michigan Sta. Quart. Bul.*, 23 (1940), No. 1, pp. 20-26, figs. 3).—Seeking to take advantage of late-season advances in prices of berries in important markets, such as Detroit and Chicago, studies were made of various factors that might retard maturity in the field. The results indicated that by selection of site and soil and by the proper use of mulches the grower could influence maturity to a moderate extent. The location of beds on northern slopes retarded the ripening of Dunlap plants by as much as 9 days. An additional 4-day delay was secured by planting on clay loam or sandy loam. The time of removing mulch had very little effect on the beginning of ripening, but a delay in removal did influence the midseason pickings significantly. Nitrogenous fertilizers did not influence the date of ripening but did increase the amount of fruit set and the yield, when moisture was not a limiting factor.

The effects of mulching red raspberries on growth and production, J. H. CLARK. (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 604-608).—The mulching with salt-marsh hay of Latham red raspberries growing on Sassafras sandy loam underlaid with a gravelly subsoil was found beneficial with respect to growth and yield, particularly where the basic fertilizer treatment was supplemented each spring with an additional 1,000 lb. of 5-10-5 material plus 200 lb. of NaNO_3 each autumn. Both the number and the size of canes were notably larger in the mulched plots. Soil temperatures during midafternoon in July were notably lower under the mulch. Studies of root distribution showed more roots in the surface 2 in. under mulch than under cultivation. In the case of the Ranere variety there were more roots per cane in the cultivated area than under mulch. In Latham there were somewhat more roots under the mulch than under cultivation.

Breeding autumn-fruiting raspberries, G. L. SLATE. (N. Y. State Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 574-578).—Observations on the autumn fruiting of various red raspberries suggested that varieties may be divided into three natural groups with respect to this character, as follows: (1) Ranere, (2) polyploid varieties, such as Erskine Park and La France, and (3) Lloyd George and its derivatives. The possibilities of Lloyd George as a parent for autumn-fruiting raspberries were revealed in a planting of seedlings of N. Y. 1950 and Lloyd George, among which were three autumn fruiter, one of which was named Indian Summer. In crosses between Indian Summer and its sibs, other Lloyd George seedlings and other nonautumn-bearing varieties, the autumn-fruiting characteristics were observed in many of the seedlings. Some were superior to Indian Summer, indicating that Lloyd George and its offspring are the best sources yet discovered for the breeding of desirable autumn-fruiting red raspberries.

Tennessee Autumn red raspberry, B. D. DRAIN (*Tennessee Sta. Cir.* 70 (1940), pp. 4, figs. 4).—A descriptive account is given on the origin, habits of growth, and plant and fruit characters of a new variety of raspberry obtained from a cross of a hybrid (Latham × Van Fleet) and Lloyd George.

The heat required to bring Tokay grapes to maturity, A. J. WINKLER and W. O. WILLIAMS. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 650-652).—In 1929, 1931, 1934, and 1936, years in which Tokay grapes were rated as very good in quality at the time of harvest the heat summations, that is, the total of mean daily temperatures above 50° F. from bloom to harvest, were 2,265, 2,320, 2,280, and 2,260 day degrees. Heat summations for the ripening period, namely, the 28 days preceding harvest, were 640, 760, 690, and 730 day degrees, respectively. In years in which the quality was rated acid or very acid, the heat summations for the growing period fell below 2,100 day degrees. Heat summations for the ripening period, however, were not as consistently correlated with quality as were those for the longer period. The value of heat summations for supplementing the present Balling standard as indications of the proper stage for harvesting Tokay grapes is discussed.

Identification of acetaldehyde among the volatile products of citrus fruits, J. B. BIALE and A. D. SHEPHERD. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 543-547, fig. 1).—An acetaldehyde derivative was obtained from the vapors given off by citrus fruits following subjection for from 12 to 25 days to restricted ventilation obtained by placement in glass containers with inlet and outlet tubes unsealed. Oranges and lemons stored continuously in air or in an artificial atmosphere of 10 percent CO₂, 10 percent O₂, and 80 percent N₂ did not show any acetaldehyde in the gaseous emanations. Storage in N₂ alone resulted in the production of none or very little acetaldehyde, but when the fruits were transferred to air a large amount of acetaldehyde was found in the emanating vapors. This was not true in the case of fruit transferred from air to N₂, from air to modified atmosphere, or the reverse. The transfer from N₂ to air also resulted in an increase of CO₂ evolution.

Changes in invert sugar and sucrose during ripening of Arizona grapefruit, R. H. HILGEMAN and J. G. SMITH. (Univ. Ariz.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 535-538, fig. 1).—Observations on fruit collected from commercial groves and from N-fertilized plats near Yuma, Ariz., showed that total sugars usually increased until midwinter and then declined. Sucrose increased rapidly in early fall and decreased in late winter and early spring. The periods of these changes varied with locality and with cultural practices. Limitation of the N supply tended to increase the supply of sugar in the fruit and to accelerate the hydrolysis of the sucrose. Heavy nitrate fertilization had the opposite

effect. Invert sugars, calculated as percentage of total sugar, decreased during a brief period in autumn and then increased at a gradually accelerated rate. It is suggested that the low point in this trend might serve as an index of maturity, since maximum amounts of sucrose are associated with ripening.

The effect of spacing on plant development and yield of dill (*Anethum graveolens* L.), H. L. SEATON and W. D. BATEN. (Mich. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 785-789; *abs. in Michigan Sta. Quart. Bul.*, 23 (1940), No. 1, p. 39).—On the basis of individual development, plants spaced 16 in. apart were significantly larger in all respects than those spaced 12, 8, or 4 in. apart. The 16-in. spacing produced more branches, more compound umbels, taller plants, larger primary umbels, larger stems, greater green and air-dry weight of entire plant, greater weight of air-dry stems and seeds, a higher percentage of seeds, and heavier seeds than spacing at closer intervals. No significant differences were exhibited by any of the four spacings on the number of primary rays in the primary umbels. This is partially explained by the fact that the effects of crowding were not operative during the early differentiation of the primary inflorescences. However, when the data are put on the basis of 0.01-acre plats, the closer spacing of 4 in. would be significantly more profitable for the grower who is producing the crop at a specified price per ton. This 4-in. spacing produced about twice as many umbels as the 16-in. interval. The number of primary rays in the primary inflorescences, on a 0.01-acre basis, was nearly four times that produced at the 16-in. spacing. As the primary umbel constitutes the most important portion of the crop, this is a highly significant consideration for the grower. The data indicate that even a closer spacing of the plants than 4 in. may be highly desirable for maximum acre yields, and that the rows may be spaced closer together than the 3-ft. spacing given in this experiment. The analyses of air-dry seeds for moisture and ether-extractable materials show no significant differences between the seeds from the plants grown at the different spacings.

Cinder and gravel culture of greenhouse flowering plants, A. LAURIE and R. HASEK. (Ohio State Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 956-960).—Carnation plants grown in either sand or gravel and subirrigated with nutrient solutions produced more flowers with longer stems than comparable plants in soil. Favorable results were secured with roses and lilies. An increase in the K content of the nutrient solution increased further the yield of the Lucile Hill rose. An attempt to supply additional carbohydrates during cloudy weather by adding glucose to the rose plats gave no strikingly positive results in February and March. In the case of sweet peas, glucose additions resulted in earlier germination, due, probably, to bacterial action on the hard seed coats. The use of selenium in nutrient solutions gave negative results as a means of controlling red spiders on roses.

House plants, J. B. WINGERT (*Iowa Sta. Bul. P14, n. ser.* (1940), pp. 393-432, figs. 30).—Among subjects considered are general environmental requirements, propagation, containers, soils, fertilization, need of rest periods, summer care, and specific cultural needs of 20 important species. In addition, there is presented a tabulated list of miscellaneous house plants suitable for general culture under home conditions.

The relationship of temperature to flower bud formation in chrysanthemums, K. POST. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 1003-1006).—In studies with Copper City, Betty Watkins, and Princeton varieties it was observed that the subjection of young plants to low night temperatures interfered with flower bud formation, delayed flowering, and decreased the number of buds per stem as compared with holding plants at night in high

temperatures. Plants given low light intensity and high temperature did not form flower buds as freely as those given high light intensity. Shoots which failed to form flowers during the early fall at high temperatures remained blind during the winter even though the temperature was increased. Late pinching and late planting are believed to delay bud formation until the temperature is reduced to the point where it prevents flower bud formation.

Bud formation, abscission, and flower production of gardenia as affected by light and temperature, C. G. KEYES. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 1034-1036).—Bud formation of gardenias occurred equally well at a night temperature of 60° F. as at 55°, but was seriously curtailed when the night temperature was 70°. Supplementary illumination did not consistently increase the number of buds formed in all treatments. Bud abscission was increased at a night temperature of 70°. Supplementary illumination did not reduce bud abscission even at low temperatures (55° or 60°). Flower production was increased by supplementary illumination only when the temperature was high (70°) during the light period and low during the subsequent period of darkness. A low-temperature period (55° or 60°) following supplementary illumination did not increase bud formation and did not reduce bud abscission.

Root growth and flower production of roses in soil and soil-peat mixtures of varying moisture contents, K. D. BRASE. (N. Y. State Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 963-966, figs. 3).—In the case of Ami Quinard rose plants grown in boxes of Ontario loam soil, with and without added peat moss and with moisture contents maintained at three levels—low, medium, and high—the greatest root development was made under high moisture conditions. The addition of peat moss was distinctly beneficial, especially with the low and medium moisture cultures. Root formation was more active in the presence of peat moss, the root systems in soil-peat mixtures forming dense masses of fine, actively growing laterals. Gain in weight of shoot growth was greatest in plants in soil-peat of medium moisture content. The smallest gain was made by plants in soil of low moisture content. Flower production was also greatest in the soil-peat mixture of medium moisture content.

Interrelationships of calcium and phosphorus concentrations on the growth of roses, J. G. SEELEY and O. W. DAVIDSON. (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 967-972, fig. 1).—In studies of the effect on growth and composition of Briarcliff rose plants of varying Ca and P concentrations of the nutrient solution maintained at different pH levels it was found that the ratio of Ca:P is of significance in the growing of roses. The effective ratio was not narrow but extended over a range easily obtainable in practice. Apparently, the need of Ca as a direct nutrient for the rose is moderate. The plants receiving 50 p. p. m. of Ca and 100 p. p. m. of P exhibited good branching, a large number of basal shoots, excellent foliage color, and a large number of blooms. This treatment apparently was the best in the experiment. P was apparently needed by the rose more than by the peach, apple, and other horticultural plants.

The effect of sulphur on growth of roses in an alkaline soil, J. C. RATSEK. (Tex. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 973-977).—That the application of S may be beneficial to roses growing in alkaline soils was indicated in studies conducted in central Texas on a black calcareous prairie soil. The three varieties used, Red Radiance, Talisman, and Joanna Hill, responded somewhat differently. In the initial year the two latter varieties increased their flower production consistently as the soil reaction became increasingly acid. Under highly buffered conditions, necessitating S in amounts

greater than 10 lb. per 100 sq. ft., the break-down and subsequent soil acidification was slow. Under less highly buffered conditions, necessitating S in amounts less than 10 lb. per 100 sq. ft., oxidation and soil acidification was rapid but the return to alkalinity was also rapid, necessitating frequent applications of S. When S is used in amounts greater than from 10 to 15 lb. the nitrate concentration in the soil may be reduced to 0. In the experiment there was no evidence that nitrate deficiency resulted in any material decrease in flower production.

Rose growing for the home gardener, J. C. RATSEK. (*Texas Sta. Cir.* 90 (1940), pp. 27, figs. 9).—This contains general cultural and varietal information.

The zinnia (State flower of Indiana), E. R. HONEYWELL (*Indiana Sta. Cir.* 254 (1940), pp. 16, figs. 20).—General information is presented on the history and development of the zinnia, varieties and types, culture, seed production, display and utilization, insect and fungus pests, etc.

Factors affecting shoot growth and flower bud formation in rhododendrons and azaleas, H. T. SKINNER. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 1007-1011, fig. 1).—The production of vegetative shoots by leaf-bud cuttings of *Leucothoe catesbaei*, *Rhododendron ponticum*, and *R. roseum elegans* was encouraged by either high temperatures or long days. A temperature of from 75° to 80° F., regardless of day length, resulted in a high percentage of shoot growths. Maximum elongation of shoots from leaf-bud cuttings occurred under conditions of high temperature and continuous light. The length of vegetative shoots of mature plants of azaleas and rhododendrons was affected more by day length than by temperature. Significantly greater numbers of flower buds were produced at temperatures of from 75° to 80° by *Azalea obtusa* Hinodigari and Pink Pearl and *R. carolinianum* and *R. mucronulatum* than at temperatures of from 50° to 55°. Short-day treatments resulted in more flower buds on *R. carolinianum* and *R. mucronulatum*, but had little effect with other varieties tested.

Chinese elm in Michigan, A. B. BOWMAN (*Michigan Sta. Quart. Bul.*, 23 (1940), No. 1, pp. 27, 28, fig. 1).—Describing the Chinese elm and discussing its desirable qualities, such as very rapid growth and adaptability to pruning, the author points out certain undesirable features, such as excessive seed dropping, rapid root penetration, brittleness of twigs, etc., that make the species less valuable as a street or shade tree.

FORESTRY

A selected bibliography of North American forestry, E. N. MUNNS (*U. S. Dept. Agr., Misc. Pub.* 364 (1940), vols. 1, p. [1]+636; 2, pp. II+637-1142).—Contained herein are a total of 21,413 references to the more important literature on forestry subjects published in Canada, Mexico, and the United States prior to 1930. The material is systematically classified by subjects, with authors alphabetically arranged under each grouping. Volume 2 contains (pp. 1087-1142) an author index.

[Report of the department of forestry], D. DENUYL, J. C. KASE, and R. C. BRUNDAGE (*Indiana Sta. Rpt.* 1939, pp. 85-91).—Included are progress reports upon studies in woodlot management, development of tree species by the experimental forest nursery suitable for field planting, windbreak plantings, marketing Indiana woodland products, and log grading.

[Forest resources of North and South Carolina] (*U. S. Dept. Agr., Forest Serv., Forest Survey Release Nos.* 1 (1939), pp. [I]+III+30, pl. 1, figs. 3; 2,

pp. [1]+III+31, pl. 1, figs. 3; 3, pp. [2]+III+34, pl. 1, figs. 3; 4 (1940), pp. [1]+III+46, figs. 7; 5, pp. [1]+III+48, figs. 9).—Presented in mimeographed form are papers dealing with the forest resources of the northern Coastal Plain of South Carolina, by E. B. Faulks; of the Piedmont region of South Carolina, by W. T. Hicks; of the southern Coastal Plain of South Carolina, by E. B. Faulks and A. R. Spillers; and of the southern and northern Coastal Plain of North Carolina, both by J. W. Cruikshank.

[Forestry studies by the Vermont Station] (*Vermont Sta. Bul.* 463 (1940), p. 19).—Among studies discussed are the photosynthetic activity of forest trees, factors influencing the rate of diameter growth of white pine, and influence of soil temperature on the development and transpiration of ponderosa pine and sugar maple seedlings.

Living and forest lands (*U. S. Dept. Agr., Misc. Pub.* 388 (1940), pp. IV+48, figs. 18).—This is a guide prepared by the Forest Service for study groups interested in the social and economic aspects of forests and forestry.

The influence of locality, season, time of day, and year on the visibility of smoke columns, G. M. JEMISON. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 5, pp. 435-437, fig. 1).—An analysis of some 21,000 observations made from lookout stations in the eastern United States, using the Byram haze meter, showed significant differences in average visibility distance in different areas. Such variations are explained on the basis of population density and industrial activity, since the smoke of homes and factories accounts for the larger part of the atmospheric haze. Visibility on all forests is generally highest during May, June, and September. The time of day that observations are made was also a factor in visibility.

Fire Control Notes, [July and October 1940] (*U. S. Dept. Agr., Forest Serv., Fire Control Notes*, 4 (1940), Nos. 3, pp. II+101-159, figs. 26; 4, pp. II+161-206, figs. 18).—In the same manner as before (*E. S. R.*, 83, p. 343), these quarterly numbers present brief articles relating to fire research and fire control, with special reference to organization, planning, and equipment.

Vegetative succession following logging in the Douglas fir region, with special reference to fire, L. A. ISAAC. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 9, pp. 716-721).—Studies on sample plats laid out in 15 widely scattered areas in western Washington and Oregon following logging operations in 1926 showed a rapid rise in percentage of total weed-brush cover until about the third year following cutting. Unless interrupted by fire or further cutting there are 4 rather distinct stages of succession before the forest again reaches the climax type. These stages are designated as moss-liverwort, weed-brush, intolerant even-aged Douglas fir, and finally the tolerant all-aged hemlock-balsam fir. The weed-brush stage is most subject to fire and may be greatly prolonged by fire. Certain exotic species of grass and weeds were found to be upsetting the natural succession, but some of the new grasses were actually improving grazing conditions. Light cover favored and heavy cover was detrimental to coniferous seedlings. Successive fires impoverished the soil, favored the herbaceous plants, retarded brush species, and eliminated the coniferous seedlings.

The results of laboratory tests as applied to large scale extraction of red pine seed, E. J. ELIASON and C. E. HEIT (*Jour. Forestry*, 38 (1940), No. 5, pp. 426-429, fig. 1).—In connection with a heavy crop of seed in 1938, a temperature of 130°-140° F. for 72 hr. was used in extraction because of a higher net output of seed. Some evidence was seen that the cleaning apparatus, consisting of revolving brushes, injured some of the seeds. The damage was more evident in sand tests than in sample germination tests. A reduction in the speed of the brushes corrected the situation. Another type of injury, the

splitting of seed along the suture, was traced to too high a relative humidity in the kiln.

Kiln schedule for extracting red pine seed from fresh and stored cones, R. C. RIETZ and K. E. KIMBALL. (U. S. D. A. and Univ. Wis.). (*Jour. Forestry*, 38 (1940), No. 5, pp. 430-434, figs. 2).—The yield of seed obtained from red pine cones kiln-dried with forced-air circulation at different temperatures and lengths of time was found dependent on cone moisture content, the lower the moisture the greater the cone opening. All the temperatures 120°, 130°, 140°, 150°, and 160° F. yielded strongly viable seed at an equilibrium moisture content of 3 percent, but at 6 percent viability was reduced sharply at 160° and somewhat at 150°. It is suggested that this injury must be associated with the increased duration of heating at the higher moisture percentage. Cones held in gunny sacks for some time before kiln treatment were more sensitive to high temperature than those held in trays. A drying condition of 150° with 3 percent wood equilibrium moisture content was the most severe drying condition that produced good yields of uninjured seeds.

Successful storage of southern pine seed for seven years, M. L. NELSON. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 5, pp. 443, 444).—Observations on the viability of samples of seed from the 1931 crop of longleaf, slash, loblolly, and shortleaf pines placed in screw-top glass jars and held at 35°-38° F. and at room temperature showed all samples at room temperature to have become almost or completely nonviable in 4 yr. or less. At the end of 7 yr. there was no deterioration in any of the four species of seeds stored cold. Stratification for 10 days in wet peat moss at low temperatures hastened the germination of loblolly and shortleaf pines, was harmful to longleaf seed, and of no material significance in the case of slash pine seed.

Early planting experiments in the spruce-fir type of the southern Appalachians, L. S. MINCKLER. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 8, pp. 651-654).—Discussing the results of planting experiments with 20 species set out from 1923 to 1931 in 78 plats near Mount Mitchell, N. C., the author states that southern balsam fir, red spruce, red pine, and Norway spruce appeared best suited for reforestation in the southern Appalachian spruce-fir type. Norway spruce was the only exotic finding a favorable environment in the area. All species were more successful on an east than on a south slope, but red pine was less exacting in this respect than the 3 leading species. Southern balsam fir showed the best survival and growth of all 20 species and has real merit for recreational and watershed protection uses, but its wide use is considered questionable because of its relatively poor quality as lumber.

Effect of season of cutting on sprouting of dogwood, J. H. BUELL. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 8, pp. 649, 650, fig. 1).—Observations 3 yr. after cutting on the sprouting of dogwood trees cut at nine different times from March 1 to August 2 showed that midsummer fellings of 1-in. dogwoods produced clumps 2.5 ft. shorter and 1.5 ft. narrower on the average than did late winter fellings. The author suggests that, if the purpose is to eliminate dogwood, summer cutting would be more effective. On the other hand, if perpetuation of the dogwood is desired, winter cutting would be more desirable than summer.

Topsoil changes in coniferous plantations, G. M. DAY. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 8, pp. 646-648).—A comparison of the soil within and without plantations of white pine, Norway pine, Scots pine, and Norway spruce, located in Vermont and New York, showed an increase in organic content of the top soil wherever a mull had developed. On the other hand, where no mull had formed the organic content was lower in the plantation than in the

top soil of adjacent open areas under grass cover. The surface layers of mineral soil in the plantations were about twice as permeable to water as those in the adjacent open areas. The mull soils showed a greater increase in permeability than did the mors. The results emphasized the need of conserving existing soil values and for starting restorative processes as soon as possible on critical areas.

Effect on trees of wind-driven salt water, A. E. Moss. (Univ. Conn.). (*Jour. Forestry*, 38 (1940), No. 5, pp. 421-425, fig. 1).—Observations following the New England hurricane of September 21, 1938, showed effects of wind-driven salt spray despite the accompanying heavy rainfall as far as 45 miles from the ocean, particularly on sensitive species such as white pine (*Pinus strobus*). Among resistant species were Colorado blue spruce, Austrian pine, pitch pine, and red pine. Injury was most severe where trees or plants were exposed to the direct force of the wind. Injury was noted on foliage, on wintering over buds, and on woody stems.

Cost of producing pulpwood on farm woodlands of the Upper Connecticut River Valley, V. S. JENSEN (*U. S. Dept. Agr., Forest Serv., 1940, pp. [4]+17+VIII, pls. 6*).—Using data obtained for 19 pulpwood operations employing 57 workmen in the vicinity of Colebrook, N. H., the costs of felling, limbing, peeling, bucking, piling, skidding, yarding, and trucking are analyzed for different species of wood, different size crews, etc.

DISEASES OF PLANTS

The Plant Disease Reporter, [October 1 and 15, 1940] (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 24 (1940) Nos. 18, pp. 361-380, pl. 1, fig. 1; 19, pp. 381-397, figs. 2*).—The following items are noted:

No. 18.—Diseases of fruits and vegetables on the New York market during the months of January, February, and March 1940, by J. S. Wiant and C. O. Bratley; root knot injury to peach trees and other plants in Kansas, by J. O. Miller; tobacco disease survey in Wisconsin, 1940, by J. Johnson; prevalence of elm dieback caused by *Dothiorella ulmi*, by E. G. Kelsheimer and C. May; unusual collections of destructive fungi on plantain and violet in the District of Columbia area, by A. E. Jenkins; hosts for *Pucciniastrum ericae* in America, by W. W. Diehl; host-parasite check list revision (continued), including *Betula*, by F. Weiss; and brief notes on ergot (*Zizania aquatica angustifolia*) on wild rice in Maine, corn diseases in Virginia, and bean rust (*Uromyces phaseoli typica*) in the Laurentian Mountains of Quebec.

No. 19.—Flag smut of wheat found in Washington, by F. D. Heald and C. S. Holton; stem rust on fall-sown oats at Fayetteville, Ark., by H. R. Rosen; pink root disease (*Phoma terrestris*) of onions on tomatoes, by H. H. Thornberry and H. W. Anderson; curly top of tomato in southern California in 1940, by J. T. Middleton; *Celastrus scandens*, a new host for *Glomerella cingulata*, by A. J. Watson; plant diseases in Massachusetts in September, by O. C. Boyd; some obscure peach diseases in Washington, by L. K. Jones; host-parasite check list revision, including *Bignonia* through *Byrsonima*, by F. Weiss; brief notes on *Sclerotinia* rot of beans in New York, rust (*Puccinia peridermiospora*) causing injury to ash trees in New Hampshire, and recovery of eelgrass on the North Carolina coast; and unusual development of rusts on small grains in Oklahoma, by K. S. Chester.

[**Phytopathological work by the Indiana Station**]. (Partly coop. U. S. D. A.). (*Indiana Sta. Rpt. 1939, pp. 11, 12, 17, 54-60, 61-64, figs. 7*).—A general summary of recent plant disease and breeding work by the station is followed by brief reports of progress (by R. C. Baines, R. W. Samson, H. R. Thomas,

V. Wright, G. B. Cummins, A. J. Ullstrup, A. M. Brunson, G. M. Smith, R. M. Caldwell, and L. E. Compton) on tests of eradicant fungicides for apple scab control; frame of dormant sprays to control apple blotch; physicochemical studies of the virus causing tomato mosaic and its transmission by seed; southern-grown plants as sources of bacterial wilt in Indiana tomato fields; tomato collar rot epidemic of 1939 traced to setting of infected plants; nitrogen nutrition of tomato seedlings as affecting susceptibility to collar rot; resistance to defoliation diseases in tomato; the taxonomy of plant rust fungi; the importance of *Helminthosporium* leaf spot and ear rot of corn in Indiana; a new kernel blemish in dent corn due to abnormal development of the kernel; effects of barrenness and defoliation on stalk rot of corn; wilt resistance in new sweet corn hybrids and inbreds; effects of leaf rust and artificial defoliation on yield, composition, and quality of winter wheats; effects of powdery mildew on yield of wheat; effects of seed treatments on yield of winter wheat seed shriveled by stem rust; and release of Wabash, a new wheat resistant to leaf rust.

[Plant disease studies by the Vermont Station] (*Vermont Sta. Bul.* 463 (1940), pp. 28, 29).—Progress is briefly reported on studies of aging of plants in relation to fertilizers and apple scab attack and the long-time potato scab project.

Diseases and pests observed during the year, J. M. WATERSTON (*Bermuda Dept. Agr. Rpt.*, 1939, pp. 28–30).—Seasonal notes on crop plant diseases in Bermuda.

Diseases of cultivated plants in the Province of Santa Fé, Argentina [trans. title], E. SCHIEL (*Inst. Expt. Invest. y Fomento Agr. Ganad. [Santa Fe, Argentina], Bol. Tec.* 13 (1939), pp. 25).—An annotated list arranged alphabetically by Latin names of host plants.

Phytosanitary aspects of the principal plants cultivated in Espirito Santo [trans. title], S. G. DA SILVA (*Rev. Soc. Brasil. Agron.*, 2 (1939), No. 4, pp. 80–84).—Diseases and pests of coffee, cacao, cereals, cotton, sugarcane, cassava, fruit trees, vegetables, and miscellaneous crop plants are briefly considered.

New and interesting plant diseases, W. C. MOORE (*Brit. Mycol. Soc. Trans.*, 24 (1940), pt. 1, pp. 59–63, pl. 1).—*Septoria* leaf blotch of *Lobelia*, *Septoria* sp. and *Ascochyta bohémica* on *Campanula*, and root and bulb rots of tulips caused by *Pythium* are briefly considered.

[Fungi and plant diseases] (*Indian Sci. Cong. Proc. [Lahore]*, 26 (1939), pp. 115–118).—Abstracts of the following papers are included: Taxonomic Studies of Indian Smuts, by B. B. Mundkur; On the Characters of *Choanephora cucurbitarum* (B. and Rav.) Thaxter, Causing a Wet Rot of Chillies, by S. Sinha; A New Species of *Bombardia* Occurring on Dry Twigs of *Thunbergia grandiflora* Roxb., by G. S. Verma; An Abnormal Sterile Form of *Polystictus sanguineus*, Linn., by S. R. Bose; A Wet Rot of Leaves of *Colocasia antiquorum* [=esculentia] Due to Secondary Infection by *Blakeslea trispora* and *Choanephora cucurbitarum* (B. and Rav.) Thaxter, by S. Sinha; Investigation of Orange Rot in Storage, by P. N. Ghatak; Studies in the Diseases of *Mangifera indica* Linn.—II, Investigation Into the Pathological Histology of the Fruits Affected With Black-Tip Disease, by S. N. Das Gupta and S. Sinha, and III, On the “Die-back” Disease of the Mango Tree, by S. N. Das Gupta and A. T. Zachariah; *Neotiella catharinaea* McLennan and Halsey on *Catharinaea mülleri*, by S. N. Das Gupta and T. S. Sadasivan; and Effect of Certain Poisonous Chemicals Upon the Spores of *Acrothecium lunatum* and *Cephalothecium roseum*, *Acrothecium lunatum* on *Peunisetum typhoideum* [=glaucum] Ears, A Study of *Monascus* Occurring in Orange-Squash, and Two Species of *Spicaria* From Interesting Habitats, all by G. S. Dhillon.

The structure and life-history of the root parasite *Dactylanthus taylori* Hook. f., L. B. MOORE (*New Zeal. Jour. Sci. and Technol.*, 21 (1940), No. 4B, pp. 206B-224B, figs. 35).—The distribution, habit, and habitat of *D. taylori* are briefly described and its hosts enumerated. A somewhat detailed account is given of the morphology of various parts of the plant, including its junction with the host root. Several doubtful points of floral structure—e. g., number of stamens and loculi, nature of ovules and seed—are dealt with. Germination, the establishment of the young plant on the host root, subsequent development, and vegetative reproduction are described. The peculiar features of the plant are briefly discussed and the position of the subfamily in current classification upheld.

An *Elsinoë* on *Toddalia*, A. E. JENKINS and A. A. BITANCOURT. (U. S. D. A. et al.). (*Philippine Agr.*, 29 (1940), No. 1, pp. 55, 56).—The type species *Isotexis toddaliac* on *T. asiatica* is transferred to *E. toddaliac*. *Toddalia* thus becomes the fifth rutaceous genus on which a species of *Elsinoë* or *Sphaceloma* has been found, the four others being *Citrus*, *Hesperethusa*, *Pleiospermium*, and *Fagara*.

The geographical distribution of the genus *Gymnosporangium*, I. H. CROWELL (*Canad. Jour. Res.*, 18 (1940), No. 9, Sect. C, pp. 469-488, figs. 43).—Species of this genus are said to occur only in the Northern Hemisphere and most abundantly in the temperate parts. Each of the 3 major continents contains a distinctive *Gymnosporangium* flora and, except for 3 species called the "tricontinental species," individual species occur naturally on 1 continent only. There are about 48 species, and 33 occur in North America, 15 in Asia, and 6 in Europe. Explanations of the types of geographical distribution are given under 4 categories: Species occupying all potential territory covered by the coincident ranges of their alternate hosts, species confined by the range of their "primary" telial host, localized species confined within a portion of the coincident ranges of their alternate host, and widely distributed species that are not limited in their range by either alternate host group.

Cancerous tumor or crown gall of plants [trans. title], V. WELLBORN (*Café el Salvador*, 10 (1940), No. 114, pp. 437-446, figs. 8).—A general discussion of crown gall due to *Phytoplasma tumefaciens* and the relations of insects to infection, with special reference to the attack on the coffee shade trees ("*pepetos*"—species of *Inga*).

A study of *Uromyces scirpi* Burr., M. FORT (*Brit. Mycol. Soc. Trans.*, 24 (1940), pt. 1, pp. 98-108, pl. 1, figs. 11).—All stages were found—urediospores and teliospores on *Scirpus maritimus* and spermagonia and aecia on *Oenanthe crocata*. No aecia were present on *Glaux maritima*. Inoculations repeatedly infected *Oenanthe* but not *Glaux*. *S. maritimus* was artificially infected from *O. crocata*. The morphology and cytology are described. It is suggested that the aecia found on *O. crocata* belong to a different specialized race of *U. scirpi* from those on *G. maritima* and, further, that the binucleate condition is due to migration to the aecial initials of the products of the nucleus of a spermatium which has fused with and entered one of the spermatogonial paraphyses.

Host plants of the brown rot fungi in Britain, H. WORMALD (*Brit. Mycol. Soc. Trans.*, 24 (1940), pt. 1, pp. 20-28, pls. 2).—Of the two found in Britain, *Sclerotinia lara* is the cause of blossom wilt of fruit trees and ornamental shrubs of species of *Pyrus* and *Prunus*, while *S. fructigena* is the fungus most frequently found associated with fruit brown rot. Observations on the occurrence of the first on pome fruits and of the second on stone fruits are described. Cross-inoculations with these fungi from various hosts have yielded positive results on a number of other hosts.

Some fungi isolated from pinewood soil, M. ELLIS (*Brit. Mycol. Soc. Trans.*, 24 (1940), pt. 1, pp. 87-97, fig. 1).—"Twenty-one species, belonging to 11 genera, were isolated from samples of pinewood soil. *Trichoderma* spp. and *Botrytis cinerea* preponderated, followed by *Penicillia* and members of the Mucorales. Most of the species have been found in various soils by other investigators, and may be regarded as characteristic of acid forest soils in temperate climates. There appeared to be little or no difference between samples taken at 4-in. and at 10-in. depths, the same species being present in both samples. A new species of *Mortierella* is described."

Virus diseases of plants and their study [trans. title], V. D. SILVEIRA (*Rev. Soc. Brasil. Agron.*, 2 (1939), No. 4, pp. 61-79, figs. 29).—A general (28 references), copiously illustrated review of virus diseases of plants and the technics of studying them.

The sizes of plant viruses, F. C. BAWDEN (*Chron. Bot.*, 6 (1940), No. 1, pp. 13, 14).—A general discussion.

The relation of viruses to plant tissues, C. W. BENNETT. (U. S. D. A.). (*Bot. Rev.*, 6 (1940), No. 9, pp. 427-473).—"It is the purpose of this paper to assemble as much as possible of the evidence [about four pages of references] bearing on the relation of plant viruses to specific tissues and to point out some of the deductions that may seem justified by the information that has been made available up to the present time."

Investigations on the problem of the biological characterization of phytopathogenic virus proteins [trans. title], G. A. KAUSCHE (*Arch. Gesam. Virusforsch.*, 1 (1940), No. 3, pp. 362-372, figs. 12).—A critical examination of the results of studies by the author and others regarding the nature and properties of plant virus proteins.

The microflora of the rhizosphere in relation to resistance of plants to soil-borne pathogens, A. G. LOCHHEAD, M. I. TIMONIN, and P. M. WEST (*Sci. Agr.*, 20 (1940), No. 7, pp. 414-418, figs. 3).—Comparative studies were made of micro-organisms in the rhizosphere, respectively, of wilt resistant and susceptible flax varieties and of black root rot resistant and susceptible tobacco varieties. Both quantitative and qualitative evidence was accumulated indicating modifications in the rhizosphere which suggested inherent differences between the resistant and susceptible varieties studied, in that there was a more pronounced "rhizosphere effect" in the case of the susceptible plants.

Seed-borne diseases present problems, W. F. CROSIER (*Farm Res. [New York State Sta.]*, 6 (1940), No. 4, pp. 1, 10, figs. 2).—A brief review of the problems involved and summary of recent work by the station on seed-borne diseases of peas, beans, vetch, small grains, and corn.

An analysis of factors causing variation in spore germination tests of fungicides.—II, Methods of spraying, S. E. A. McCALLAN and F. WILCOXON (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 4, pp. 309-324, figs. 5).—Methods of obtaining spores have been considered previously (*E. S. R.*, 82, p. 783). The present paper compares the relative precision of four methods of spraying fungicides in the laboratory, using tests in which brilliant blue dye was sprayed, then dissolved off the slides, and the amount determined in a colorimeter. A comparison of observed deposit of various copper fungicides in a settling tower with that expected by calibration with the dye showed an average agreement within 5.4 percent. Comparisons of the methods by actual spore germination tests favored the settling tower. It is concluded directly from the dye and indirectly from spore germination tests that the settling tower method is the most precise, followed in order by stationary horizontal sprayers, free-hand spraying with controlled pressure and time, and last, freehand spraying

with a bulb atomizer. The equipments developed and found most satisfactory for the first two of these methods are described and illustrated.

p-Dichlorobenzene as a vapor fumigant, F. R. DARKIS, H. E. VERMILLION, and P. M. GROSS (*Indus. and Engin. Chem.*, 32 (1940), No. 7, pp. 946-949, figs. 4).—*p*-Dichlorobenzene has come into successful use in combating the downy mildew or blue mold of tobacco. The data here presented indicate the pronounced influence of crystal size and of temperature on the rate of vaporization of *p*-dichlorobenzene. For estimation of the amount of vapor in the atmosphere, four methods were tried out, the results favoring a procedure for making estimations in seedbeds in which sodium hydroxide is used for drying, and the small amount of moisture passing by it is allowed for by a blank determination on the *p*-dichlorobenzene-free atmosphere from an adjacent bed. This is subtracted from the weight of the *p*-dichlorobenzene condensed out in the determination paralleling the blank. This method of freezing out *p*-dichlorobenzene in a tared condenser proved as accurate as the combustion method. It could not only be carried out more quickly, but was also more easily applicable to field conditions and was sufficiently accurate for the purpose. Data on the vapor pressure—necessary to field and laboratory experimentation—are also presented.

Formaldehyde and steam mixture for sterilizing greenhouse soil (*Agr. News Letter*, 8 (1940), No. 5, pp. 71, 72, fig. 1).—The procedure followed is a modification of that described by Beachley (E. S. R., 78, p. 346). Only one treatment a year between spring and fall crops is ordinarily required. The beds are filled to a depth of about 1 ft. over tile piped for steam from a 2-in. line. A reservoir for formaldehyde, connected into this by a ½-in. pipe with valve, has a sight glass on the side which enables the operator to determine how fast the formaldehyde level drops as it is fed into the line. The beds are first covered with rubberized canvas. Steam alone is used for the first 3 hr., while during the last hour formaldehyde is mixed with the steam at the rate of 100 lb. per bed of 4,732 sq. ft. The process thus requires only 4 hr. as against 8 to 15 hr. formerly required where steam alone was used for soil sterilization. The saving in fuel for generating steam is said to more than offset the cost of the chemical.

Different methods of combating smut (*Ustilago bromivora*) of rescue grass (*Bromus unioloides*) [trans. title], M. O. BENTANCUR (*Arch. Fitotec. Uruguay*, 3 (1939), No. 2, pp. 170-173, fig. 1; *Eng., Ger. abs.*, p. 173).—Rescue grass was included in the grass tests at the National Plant Breeding Institute "La Estanzuela" because of its importance as a forage crop, but it proved susceptible to this smut and in a very severe form. Of four seed treatments tried (three with hot water and one with formalin), immersion in water for 110 min. at 47°-48° C. gave the best results.

Mosaic of spring cereals in the Voronezh district, V. K. ZAZHURILLO and G. M. SITNIKOVA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S.*, n. ser., 26 (1940), No. 5, pp. 474-478, figs. 2).—Among the spring grains mosaic was found to attack soft and hard wheats, three oats species, and barley. External and internal symptoms are described, *Deltocephalus striatus* is shown to be a vector of the virus, and two viruses are shown to infect these spring grains, viz. winter wheat mosaic and a virus disease named "zakuklivanie," characterized by profuse growth of shoots, antholysis, and floral proliferation.

Interrelations between the virus of a new grain mosaic disease (zakuklivanie) and its carrier *Delphax striatella* Fallen, K. S. SUKHOV and M. N. SUKHOVA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S.*, n. ser., 26 (1940), No. 5,

pp. 479-482).—*D. striatella* is shown to be a vector of this disease of the small grains, an incubation period of at least 6 days in the insect being necessary to transmission of the virus. Of 108 larvae collected as they were emerging from winter hibernation, 20.3 percent were shown to be infective when tested on healthy oats grown under isolation. After long search the disease was also found in some perennial grasses (e. g., *Agropyron repens* and *Bromus inermis*), but never exceeding 0.01 percent incidence. It is thus concluded that the main factor in the overwintering of the virus is the insect vector. *Setaria* (= *Chaetochloa*) *viridis* and *Panicum crusgalli* (= *Echinochloa crusgalli*) have also been found affected by this disease, and 15 percent infection was obtained in rice by artificial inoculation. Inoculated into oats, the virus spread in the tissues at the rate of about 7 cm. per hour.

Wheat stem rust and old and new varieties in 1940, L. R. WALDRON (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 1, pp. 7, 8).—While far-reaching conclusions are not deemed possible from the one experiment (Fargo, 1940) discussed, in which many named old varieties with some new varieties and selections were included, it is noted that rust caused marked injury on the late and very susceptible sorts, the very resistant wheats underwent but little damage, while the earlier and partly resistant varieties showed only moderate damage. It is not thought necessary to assume that the older varieties have "run out" or deteriorated, but more likely that the factors building up a rust epidemic have become modified through the years than that the wheat varieties themselves have changed.

Wilt disease of abacá, or Manila hemp (*Musa textilis* Née), B. S. CASTILLO and M. S. CELINO (*Philippine Agr.*, 29 (1940), No. 1, pp. 65-85, figs. 5).—This presents the results of a general study by which it was shown through morphological, cultural, and inoculation experiments that the fungus associated with abacá wilt is identical with *Fusarium oxysporum* f. 3 (= *F. cubense*), cause of banana wilt.

Studies on the control of internal breakdown of table beets by the use of boron, G. J. RALEIGH, O. A. LORENZ, and C. B. SAYRE. (Cornell Univ. and N. Y. State Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 791, 792).—An abstract.

The effect of different forms of copper in sprays and dusts on vine growth, fruit production, leaf injury, and disease of cantaloupes under field conditions: Progress report, H. L. STIER and C. H. MAHONEY. (Md. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 815-820).—In this test on the Eastern Shore (1939), all the copper sprays and dusts used markedly decreased defoliation and disease in cantaloups. Bordeaux mixture, yellow copper oxide, red copper oxide, Basi-Cop, Grasselli Compound A, and Duo-Copper were used in the sprays; and yellow copper oxide, red copper oxide, Cupro-K, and monohydrated copper sulfate in the dusts. The greatest marginal chlorosis occurred on plants in the bordeaux and yellow copper oxide spray plats, and sprays when compared with dusts containing the same compounds and applied approximately at the same rate per acre in terms of Cu caused significantly greater marginal chlorosis. Although the Cu appeared to be the principal cause of this injury, it seemed to be influenced also by soil moisture, fertility level, and weather conditions. Compared with one another or with the control plats, none of the treatments caused significant differences in the total number of fruit set. Bordeaux and Basi-Cop sprays and red copper oxide dust plats showed a significantly greater number of fruits in the crown set than the controls, but length of the main stem was similar for plants in all plats including the controls.

Relative nodulation of varieties of *Medicago sativa* varying in susceptibility to alfalfa wilt, J. T. KROULIK and P. L. GAINNEY. (Kans. Expt. Sta.).

(*Soil Sci.*, 50 (1940), No. 2, pp. 135-140).—No evidence was obtained to indicate any association of resistance of *M. sativa* to infection by *Rhizobium meliloti* with resistance to infection by *Phytophthora insidiosa*. The results of the study substantiated previously reported data from various sources that highly significant differences in infectivity may be expected to arise from inoculating *M. sativa* with different strains of *R. meliloti*, that highly infective strains are relatively inefficient in nitrogen fixation, and that highly significant differences in the amount of nitrogen fixed may result when different strains of *R. meliloti* are used on the same variety of alfalfa or when the same strain of *R. meliloti* is used for inoculating different varieties.

Most cauliflower varieties resistant to cabbage yellows, O. A. RETNICK and W. O. GLOVER (*Farm Res. [New York State Sta.]*, 6 (1940), No. 4, p. 8).—Controlled greenhouse tests under favorable conditions for infection—temperature being the most important factor—indicated that while all cauliflower strains used were susceptible to infection, some showed much more resistance than others. It appears that in case especially virulent races of the causal *Fusarium* should ever be encountered resistant cauliflower strains could readily be developed.

A study of horseradish diseases and their control, K. J. KADOW and H. W. ANDERSON (*Illinois Sta. Bul.* 469 (1940), pp. 529-583, figs. 23).—This handbook, in addition to describing the plant and its taxonomy, its importation into America, its geographical distribution, and the cultural practices used for it, presents data on leaf diseases, virus diseases and "deterioration," and root rots, in each case discussing such matters as the symptoms, cause, host plants, overwintering of the causal agent, and control.

The occurrence of onion yellow-dwarf in New Zealand, E. E. CHAMBERLAIN and G. T. S. BAYLIS (*New Zeal. Jour. Sci. and Technol.*, 21 (1939), No. 4A, pp. 229A-236A, figs. 4).—A serious virus disease recently appearing in New Zealand seems to be identical with yellow dwarf as described in other countries. Although it has been observed in the field only on onions, it has been transmitted experimentally to shallots. The virus overwinters in infected bulbs and is transmissible by artificial inoculation and by four species of aphids tested. Regulations to prevent its spread are outlined.

Insects as vectors of yellow dwarf, a virus disease of onions, H. D. TATE (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 14 (1940), No. 3, pp. 267-294).—In transmission tests with this virus, successful infection was obtained by transfer from diseased to healthy plants with 48 aphid species, but all tests with other insects (two doubtful exceptions) gave negative results. The incubation period in the plant proved to be relatively short—7-12 days in most cases, with an average of 10.3 days. Aphids acquired the virus during the first feeding on diseased plants and immediately thereafter were capable of infecting healthy ones. Infective aphids fed either on healthy susceptible or immune hosts, or confined without food, became nonviruliferous within a few hours. Under certain conditions the symptoms became completely masked, not becoming evident until after the bulbs had undergone a rest period and had then been regrown. However, such plants served as sources of infection. Although the onion plant serves only as an incidental or transitory host of aphids in Iowa, observations indicated that they are present in sufficient numbers and at the proper time to play an important role in field dissemination of the disease. Control may be accomplished by destruction of left-over bulbs in the field coupled with planting of disease-free sets grown in non-infected areas. The disease was transmitted by aphids to over 30 varieties of cultivated onions, but tests with a large number of other plant species gave negative results.

A comparison of New Improved Semesan Bel and different strengths of yellow oxide of mercury as materials for treating seed potatoes under Long

Island conditions, H. S. CUNNINGHAM (*New York State Sta. Bul.* 694 (1940), pp. 13).—The data presented, based on experiments conducted in 1936-38, indicate that under Long Island conditions treating Green Mountain seed with any of the materials used is unlikely to result in increased yields, and in certain years they may be adversely affected. From this and previous work, treating Green Mountain seed is not recommended unless it is heavily infested with *Rhizoctonia*. Treating Irish Cobbler seed may be expected to give increased yields, and it is also evident that much weaker mixtures of yellow oxide of mercury will be more advantageous than the stronger mixture formerly recommended and will materially reduce the cost. New Improved Semesan Bel is recommended for Irish Cobblers but not for Green Mountains on Long Island. Regardless of strength, the emergence of both Irish Cobblers and Green Mountains is delayed by treating the seed with yellow oxide of mercury, and during the period of this test New Improved Semesan Bel had the same effect in 2 out of 3 yr. This delayed emergence does not affect subsequent growth and certainly does not adversely affect the yield of Irish Cobblers.

Bacterial wilt and ring rot disease of potatoes, E. W. BODINE. (Colo. Expt. Sta.). (*Calif. Dept. Agr. Spec. Pub.* 174 (1940), pp. 99-102).—A brief general discussion of the disease due to *Phytophthora septentrionalis* and its status in Colorado.

Rhizoctonia solani and R. crocorum in Argentina [trans. title], J. B. MARCHIONATTO (*Jour. Agron. y Vet., Univ. Buenos Aires*, 1939, pp. 327-341, pls. 2, figs. 10).—On potato infection by these two fungi, with mycological comparisons and control methods. There are 18 references.

The endophyte of rye-grass (*Lolium perenne*), J. C. NEILL (*New Zeal. Jour. Sci. and Technol.*, 21 (1940), No. 5A, pp. 280A-291A, figs. 9).—Evidence is given to indicate that an endophytic fungus is normally present in the leaves of plants of certified perennial ryegrass in New Zealand when grown from seed of the current season's harvest. A method of culture is described which has resulted in the consistent isolation of a fungus from endophyte-bearing seedlings and from detached leaves. The identity of the fungus has not yet been determined.

U. S. 200 × 215, a new sugar beet variety resistant to leaf spot, G. H. COONS and D. STEWART. (U. S. D. A.). (*Sugar Jour.*, 3 (1940), No. 2, pp. 7-10)

Atlas of the pests and diseases of the sugar beet, L. DECoux and G. ROLAND (*Atlas des ennemis et maladies de la betterave. Bruxelles: A. & G. Bulens Bros.*, 1938, pp. 56, figs. 20).—A handbook illustrated in color.

Report to the Provincial Deputation on the sugarcane disease in the Fourth Department of the Island of Puerto Rico, C. GRIVOT GRAND-COURT, A. STAHL, and J. J. ACOSTA Y CALBO (*Informe dado a la exema. Diputacion Provincial sobre la enfermedad de la caña de azucar en el Cuarto Departamento de la Isla de Puerto Rico. [Mayaguez]: Romero, 1939, pp. 53*).—This is a reprinting of a report made in 1876 by the above authors on a disease of sugarcane which evoked great interest in the 1870's, with an introduction by O. F. Bravo. The various sections of the report deal with the grave situation created in Puerto Rico by this disease, a brief description of it and the history of its spread, the disease per se and its relations with insects, unsuccessful remedies and collected observations, its importance in Mauritius and Bourbon (Réunion), remedies and advice including the authors' insistence upon the substitution of new varieties which from their observation had proved resistant, and the nomenclature of the new cane varieties introduced into Mauritius from 1870 to 1872.

Chlorotic streak, a virus disease of sugarcane reported in Louisiana (*Sugar Bul.*, 18 (1940), No. 18, pp. 1, 2).—A brief summary of the present status of this disease in the United States.

A progress report on the study of chlorotic streak of sugarcane in Louisiana, E. V. ABBOTT. (U. S. D. A.). (*Sugar Bul.*, 18 (1940), No. 19, pp. 3-6).—The known distribution in Louisiana, varieties affected, effects of the disease on germination and yields of sugarcane, relation of drainage and soil type to its prevalence, and control measures are considered.

Hot water treatment of seed cane, C. W. EDGERTON and I. L. FORBES. (La. Expt. Sta.). (*Sugar Bul.*, 18 (1940), No. 18, pp. 4, 5).—The results of preliminary experiments with the hot-water method are summarized, the following points of interest being brought out: This treatment apparently destroys all the chlorotic streak virus, cane with this disease and not treated sometimes germinates very poorly and the young shoots produced often fail to develop satisfactorily, and the effect of the hot-water treatment on cane free from chlorotic streak apparently depends on weather conditions during the following winter. In some years better stands are obtained, while in others the effects are not so satisfactory. More work needs to be done before definite recommendations can be made.

A tobacco vein-banding necrosis, E. E. CHAMBERLAIN (*New Zeal. Jour. Sci. and Technol.*, 21 (1940), No. 5A, pp. 271A-275A, fig. 1).—A disease causing necrosis of foliage and stems of tobacco is reported as recently appearing in the Nelson District of New Zealand. The evidence presented suggested that it is due either to a strain of tobacco mosaic or to a mixed virus one component of which is tobacco mosaic and the other a virus not transmissible by artificial inoculation.

Tobacco varieties resistant to "cabeça" virus [trans. title], A. R. LIMA and A. S. COSTA (*Rev. Agr. [Brazil]*, 15 (1940), No. 3-4, pp. 133-140, fig. 1; *Eng. abs.*, pp. 139, 140).—Several commercial varieties of tobacco and species of *Nicotiana* were tested for resistance to this virus, probably identical with tomato spotted wilt (*Lycopersicum virus 3*). *N. glauca* was infected artificially but with difficulty, and under natural conditions it was practically immune. The cross *N. tabacum* × *N. glauca* was not tested on account of poor development, but the allotetraploid proved resistant as compared with Turkish tobacco. A strain of Sumatra tobacco proved resistant, as verified by 3 years' trials in the field, and inoculated plants showed a smaller number of lesions but a more severe necrosis than two other varieties tested. It is pointed out that the resistance of this variety may lie in its greater ability to localize the virus.

Solubility studies on purified tobacco mosaic virus, H. S. LORING (*Jour. Gen. Physiol.*, 23 (1940), No. 6, pp. 719-728, fig. 1).—Different samples of purified tobacco mosaic virus show a relatively wide variation of solubility in $(\text{NH}_4)_2\text{SO}_4$ solution. This variation and the type of solubility curve obtained in the presence of varying amounts of solid phase indicate that the purified virus, whether isolated by mild treatment with $(\text{NH}_4)_2\text{SO}_4$ or by ultracentrifugation, is not a homogeneous chemical substance but contains more soluble and less soluble virus fractions of comparable specific activities. Long contact with strong $(\text{NH}_4)_2\text{SO}_4$ solutions or 0.1 M phosphate buffer results in a decreased solubility. The variation in solubility of samples isolated from different plants by the same method seems to depend in part on the length of time the plants have been inoculated before the cuts are made, and probably also on the conditions under which they are grown. Virus preparations isolated from plants of different genera grown under the same conditions and inoculated at the same time, however, behaved like identical substances in solubility experiments. There are 16 references.

Purification of tomato bushy stunt virus by differential centrifugation, W. M. STANLEY (*Jour. Biol. Chem.*, 135 (1940), No. 2, pp. 437-454, figs. 3).—

Purified preparations of this virus were obtained by this method from infected frozen and unfrozen plants of tomato, *Datura stramonium*, and *Solanum nodiflorum*. The specific activity of virus was fully as great from frozen as from unfrozen plants. The properties of the purified preparations were apparently the same regardless of host, but the yield of virus from *Datura* was four or five times that from the other two hosts. Purified preparations were also obtained from similar starting materials by a chemical method involving heat treatment at 60° C. and repeated precipitation by $(\text{NH}_4)_2\text{SO}_4$. Although many of the properties of such preparations were apparently indistinguishable from those obtained by the centrifuge method, their specific virus activity was considerably lower—believed due to the heat treatment. Nucleic acid of the ribose type was isolated from a preparation of bushy stunt virus by differential centrifugation. This virus appears to be a nucleoprotein containing ± 17 percent of nucleic acid and having an ultraviolet light absorption maximum at about 2,650 a. u., a sedimentation constant of $S_{20w}=132 \times 10^{-13}$, and a diffusion constant of $D_{20}=1.15 \times 10^{-7}$. The sedimentation constant of chemically purified preparations proved to be the same as in the centrifuged material. Purified preparations, whether isolated by differential centrifugation or by chemical means, may be obtained in the form of rhombic dodecahedral crystals having edges as great as 0.1 mm. Since the chemically prepared material involving heat treatment is partially inactivated, yet yields crystals similar to the fully active virus, crystallinity cannot be used as a criterion of purity with respect to virus activity. There are 18 references.

The diffusion constant of tomato bushy stunt virus, H. NEURATH and G. R. COOPER (*Jour. Biol. Chem.*, 135 (1940), No. 2, pp. 455-462).—The diffusion constant of the ultracentrifugally prepared virus was measured with the refractometric scale method, an average value of $D_{20}=1.15 \times 10^{-7}$ being obtained for dilute virus solutions. From this value and the sedimentation constant, a molecular weight of 10,600,000 and a dissymmetry constant of $f_D/f_0=1.27$ was obtained. Assuming negligible hydration, this would correspond to a molecular axial ratio of 5.4:1 and 5.8:1 for prolate and oblate ellipsoids of revolution, respectively. About 77 percent hydration must be assumed to account for the value of the dissymmetry constant on the assumption of spherical shape. There are 17 references.

Studies on the sedimentation rate of bushy stunt virus, M. A. LAUFFER and W. M. STANLEY (*Jour. Biol. Chem.*, 135 (1940), No. 2, pp. 463-472).—"The sedimentation constant of centrifugally purified bushy stunt virus was found to be 131.6×10^{-13} for the virus dissolved in 0.1 M phosphate buffer at pH 7 and 132.8×10^{-13} for the virus dissolved in 0.1 M borate buffer at pH 7. Some variability was observed in a series of determinations of the sedimentation rate made with the same sample of virus, but no pronounced effect of changes in the concentration of phosphate buffer was demonstrated. In a study on a single preparation of bushy stunt virus in which five laboratories collaborated, it was demonstrated that the results from laboratory to laboratory are in good agreement. The sedimentation constant of about 132×10^{-13} which was obtained differs significantly from the value 146×10^{-13} reported previously for virus isolated by chemical means in another laboratory, and indicates that a real difference exists between the latter material and the samples used in the present investigation." There are 16 references.

Response of field grown tomatoes to soil fumigation with chloropicrin, F. L. HOWARD and F. K. CRANDALL. (R. I. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 939-941).—In three seasons' tests in the market garden plats of the station, production was increased 46, 378, and 246 percent, respec-

tively. In the extensive 1939 trial the productivity of the soil was changed from almost 5 tons to over 17 tons per acre of first-quality tomatoes as a result of the chloropicrin fumigation. The chemical does not appear to serve as a direct plant-growth stimulant or as a nutrient material, since it is completely volatile. While the basic problem of the cause of this more prolific development is being studied further, the evidence at hand indicates that the injurious competing and pathogenic soil-harbored organisms may be limiting factors in tomato production.

Tomato stem rot or canker (*Didymella lycopersici* Kleb.), T. SMALL (*Jersey Expt. Sta., Howard Davis Farm, Trinity, Rpt., 1939, pp. 22-32*).—Field studies on the Island of Jersey indicated that primary infections appear at the base of the stem on some of the plants. Later on, secondary infections may appear (presumably initiated by spores from the primary sources) throughout the crop on all aerial parts including the fruits. However, attacks on the leaf blades are uncommon. The 1939 evidence supported the view that the source of the primary infections is to be found in the propagating stages, so that if perfectly sound plants are set out in the field there is little risk of stem rot. Suggested control measures are outlined.

A streak disease of tomatoes in New Zealand, E. E. CHAMBERLAIN (*New Zeal. Jour. Sci. and Technol., 21 (1940), No. 5A, pp. 266A-271A, figs. 3*).—The evidence obtained suggested that the disease described is due either to tobacco mosaic, which under certain conditions develops streak symptoms, or to a mixed virus one component of which is tobacco mosaic and the other a virus not transmissible by artificial inoculation.

Turnip-mosaic, E. E. CHAMBERLAIN (*New Zeal. Jour. Sci. and Technol., 21 (1939), No. 4A, pp. 212A-223A, figs. 7*).—The host range in New Zealand has been extended to include 18 cruciferous and 2 solanaceous species. The symptoms on the newly recorded hosts are described, and the evidence presented suggests that the disease overwinters on cruciferous weeds. The properties of the virus were studied. A comparison with crucifer viruses occurring elsewhere has shown that it is similar to the American black ring of cabbage in methods of transmission, insect vectors, physical properties, and host range, but differs from it in symptom expression.

Functional disorders of apples, C. A. EAVES and H. HILL (*Canada Dept. Agr. Pub. 694 (1940), pp. 19, pls. 11*).—A compendium of information (32 references), illustrated (by A. Kellett) in part by colored plates, on functional disorders of apple fruits on the tree and functional disorders and fungal rotting of the fruits in storage, including a classification within the two groups, factors influencing the troubles, and control measures.

Cork experimentally produced on Northern Spy apples, A. J. HEINICKE, D. BOYNTON, and W. REUTHER. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc., 36 (1939), pp. 47-52, figs. 2*).—An experiment is described which apparently indicates that the inability of the roots to function properly due to unfavorable soil environment induced by flooding resulted, among other things, in an abnormality of the fruit that could not be distinguished from the cork caused by boron deficiency. It was also found that deficiencies of nutrients in the tissue in the top of the tree are not necessarily due to a deficiency of the elements in the soil. When the soil conditions are such that the roots are unable to function properly, especially if the oxygen content is abnormally low, the nutrients are evidently taken up in much smaller amounts than normally. Chemical analysis of the leaves showed clearly that the flooding resulted in a reduced percentage of ash as compared with nonflooded trees. The percentage of B in the ash and

the amount per leaf was also considerably less than in the controls, and the K was reduced even more. The total N was also low compared with the control trees.

Boron deficiency of apples, A. B. BURRELL. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), p. 52).—An abstract in which terms are suggested for the different symptoms manifested.

The influence of bordeaux mixture on the rate of photosynthesis and transpiration of apple leaves, F. W. SOUTHWICK and N. F. CHILDERS. (Ohio Expt. Sta. and State Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), p. 374).—An abstract.

The effect of two mild sulphur sprays on the photosynthetic activity of apple leaves, E. L. AGNEW and N. F. CHILDERS. (Ohio Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 379–383, fig. 1).—Tested in six separate experiments, three of which involved the commercial Sulfix dry lime-sulfur and three the Magnetic Spray wettable sulfur, these sprays showed little or no injurious effects on photosynthetic activity except for one test where the Sulfix dry lime-sulfur was used. In this test the reduction in assimilation was associated with the highest maximum temperatures, which ranged from 83° to 86° F. for the first 3 days after spraying. After application of the Magnetic Spray sulfur, the daily temperature reached 88° on 2 days and was above 80° on 6 of the test days in this group of three tests. From these results and those of other workers, it is believed clearly evident that sprays containing sulfurs in suspension have less effect on photosynthesis of apple leaves than sprays containing sulfurs in solution.

“Peach mosaic disease in western Colorado,” E. W. BODINE. (Colo. Expt. Sta.). (*Calif. Dept. Agr. Spec. Pub.* 174 (1940), pp. 78–81).—A brief general discussion of peach mosaic, said to be the most serious peach disease in Colorado.

The effect of certain fungicides on the photosynthetic activity of sour cherry leaves, L. M. MURPHY. (Mich. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 375–378).—“From this study, it appears that from the standpoint of photosynthetic efficiency Cupro K is superior to Copsil, 6–8–100 bordeaux, and lime-sulfur as a spray for sour cherries.”

A new copper spray for cherry leaf spot control, R. H. DAINES (*N. J. State Hort. Soc. News*, 21 (1940), No. 4, pp. 1226, 1237, fig. 1).—In a 3-yr. test of various copper fungicides on cherries, the one material appearing most satisfactory from the standpoints of cost, adherence of spray residue to foliage, control of leaf spot, and practical noninjuriousness was home-made copper phosphate, directions for the preparation of which are given.

“The red stele disease of strawberries,” HAROLD E. THOMAS. (Univ. Calif.). (*Calif. Dept. Agr. Spec. Pub.* 174 (1940), pp. 105–109).—A general discussion of the disease due to *Phytophthora* and its status in California.

Observations on a disease of citrus [trans. title], F. R. MILANEZ (*Rodriguésia*, 4 (1940), No. 13, pp. 199–263, pls. 18, figs. 7).—The present study, including a review of the literature (35 references), led the author to the conclusion regarding a diseased condition in citrus trees involving death of the fibrous roots that an endophytic fungus, as a true parasite, is the immediate cause of the death of those roots, which have been previously impoverished by a fungus-insect association (*Boletus tropicus* and *Pseudococcus comstocki*) acting superficially. The host-parasite relations are discussed in detail and illustrated.

Necrosis of the coffee tree [trans. title], V. WELBORN (*Rev. Inst. Defensa Café Costa Rica*, 10 (1940), No. 70, pp. 75–84).—On phloem necrosis of coffee and its insect transmission.

A preliminary report of pecan leaf scorch studies, M. B. HARDY, H. LUTZ, and S. MERRILL, JR. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 489-492).—The results reported indicate a significant decrease in the incidence of leaf scorch following treatments designed primarily to increase the water supply to a tree or to decrease the rate of water loss by transpiration. It was also shown that the incidence was greater on fruiting than on nonfruiting shoots, but whether this relationship was due to increased demand for moisture or for some nutrient element has not yet been definitely determined. Observations and other data presented showed leaf scorch to be more severe in years of less rainfall, under conditions where root crowding was excessive, and in soils with low water-holding capacity and fertility.

The anthracnose of persimmon [trans. title], S. GONÇALVES DA SILVA (*Biologico*, 6 (1940), No. 5, pp. 125, 126).—A note on this disease of persimmon—also affecting various other tropical fruits—due to *Collectotrichum gloeosporioides* and its control, including resistant varieties.

The wilt disease of Ricinus in the northeast [trans. title], S. C. ARRUDA and J. DESLANDES (*Biologico*, 6 (1940), No. 6, pp. 144-148).—It is concluded that the disease in northeastern Brazil and the one in São Paulo are both due to a variety of *Fusarium orthoceras*.

Symptoms of potassium deficiency in carnation plants, A. J. SZENDEL. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), p. 1012, fig. 1).—The symptoms of K deficiency in plants grown in nutrient solution culture are described.

Certain mineral deficiency symptoms of gardenias grown in culture solutions, C. G. KEYES. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 1057, 1058).—The symptoms of deficiencies in Ca, K, Mg, and B experimentally induced in nutrient solutions are described.

Principles of disease control applicable to bulbous iris, F. P. McWHORTER (*Oregon Sta. Cir. Inform.* 221 (1940), pp. 5).—A practical discussion of mosaic, leaf spots caused by *Heterosporium* and *Mystrosporium*, and bulb rots caused by bacteria and blue mold, including symptoms, methods of spread, and the most effective means for control thus far available, based on State and Federal research, which have proved to be of value in the hands of growers.

Spread of rose virus diseases, P. BRIERLEY and F. F. SMITH (*Amer. Nurseryman*, 72 (1940), No. 1, pp. 5-8, figs. 6).—A general discussion of rose mosaic, yellow mosaics, and streak, their spread in the nursery, and suggestions for their control based on eliminating nursery practices found capable of spreading infection in budding operations.

The detrimental effect of walnut to rhododendrons and other ornamentals, P. P. PIRONE (*North. Nut Growers Assoc. Proc.*, 30 (1939), pp. 73, 74).—Notes on an interesting case of poisoning to *Rhododendron catawbiense* by *Juglans nigra* in a New Jersey nursery and on a case of toxicity to various species in a commercial planting of perennials near a large black walnut in a fence row, with reference to similar observations by others where *Kalmia latifolia* and other rhododendrons had shown unfavorable responses when planted near walnut trees.

Notes on Gymnosporangium cupressi, W. H. LONG and L. N. GOODING (*Mycologia*, 32 (1940), No. 4, pp. 489-492, fig. 1).—The pycnial and aecial stages of this rust on *Amelanchier* are described.

Brown-spot (Alternaria passifloræ Simmonds): A disease of the passion-vine in New Zealand, R. M. BRIEN (*New Zeal. Jour. Sci. and Technol.*, 21 (1940), No. 5A, pp. 275A-279A, figs. 4).—A general study of this disease of *Passiflora edulis*.

An entomogenous fungus on spider mites on water hyacinth, V. K. CHARLES. (U. S. D. A.). (*Mycologia*, 32 (1940), No. 4, pp. 537-540).—*Rhizotrichum depauperatum* n. sp. on *Paratetranychus yothersi* on leaves of *Piaropus crassipes*.

Diseases of trees, L. R. TEHON (*Amer. Nurseryman*, 72 (1940), No. 1, p. 24).—Note on the virus leaf-casting yellows disease of peach reported in California.

Balloon releases and Dutch elm disease spread, E. P. FELT (*Bartlett Tree Res. Labs. Bul.* 3 (1939), pp. 20-25, figs. 4).—A continuation of the balloon work of 1936, previously reported (E. S. R., 77, p. 648), indicates the possibility of a somewhat direct connection between the occurrence of the Dutch elm disease and the drifting of elm bark beetles considerable distances with the wind.

Notes on Gymnosporangium in Oklahoma, W. W. RAY (*Mycologia*, 32 (1940), No. 4, pp. 572-574).—Notes on species of this rust genus on *Juniperus* spp. in the State.

The plane tree disease, J. A. MILLER (*Bartlett Tree Res. Labs. Bul.* 3 (1939), p. 27).—A note calling attention to the spread and seriousness of this disease of the London plane tree due to a species of *Ceratostomella*.

Three new Hyphomycetes preying on free-living terricolous nematodes, C. DRECHSLER. (U. S. D. A.). (*Mycologia*, 32 (1940), No. 4, pp. 448-470, figs. 3).—*Dactylella doedycoides*, *Dactylaria haptospora*, and *Tridentaria implicans* are all described as new species, illustrated, and their parasitic relations discussed. Corrections concerning *D. brochopaga* and *Arthrobotrys superba* are also included.

A simple ultrafiltration apparatus, T. B. COOLIDGE (*Jour. Biol. Chem.*, 135 (1940), No. 2, pp. 541, 542, fig. 1).—The membrane used for this ultrafiltration tube is Visking sausage casing, sold in 500-ft. rolls. This is soaked 20 min., knotted, invaginated, and filled as illustrated.

ECONOMIC ZOOLOGY—ENTOMOLOGY

[Work in economic zoology and entomology by the Indiana Station], G. A. FICHT, T. E. HENTON, W. B. CARTWRIGHT, C. BENTON, P. LUGINBILL, H. R. PAINTER, E. V. WALTER, D. W. LAHUE, G. E. GOULD, G. E. MARSHALL, J. J. DAVIS, B. E. MONTGOMERY, L. F. STEINER, J. E. FAHEY, and G. C. ODERKIRK. (Partly coop. U. S. D. A. et al.). (*Indiana Sta. Rpt.* 1939, pp. 18, 19, 71-77, 78-81, figs. 5).—The work of the year (E. S. R., 81, p. 671) reported upon includes control of the mint flea beetle; European corn borer and its possible control by the use of electric traps; root nematode of tomatoes; cutworms and armyworms; gladiolus thrips; hessian fly; white grub, particularly *Phyllophaga hirticula*; corn earworm; chinch bug; potato insects; Mexican bean beetle; cucumber beetle; cockroaches; codling moth control; oriental fruit moth; forest insects; and rodent control.

[Contributions on wildlife research and management] (U. S. Dept. Int., Bur. Biol. Survey, Wildlife Leaflets BS-141 (1939), pp. 4; BS-142, pp. 11; BS-143, pp. 4; BS-144, pp. 6; BS-145, pp. 5; BS-146, pp. [2]; BS-147, pp. 37; BS-148, pp. 10; BS-149, pp. 5, pl. 1; BS-150 (1940), pp. 7; BS-151, pp. 3; BS-152, pp. 5; BS-153, pp. 4, pl. 1; BS-154, pp. [2]+34, fig. 1; BS-155, pp. 2; BS-156, pp. 18; BS-157, pp. 4, pls. 2; BS-158, pp. 21, figs. 37; BS-159, pp. 6; BS-160, pp. 6; BS-161, pp. 5; BS-162, pp. 6; BS-163, pp. 2; BS-164, pp. 7; BS-165, pp. 22).—In continuation of this series (E. S. R., 82, p. 214), the following are presented: Protecting Blueberries From Damage by Herring Gulls, by R. C. McClanahan (BS-141); Big-Game Inventory of the United States, 1938

(BS-142); Suggestions for the Control of Vagrant Domestic Pigeons (BS-143); Raising Deer in Captivity (BS-144); Birdbanding, by F. C. Lincoln (BS-145), which supersedes BS-53 (E. S. R., 76, p. 355); Lake Mattamuskeet Wildlife Refuge (BS-146); Abstract of Fur Laws, 1939-40, compiled by F. G. Grimes (BS-147); Status of the American Bison in the United States and Alaska, 1939 (BS-148); Protecting Field Crops From Waterfowl Damage by Means of Reflectors and Revolving Beacons, by F. M. Uhler and S. Creech (BS-149); Suggestions for Bird Field Study, by M. T. Cooke (BS-150); Raising Chinchillas in Captivity (BS-151); Suggested Action Program for Sportsmen's Organizations (BS-152); The Biological Survey Mammal Collection (BS-153); Flora of the Patuxent Research Refuge, Maryland, by N. Hotchkiss (BS-154), previously noted (E. S. R., 83, p. 597); Raising Mealworms, by F. H. May (BS-155); Ornamental Woody Plants Attractive to Birds, by M. Katz (BS-156); Sullys Hill National Game Preserve, North Dakota (BS-157), which supersedes BS-61 (E. S. R., 76, p. 355); Original and Present Breeding Ranges of Certain Game Birds in the United States, by R. C. McClanahan (BS-158); The Chukar and Hungarian Partridges in America, by C. Cottam, A. L. Nelson, and L. W. Saylor (BS-159); Wildlife in Land Planning (BS-160), which supersedes BS-71 (E. S. R., 77, p. 652), and Wildlife Technology (BS-161), both by W. L. McAtee; Birds as a Factor in Controlling Insect Depredations, by C. Cottam and F. M. Uhler (BS-162); Common Salt as a Curative for Cannibalism Among Game Birds in Captivity, by R. B. Nestler (BS-163); Research in the Administration of Federal Refuges, by E. R. Kalmbach (BS-164); and The Status of Migratory Game Birds, 1939-40 (BS-165).

Wildlife Review, [August 1939-August 1940] (*U. S. Dept. Int., Bur. Biol. Survey, Wildlife Rev. Nos. 22 (1939), pp. 50; 23, pp. 35; 24, pp. 52; 25, pp. 22; 26 (1940), pp. 54; 27, pp. 41; 28, pp. 51*).—A continuation of this series (E. S. R., 81, p. 537).

A game survey in northeastern Tennessee, L. WING. (Wash. State. Col.). (*Jour. Tenn. Acad. Sci., 15 (1940), No. 3, pp. 309-320*).

Anesthesia of fur-bearing animals, W. WISNICKY. (Wis. Expt. Sta.). (*North Amer. Vet., 21 (1940), No. 5, pp. 277-280, figs. 6*).

Check-list of birds of the world, IV, J. L. PETERS (*Cambridge: Harvard Univ. Press., 1940, vol. 4, pp. XII+291*).—This further volume (E. S. R., 77, p. 654) lists the birds of the orders Cuculiformes (plantain-eaters and cuckoos), Strigiformes (owls), Caprimulgiformes (oil-birds and goatsuckers), and Apodiformes (swifts and hummingbirds).

Natural history of the birds of eastern and central North America (*Boston: Houghton Mifflin Co., 1939, pp. XXVI+554, pls. 97*).—This revised and abridged single-volume edition, by J. B. May, of the earlier work by E. H. Forbush (E. S. R., 68, p. 635), includes more than 100 additional species. The 4 additional colored plates were prepared by R. T. Peterson.

A contribution to the herpetology of Florida, A. F. CARR, JR. (*Fla. Univ. Pub., Biol. Sci. Ser., 3 (1940), No. 1, pp. [3]+118*).—A brief introduction is followed by discussions of the derivation of the fauna of Florida and habitat distribution. A key for their identification and an annotated list of the forms occurring in the State, 162 in number, follow. Their Florida range, habitat, abundance, and habits are considered and a principal reference indicated. A bibliography of 7 pages and a subject index are included.

An introduction to nematology (*Babylon, N. Y.: M. B. Chitwood, [1938], sect. 1, pts. 2, pp. [2]+55-123, figs. 58; [1940], 3, pp. [2]+125-204, figs. 35; sect. 2, pt. 1, pp. 205-240+[2], figs. 18*).—In continuation of this work (E. S. R., 78, p. 814) part 2 of section 1, by B. G. and M. B. Chitwood, includes Cephalic Structures and Stoma (pp. 55-75), The Esophagus, Including the Esophago-

intestinal Valve (pp. 76-99), The Intestine or Mesenteron (pp. 100-112), and The Posterior Gut (Structures of the Proctodeum) (pp. 113-122). Part 3 of section 1 includes The Excretory System, by M. B. and B. G. Chitwood (pp. 125-134); The Reproductive System (pp. 135-158) and Nervous System (pp. 159-174), both by B. G. and M. B. Chitwood; Nemic Ova, by R. O. Christenson, L. Jacobs, F. G. Wallace, and M. B. Chitwood (pp. 174-189); and Nemic Relationships, by B. G. Chitwood (pp. 190-204). Part 1 of section 2 includes Gametogenesis, by A. C. Walton (pp. 205-215); Nemic Embryology, by B. G. Chitwood (pp. 216-226); and Postembryonic Development, by M. B. Chitwood (pp. 227-240). A copious bibliography accompanies each of the several chapters.

A comparative study of the eggs of various species of nematodes parasitic in domestic ruminants, D. A. SHORB. (U. S. D. A.). (*Jour. Parasitol.*, 26 (1940), No. 3, pp. 223-231, figs. 4).—The author has found that 15 genera of nematodes, the eggs of which occur in feces, have been reported in the United States as parasites of domestic ruminants. Eight of these genera are said to have more than 1 species represented in one or more of the common domestic ruminants. The species of these genera can be identified more or less definitely by differences in size and shape of their eggs. Precise identification is facilitated by host relationship and geographical distribution of the species considered.

Effect of tropical sunlight on eggs of *Ascaris suis* (Nematoda), the large intestinal roundworm of swine, L. A. SPINDLER. (U. S. D. A.). (*Jour. Parasitol.*, 26 (1940), No. 4, pp. 323-331).—In reporting further (E. S. R., 76, p. 848; 77, p. 244), 14 tests upon undeveloped eggs of the swine ascarid in Puerto Rico, both in water and when dry, revealed that they were less resistant to the effects of sunlight than fully developed eggs. All the 1-celled eggs in water failed to survive continuous exposure to sunlight as long as 3 hr., and none survived 2¾ hours' exposure in a dried condition. Some embryonated eggs in water survived 5 hr. and some as long as 9 hr. Embryonated eggs exposed in a dried condition failed to survive exposure periods as long as 5 hr.

Euparyphium melis (Trematoda: Echinostomidae) from the snowshoe hare, A. B. ERICKSON. (Minn. Expt. Sta. et al.). (*Jour. Parasitol.*, 26 (1940), No. 4, p. 334).—*E. melis*, the adult of which is normally a parasite of the intestines and stomachs of minks, was found to be present in 1 of more than 600 snowshoe hares (*Lepus americanus phaeonotus*) collected in Morrison County, Minn.

Some helminth parasites of the Panama otter [*Lutra repanda*], A. McINTOSH. (U. S. D. A.). (*Jour. Parasitol.*, 26 (1940), No. 3, pp. 219-222, figs. 6).

Studies on blood protozoa obtained from Mexican wild birds, R. HEWITT (*Jour. Parasitol.*, 26 (1940), No. 4, pp. 287-295, figs. 21).—Report is made of blood protozoa belonging to the genera *Plasmodium*, *Haemoproteus*, *Leucocytozoon*, and *Trypanosoma* from 3 species of wild birds obtained in the vicinity of Mexico City, including 61 common house finches (*Carpodacus mexicanus frontalis*), 30 *Molothrus* sp., and 3 cedar waxwings (*Bombycilla cedrorum*).

A catalogue of parasites of domestic animals from Formosa, M. SUGIMOTO ([*Tokyo: Yoken-do*], 1939, pp. [5]+244).—Part 1 of this catalog (pp. 1-81) is devoted to the Cestoda or tapeworm, 34 forms of which are recognized from Taiwan (Formosa), and part 2 (pp. 83-210) to roundworms, including the Nematoda and Acanthocephala. Arranged in systematic order, a quite complete synonymy is given for each form, together with a list of hosts, location, and distribution. A host list with their parasitic cestodes and roundworms, arranged in systematic order, follows (pp. 211-227). An index is included.

Money losses due to destructive insects, H. B. WEISS (*Jour. N. Y. Ent. Soc.*, 48 (1940), No. 2, pp. 195-199).

Insects and their rôle in Indian agriculture, T. V. R. AYYAR (*Indian Sci. Cong. Proc. [Lahore]*, 26 (1939), pt. 2, pp. 271-315, figs. 4).

Fluctuations in insect numbers, H. F. BARNES (6. *Cong. Internacl. Ent.*, Madrid, 1935, [I], *Trabs.*, pp. 181-186, figs. 4).

Immunity and serotherapy of insects [trans. title], V. ZERNOFF (6. *Cong. Internacl. Ent.*, Madrid, 1935, [I], *Trabs.*, pp. 153-161).

A discussion of the microbial flora of insects, E. A. STEINHAUS. (Ohio State Univ.). (*Jour. Bact.*, 40 (1940), No. 1, pp. 161, 162).—In a survey made of the extracellular bacterial flora of certain insects, 83 strains of bacteria, 2 of yeasts, and 2 of molds were isolated from 23 species. The insects examined included species from 7 orders of the class Hexapoda. Of the bacteria isolated, 45 were Gram-negative short rods, 14 were Gram-positive cocci, and 12 were Gram-positive spore formers. Based on cultural and physiologic characteristics, 31 new species were represented among the 83 strains. Twenty strains of the Gram-negative short rods were coliforms. The bacterial flora may differ in the various parts of the alimentary tract. Thus the large milkweed bug had a flora in its pylorum and rectum distinctly different from that in the 4 stomachs which precede them.

A survey of insecticide materials of vegetable origin, edited by H. J. HOLMAN (*London: Imp. Inst.*, 1940, pp. VIII+155).—This survey of alkaloid-containing materials (nicotine, etc.), plants containing rotenone and allied compounds, pyrethrum, quassia, and plant oils includes a list of 372 references to the literature and an appendix devoted to structural formulas.

Metallic salts and alkaloids in agriculture, R. HURSON (*Michigan Sta. Quart. Bul.*, 23 (1940), No. 1, p. 46).—This abstract of a résumé of the extent to which metallic salts and alkaloids are used in agriculture, particularly as insecticides, cites statistics on the increased use of arsenicals on crops during the last 20 yr. Statistics on annual consumption of insecticides and the probable effect upon the market for arsenicals of the introduction of plant insecticides, such as pyrethrum, nicotine, derris, and cube, are included. A list of 36 metallic salts and alkaloids other than those used in large quantities was added, indicating the constantly growing uses of poisonous materials for insect control. There was also included an evaluation of crop rotation, cultural methods, resistant varieties, and growth stage on the sale of insecticides.

Change in spray residue tolerance will aid apple and pear growers, S. W. HARMAN (*Farm Res. [New York State Sta.]* 6 (1940), No. 4, p. 6).—Attention is drawn to the advantages which fruit growers may expect from the recent changes in the Federal spray residue tolerance for lead and arsenic on apples and pears. Based on the results of a 3-yr. study made by the U. S. Public Health Service, the tolerance for lead has been increased from 0.025 to 0.05 gr. per pound of fruit and the tolerance for arsenic from 0.01 to 0.025 gr. of arsenic trioxide per pound of fruit. It is concluded that the average fruit grower should now be able to use lead arsenate for the first-brood codling moth worms with little danger of exceeding the tolerance. Although the second-brood or August sprays are likely to build up excessive deposits, by the use of lead arsenate substitutes now available growers should have little difficulty in selecting a satisfactory second-brood program. A table based upon work at the station in determining the spray residue deposits likely to be found on fruit at harvest from various spray schedules is included.

The wheat field survey for 1940, T. H. PARKS (*Ohio Sta. Bimo. Bul.* 206 (1940), pp. 147-150, figs. 3).—The annual wheat insect survey of 1940 (E. S. R.,

82, p. 72) covering 34 counties of Ohio showed the hessian fly to be reduced to quite satisfactory numbers. The percentage of wheat straws found infested, namely, 4 percent, as compared with 20.5 percent in 1939, is indicated for the counties surveyed. The wheat jointworm was found present to about the same extent as in 1939.

Potato insect investigations in 1939, W. A. RAWLINS. (Cornell Univ.). (*Amer. Potato Jour.*, 17 (1940), No. 6, pp. 135-139).—A review, presented with a list of 30 references to the literature.

Resistance in wild potatoes to attack by the potato leafhopper and the potato flea beetle, J. P. SLEESMAN. (Ohio Expt. Sta.). (*Amer. Potato Jour.*, 17 (1940), No. 1, pp. 9-12).—A survey made of the potato leafhopper populations and the amount of feeding by the adult flea beetle on 12 species of *Solanum* at McGuffey, Ohio, is reported upon. The rate of mortality of leafhopper nymphs on 4 species of *Solanum* was determined in laboratory feeding tests, as was the amount of feeding by adult flea beetles on 2 species of *Solanum*, both in 1938. *S. polyadenium* was found to be highly resistant, if not immune, to attack by the potato leafhopper, as were the 3 closely related species *S. chacoense*, *S. commersonii*, and *S. caldasii*. *S. bulbocastanum* revealed fair resistance to flea beetle attack, while *S. polyadenium* was highly immune. Only slight feeding by the adult flea beetles occurred on the latter species.

[Contributions on economic insects attacking trees and shrubs and their control] (*Bartlett Tree Res. Labs. Bul.* 3 (1939), pp. 28-39, 40-43, figs. 2).—Contributions presented include Holly Leaf Miner (*Phytomyza ilicicola* Loew) (pp. 28, 29) and Dogwood Club Gall *Mycodiplosis alternata* Felt (pp. 30-33), both by E. P. Felt and S. W. Bromley; Rhododendron Whitefly *Dialeurodes chittendeni* Laing (p. 34) and A Rhododendron Midge, *Giardomyia rhododendri* Felt (p. 35), both by E. P. Felt; and Aphids of Coniferous Trees (pp. 36-39), Tests With Wetting Agents for Arsenate of Lead (pp. 40-42), and Coloidal Arsenates of Lead (pp. 42, 43), all by S. W. Bromley.

Protecting shade trees from insect damage, W. P. FLINT and M. D. FARRAR. (*Illinois Sta. Cir.* 509 (1940), pp. 60, figs. 36).—A practical summary in which insect enemies of the more important shade trees are considered.

The silverfish in a new role, R. E. SLABAUGH. (Univ. Ill.). (*Ill. State. Acad. Sci. Trans.*, 32 (1939), No. 2, pp. 227, 228).—Report is made of the attack on rayon fabric, including curtains, knit underwear, and dresses, by the firebrat. This silverfish, unlike the true silverfish (*Lepisma saccharina*), flourishes in a temperature as high as 100° F. Its attack results in scraped areas or holes in the rayon fabric. An examination has shown rayon to be attractive, those fabrics containing sulfonated compounds varying in attractiveness with the amount of fatty material contained. Some of the finishing agents are also very eagerly sought and much more attractive than others. It is suggested that the pest be destroyed before increasing to injurious abundance; that it may be feasible to protect the fabric by the application of a protective proofing.

Summer sprays for control of the gladiolus thrips, E. I. MCDANIEL (*Michigan Sta. Quart. Bul.*, 23 (1940), No. 1, pp. 8, 9).—Brief reference is made to the results of experimental work and investigations of the gladiolus thrips by the U. S. D. A. Bureau of Entomology and Plant Quarantine and experiment stations which indicate that sprays using tartar emetic as the killing agent and brown sugar as the attractant are superior to other combinations. The author's experiments indicate that calcium antimony tartrate at the rate of 2 and 4 lb. plus 16 lb. of brown sugar per 100 gal. of water is nearly if not fully as effective as the tartar emetic formula recommended by the Bureau of Entomology and Plant Quarantine (E. S. R., 81, p. 242). "In 1939, both

tartar emetic and calcium antimony tartrate were checked on experimental plats at Michigan State College in comparison with (1) standard paris green, brown sugar formula, now in general use; (2) paris green 2 lb., brown sugar 64 lb., [and] water 100 gal.; and (3) for small dosages, 2 level tablespoonfuls paris green [and] 2 lb. brown sugar in 3 gal. of water. Better quality flowers, less injury to the foliage, together with from 10 to 15 percent more effective control of the gladiolus thrips, resulted from the use of either tartar emetic or calcium antimony tartrate than did the use of the paris green formula." Reference is also made to the value of nicotine, four applications of which, at intervals of from 48 to 72 hr., are required. Emphasis is placed upon the importance of cutting the tops of the corms as soon as possible, to prevent migration from wilting foliage thereto, and curing them in deep shade as far from the source of infestation as possible. They should be stored in a well-ventilated place at temperatures of 50°-40° F. through the winter and treated before planting to destroy any thrips that may remain.

A century of new American Thysanoptera, I, J. D. HOOD. (Cornell Univ.). (*Rev. Ent.*, 11 (1940), No. 1-2, pp. 540-583, fig. 1).—Descriptions are given of 10 new species from New York, 3 from Florida, and 1 each from Texas, Arizona, Cuba, and Peru.

Preliminary report on lubberly locust control, J. R. WATSON and H. E. BRATLEY (*Fla. Ent.*, 23 (1940), No. 1, p. 7-10).

Mitotic response of roach hemocytes to certain pathogenes in the hemolymph, O. E. TAUBER. (Iowa State Col.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 1, pp. 113-119, figs. 2).

Six new South American Tingitidae (Hemiptera), C. J. DRAKE and M. E. POOR (*Rev. Ent.*, 11 (1940), No. 1-2, pp. 226-231).

A quantitative study of the periodical cicada with respect to soil of three forests, E. J. STRANDINE (*Amer. Midland Nat.*, 24 (1940), No. 1, pp. 177-183, figs. 5).

Peach aphids, M. L. BOBB. (Va. Expt. Sta.). (*Va. Fruit*, 28 (1940), No. 3, pp. 22, 25).

A study of the variation of size within two species of aphides, G. H. L. DICKER and S. C. PEARCE (*Bul. Ent. Res.*, 31 (1940), No. 1, pp. 45-56, fig. 1).—Report is made of studies of *Macrosiphum rubiellum* Theob., a blackberry aphid, and *Aphis idaci* van der Goot which infests raspberries.

The ecology of aphids in a subtropical climate, F. S. BODENHEIMER (*6. Cong. Internat. Ent., Madrid, 1935, [I], Trabs.*, pp. 49-58, figs. 2).

Life-history of Pterochlorus persicae (peach-stem aphid), A. S. TALWAR (*Indian Sci. Cong. Proc. [Lahore]*, 26 (1939), pt. 3, p. 140).

Biological control of prickly-pear in the Palu Valley (N. Celebes) [trans. title], P. VAN DER GOOT (*Landbouw [Buitenzorg]*, 16 (1940), No. 7, pp. 413-429, pls. 4, fig. 1; *Eng. abs.*, pp. 428, 429).—Report is made of the introduction, commenced in December 1934, of the mealybug *Dactylopius tomentosus* Lam. as a means of combating the pricklypear (*Opuntia nigricans* (= *O. dilleni*)). This pest had become increasingly harmful in the Palu Valley, the abandoned rice fields and grazing country being rapidly covered by a dense growth. The first results obtained were observed as early as May 1936. By the end of 1939 the cactus had disappeared everywhere, giving place to new growth of lamtoro (*Leucaena glauca*), with many fields again being tilled or used for grazing purposes.

A contribution to the study of Pseudococcus comstocki in Palestine, H. Z. KLEIN and J. PERZELAN (*Hadar*, 13 (1940), No. 4, pp. 107-110, figs. 3).—A study of the biology of Comstock's mealybug, which first came to attention

in Palestine in August 1937, as reported by Bodenheimer (E. S. R., 80, p. 797), and has spread over a large territory and seriously attacked many groves, is reported upon. It was found that under laboratory conditions this mealybug has seven annual generations, although in the grove in the coastal zone there seem to be six generations as a rule. The life cycle from oviposition to maturity of hatched females lasts from 5 to 6 weeks in summer and up to 3 mo. in winter, with the males requiring from 2 to 14 days less for development. All varieties of citrus are favorable host plants. The period of development on potato is similar to that observed on citrus. In cases of severe attacks nearly half of the seasonal crop was affected. In such cases there was no blossoming at all in the following season or only very limited blossoming.

Factors influencing the development and control of scale insects on citrus, W. L. THOMPSON. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 52 (1939), pp. 104-111).—Experimental work has shown the purple and red scales to develop more rapidly following inert residue- and fungicidal-sprays than when such sprays are omitted. Trees supplied with certain elements such as zinc and magnesium in addition to the regular fertilizer are more favorable to purple scale development because of the higher percentage of green leaves and increased foliage which remains on the tree longer. Oil emulsion sprays at a concentration of from 1.25 to 1.5 percent of oil applied against the purple scale proved more effective than sulfur sprays, although the latter when thoroughly applied from three to four times a year have held light infestations in check.

Black scale control, A. M. BOYCE, J. F. KAGY, G. L. MCCALL, and J. P. LADUE. (Calif. Citrus Expt. Sta.). (*Calif. Citrog.*, 25 (1940), No. 10, pp. 314, 342-344).—This is a summary of work with low dosages of oil with rotenone-bearing materials, the details of which are given in three tables. It appears that greater effectiveness from the toxic principles of rotenone-bearing root is obtained when these toxic principles are extracted from the root and solubilized with oil than when the powdered root containing the toxic principles as they occur naturally is used. It is pointed out that low dosages of oil with rotenone-bearing materials are more effective on larger-sized black scale than the full dosage of oil, i. e., 1½ percent, alone. "Practical usage of low dosage oil with rotenone-bearing materials has demonstrated that such materials are of value in citrus pest control. However, there are important limitations to the general usage of such materials which are well known to those dealing with pest control on citrus."

The sycamore scale [*Stomacoccus platani* Ferris] and its control, R. H. SMITH (*Calif. Cult.*, 87 (1940), No. 20, p. 544).

The life history of the peach borer (*Synanthedon exitiosa* Say) in Ontario, T. ARMSTRONG (*Sci. Agr.*, 20 (1940), No. 10, pp. 557-565, pls. 2, figs. 2).—Report is made of a 4-yr. study of the bionomics and control of the peach borer, which has become increasingly troublesome throughout the peach-growing areas of the Niagara Peninsula and western Ontario. Two hymenopterous parasites were reared in the Niagara district in 1937 from peach borer cocoons, namely, *Microbracon sanninoideae* Gahan and *Phaeogenes ater* Cress., the parasitism in that year amounting to 2.5 percent.

Pecan foliage as food for the pecan nut casebearer (*Acrobasis caryae* Grote), S. O. HILL. (U. S. D. A.). (*Fla. Ent.*, 23 (1940), No. 2, pp. 27-29).—In experiments in which newly hatched larvae were placed on the under side of pecan leaflets they were found to consume the undersurface. Such larvae reared on leaves and twigs completed their growth in the same period as those reared on pecan nuts. The experiment explains to some extent why the pecan nut casebearer can survive in orchards when there are no nuts on the trees.

Observations of the tobacco budworm as an enemy of cotton in Peru [trans. title], J. E. WILLE (*Rev. Ent.*, 11 (1940), No. 1-2, pp. 584-588).

The use of electric light traps in the control of the European corn borer, G. A. FICHT, T. E. HIENTON, and J. M. FORE. (Ind. Expt. Sta. and U. S. D. A.). (*Agr. Engin.*, 21 (1940), No. 3, pp. 87-89, figs. 2).—In preliminary studies of the attraction of electric light traps (E. S. R., 82, p. 78) for the European corn borer a total wattage of 2,000 per acre resulted in the almost complete elimination of borer infestation within the lighted area. Later work has led to a reduction in the number of lamps used per unit area, with consequent reduction in the cost of installation and operation. Several factors appear to influence the number of moths captured at various traps or to have a bearing on the flight of the corn borer adults to lights, the most important of which appear to be the height of the corn under or surrounding the traps, the distribution of the traps, the height of the traps above the corn, the position of the traps with regard to the prevailing winds, and the height of the traps with regard to the topography or contour of the lighted area. Such influences are not easily segregated into individual factors, since the moths have probably been influenced by a combination of factors. Of these, the height of the corn under or in the immediate vicinity of the traps is thought to be the greatest single factor determining the flight of moths to traps of equal light output.

An account of *Diatraea saccharalis* F., with special reference to its occurrence in Barbados, R. W. E. TUCKER (*Trop. Agr. [Trinidad]*, 17 (1940), No. 7, pp. 133-138).—Presented with a list of 25 references to the literature.

Preliminary experiments with lead arsenate and calcium arsenate in combating the cotton leaf worm [trans. title], B. T. SNIPES (*Rev. Ent.*, 11 (1940), No. 1-2, pp. 501-532, figs. 7; *Eng. abs.*, pp. 531, 532).—The highest degree of control of the cotton leaf worm was obtained by dusting with equal parts of lead arsenate and sulfur, although the results of dusting with calcium arsenate and spraying with a 0.5 percent calcium arsenate solution were not statistically less efficient. Spraying with lead arsenate at 0.5 percent gave less control, and a 0.25-percent concentration of this insecticide was not satisfactory against this pest.

Investigations on the cotton bollworm (*Heliothis armigera* Hübn. (obsoleta Fabr.)).—II, The incidence of parasites in quantitative relation to bollworm populations in South Africa, F. S. PARSONS (*Bul. Ent. Res.*, 31 (1940), No. 1, pp. 89-109, figs. 4).—This contribution is in continuation of that noted (E. S. R., 82, p. 800).

Scientific survey of Porto Rico and the Virgin Islands.—Vol. XII, pt. 2, Insects of Porto Rico and the Virgin Islands: Moths of the family Noctuidae, W. SCHAUS (*New York: N. Y. Acad. Sci.*, 1940, pp. [2]+177-290).—This second contribution (E. S. R., 67, p. 573) deals with the synonymy and habitat of the noctuid moths of Puerto Rico and gives technical descriptions of many of the forms. Three genera are erected and 16 species described as new.

Mosquito control: Practical methods for abatement of disease vectors and pests, W. B. HERMS and H. F. GRAY (*New York: Commonwealth Fund; London: Oxford Univ. Press*, 1940, pp. XII+317, figs. 60).—Following an introduction, the subject of mosquito control is dealt with under the headings of economic importance of mosquitoes (pp. 11-21); laws and agencies for mosquito abatement (pp. 22-47); preliminaries to abatement procedures (pp. 48-66); education of the public (pp. 67-84); finding mosquito breeding places (pp. 85-100); abatement methods—general principles (pp. 101-109); drainage and reclamation of fresh-water marshes (pp. 110-133) and of salt-water marshes (pp. 134-158); filling, pumping, and flushing (pp. 159-164); oils and larvicides (pp.

165-199); methods of application of oils and larvicides (pp. 200-220); mosquito control by use of fish (pp. 221-229); supplementary protective measures (pp. 230-245); special features of mosquito control in urban areas (pp. 246-259) and in rural areas (pp. 260-275); and species sanitation and naturalistic control (pp. 276-287). The principal malaria-transmitting anophelines of the world are listed, with their regions of malaria transmission and typical breeding places, in an appendix (pp. 289-293). Additional appendixes consider the suggestive associations of mosquitoes grouped according to typical larval habitats (p. 294), a classification of mosquito abatement methods (pp. 295-297), and a selected list of books and articles on mosquito species and biology (pp. 298-303).

A comparative evaluation of paris green and pyrethrum emulsion as anopheline larvicides in Georgia: A progress report, J. M. HENDERSON and R. S. HOWARD, JR. (*Amer. Jour. Trop. Med.*, 20 (1940), No. 4, pp. 585-592).—It is concluded from the work conducted that pyrethrum-oil emulsion is a "competent anopheline larvicide, the efficiency of which varies directly with its rate of application. Under the conditions of observation, the materials cost of pyrethrum larvicide was from 10 to 15 times that of the amount of paris green-lime mixture required to produce equivalent mortality. It is likely that non-materials costs would increase this economic differential in favor of the paris green. The pyrethrum killed or injured numerous invertebrate mosquito predators, while paris green did not appear to have this effect."

Oviposition experiments with anopheline mosquitoes, M. BATES (*Amer. Jour. Trop. Med.*, 20 (1940), No. 4, pp. 569-583).—Observation on the behavior of mosquitoes in the laboratory and the distribution of eggs in nature is said to have convinced the author that the Albanian *Anopheles*, especially species of the *maculipennis* group, normally oviposit while hovering over the water. Field observations are said to have shown that the differences "between the larval habitats of various species are largely the direct result of selection of oviposition site by the adult females. *A. atroparvus* in laboratory experiments showed a pronounced preference for dark background colors in ovipositing and for water containing calcium. It seemed to be more or less indifferent to the sodium chloride content of the water. Experiments and observations on time of oviposition gave conflicting results, but seem to indicate that oviposition may depend on a combination of stimuli rather than on some single factor in the daily cycle of environmental changes."

A preliminary survey of the anopheline mosquito fauna of southeastern Minnesota and adjacent Wisconsin areas, R. H. DAGGY, O. J. MUEGGE, and W. A. RILEY (*Minn. Med.*, 23 (1940), No. 8, pp. 556-564, figs. 3).

The relation between the amount of arsenic a fish gets from mosquito-control dusting and the lethal dose, E. M. McCORMICK. (Ohio State Univ.). (*Jour. Tenn. Acad. Sci.*, 15 (1940), No. 3, pp. 342-351).—The tests reported do not show that arsenic from mosquito-control dusts is taken internally to any great extent by fish (*Gambusia* and catfish) in the wild. Fish experimentally exposed in the laboratory were thought to have died from factors other than arsenic poisoning.

The mosquitoes of Costa Rica, H. W. KUMM, W. H. W. KOMP, and H. RUIZ (*Amer. Jour. Trop. Med.*, 20 (1940), No. 3, p. 385-422, figs. 2).—A survey made of the mosquito population of Costa Rica, in which 14,961 adult mosquitoes and 9,743 larvae, representing 93 species, were examined, is reported upon.

The juniper midge *Contarinia juniperina* Felt, a pest of red cedars, R. L. PARKER and O. E. WENGER. (Kans. Expt. Sta.). (*Jour. Kans. Ent. Soc.*, 13 (1940), No. 2, pp. 46-50, figs. 2).—The so-called juniper midge, the newly described species *C. juniperina* (E. S. R., 81, p. 682), is reported to have been a

source of injury to the terminal growth of red cedars in various localities of Kansas during the years 1935-39. Its injury was first attributed to winter drought or dry freezing of immature growth. A description of several stages of the insect and notes on its biology are given. The midge hibernates in the injured twigs or surface soil beneath infested trees. Soil fumigants, ethylene dichloride emulsion, dichloroethyl ether, and paradichlorobenzene, applied during the early spring to infested soil, either bare or covered with needles, gave effective control of such hibernating insects. Its natural enemies include an undescribed hymenopterous parasite of the genus *Platygaster*, great numbers of which were observed.

The gall midges attacking the seed-heads of cocksfoot (*Dactylis glomerata* L.), H. F. BARNES (*Bul. Ent. Res.*, 31 (1940), No. 1, pp. 111-119, pls. 2).—An account is given of four gall midges, the larvae of which damage the seed of cocksfoot grass, namely, *Contarinia dactylidis* (H. Lw.), *Dasyneura dactylidis* Metc., *Sitodiplosis dactylidis* n. sp. (described from England and Ireland), and *Stenodiplosis geniculati* Reut., a well-known pest of foxtail grass. A new variety, *S. geniculati dactylidis*, is described from cocksfoot in New Zealand. The occurrence of predaecous midges of the genus *Lestodiplosis* is also noted.

Two new pests of apple and black currant, H. F. BARNES (*Bul. Ent. Res.*, 31 (1940), No. 1, pp. 85-87, pl. 1).—The apple blossom midge *Contarinia mali* Barnes, recently reported as attacking apple blossoms and preventing fruit formation in Japan, and the black currant flower midge *Dasyneura ribis*, which attacks black currant flowers in Finland, are noted, the latter being described as new to science.

Three new western Simuliidae (Diptera), G. S. STAINS and G. F. KNOWLTON. (Utah Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 1, pp. 77-80, fig. 1).—Three species of bloodsucking flies collected in Utah, described as new to science, are *Simulium (Simulium) twinni*, *S. (Eusimulium) hardyi*, and *S. (Eusimulium) flaviantennus*.

New midwestern Dolichopodidae (Diptera), F. C. HARMSTON and G. F. KNOWLTON. (Utah. Expt. Sta.). (*Jour. Kans. Ent. Soc.*, 13 (1940), No. 2, pp. 58-61, figs. 9).—Three species of dolichopodids are described as new, namely, *Argyra similis* and *Rhaphium rossi* from Illinois and *Chrysotus chlanoflava* from North Dakota.

Tachytrechus studies (Dolichopodidae, Diptera), F. C. HARMSTON and G. F. KNOWLTON. (Utah Expt. Sta.). (*Canad. Ent.*, 72 (1940), No. 6, pp. 111-115, figs. 5).—A key is given to the males of North American *Tachytrechus*, and two species, *T. utahensis* from Utah and *T. tahoensis* from California, are described as new.

The Tabanidae of the Antilles (Dipt.), J. BEQUAERT (*Rev. Ent.*, 11 (1940), No. 1-2, pp. 253-369, figs. 34).—A revision of the dipteran family Tabanidae (horseflies, deer flies, etc.) of the Antillean region, the Caymans, Bahamas, and the Bermudas. Eleven new species are described.

The Sarcophaginae and their relatives in New York, I, H. C. HALLOCK. (Pa. State Col.). (*Jour. N. Y. Ent. Soc.*, 48 (1940), No. 2, pp. 127-153, figs. 97).—This account of the muscoid Diptera of the subfamily Sarcophaginae includes a key to the genera and a list of references to the literature.

Notes on Oklahoma bot flies, G. W. EDDY and K. C. EMERSON. (Okla. A. and M. Col.). (*Jour. Kans. Ent. Soc.*, 13 (1940), No. 2, pp. 44, 45).—Unpublished records of specimens of three species of Gasterophilidae (the horse botfly, the throat botfly, and *Gastrophilus inermis* Brauer), the common cattle grub, and two Cuterebridae (*Cuterebra cuniculi* (Clark) and *C. (Bogeria) buccata* (Fab.)) are presented, together with observations of *C. (Bogeria) buccata*.

The medication of cattle for the control of horn flies, W. G. BRUCE. (U. S. D. A.). (*Jour. Kans. Ent. Soc.*, 13 (1940), No. 2, pp. 41-43).—This further contribution (E. S. R., 82, p. 362) summarizes the general results of 68 tests of 29 chemicals, in which 4 gave a 100 percent kill of the hornfly larvae in the droppings of cattle. Of these azobenzene, 2,4-dinitrophenylhydrazine, and phenothiazine are considered unsuitable for practical use. "The chemicals were administered by mouth, either mixed with the bran or in water or in a capsule. Rotenone was effective in much smaller doses than any other chemicals and had no apparent harmful effect on the animal. The minimum dose of rotenone that killed all hornfly larvae was 0.4 gm. per hundredweight. The droppings voided during a period of approximately 30 hr., beginning less than 10 hr. after administration of this dose, were rendered unfavorable for the development of hornfly larvae. The minimum effective dose is 0.3 gm. per hundredweight administered daily. A few flies emerged from droppings of cattle fed this dosage, but they were so small and weak that they probably would be unable to reproduce. . . . Phenothiazine was effective in doses as small as 1 gm. per hundredweight but had the undesirable quality of imparting reddish tinge to the milk of cows. Furthermore, in doses of 2.25 gm. or more per hundredweight this chemical produced certain physiological disturbances as indicated by the loss of appetite, gaunt appearance, dullness of the eyes, and nervousness."

The prevention and treatment of blowfly strike in sheep.—Report No. 2, L. B. BULL ET AL. (*Austral. Council Sci. and Indus. Res. Pam.* 98 (1940), pp. [1]+45, figs. 19).—This second report (E. S. R., 69, p. 557) considers measures to reduce (1) inherent predisposition, (2) immediate susceptibility, and (3) fly abundance. The treatment of strike is briefly considered. A list is given of 27 references to the literature.

Further studies on *Rhagoletis pomonella* (Walsh), A. D. PICKETT and M. E. NEARY (*Sci. Agr.*, 20 (1940), No. 10, pp. 551-556).—In continuation of earlier studies of the apple or blueberry maggot by Pickett (E. S. R., 77, p. 666) the authors report experiments which have proved the progeny from a cross of apple and blueberry forms to be fertile. The progeny of a cross of hawthorn and apple flies also proved to be fertile. One pupa was obtained from 80 hawthorn flies confined on snowberry (*Symphoricarpos racemosus*), this being the only fruit other than apple (in which they oviposit quite readily and the larvae develop to maturity) that the authors have been able to induce the hawthorn flies to oviposit in. It is quite possible that the failure of the flies to oviposit in blueberry is due to their late emergence. The present and earlier findings published show that adults reared in apple possess a considerable amount of adaptability in respect to hosts, producing offspring which developed to the mature larval stage in blueberry, hawthorn, pear, plum, mountain-ash, snowberry, and sweet cherry. To these, tomato, sour cherry, and *Cornus amomum*, reported by Hall (E. S. R., 82, p. 647), should be added. It is considered quite likely that the pest can develop in the cranberry.

The seed-corn maggot, a pest of red cedar seedlings, B. H. WILFORD. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 8, pp. 658, 659).—Report is made of the finding of the seed-corn maggot's seriously injuring young seedlings of red cedar (*Juniperus virginiana* L.) in the Wilson County cedar nursery near Lebanon, Tenn., in 1938. Reported as infesting larch roots as early as 1918, and its presence noted in acorns and peach seedlings, it had not been recognized as causing serious injury to forest seedlings previous to 1938. Examinations of an infested cedar stem just below the ground line reveals one or more maggots

attacking the roots or boring through and beneath the thin bark of the stem. From their points of entry the maggots feed up the stem to a short distance above the ground and down into the roots. They eat the soft tissue beneath the bark, often leaving a slender woody core encased in lacerated bark. Rapid disintegration of damaged but undevoured soft parts of the roots and stems follows. "The shredded bark and damaged roots are distinguishing evidence of maggots feeding, even after the insects have matured and emerged. Where the lateral roots only are damaged and the tap root is uninjured, or only lightly injured, adventitious root buds develop. If conditions favorable for growth prevail, new roots are formed and some damaged plants recover." Attention is drawn to the damage to cedar seedlings by the generally unhealthy appearance of the extremely young plants. This is followed by wilting and yellowing of the stems at and above the ground line. "Preliminary tests indicate that satisfactory control can be obtained with miscible carbon disulfide applied to the soil when the maggots are feeding. The carbon disulfide (50-percent strength) should be diluted with water (1 qt. of the stock chemical to 50 gal.) and sprinkled evenly on the soil at the rate of 1 pt. per square foot of surface. The chemical apparently causes no injury to cedar seedlings."

New genera and species of lady-beetles related to *Serangium* Blackburn (Coleoptera: Coccinellidae), E. A. CHAPIN (*Jour. Wash. Acad. Sci.*, 30 (1940), No. 6, pp. 263-272, figs. 24).—The genera *Catana* and *Serangiella* are erected, and several species of economic importance, namely, *Delphastus nebulosus* from Puerto Rico, *D. collaris* from the Canal Zone, *C. clauseni* from Sumatra, Federated Malay States, and Cuba, *Serangium japonicum* from Japan and China, *S. comperei* from the Fiji Islands, and *S. bakeri*, *S. luzonicum* and *S. metasternalis* from the Philippine Islands, are described as new.

Bionomics of two coccinellids, *Adonia variegata* Goetz. and *Brunus suturalis* F., predated on aphids, A. P. KAPUR (*Indian Sci. Cong. Proc.* [Lahore], 26 (1939), pt. 3, pp. 146, 147).

Preliminary report on wireworm investigations in the Everglades, J. W. WILSON. (Fla. Expt. Sta.). (*Fla. Ent.*, 23 (1940), No. 1, pp. 1-6).—In wireworm investigations in the Florida Everglades, *Melanotus communis* Gyll., the Gulf wireworm, *Glyphonyx recticillis* (Say.), *Aeolus dorsalis* Say., *Dolopius* sp., and *Conoderus* sp. were found present. *M. communis*, the species studied, is the source of severe injury to the four major crops of the area, namely, sugarcane, celery, peppers, and potatoes. Life history studies, commenced in April 1939, show that this species is capable of completing its life cycle in 1 year's time in south Florida, but all stages are likely to be found at any time during the year, and it is capable of surviving for long periods of time without moisture on the muck soil. The results of seedbed treatment with soil fumigants, the wireworm population in cover crop plats, and the increase in wireworm population after summer cover crop and fallow treatment are presented in tables.

A key to the species of Ptinidae occurring in dwellings and warehouses in Canada (Coleoptera), W. J. BROWN (*Canad. Ent.*, 72 (1940), No. 6, pp. 115-122).

Meal beetle larvae as intermediate hosts of the poultry tapeworm *Railletina cesticillus*, G. W. LUTTERMOSER. (U. S. D. A.). (*Poultry Sci.*, 19 (1940), No. 3, pp. 177-179).—The author reports having successfully experimentally infested the larvae of the red flour beetle and the confused flour beetle with the common chicken tapeworm *R. cesticillus*. "Pupae and adult insects developing from infected beetle larvae were also found to be infected with cysticercoids of *R. cesticillus*. Evidence is presented to show that the process

of metamorphosis of the beetles from larvae to pupa, or pupa to adult, does not destroy all of the cysticeroids present. The larvae became infected when offered the gravid segments of *R. cesticillus* in the presence of either a large or a small amount of food, such as bran."

A comparative study of the larvae of six species of *Silpha* (Coleoptera, Silphidae), C. K. DORSEY. (Md. Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 1, pp. 120-139, figs. 58).

Is our bee pasture changing? H.-F. WILSON (*Amer. Bee Jour.*, 80 (1940), No. 6, p. 260, figs. 2).

A new species of *Pseudogonatopus* (Hymenoptera: Dryinidae), H. E. BROWN. (Univ. Mo.). (*Ent. News*, 51 (1940), No. 1, pp. 10, 11, fig. 1).—Under the name *P. magnus*, a description is given of a new dryinid from Indiana which, because of its large size, is thought to be a parasite of the larger fulgorids.

Do *Habrobracon* females sting their eggs? A. R. WHITING (*Amer. Nat.*, 74 (1940), No. 754, pp. 468-471).—The studies reported led to the conclusion that either (1) females sting eggs very rarely or (2) stung eggs can continue development after such injury, and (3) that normal cleavage and even blastoderm formation are no indication of ultimate hatching.

Studies on the Ichneumonidae of New England (Hymenoptera).—I, The external morphology of *Arotus amoenus* Cresson, H. D. PRATT (*Jour. N. Y. Ent. Soc.*, 48 (1940), No. 2, pp. 155-193, figs. 19).—The external morphology of *A. amoenus*, one of the larger and more primitive of the ichneumon flies and common throughout New England, is reported upon.

The African species of *Metaphycus* Mercet, H. COMPERE. (Calif. Citrus Expt. Sta.). (*Bul. Ent. Res.*, 31 (1940), No. 1, pp. 7-33, figs. 4).—Seventeen of the 23 recognized African species of Hymenoptera of the parasitic genus *Metaphycus* are described as new.

The introduction of an indigenous blowfly parasite *Alysia ridibunda* Say into Uvalde County, Texas, A. W. LINDQUIST. (U. S. D. A.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 1, pp. 103-112).—Studies of the blowfly braconid parasite *A. ridibunda*, discovered by the author in southern Arizona and New Mexico and recorded in 1932 (*E. S. R.*, 67, p. 558), and known to occur generally over the eastern portions of the United States and in parts of Canada, are reported. Laboratory rearing revealed the duration of the immature stages to be from 19 to 350 days. Reared in the laboratory, a total of 50,221 adults were released in Uvalde County in the fall of 1934 and the spring of 1935. By July 1, 1935, it had "built up a tremendous population and was found on practically every carcass and small piece of carrion. The parasitization of blowfly larvae by *A. ridibunda* ranged up to 100 percent, with an average of 37.1 percent from April 1 to September 21, as indicated by exposure in pint jars of 4-oz. meat baits infested with blowfly larvae. During 1936 the parasite diminished greatly in numbers, in 1937 only two specimens were seen, and in 1938 only three were observed. In 1935 the parasite emerged from 80.9 percent of *Sarcophaga* larvae and from 10.4 percent of the *Lucilia* larvae collected in the field in that year. This indicated that *Sarcophaga* was a preferred host. No emergence occurred from other species of blowfly larvae. The parasite oviposited on larvae of the [secondary] screwworm *Cochliomyia americana* in the laboratory, but both host and parasite succumbed. The examination of approximately 300 cases of myiasis in domestic animals failed to reveal the parasite working on larvae in wounds, but adults oviposited in larvae of *C. americana* in wounds on guinea pigs in the laboratory and both the host and parasite larvae died. Dispersion from the release area in 1935-36 proceeded farther west-

ward than in other directions and greater numbers occurred in that direction. The point of recovery farthest from the point of release was 27 miles to the west. The causes for the remarkable increase in the population of *A. ridibunda* shortly after its release and the subsequent marked decrease are not fully understood."

Host selection by hymenopterous parasites of the moth *Plutella maculipennis* Curtis, D. C. LLOYD (*Roy. Soc. [London], Proc., Ser. B, 128 (1940), No. 853, pp. 451-484, pls. 2, fig. 1*).—An investigation being made of the incidence in the laboratory and field of superparasitism and multiparasitism in the primary parasites of the diamondback moth, dealing mainly with *Diadromus collaris* Grav., *Angitia cerophaga* Grav., and *Apanteles plutellae* Kurdj., is reported upon. A list of 21 references to the literature is included.

The life-history and morphology of *Euderus livida* (Ashmead), a larval parasite of the tur-pod fly *Agromyza obtusa*, T. AHMAD (*Indian Sci. Cong. Proc. [Lahore], 26 (1939), pt. 3, pp. 140, 141*).

Hymenopterous parasites of willow insects, E. M. CALLAN (*Bul. Ent. Res., 31 (1940), No. 1, pp. 35-44, figs. 2*).—Eight Ichneumonoidea, 14 Chalcidoidea, and 6 Proctotrupeoidea are recorded as parasites of willow-infesting insects. The majority of records are of parasites reared from insects inhabiting the wood of the cricket-bat willow (*Salix alba caerulea*), "the more important being *Torymus pulchellus* Thoms., *Tridymus salicis* Nees, *Eupelmus urozonus* Dalm., *Microterys clavellatus* Dalm., *Tetrastichus roesellae* DeG., *T. inunctus* Nees, *T. flavovarius* Nees, *T. ? acuminatus* Ratz. and *Platygaster* sp. *M. clavellatus* is recorded for the first time as a parasite of Cecidomyiidae. Evidence is given for the separation of the gall midges *Rhabdophaga* sp. and *R. saliciperda* Duf. as distinct species, based both on structural differences and on a study of their parasites, for the three parasites found most commonly attacking *Rhabdophaga* sp. were never bred from *R. saliciperda*, and the most common species parasitizing *R. saliciperda* was never obtained from *Rhabdophaga* sp. It is confirmed that *Eurytoma salicis* Thoms. supplements its animal diet with vegetable food. The rate of parasitism of *Euura atra* Jur. by *Eurytoma salicis* is given as 19.8 percent and that of *Rhabdophaga* sp. by *Platygaster* sp. as 40.5 percent. Histograms are given of *Rhabdophaga* sp. and its parasites *Torymus pulchellus*, *Tetrastichus roesellae*, and *Platygaster* sp., the emergence of *Platygaster* sp. coinciding approximately with that of its host. Histograms are given of *Euura atra* and its parasite *Eurytoma salicis*, the emergence of which did not start until that of its host was practically complete."

Biological notes on Indian parasitic Chalcidoidea, H. S. PRUTHI and M. S. MANI (*Imp. Council Agr. Res. [India], Misc. Bul. 30 (1940), pp. [1]+44, pls. 22*).—In this commencement of a series of biological notes in which Chalcidoidea are dealt with, it is stated that about 450 parasitic species have been recorded thus far from India, of which, in the case of about 175, hosts are known and described in this bulletin. It is pointed out that certain families of the tribe, including Agaonidae, Torymidae (part), and Eurytomidae (part), etc., are phytophagous and are not dealt with. A host-parasite index, arranged by orders, a list of references, and an index to the parasites are included.

The black wheat-stem sawfly, J. S. HOUSER (*Ohio Sta. Bimo. Bul. 206 (1940), p. 151, fig. 1*).—Observations in 1940 of the black wheat-stem sawfly (E. S. R., 80, p. 236), first discovered in the wheatfields of eastern Ohio in 1934, revealed but little advance in its spread westward. There was a sharp decline in the intensity of infestation, particularly in the older territory, as evidenced by the 1-percent infestations recorded in the counties of Mahoning,

Columbiana, and Carroll, where in 1936 in the first mentioned there had been an infestation of 65 percent of all wheat examined and in the latter 2 an infestation of 68 percent. The percentage of wheat infested in the 18 counties surveyed is indicated on an accompanying map.

A "ticktorium" for the propagation of a colony of infected *Ornithodoros turicata*, V. T. SCHUHARDT (*Jour. Parasitol.*, 26 (1940), No. 3, pp. 201-206, figs. 4).

ANIMAL PRODUCTION

[Animal production and poultry studies in the Southern States] (*Assoc. South. Agr. Workers Proc.*, 41 (1940), pp. 88-94, 94-101, 104, 105, 108-110, 210-212, 213-219).—Abstracts of the following papers presented at Birmingham, Ala., February 7-9, 1940, are included: Grass-Fed or Grain-Fed Beef—What's the Difference, by R. E. Hunt (Va. Expt. Sta.); Year-Round Grazing and Hogging-off Program for Hogs, by B. L. Southwell (Ga. Coastal Plain Sta.); Harvesting Crops With Livestock in the South, by C. I. Bray (La. Sta.); Roughage Problems With Special Emphasis on Quality, by E. O. Pollock, and Hay Problems With Emphasis on Quality, by A. D. Harlan (both U. S. D. A.); The Horse and Mule Outlook, by M. P. Jarnagin (Univ. Ga.); How Can the Small Farmer Be Induced to Become Feed Conscious and Livestock Minded? by R. S. Sugg; "Livestock Wintering Problems," by G. W. Barnes (Tex. A. and M. Col.); The Influence of Corriedale, Southdown, and Hampshire Breeding in Lamb and Wool Production, by H. H. Leveck (Miss. State Col.); Curing, Care, and the Storage of Meat on the Farm, by J. B. Francioni, Jr. (La. State Univ.); Poisonous Plants as a Problem in Southern Livestock Production, by E. V. Smith (Ala. Sta.); Microscopical Analysis and Effective Feed Control, by D. S. Coltrane; Fats in the Dairy Ration, by G. H. Wise (S. C. Sta.); Mineral Matter in Mixed Dairy Feeds, by P. T. D. Arnold and R. B. Becker (Fla. Sta.); "Value of Poultry Houses," by D. F. King, and Summer Green Feeds for Poultry, by G. J. Cottier (both Ala. Polytech. Inst.); The Effect of Feeding Upon the Interior Quality and Hatchability of Eggs, by H. J. Davis, and The Hatcheryman—A Key to Improved Poultry in the South, by C. W. Upp (both La. State Univ.); Alabama Poultry Improvement Project, by R. B. Jones; How a Certified Hatchery Can Improve the Quality of Poultry on Southern Farms, by P. A. Raper; Florida Poultry Problems, by D. F. Sowell; Georgia Poultry Problems, by A. Gannon (Univ. Ga.); Important Poultry Problems in Kentucky, by W. M. Insko, Jr. (Univ. Ky.); Poultry Problems in Mississippi, by G. R. Sipe (Miss. State Col.); Poultry Problems in South Carolina, by P. H. Gooding; and Important Poultry Problems of Arkansas, by R. M. Smith (Univ. Ark.).

[Livestock investigations in Indiana] (*Indiana Sta. Rpt. 1939*, pp. 10, 11, 15, 16, 23, 29, 38, 51-54, 102, 103, 104, 105).—In addition to a brief recital of outstanding research accomplishments in animal and poultry husbandry during the preceding decade, and notes on the calcium-phosphorus ratio for chicks and swine, meat meals for swine, and ground soybeans for calves, progress results are presented for the following lines of investigation: The value of mixed shelled corn and ground ear corn for fattening calves, cottonseed meal v. soybean oil meal for calves, the effect of varying the level of soybean oil meal as supplement to rations for fattening calves, the value of corn silage in the fattening ration, and the relative returns secured from the fattening of spring and fall calves, all by F. G. King; the need of legume hay in the winter ration of breeding ewes, the value of lime and protein supplements to

nonleguminous roughage for ewes, deleterious effect of iodine supplement in lamb rations, and long v. cut legume hay for fattening lambs, all by C. Harper; the effect of hominy feed on the quality of pork, nutritive value and mineral deficiencies of soybeans and soybean products for swine, and the effect of different kinds of fat in the ration on the character of fat formed in the hog, all by C. L. Shrewsbury and C. M. Vestal; comparison of protein mixtures for growing and fattening hogs and for brood sows, by Vestal; the vitamin A activity of carotene in different vegetable fats, by H. R. Kraybill, Shrewsbury, and F. P. Zscheile; and the influence of the ration on which hogs were fattened and the influence of type and finish on carcass and product grades, by J. R. Wiley.

From investigations with poultry, results are noted on the effect of ultra-violet irradiation on growth of chicks, by R. E. Roberts, T. E. Henton, and J. M. Fore; the utilization of fat by chickens, by D. Whitson, S. M. Hauge, C. W. Carrick, and Roberts; alfalfa leaf meal as a substitute for wheat by-products in broiler rations, by Roberts and Carrick; the use of dried skim milk and of soybean products in laying rations, and the value of electric lights for turkeys, all by Carrick; and starting and growing rations for turkeys, by Roberts.

Reactions of animals to environmental temperature, humidity, and air movement, S. BRODY. (Mo. Expt. Sta.). (*Agr. Engin.*, 21 (1940), No. 7, pp. 265-268, figs. 9).—A discussion of the thermoregulatory mechanism of sweating and nonsweating species of animals and the response of members of these respective species to varying atmospheric conditions.

Importance of quality of protein, L. C. NORRIS. (Cornell Univ.). (*Flour & Feed*, 41 (1940), No. 4, pp. 5, 6, 30, 31, 33).—A general discussion, including data on the amino acid composition and the biological value of numerous feed proteins.

The riboflavin content of certain hays and grasses, C. H. HUNT and R. M. BETHKE. (Ohio Expt. Sta.). (*Jour. Nutr.*, 20 (1940), No. 2, pp. 175-180).—Employing the rat-growth bio-assay technic, samples of the oat plant, the wheat plant, and bluegrass, representing one stage of maturity, and samples of alfalfa and timothy, representing two stages of maturity, were assayed for riboflavin content. The oat plant cut at the 10-in. growth stage and cured in subdued light was highest in riboflavin, with an estimated content of 26 μ g. per gram, followed by wheat (10-12-in. height) 17, timothy (before heading) 17, alfalfa (before bloom) 16, alfalfa (beginning to bloom) 12, timothy (in head before bloom) 12, and bluegrass (beginning to head) 10. Alfalfa exposed to strong sunlight for 48 hr. after cutting lost approximately 25 percent of its riboflavin content.

Chemical changes in phosphoric acid silage, E. PAGÉ and L. A. MAYNARD. (Cornell Univ.). (*Indus. and Engin. Chem.*, 32 (1940), No. 8, pp. 1140-1143, figs. 2).—A mixed crop, consisting of 62.2 percent clover, 19.8 alfalfa, 16.2 grasses, and 1.8 percent weeds, was ensiled in a tower silo 12 ft. in diameter. Phosphoric acid was added at varying rates to layers of the green material, the layers being separated by waterproof rubber sheets. Layers 1 to 7 (order of filling) received 20, 16, 8, 0, 16, 8, and 20 lb. of phosphoric acid per ton, but contained, as analyzed, 24, 11, 7, 0, 15, 9, and 20 lb. per ton, while the pH of the outgoing silage was 3.73, 4.05, 4.1, 4.23, 4.2, 4.46, and 4.3, respectively. Silage of good odor and appearance resulted in each instance. Of the two layers which received the same amount of acid, the lower one of each pair had a lower pH and contained less ammonia and more lactic acid, indicating that layers under higher pressure attained an anaerobic condition more rapidly than

the upper ones. The layer receiving no acid contained the highest amount of ammonia, despite its relatively high lactic acid content. From the data obtained on nitrogen distribution, volatile acid content, and residual acidity, it is concluded that while phosphoric acid is of definite value as a preservative its action must be supplemented by a strong lactic acid production for best results.

Commercial feeding stuffs—report on inspection, 1939, E. M. BAILEY (*Connecticut [New Haven] Sta. Bul. 436 (1940), pp. 349-450*).—This is the usual report of the guaranteed and found analyses of 849 samples of feeding stuffs collected for official inspection during the calendar year 1939 (E. S. R., 81, p. 691); assays of 45 vitamin D carriers, by R. B. Hubbell and Bailey; and 89 samples examined for poisons, by C. E. Shepard and Bailey.

Commercial feeding stuffs, H. R. KRAYBILL ET AL. (*Indiana Sta. Cir. 255 (1940), pp. 42, fig. 1*).—This circular presents the 1939 report (E. S. R., 81, p. 825) on registration and analyses of 3,380 samples of commercial feeding stuffs, together with information concerning the State law and regulations, suggestions for purchasers, official definitions of feeding-stuff ingredients, etc.

The adsorption of the vitamin A suppressing factor from soybean oil, S. M. HAUGE, J. H. HILTON, and J. W. WILBUR. (*Ind. Expt. Sta.*). (*Jour. Dairy Sci., 23 (1940), No. 8, pp. 719-723*).—In an effort to remove the vitamin A-suppressing factor from crude soybean oil (E. S. R., 77, p. 388) it was treated with two adsorbents, one of which, Nuchar, removed the factor from the oil by adsorption rather than inactivation, while the other, a special sodium aluminum silicate compound, was without effect. It was not possible to elute with acetone the active principle adsorbed on Nuchar.

Experimental studies on diets deficient in vitamin B and their influence on the intestinal yeast flora of animals, I. FROILANO DE MELLO (*Indian Acad. Sci. Proc., 11 (1940), No. 6, Sect. B, pp. 225-235*).—White rats, hens, rabbits, and pigeons were each confined to a diet of polished rice until symptoms of B avitaminosis occurred. Under such feeding regime the number of intestinal yeasts markedly increased and continued to increase as the animals became weaker. After return to normal feeding the yeast infestation gradually decreased to the level of the normal state of health.

Phosphorus metabolism in the musculature of dystrophic vitamin E-deficient rats, G. D. LU, G. A. EMERSON, and H. M. EVANS. (*Univ. Calif.*). (*Amer. Jour. Physiol., 129 (1940), No. 2, p. 408*).—Chemical studies were made of the musculature of a hind limb of 11 adult rats rendered dystrophic from vitamin E deficiency and also of that of 7 normally fed animals. The affected musculature showed slightly less inorganic phosphorus, no change in creatine phosphate, and a marked decrease in total acid-soluble phosphate and in total phosphate. The ratio of creatine-phosphate-phosphorus to total acid-soluble phosphorus was increased. A marked decrease in the ability of the affected musculature to phosphorylate glycogen was apparent.

Pasture studies.—XVII, The relative ability of steers and rabbits to digest pasture herbage, E. W. CRAMPTON, J. A. CAMPBELL, and E. H. LANGE (*Sci. Agr., 20 (1940), No. 9, pp. 504-509*).—Continuing these investigations (E. S. R., 83, p. 383), the results of four comparisons of the digestibility of dried pasture herbage clippings by steers and by rabbits are summarized. The rabbits digested dry matter only 71 to 85 percent as efficiently as the steers and their digestion coefficient were lower for every nutrient. Ratios between digestion coefficients for each fraction and dry matter digestibility indicated that, relatively, rabbits digested the crude protein of their diets consistently better, and crude fiber, total carbohydrates, cellulose, and lignin or organic matter less efficiently than did the steers. It is concluded that the digestibility of carbohydrate fractions isolated by the present feeding stuffs analysis is not predictable for one

species from the behavior of the other. Methods by which the rabbit might be successfully used as a pilot animal in pasture studies are discussed.

The composition and nutritive value, when fed to ruminants, of pea-pod meal and broad-bean-pod meal, H. E. WOODMAN and R. E. EVANS (*Jour. Agr. Sci. [England]*, 30 (1940), No. 2, pp. 189-201).—Data are presented on the chemical composition of pea pod meal and broad bean pod meal prepared from the artificially dehydrated pods and the digestion coefficients of these two products obtained by digestion trials with sheep. On a dry-matter basis the pea pod meal and bean pod meal, respectively, contained 10.82 and 11.17 percent digestible crude protein, 0.94 and 0.62 percent digestible ether extract, 46.12 and 44.81 percent digestible nitrogen-free extract, and 10.63 and 10.37 percent digestible crude fiber, with starch equivalents of 60.94 and 59.58. Both products are considered desirable constituents in the rations of sheep and cattle.

Wheat to meat is hard to beat, D. E. RICHARDS. (Oreg. Expt. Sta.). (*East. Oreg. Wheat League Proc.*, 12 (1939), pp. 22-27).—A general discussion of the value of wheat for sheep, cattle, and swine under eastern Oregon conditions.

Calcium and phosphorus deficiencies in cattle and horses: Clinical picture, treatment, and prevention, H. SCHMIDT. (Tex. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 96 (1940), No. 757, pp. 441-458, fig. 1).—A review, with 74 references.

The influence of atmospheric temperature upon haemoglobin and other constituents of the blood of cattle, M. MANRESA, N. C. REYES, F. GOMEZ, L. P. ZIALCITA, and P. R. FALCON (*Empire Jour. Expt. Agr.*, 8 (1940), No. 30, pp. 97-100).—An investigation by the University of the Philippines with Indian Nellore cattle revealed a negative correlation between the hemoglobin index of blood and atmospheric temperature. In an intensive study of the blood of purebred Holstein, pure Indian Nellore, and F₁ Holstein × Nellore crossbreds, it was found that the hemoglobin content, red blood cell count, specific gravity of the blood, and phosphorus-calcium ratios in the blood serum bore a direct positive correlation to the ability of the animals to adapt themselves to existing temperature conditions, while uric acid, serum phosphate, and size of red blood cells were inversely related to adaptability. It is concluded that temperature is the most important limiting factor in the Philippines in the raising of cattle and also other classes of animals imported from temperate countries, and that success with such animals is almost impossible.

Bionomic studies on indigenous and exogenous cattle in the semi-arid regions of the Union of South Africa, J. H. R. BISSCHOP (*Empire Jour. Expt. Agr.*, 8 (1940), No. 30, pp. 138-147).—Since 1925 an experiment has been in progress in which foundation groups of indigenous nondescript cows and heifers have been systematically graded up with purebred Africander, Friesian, Red Poll, and Sussex bulls, respectively, representing the indigenous, dairy, dual-purpose, and beef types of cattle. At present the herd consists mainly of $\frac{7}{8}$ - and $\frac{15}{16}$ -bred animals. Data on prevailing environmental conditions, body conformation, milk and beef production, and reproduction of the experimental groups, and the characteristics of their blood, skin, and hair are each briefly summarized. The indigenous grades have maintained themselves phenotypically for three generations, but comparable groups of exogenous grades have failed to do so.

The comparative digestive powers of zebu and high-grade European cattle, M. H. FRENCH (*Jour. Agr. Sci. [England]*, 30 (1940), No. 3, pp. 503-510).—This report from the veterinary laboratory, Tanganyika Territory, indicates no significant difference in the ability of zebu cattle and grade (zebu × Ayrshire) cattle to digest native feeding stuffs.

A comparison of shelled corn, ground shelled corn, and ground snapped corn for winter-finishing baby beeves, M. JACOB, H. R. DUNCAN, L. R. NEEL, and B. P. HAZLEWOOD (*Tennessee Sta. Cir. 69 (1940), pp. 4, fig. 1*).—A summary is presented for six trials comparing shelled corn, ground shelled corn, and ground snapped corn, each fed with cottonseed meal, alfalfa, or mixed hay, and corn or sorghum silage for the winter finishing of baby beeves. Average daily gains of 1.8, 1.85, and 1.68 lb. per head and net profits per bushel of corn fed of 43, 36, and 42 ct. were obtained on the shelled corn, ground shelled corn, and ground snapped corn rations, respectively. Satisfactory slaughter calves were produced on each of the rations over a 180-day feeding period. Much larger pork gains per steer were secured on the shelled corn ration. It is suggested that machinery available, costs of the various operations, and the relative price of hogs and cattle should be the governing factors in choosing between shelled corn and ground snapped corn.

Studies on the total ketone bodies, sugar, and calcium of the blood of nonpregnant, nonlactating ewes, J. SAMPSON and L. E. BOLEY. (Univ. Ill.). (*Jour. Amer. Vet. Med. Assoc., 96 (1940), No. 757, pp. 480-485, figs. 2*).—Analyses of blood samples collected at intervals during the day from nonpregnant, nonlactating ewes failed to reveal any appreciable diurnal variations in the total ketone bodies, sugar, or calcium of the blood. Neither moderate nor vigorous exercise affected the blood calcium level, but the former caused a slight increase and the latter a very pronounced increase in blood sugar. Fasts of 7 or 8 days' duration produced a definite decrease in blood sugar, no change in blood calcium, and an appreciable increase in total ketone bodies. A characteristic listlessness occurred in all ewes during the latter part of these fasting periods. Varying the ration and the level of feed intake over short periods significantly influenced the blood sugar level but did not appreciably change the serum calcium or concentration of ketone bodies.

Record of performance in sheep, C. L. COLE (*Michigan Sta. Quart. Bul., 23 (1940), No. 1, pp. 6-8*).—A study of the gross income from individual ewes representing four breeds, computed by taking the value of the lambs at 135 days of age plus the value of 12 months' growth of wool, showed a wide range between individuals within each of the breeds but only small differences between the averages for the four breeds. Low and high gross incomes were for Hampshires \$6.45-\$18.18, Oxfords \$9.49-\$16.56, Rambouillets \$8.07-\$16.18, and Shropshires \$8.15-\$15.63. There was a great difference in the growth rate of lambs within breeds and also in the degree of finish of lambs at 135 days of age. These results emphasize the need of greater attention to the actual production performance of individuals making up the breeding flock.

Corriedale sheep: The dual-purpose breed, F. S. HULTZ (*Laramie, Wyo.: Amer. Corriedale Assoc., [1940], pp. 123, [figs. 23]*).—A brief history, with particular reference to the development of this breed of sheep in the United States since the first importations in 1914.

Comparative value of corn, oats, and barley in fattening lambs, H. M. BRIGGS. (Okla. Expt. Sta.). (*Southwest. Sheep and Goat Raiser, 10 (1940), No. 9, p. 28*).—In a feeding trial of 100 days' duration in which feed intake was controlled to permit approximately equal gains in all groups of lambs, shelled corn, whole oats, whole barley, and mixtures of corn and oats, corn and barley, and oats and barley were compared. All groups received equal amounts of cottonseed cake and alfalfa hay. Oats and barley had values of 96.6 and 92.4 percent, respectively, that of corn when each was fed singly. When fed to replace one-half of the corn, oats and barley had values of 89 and 72.1 percent, respectively, that of the corn replaced. A mixture of oats and barley was slightly

more valuable than the combination of corn and barley. Lambs fed corn as the only grain yielded the highest and those fed barley the lowest grading carcasses.

Co-ordinated experiments in pig husbandry, R. W. SHORROCK (*Empire Jour. Expt. Agr.*, 8 (1940), No. 30, pp. 159-167).—A coordinated experimental program involving most of the several research centers of the British Isles, is described.

The relation of environmental conditions to breeding and selection for commercial types in pigs, C. P. McMEEKAN and J. HAMMOND (*Empire Jour. Expt. Agr.*, 8 (1940), No. 29, pp. 6-10, pls. 2, fig. 1).—A discussion and summary of research previously noted (E. S. R., 82, p. 235).

Swine production in the South, B. L. SOUTHWELL, J. T. WHEELER, and A. O. DUNCAN (*Danville, Ill.: Interstate, 1940, pp. 307+[3], figs. 98*).—This treatise is intended primarily as a text for pupils enrolled in the courses in vocational agriculture in the South.

Meat meal for pigs, P. C. ANGOVE (*Jour. Dept. Agr. So. Austral.*, 43 (1940), No. 11, pp. 791-797).—In the pig feeding test reported 5 percent of digested meat refuse (36 percent protein) and 5, 7.5, and 10 percent of meat meal (66 percent protein) were fed as supplements to crushed barley plus a limited amount of green feed for fattening bacon pigs. Average daily gains of 1.2, 1.28, 1.33, and 1.38 lb. per head were secured through use of these respective supplements as compared with 1.09 lb. when no protein supplement was fed. Minimum feed requirement per pound of gain occurred with the 5 percent of meat meal in the ration, following in descending order by 7.5 and 10 percent of this product, 5 percent of meat refuse, and no supplement. The high value of these packing-house byproducts as supplements to barley for bacon pig production is clearly demonstrated.

Carcass studies on some grain-fed and garbage-fed hogs, E. H. HUGHES and N. R. ITTNER. (Univ. Calif.). (*Food Res.*, 5 (1940), No. 1, pp. 83-87).—Carcasses from grain-fed hogs and from hogs fed largely or entirely on garbage were compared on the basis of carcass grade (after 48 hr. in the cooler) and refractive index values of the fat. The grain-fed hogs yielded a firmer carcass, and the water content of the muscle from cured and smoked meat was lower than that of the garbage-fed hogs. Processing did not influence the refractive index values. Both lots showed a loss of about 15 percent of the moisture of the muscle tissue during curing and smoking.

Avitaminosis in swine, R. GWATKIN and I. W. MOYNIHAN (*Canad. Jour. Compar. Med. and Vet. Sci.*, 4 (1940), No. 7, pp. 197-200, figs. 4).—This report from the Veterinary Research Station, Lethbridge, Alta., describes deficiency symptoms which developed in an experimental swine herd receiving ground grain, tankage, and salt mixture in dry lot. Loss of appetite, decrease in weight, and muscular incoordination generally occurred. Detailed case histories of two individuals are presented. Animals supplied with pilchard oil, milk, and green feed promptly recovered from this disorder, suggesting vitamin A and possibly vitamin D deficiency as the causative factor.

Practical poultry management, J. E. RICE and H. E. BOTSFORD (*New York: John Wiley & Sons; London: Chapman & Hall, 1940, 4. ed., pp. XIX+604, pls. 2, figs. 333*).—The fourth edition of this well-known book has been revised and brought up to date (E. S. R., 64, p. 66).

Metabolizable energy of some chicken feeds, G. S. FRAPS, E. C. CARLYLE, and J. F. FUDGE (*Texas Sta. Bul. 589 (1940), pp. 23*).—Using the following values for the individual components of feeding stuffs and excreta—protein 5.7 Calories per gram, fat 9.47, nitrogen-free extract and crude fiber 4.2, uric acid in

excreta 2.735, and ammonia in excreta 5.8 Calories per gram—a comparison of the heats of combustion found by analysis with those calculated by the usual method showed average percentage differences of 2.1 for 48 samples of feeds, 0.9 for 62 mixed rations, and 2.1 percent for 136 samples of excrements, with standard deviations of 2.8, 1.8, and 2.8 percent, respectively. The metabolizable energy values of feeds as determined by 128 tests with growing chickens compared closely with calculated values when a correction was made for protein retained. Using values of 4.4 Calories per gram of digestible protein, 9.47 Calories per gram of digestible ether extract, and 4.2 Calories per gram of nitrogen-free extract and crude fiber, the average difference between determined and calculated values was 2 percent, with a standard deviation of 2.8 percent. The heat of combustion of lactose was found to be 3.7 Calories per gram rather than 4.2 used for nitrogen-free extract in ordinary feeds, suggesting that when lactose makes up a considerable portion of the total carbohydrate content of the ration an allowance should be made in calculating metabolizable energy value.

Values of various protein feeds for growing chicks, R. M. SHERWOOD and J. R. COUCH (*Texas Sta. Bul.* 588 (1940), pp. 20).—Continuing this line of investigation (E. S. R., 81, p. 93) six additional experiments, each involving six rations, were compared to determine the relative value of different combinations of protein-rich feeds for growing chicks. The protein concentrates included fish meal, meat and bone scraps, liver meal, cottonseed meal, soybean oil meal, peanut meal, and linseed meal, three or four of these being used in combination in each ration tested. In all cases rations containing 6 percent of the vacuum-dried fish meal produced, regardless of other constituents, greater gains with less feed required per unit of gain than when the fish meal was not fed. Liver meal was not a satisfactory substitute for fish meal in the combinations tested. Cottonseed meal and soybean oil meal were of about equal value when fed with other protein supplements, and both were superior to peanut meal or linseed meal. Rations containing 6 percent fish meal plus 5 percent choice dehydrated alfalfa leaf meal were not improved by the addition of whey as a source of vitamin G, but other combinations containing the alfalfa leaf meal but not the fish meal were improved by the inclusion of dried whey. From 3 to 3.6 units of feed were required for each unit of gain in live weight.

Studies on the metabolism of fowls.—III, The determination of the comparative nett energy of Sussex ground oats and white maize meal for fattening cockerels, T. DEIGHTON and J. C. D. HUTCHINSON (*Jour. Agr. Sci. [England]*, 30 (1940), No. 3, pp. 463-484, figs. 2).—Continuing this series of investigations (E. S. R., 83, p. 811) and employing direct calorimetry methods previously described (E. S. R., 82, p. 807), the comparative net energy for fattening of Sussex ground oats and white corn meal was determined on Light Sussex cockerels by difference experiments. The heat production of each experimental subject was determined during five 3-hr. periods daily while on a maintenance diet, on a supermaintenance diet containing the ground oats, on a supermaintenance diet containing the corn meal, and finally during a second period on the maintenance ration. The computed net energy per gram of dry matter was 2.573 kg. calories and 3.048 kg. calories for the ground oats and corn meal, respectively. There was no significant difference in the utilization of the metabolizable energy from the two cereals, the higher net energy value of corn being due to its higher digestibility.

Steamed potatoes for laying pullets, H. TEMPERTON and F. J. DUDLEY (*Harper Adams Util. Poultry Jour.*, 25 (1939-40), No. 7, pp. 177, 178).—In an experiment conducted at the National Institute of Poultry Husbandry, White

Leghorn pullets receiving a conventional-type mash and grain ration were compared with similar groups receiving 31, 41, and 50 percent, respectively, of steamed potatoes in their ration. Over a period of 6 mo. (October to April) there were no significant differences between the four pens in egg production or mortality, and feed costs were essentially the same for all lots. Only in gain in body weight did the control group significantly excel the potato-fed groups.

An experiment on the feeding of steamed potatoes and swedes to laying ducks, M. M. WRIGHT and F. J. DUDLEY (*Harper Adams Util. Poultry Jour.*, 25 (1939-40), No. 9, pp. 225, 226).—In an experiment similar to the one described above, Khaki-Campbell ducks receiving steamed potatoes or swedes in their ration compared favorably with birds on a conventional mash and grain ration with reference to rate and efficiency of egg production, maintenance of body weight, and mortality.

Steamed potatoes in table poultry rations, A. M. McMILLAN and F. J. DUDLEY (*Harper Adams Util. Poultry Jour.*, 25 (1939-40), No. 10, pp. 251, 252).—The substitution of steamed potatoes for corn meal at varying levels up to 15 percent of the total ration of growing chicks proved satisfactory. The rate of growth was similar on all rations. Mash consumption was reduced and the feeding costs lowered when the higher levels of corn meal were partially replaced by the potatoes.

Egg-white injury in chicks and its relationship to a deficiency of vitamin H (biotin), R. E. EAKIN, W. A. MCKINLEY, and R. J. WILLIAMS (*Science*, 92 (1940), No. 2384, pp. 224, 225).—Chicks fed from 10 days of age on a diet containing 20 percent of dried egg white developed a pronounced syndrome characteristic of egg white injury by the eighth week, while chicks maintained on a diet like the above in all respects except that purified casein replaced the dried egg white remained in normal condition. The egg white and casein diets contained 0.67 γ and 0.39 γ of biotin per gram, respectively. Balance trials indicated that each group of chicks was excreting from 10 to 20 percent of their biotin intake as free biotin and from 15 to 25 percent as bound biotin. Analysis of body tissues of birds from 8 to 10 weeks of age showed the tissues of injured chicks to be consistently lower in biotin content than those of the control chicks. It is suggested that the biotin present in the egg white diet was not available to the tissues, presumably being destroyed by interaction with the egg white, hence it is probable that the injury caused by egg white is not due to any direct toxin but rather is produced indirectly by the action of the egg white in making the biotin of the diet unavailable.

Blood calcium levels of the fowl following injections of theelin, T. B. AVERY, H. M. SCOTT, and R. M. CONRAD. (Kans. Expt. Sta.). (*Endocrinology*, 27 (1940), No. 1, pp. 83-86).—Although intramuscular injections of 2,295 rat units of theelin per kilogram of body weight in molting hens over a period of 15 days failed to change the level of blood calcium, injections of 500 and 1,000 rat units into pullets caused transitory increases in blood calcium on the seventh and thirty-first days.

Levels of protein in rations for young turkeys, R. E. ROBERTS (*Indiana Sta. Bul.* 448 (1940), pp. 24, fig. 1).—Two starting rations for turkey poults, differing only in that one contained 10 percent of soybean oil meal and about 20 percent of total protein while the other contained 20 percent of soybean oil meal (10 percent soybean meal substituted for an equal amount of corn) and about 23 percent of total protein, were compared in two experiments, each involving pens of birds in confinement and on range. The average consumption of feed per bird to 12 weeks of age was approximately 2 lb. greater on the

higher protein feed, and the average total gain was also greater on this ration, an average of about 3 lb. of feed being required per pound of gain on each ration. Since other experiments have indicated that chicks grow equally well on the two levels of protein feeding, it is suggested that poults require more protein during the starting period than is needed by chicks. The rate of mortality was not significantly influenced by the ration.

Experiments during the growing period (from 12 to 24 weeks) involved a comparison of mash feeding on a ration containing 20.8 percent protein v. mash and grain feeding, with birds having continuous free access to all feeds. The total feed consumption per bird was less on the mash and grain ration than on the all-mash diet, the difference ranging from 6 to 14 percent in the different trials. The rate of grain consumption gradually increased with increasing age, approximately one-half as much grain as mash being consumed over the entire period. The final weight of both males and females on the all-mash rations was only slightly greater than the weight of those fed mash and grain, with a consequent saving of from 0.4 to 0.8 lb. of feed per unit of gain in favor of the mash and grain system. At 24 weeks the males exceeded the females in weight by slightly over 4 lb. on the average. The males required approximately 0.3 lb. less feed per pound of gain than the females. Birds which were heaviest at 12 weeks of age tended to be heavier at the end of the growing period.

The stone yard for small turkey flocks, A. BERRIDGE (*Michigan Sta. Quart. Bul.*, 23 (1940), No. 1, pp. 33-35, fig. 1).—A stoneyard prepared by completely covering the ground with small field or cobblestones, as described and illustrated, has proved a satisfactory way of maintaining sanitary conditions for growing turkeys. Recommended management practices are discussed.

"Pigeon dermatitis," a vitamin B deficiency state with anemia, W. DAMESHEK and P. G. MYERSON (*Amer. Jour. Med. Sci.*, 199 (1940), No. 4, pp. 518-539, figs. 16).—White King pigeons, weighing from 300 to 550 gm., when maintained on a diet of polished rice and water with vitamin B₁ supplied through injections developed a dermatitis characterized by loss of weight and changes in the feathers and epidermis and accompanied by a progressive anemia associated with a hyperplastic, immature marrow. Administration of riboflavin, nicotinic acid, vitamin B₆, or the filtrate factor failed to alleviate the deficiency condition. Marked recovery followed the addition of yeast concentrate to the diet or the injection of dilute liver extract or vitamin B₂ complex. Concentrated liver extract gave a partial or delayed response. Injection of a purified chick antidermatitis principle resulted in a definite reticulocyte response, although erythrocyte count failed to increase. It is suggested that lack of this principle, either alone or in association with some unknown factor, may be responsible for the deficiency condition described. A possible relationship between pigeon dermatitis and pernicious anemia also is suggested.

DAIRY FARMING—DAIRYING

[Investigations with dairy cattle and dairy products] (*Indiana Sta. Rpt.* 1939, pp. 18, 31, 64-69).—In addition to short summaries of research accomplishments for the past decade, results are briefly reported for studies on the vitamin A requirements of dairy cows, and the vitamin A-suppressing factor in soybean oil, both by J. H. Hilton, J. W. Wilbur, and S. M. Hauge; and a comparison of Sudan grass pasture v. bluegrass pasture in maintaining summer milk production, the influence of soybeans or of soybean products on milk production, fat composition, and physiological and metabolic processes, and input as related to output in milk production (coop. U. S. D. A.), all by Hilton, Wilbur, R. W. Bratton, and W. F. Epple.

Reports of studies on dairy products, by E. H. Parfitt, W. H. Brown, B. E. Horrall, Hilton, Epple, and J. C. Crane, include the cause and remedies of some abnormal flavors in milk, particularly "cappy flavor"; factors affecting body, texture, and quality of ice cream; the lecithin content of milk and its products; factors affecting the quality of Indiana butter, including lactic acid content, copper content, and relation of yeast and mold counts to bacterial count and phosphatase reaction; significance of mold mycelia in butter; the application of the Burri smear technic to butter; methods of washing and sterilizing milking machines; and enzymes in sweet and sour farm-skimmed cream.

Marketing studies, by V. C. Manhart, K. C. Boxell, and Horrall, relate to the effects of quality and associated factors on returns secured by the producer of milk and cream, and consumer reaction to graded butter.

[**Investigations with dairy cattle and dairy products in Vermont**] (*Vermont Sta. Bul.* 463 (1940), pp. 15-18).—Progress reports (E. S. R., 82, p. 381) are presented for the following: The effect of feeding vitamins A and D in concentrated cod-liver oil with different grades of hay to dairy calves; the conservation of nutrients in grasses and legumes by ensiling, artificial drying, and natural curing; artificial insemination of dairy cows; the efficiency of various materials for dairy barns; factors affecting the accuracy of the Babcock test; factors affecting the body of market cream; and the value of the resazurin test for evaluating the sanitary properties of the milk.

[**Progress in dairy research at Reading**] (*Univ. Reading, Natl. Inst. Res. Dairying, Ann. Rpt.*, 1939, pp. 16-78, fig. 1).—A description of the research activities of the National Institute for Research in Dairying and brief summaries of 85 papers published during the year ended September 1939.

Cull apples for dairy cows, A. D. PRATT and C. W. HOLDAWAY (*Virginia Sta. Bul.* 326 (1940), pp. 8).—A reversal-type feeding trial was conducted in which 9 lactating Holstein cows alternately received, in addition to grain, timothy hay alone, hay and cull apples (36 lb. per cow daily), or hay and corn silage. Equivalent amounts of dry matter were supplied in each instance. Milk production was satisfactorily maintained when apples were included in the ration. One lb. of dry matter from apples proved to be worth slightly more than 1 lb. from timothy hay but slightly less than 1 lb. from corn silage. With silage valued at \$4.50 per ton apples were worth \$2.36 per ton, and with timothy hay worth \$14 per ton apples were worth \$2.15 per ton.

The vitamin A requirements of dairy cows for the production of butterfat of high vitamin A value.—I, **Artificially dried alfalfa hay (carotene)**, J. W. WILBUR, J. H. HILTON, and S. M. HAUGE. (Ind. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 8, pp. 765-769, fig. 1).—In two feeding experiments, each with two Guernsey cows, a basic ration of dried beet pulp, white corn, oats, and linseed oil meal was fed throughout, while artificially dehydrated alfalfa hay of excellent quality was added to the ration in increasing increments during successive 21-day feeding periods to provide a carotene intake equivalent to approximately 70,000-900,000 units of vitamin A per cow daily. The vitamin A potency of the milk fat produced during the successive feeding periods was determined by bio-assay. Under the conditions of these experiments it appeared that a daily intake of approximately 550,000 units of vitamin A per cow was required to return the vitamin A potency of the milk to its highest value.

Stables for dairy cattle, J. R. DICE (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 1, pp. 4, 5).—A summary of research (E. S. R., 82, p. 671).

Milk flavor important in goat breeding, J. C. MARQUARDT (*Farm Res. [New York State Sta.]*, 6 (1940), No. 4, p. 11, fig. 1).—The possibility of improving

goat milk flavor through the selection of breeding does on the basis of high quality in flavor of their milk is briefly discussed.

Ascorbic acid content of goat's milk and blood: Influence of ascorbic acid injection and diet, M. S. RICHMOND, G. H. SATTERFIELD, C. D. GRINNELLS, and W. J. DANN. (N. C. Expt. Sta.). (*Jour. Nutr.*, 20 (1940), No. 2, pp. 99-108, figs. 3).—A large number of blood and milk samples taken from five Toggenburg goats receiving a normal ration over a 10-mo. period were titrated for ascorbic acid content. Values ranged from 0.6 to 0.8 mg. per 100 cc. of blood and from 0.5 to 2 mg. per 100 cc. of milk, with no consistent relationship between the content of the milk and that of the blood. Intraperitoneal injections of 1 or 2 mg. of ascorbic acid resulted in a rapid rise in blood ascorbic acid, a rapid very large rise in that of the urine, and a slower small rise in that of the milk. Ascorbic acid values of the blood during periods when goats were alternately fed a normal and a vitamin C-free diet showed that blood values are not closely dependent on the amount of ingested ascorbic acid. The diet affected the ascorbic acid content of the milk more than that of the blood.

Influence of age of cow on ascorbic acid content of certified milk, A. D. HOLMES, F. TRIPP, E. A. WOELFFER, and G. H. SATTERFIELD. (Univ. N. C. et al.). (*Food Res.*, 5 (1940), No. 3, pp. 263-273).—Continuing this series of investigations (E. S. R., 81, p. 270), an analysis of previously described data with reference to the age of the cows did not reveal any consistent relationship between the age of a cow and the amount of ascorbic acid in her milk.

The effect of holder and flash pasteurization on some flavors of milk, I, II, R. D. MACCURDY and G. M. TROUT. (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 9, pp. 843-854, figs. 6; pp. 855-860).—Two reports are noted.

I. *The effect of miscellaneous flavors common to commercial raw milk.*—Samples of milk from each of 10 producers secured weekly over a 6-mo. period were subdivided and treated to give the following milks—raw, aerated and unaerated and pasteurized at 143° F. for 30 min., and flash pasteurized at 160°. All lots were scored and rescored after 1 and 3 days' storage. Feed flavor was the predominating feed defect in day-old raw samples, while heated flavor was most common in the holder-pasteurized lots. Flash-pasteurized samples showed a higher percentage of excellent flavor and also greater stability of excellent flavor during storage than the others. The mean flavor score of raw and holder-pasteurized day-old milks did not differ significantly, but the latter were of significantly better flavor after 3 days' storage. All samples declined significantly in flavor during 3 days' holding at 40°. Pasteurization increased the frequency of heated, oxidized, cooked, and old flavors, but decreased the frequency of feed, high acid, cowy, rancid, unclean, and other off-flavors. Mean flavor scores gradually declined from January to June, with the incidence of feed flavors gradually increasing. The incidence of oxidized flavor gradually increased to May and then declined sharply.

II. *The effect on corn and alfalfa silage flavors.*—By feeding graded levels of silage in proportion to milk production, it was found that feed flavors were produced in milk when 0.79 lb. of corn silage or 0.4 lb. of alfalfa silage per pound of milk produced were fed to cows 1 hr. before milking. Pasteurization reduced but did not entirely eliminate such off-flavors. Vacuum-holder pasteurization or forced-aeration holder pasteurization were superior to conventional pasteurization methods in removing silage flavors. The addition of a sufficient quantity of excellent-flavor milk to the silage milk reduced the flavor intensity so that pasteurization entirely removed it.

Variation in the oxidation-reduction potential as a cause for the oxidized flavor in milk, G. R. GREENBANK. (U. S. D. A.). (*Jour. Dairy Sci.*, 23 (1940),

No. 8, pp. 725-744, figs. 5).—This report of extensive investigations dealing with most of the factors known to be concerned in oxidized-flavor development presents information on the detection of samples susceptible to flavor development; causes of variation in susceptibility of individual milks; the effect of different feeds, particularly pasture; different storage temperatures; the presence of metals in milk, including variation in the time of adding metals; heating; bacterial growth; variations in ascorbic acid content; removal of air, light, and antioxidants on the intensity of oxidized-flavor development; the removal of oxidized flavor by a reducing agent; the promotion or inhibition of oxidized flavor by oxidizing agents; and controlling the development of the flavor by variations in the oxidation-reduction potential. The results of these investigations point to a direct relationship between the oxidation-reduction potential of the system and the tendency of a milk to develop off-flavors. It is concluded that the oxidized flavor of milk is caused by a mild oxidation of some minor constituent or constituents and, further, that more complete oxidation of the constituent or constituents involved results in the formation of tasteless compounds and hence no oxidized flavor. Copper is considered an ideal catalyst for flavor development because the Eh value of the milk when this metal is added is great enough to promote oxidation but not great enough to promote a rapid oxidation of the reaction concerned to completion. The protective influence of heating milk or feeding the animals producing the milk on green feeds is attributed to an increase in the poisoning action of the milk, thereby inhibiting flavor development.

Enzymes and other substances as antioxidants in milk, D. H. NELSON and C. D. DAHLE. (Pa. Expt. Sta.). (*Milk Dealer*, 29 (1940), No. 10, pp. 41, 42, 44, 46, 48, 50, 52-55).—Milk obtained from individual cows known to produce milk resistant to spontaneous oxidized flavor was used in all the experiments, and control samples consisted of the pasteurized milk plus 1 or 2 p. p. m. of copper. Pure ascorbic acid was highly effective in inhibiting oxidized flavor development, and the ascorbic acid practically disappeared before the oxidized off-flavor appeared. The addition of fresh orange juice or tomato juice to the milk afforded even greater protection against this off-flavor than would be expected on the basis of the ascorbic acid contributed by them. The addition of 0.3 percent oat flour to milk also inhibited this off-flavor but did not reduce the rate of ascorbic acid destruction, indicating that oxidized flavor will not necessarily develop in the absence of ascorbic acid. Citric acid when added to milk failed to exhibit antioxidative properties. Of three pancreatic enzymes tested, pepsin exhibited no antioxygenic effect while both trypsin and steapsin (particularly the latter) effectively inhibited oxidized flavor development, suggesting that the beneficial effect of such enzymes is due to their action on the fatty material rather than on the protein fraction of the milk. An alcoholic solution of gum guaiac, which is water insoluble and only slightly soluble in fat, was a highly effective antioxidant for copper-induced oxidized flavor. However, concentrations which could be used without imparting an undesirable flavor to milk did not inhibit oxidation of ascorbic acid. The addition of 5 percent crude sugar inhibited oxidized flavor during 3 days' storage, but refined sugar was ineffective in this respect.

Trypsin: An anti-oxygen for milk, F. J. DOAN and G. M. MILLER. (Pa. Expt. Sta.). (*Milk Plant Mo.*, 29 (1940), No. 9, pp. 42-47).—Small amounts of trypsin were added to batches of cold, fresh, raw milk containing 1 p. p. m. of copper, the quantity of the enzyme ranging from 0.00032 to 0.0064 percent. The milks were then pasteurized, cooled, and examined for flavor after from 24 to 48 hr. A quantity of enzyme in excess of 0.00128 percent proved highly

effective in preventing the development of oxidized flavor in the milk. Proteolysis resulting in a bitter flavor and coagulation of the milk on boiling became noticeable when the concentration of trypsin reached 0.0064 percent. Heated trypsin proved inert as an antioxidant, indicating that the inhibitory effect observed is contingent on a short period of enzymatic action prior to pasteurization.

Effect of subcutaneous implantation of adrenalin tablets on blood-sugar and milk composition in lactating ruminants, A. C. BOTTOMLEY, S. J. FOLLEY, F. H. A. WALKER, and H. M. S. WATSON (*Jour. Endocrinol.*, 1 (1939), No. 3, pp. 287-299, figs. 7).—In experiments at the National Institute for Research in Dairying, adrenalin (in the form of the free base) tablets were implanted subcutaneously at an approximate rate of 50 gm. per 100 lb. of live weight in three lactating goats and one lactating cow. In each instance a pronounced hyperglycemia was maintained for many hours following the implant. Blood lactic acid rose appreciably during the same period, and coincidentally the lactose content of the milk increased. In most cases milk yield declined slightly and the solids-not-fat of the milk tended to increase temporarily, but the milk fat was not uniformly affected. The normal arterial blood lactic acid content in the normal lactating goat was found to range from 5.4 to 15 mg. percent.

Checking the sanitary quality of milk and other dairy products, H. H. WEISER. (Ohio State Univ.). (*Milk Dealer*, 29 (1940), No. 11, p. 36).—Using a medium of nutrient agar plus 5 percent of sterile defibrinated horse blood, 75 samples of mastitis milk (both incubated and unincubated) were examined by the Burri smear technic. Streptococcus colonies were observed in 40 of the unincubated and 55 of the incubated samples. The types of streptococci present were also determined by the action of the colonies on the blood agar. The desirability of incubation before inoculation is apparent from the results. It is suggested that by varying the composition of the medium to suit the needs of the various types of bacteria the Burri technic may be very useful in studying the numbers and types of organisms in milk as well as in other dairy products.

Observations on the growth responses of *Streptococcus lactis* in mastitis milk, C. C. PROUTY. (Wash. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 9, pp. 899-904).—In a study involving milk samples from both infected and non-infected udder quarters of cows suffering from mastitis it was found that milks having an initial pH greater than 6.9 usually failed to support growth of *S. lactis*. Adjusting the pH of mastitis milk to that of normal milk resulted in only partially overcoming delayed acid development. *S. lactis* development was retarded by the addition of as little as 10 percent of very abnormal mastitis milk to normal milk. Holder pasteurization of mastitis milk generally had little effect on the retarding influence on the growth of *S. lactis*, although in some samples such heat treatment partially overcame the retarding influence.

Studies of the resazurin test for milk, J. M. BRANNON. (Univ. Ill.). (*Milk-Plant Mo.*, 29 (1940), No. 5, pp. 51, 54, 55).—Data are presented on the comparative results obtained by examining milk with the methylene blue reduction and resazurin tests, the plate count, and the direct microscopic count. On the whole, there was close agreement of the different methods. The resazurin test was generally more rapid than the methylene blue reduction test, but the latter is considered by the author to be simpler and more dependable in the hands of the less-experienced operator. It is recommended that the direct microscopic count be used in conjunction with either color test.

Physical and chemical properties of the fat globule adsorption "membrane."—II, Nature and origin of surface active materials involved in curd

tension reduction and prevention of rennet clot of cow's milk by "membranes" from natural and synthetic creams, L. S. PALMER and N. P. TARASSUK. (Minn. Expt. Sta. coop. Univ. Calif.). (*Jour. Dairy Sci.*, 23 (1940), No. 9, pp. 861-871).—Continuing this series (E. S. R., 81, p. 833), further experiments gave evidence that the addition of artificial fat globule membrane sols derived from spray-dried whey to natural or remade skim milk markedly reduced its curd tension. Interference with the normal clotting of milk by rennet due to the protein denaturation of these sols is suggested as an explanation of this phenomenon. Normal rennet clot was completely prevented and surface tension and pH were lowered by emulsifying a small amount of diglycol laurate into raw milk at room temperature, aging the emulsion at low temperature, and adding rennet at 35° C. Remade buttermilk from creams whose butterfat globule membrane was diglycol laurate behaved in a similar manner, which is explained on the basis of the liberation of lauric acid from the diglycol ester by natural milk enzyme. It did not occur if the milk was first pasteurized.

Lipolytic activity in milk and cream, D. C. ROAHEN and H. H. SOMMER. (Univ. Wis.). (*Jour. Dairy Sci.*, 23 (1940), No. 9, pp. 831-841).—The results of a series of experiments are included in this report. When 10 gm. of raw cream was inoculated into 100 gm. of a substrate consisting of sugar-saturated cream, lipolysis was greatly limited by the addition of from 0.05 to 0.15 cc. of formalin and markedly accelerated by the addition of from 1 to 2 gm. of tributyrin, as measured by the titer of the steam distillate. Gravity-separated cream showed considerably greater lipolysis than separator cream from the same milk, as measured by the titer of the distillate and the acid number of the fat. Lipolysis of whole milk was increased by shaking. However, when the same milk or cream was inoculated into the sugar-cream substrate shaking decreased lipolysis. Lipolytic activity in whole milk was affected by temperature, it being relatively very high at 37° C., less at 27°, and much less at from 3° to 4°. Cream held at from 3° to 4° exhibited maximum lipolysis at pH 8.4 to 8.6. Cream separated at 110° F. showed less lipolysis than that separated at 75°. Individual milk samples from the same cow and from different cows varied in lipolysis, but no relationship between stage of lactation and lipolytic activity could be established.

Watery appearance of frozen homogenized milk, G. M. TROUT (*Michigan Sta. Quart. Bul.*, 23 (1940), No. 1, pp. 10-19, figs. 8).—Pasteurized milks homogenized at pressures of 500, 1,500, 2,500, and 3,500 lb. were compared with unhomogenized samples in a series of freezing and thawing tests. The homogenized samples froze at a slightly faster rate than unhomogenized milk, with freezing time tending to increase as homogenization pressures decreased. The frozen plugs forced above the neck of ordinary milk bottles were very similar in appearance for the homogenized and unhomogenized samples. On thawing the homogenized milk presented a thin watery appearance at the top of the container, the volume of watery-appearing material increasing with increasing homogenization pressures. On mixing, the thawed samples of homogenized milk appeared as smooth as unfrozen milk. Creaming did not occur in the homogenized milk after freezing and thawing.

[**Investigations in dairy bacteriology**] (*3. Internatl. Cong. Microbiol.*, New York, 1939, *Rpt. Proc.*, pp. 713-728).—Abstracts of the following papers, presented before the subsection in dairy bacteriology, are noted: The Ripening Process of Hard Cheese, by S. Orla-Jensen; Bacteriological Methods in Cheese Research [trans. title], by R. Burri; Acidoproteolytic Cocci in American Cheeses, by C. Gorini; The Presence of Propionic Acid Bacteria in Different

Types of Cheese [trans. title], by K. J. Demeter and A. Janoschek; Dye Reduction Tests for Controlling Milk Quality, by C. K. Johns; Application of the Burri Smear Culture Technic to Various Solid Dairy Products, by B. W. Hammer; The Germicidal Activity of Hydrogen Peroxide Upon Bacterial Spores, by H. R. Curran, F. R. Evans, and A. Leviton; The Coli Bacilli and Coli Phages in Milk [trans. title], by I. Lipska; Some Media for the Detection of Gram-Negative Bacteria in Pasteurized Milk, by C. N. Stark; A Potentiometric Method of Detecting Milk Susceptible to Oxidation, by A. C. Fay, J. L. Mahoney, and E. W. Woelffer; The Use of Tributyrin Agar in Dairy Bacteriology, by J. A. Anderson; and Thermal Death Studies of Bacteria in Non-aqueous Environments, by C. S. Mudge and D. C. Foord.

Bacteriological studies on the cleaning of milking machines, E. H. PARFITT (*Indiana Sta. Bul.* 449 (1940), pp. 7).—Based on the principle of cleaning milking machines as previously described (E. S. R., 66, p. 168), the influence of certain modifications in the method of washing and sterilizing has been investigated. The addition of a rinse solution containing 200 p. p. m. of chlorine through the entire system just before use resulted in a greater decrease in the bacterial population of the machines than a clear-water rinse of the same volume. A hot-water rinse immediately following the cold-water rinse in washing the machine yielded a lower bacterial count than when the hot-water rinse was omitted. The use of lye solution in the teat cups and milk tubes during cold weather (house temperature from 25° to 35° F.) was found to be advantageous in reducing the bacterial count. A procedure, as described, for sterilization of the vacuum check valve proved effective in eliminating thermophilic organisms from the system.

The gas requirements of molds, II, III, N. S. GOLDING. (Wash. Expt. Sta.) (*Jour. Dairy Sci.*, 23 (1940), No. 9, pp. 879-889, figs. 7; pp. 891-898, figs. 4).—Two additional reports in this series are noted (E. S. R., 77, p. 846).

II. *The oxygen requirements of Penicillium roqueforti (three strains originally isolated from blue veined cheese) in the presence of nitrogen as diluent and the absence of carbon dioxide.*—Three strains of blue mold isolated from cheese were each grown at seven different temperatures (from 46° to 90° F.) in an atmosphere devoid of CO₂ and containing from 21 to 2.1 percent O₂, obtained by adding N₂ to the air. Only in the case of the greatest O₂ dilution did a significant decrease in mold growth occur, retardation at this O₂ level ranging from 16 to 54 percent. Greatest retardation occurred at the higher temperatures.

III. *The effect of various concentrations of carbon dioxide on the growth of Penicillium roqueforti (three strains originally isolated from blue-veined cheese) in air.*—Using the same strains of mold and the same temperature range as above, the molds were grown in atmospheres of air devoid of CO₂ and in mixtures of air and CO₂ in 8:2, 6:4, 3:7, and 2:8 ratios. In each instance maximum growth occurred when 20 percent CO₂ was added to the air, while higher concentrations of CO₂ tended to inhibit growth. The three strains, while following the same trends, showed differences in CO₂ tolerance. The acceleration in growth due to low concentrations of CO₂ and also inhibition due to high concentrations took place sooner at the lower temperatures.

Butter: Its composition and deterioration, H. H. KRETCHMAR (*Jour. Dept. Agr. West. Austral.*, 2. ser., 17 (1940), Nos. 1, pp. 93-134, figs. 3; 2, pp. 141-152).—A comprehensive review, including 104 references.

The effect of standardizing the acidity in the manufacturing of cottage cheese and cultured buttermilk, L. E. MULL, W. H. E. REID, and W. S. ARBUCKLE (*Missouri Sta. Res. Bul.* 319 (1940), pp. 36, figs. 4).—Using a short-time

(5-hr.) method of cottage cheese manufacture throughout the series, the reported variable procedures used in the experimental manufacture included: Adjusting the acidity of the skim milk by the addition of a stabilizer to 0.0, 0.05, or 0.1 percent before adding the starter and rennet, to 0.05 percent after adding the starter or after both starter and rennet were added, and 0.05 percent with more than the normal amounts of starter and rennet added; also washing in either normal or alkaline water; creaming with normal cream (0.2 percent acidity) or cream standardized to 0.1 or 0.0 percent acidity; and storing as dry curd, in plain water, in alkaline water, or as creamed curd. Observations on the body and flavor of the cheeses in a fresh condition and after varying periods of storage led to the conclusion that the use of a moderate amount of standardizer in the skim milk resulted in an improved flavor of the cottage cheese, while an excess amount produced an unnatural flavor and impaired the keeping quality. Slight alkalinity of the wash water gave a clean, mild, full-flavored product, but excess standardizer in the wash water produced a slick gelatinous curd of unnatural flavor, weak body, and poor keeping quality. Reducing the acidity of the cream improved the flavor but tended to impair the keeping quality of the cheese. The use of a standardizing agent at more than one step in the manufacturing process was detrimental to the body and keeping quality of the cheese. Prolonged storage of the curd in alkaline water resulted in unnatural flavor and weak body. As the pH decreased, the keeping quality of the cheese tended to decrease. In studies with cultured buttermilk, acidity standardization of the original milk, an increase in the amount of starter, and a higher than normal setting temperature resulted in the production of a high-quality buttermilk in 5 hr. Adjusting the acidity after incubation resulted in an unnatural, sweet flavor. As with cottage cheese, this product showed a close correlation between pH and keeping quality.

Many cheese varieties improved by research, J. C. MARQUARDT (*Farm Res. [New York State Sta.]*, 6 (1940), No. 4, p. 3, figs. 3).—Advancements in manufacturing and curing methods for Trappist-type cheese are discussed. The importance of technical control of setting and salting, and particularly of humidity and temperature control in the curing room, is stressed.

Effect of various bacteria on flavor of Cheddar cheese made from pasteurized milk, W. C. HARRIS and B. W. HAMMER. (Iowa State Col.). (*Jour. Dairy Sci.*, 23 (1940), No. 8, pp. 701-708).—In the experiments described pasteurized cheese milk received, in addition to a regular cheese starter, an inoculation of an organism to be tested. Of 34 pure cultures of micrococci originally isolated from Cheddar cheese, 7 were found to have an undesirable effect on cheese flavor, 14 had no definite effect, and 13 definitely improved cheese flavor. It appeared that micrococci to be employed in the manufacture of Cheddar cheese should be selected on a strain rather than on a species basis, since strains belonging to the same species differed in their effect on flavor. Of 7 strains of propionic acid bacteria tested, some improved cheese flavor when used in relatively small numbers, and all improved the flavor when added in large numbers. It appeared that various organisms other than the usual cheese cultures might be used to advantage in improving the flavor of pasteurized milk Cheddar cheese.

The relationship of moisture in Swiss cheese to quality and yield, G. P. SANDERS, R. R. FARRAR, R. E. HARDELL, F. FEUTZ, and L. A. BURKEY. (U. S. D. A., Univ. Wis., and Ohio State Univ.). (*Jour. Dairy Sci.*, 23 (1940), No. 9, pp. 905-918, figs. 5).—A study of the relationship of moisture content to grade for 418 factory-made Swiss cheeses and 218 experimental cheeses led to the conclusion that the presence of an excessive amount of moisture is generally detri-

mental to the quality of the cheese. The effects of 21 variables in the milk and manufacturing process upon the moisture content of the cheese are described. In general, those practices which permit inclusion of a comparatively large amount of moisture did not result in sufficient increase in yield to justify their use.

The application of the frozen pack method to preservation of soft cheese, N. S. GOLDING and M. E. MORGAN. (Wash. Expt. Sta.). (*Milk Dealer*, 29 (1940), No. 9, pp. 42, 44, 46, 48).—Processes employed included the packaging of Neufchâtel, Neufchâtel plus pimienta, and Gervais cheeses in ½-lb. flat cans, sealing under air pressure or under vacuum, and freezing either immediately or 1 or 4 days after sealing. Samples were removed from frozen storage and examined for quality at frequent intervals up to several months. In general the cheese responded well to frozen storage. Texture and palatability were not noticeably affected. Defects apparent in the fresh cheese were still present after frozen storage, but did not increase. Pasteurization of the cheese milk or cream at 170° F. for 10 min. was generally less desirable than heating at 145° for 30 min. since the former tended to produce cooked flavor. There was no recognizable difference in air-sealed and vacuum-sealed cheeses up to 8 weeks, but slight oxidized flavor developed in the air-sealed lots after prolonged storage.

The application of the frozen pack method to preservation of Devonshire or clotted cream, N. S. GOLDING and M. E. MORGAN. (Wash. Expt. Sta.). (*Milk Dealer*, 29 (1940), No. 10, pp. 42, 67-69).—In this experiment clotted cream prepared by the conventional method was subjected to packaging and frozen storage in a similar manner to that employed with soft cheese as noted above. Freezing immediately after packaging was superior to freezing 4 days after sealing, as some defects developed in the cream during the intervening period. No significant changes occurred in the frozen product during approximately 6 mo. of storage, indicating that this method of handling is well suited to clotted cream.

Value of salt in cheesemaking, J. C. MARQUARDT and L. RESI. (N. Y. State Expt. Sta.). (*Natl. Butter and Cheese Jour.*, 31 (1940), No. 10, pp. 32, 34, 36).—A summary of the salt content of cheese entered in competition at the 1940 New York State fair, including 193 samples representing 8 types of cheese. Average salt values for the different types were export Cheddar 1.64, home-trade Cheddar 1.55, washed curd 1.62, sage 1.54, young American 1.52, pimienta and miscellaneous 1.75, picnic twins 1.5, and single daisies 1.52 percent.

Retarding mold in cheese, F. W. MILLER, JR. (*Natl. Butter and Cheese Jour.*, 31 (1940), No. 8, pp. 12, 13, 38).—In an effort to control mold development on cheese slices, ½- and 1-lb. wedges of cheese were dipped in solutions of varying concentration of propionic acid or its calcium or sodium salts for a few seconds, then drained and wrapped in Cellophane. The most favorable results were secured by dipping in an 8-percent propionic acid solution. This treatment greatly increased the mold-free life of the cheese without affecting its flavor or color. Solutions of the salts were effective when used in higher concentrations.

A study of the characteristics of a milk supply as related to the manufacture of plain condensed skimmilk for ice cream making, L. K. CROWE and D. D. DEANE. (Nebr. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 9, pp. 919-929, fig. 1).—Nine lots of mixed herd milk of normal composition were processed at approximately 4-week intervals from October through May. The freshly separated skim milk was condensed to a total solids content of about 33.5 percent, and portions of each lot were placed in storage at 0° F. Ice cream mixes were prepared from each lot of the condensed milk when fresh and after 4 weeks' frozen storage. No definite relationship was found between the acidity of the milk products and the pH and protein stability. No milk was found to produce condensed skim milk unstable to freezing and storing for 4 weeks, and

such treatment did not alter its physical appearance or body other than to make it slightly sandy. Titratable acidity increased during frozen storage, but protein stability was affected only slightly. No significant trends in titratable acidity, pH, or viscosity of the ice cream mixes could be attributed to changes produced by the frozen storage, and ice creams produced from the fresh and frozen condensed skim milk were similar in quality.

Further observations on basic viscosity of ice cream mixes and a simplified procedure to obtain it, E. S. PENCZEK and A. C. DAHLBERG. (N. Y. State Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 8, pp. 691-700, fig. 1).—A comparison of the effect of a hand-operated emulsifier and the Whitaker device (E. S. R., 61, p. 869) on the viscosity of ice cream mixes led to the conclusion that the former is simpler, more practical, and more efficient than the latter in reducing the apparent viscosity of the mix to basic viscosity. The lower minimum viscosity obtained by the hand emulsifier was not due to the size of the fat clumps and fat globules but rather to the fact that it was more effective than the Whitaker device in breaking down the gel structure. None of the methods employed was capable of destroying the regelatinizing power of the gelatin used in these trials.

Relationship of hydrometer readings to the composition and some physical properties of pan condensed ice cream mixes, R. A. LARSON (Mich. State Col.). (*Ice Cream Rev.*, 23 (1940), No. 10, pp. 34, 92-96, 98).—A summary of research previously noted (E. S. R., 83, p. 394).

Technical literature of ice cream for 1939, A. LEIGHTON. (U. S. D. A.). (*Ice Cream Rev.*, 24 (1940), No. 1, pp. 34, 36, 38, 42, 46, 48, 50, 51).—A comprehensive review, including a bibliography of 161 references.

VETERINARY MEDICINE

[Work in animal pathology by the Indiana Station], A. L. DELEZ, L. P. DOYLE, R. A. CRAIG, C. NEWTON, and F. L. WALKEY (*Indiana Sta. Rpt. 1939*, pp. 24, 105-109).—The work of the year (E. S. R., 81, p. 707) reported upon includes studies of Bang's disease, death loss in newborn pigs, and lesions produced by the hog cholera virus; encephalomyelitis in horses and mules and in chicks (leg weakness, epidemic tremors); transmission of paralysis, leucosis, and neoplastic conditions in chickens; hog cholera serum and virus tests; laboratory diagnoses of diseases of poultry and livestock; and agglutination tests for Bang's disease (brucellosis) and pullorum disease.

Early history of preventive medicine, with special reference to the viruses of animal origin, B. M. LYON (*Vet. Med.*, 35 (1940), No. 8, pp. 430-435, figs. 3).

The synergism of human influenza and canine distemper viruses in ferrets, F. L. HORSFALL, JR., and E. H. LENNETTE (*Jour. Expt. Med.*, 72 (1940), No. 3, pp. 247-259, fig. 1).—Report is made of a study of infections produced in ferrets by human influenza virus and canine distemper virus. "Cross-immunity and cross-neutralization tests showed that these two viruses were not related antigenically. Ferrets infected with influenza virus alone rapidly produced considerable quantities of neutralizing antibodies, and after the sixth day virus was not demonstrable in their lungs. Ferrets infected with both influenza and distemper viruses simultaneously produced but small amounts of neutralizing antibody, and influenza virus persisted in undiminished concentration in their lungs throughout the course of the infection."

Progress in chemotherapy of bacterial and other diseases, with special reference to the prontosils, sulfanilamide and sulfapyridine, J. A. KOLMER (*Arch. Int. Med.*, 65 (1940), No. 4, pp. 671-743).—This review of the history and present status of knowledge of the subject is presented with a 19-page list of references to the literature.

The effect of sulfanilamide on several parasitic infections of laboratory rats and mice, S. ZURETT and J. T. CULBERTSON (*Jour. Parasitol.*, 26 (1940), No. 3, pp. 235, 236).—It was found that sulfanilamide was without effect in experimental infections with *Trypanosoma lewisi*, *T. cruzi*, and *T. equiperdum* in rats and in experimental infection with *T. duttoni* in mice. It was likewise without effect upon natural protozoan infections of mice with *Endamoeba muris*, *Trichomonas muris*, *Giardia muris*, and *Hexamita muris*.

Sulfapyridine in avian tuberculosis: The effect of sulfapyridine on the bacillaemia of rabbits infected experimentally with avian tubercle bacilli, A. G. KARLSON and W. H. FELDMAN (*Amer. Rev. Tuberc.*, 42 (1940), No. 1, pp. 146-150, fig. 1).—In the experimental work reported the daily administration of sulfapyridine failed to prolong the lives of rabbits artificially infected with avian tubercle bacilli. "Sulfapyridine failed to modify the gross changes characteristic of the Yersin type of tuberculosis in rabbits inoculated with avian tubercle bacilli. In rabbits that received sulfapyridine before being infected and twice daily thereafter, the number of cultivable avian tubercle bacilli in the blood was reduced apparently as a consequence of the drug."

Changes in the insecticidal value of the roots of cultivated devil's shoe-string (*Tephrosia virginiana*) at four seasonal growth periods, A. F. SIEVEBS, M. S. LOWMAN, G. A. RUSSELL, and W. N. SULLIVAN. (U. S. D. A. and Tex. Expt. Sta.). (*Amer. Jour. Bot.*, 27 (1940), No. 5, pp. 284-289, fig. 1).—The authors' studies indicate that at the full-bloom stage the roots of *T. virginiana* are significantly more toxic to houseflies than at the dormant and emergence stages, but their superiority over those at the mature-seed stage is less so. The chloroform extractive and rotenone content is also highest at the full-bloom stage. The toxicity of the roots of the several clonal progenies of the same parent does not vary significantly, but significant differences were found in this respect between the progenies of different parents.

Destruction of eggs and non-infective larvae, T. W. M. CAMERON (*Canad. Jour. Compar. Med.*, 3 (1939), No. 9, pp. 248-254).—The results obtained from the mixing of numerous chemicals with feces that contained nematode eggs varied with the nature and quantity in their effect upon the eggs and larvae.

The comparative value of some further chemicals in the treatment of manure against sclerostome larvae, I. W. PARNELL (*Canad. Jour. Compar. Med. and Vet. Sci.*, 4 (1940), No. 3, pp. 76, 77, fig. 1).—Substances additional to those noted by Cameron above are reported upon.

Effects of freezing temperatures on the embryonation of eggs and infectivity of larvae of *Heterakis gallinae*, A. B. WICKWARE (*Canad. Jour. Compar. Med. and Vet. Sci.*, 4 (1940), No. 4, pp. 110-116).—"Nonembryonated eggs of *H. gallinae* were successfully embryonated after exposure to freezing temperatures for periods ranging from 67 to 172 days. Except for those eggs that hatched normally after exposure to a -2° F. freezing temperature for a period of 67 days, the percentage rate of eggs reaching the coiled embryo stage was lower in each instance than in normal control cultures. The percentage rate of infectivity of such eggs for young chicks, with experiments considered collectively, was also somewhat lower than the rate observed in the control group."

Transmission of immunity to *Trichinella spiralis* from infected animals to their offspring, E. A. MAUSS (*Amer. Jour. Hyg.*, 32 (1940), No. 2, Sect. D, pp. 75-79).—In experiments conducted with the offspring of trichinous rats, rabbits, and hamsters the percentage development of infecting doses of trichina larvae was lower than in the offspring of uninfected animals. This lowered susceptibility to infection was lost by the hamsters as early as the third

week after birth, and the time before parturition of infection of the mother hamsters did not appear to influence the degree of immunity transmitted to the young. Examination for trichinae after complete digestion of the musculatures of 5 rats, 5 rabbits, and 24 hamsters, all offspring of infected mothers, revealed not one case of prenatal infection, eliminating actively acquired immunity as a possible cause for the partial immunity demonstrated to exist in these animals.

The in vitro effect of immune serum upon *Trichinella spiralis* larvae, E. A. MAUSS (*Amer. Jour. Hyg.*, 32 (1940), No. 2, Sect. D, pp. 80-83).—It was found that "*T. spiralis* larvae which have been incubated at 37° C. for 18 hr. in 43 percent homologous immune serum are only 30 percent as infective as larvae which have been incubated under the same conditions in 43 percent normal serum. There is a similar reduction in infectivity of larvae exposed to 0.9 saline solution, but the reduction becomes statistically insignificant when 10 percent normal rabbit serum is added to the saline."

Methods of exposing experimental animals to virus infection through mosquito vectors, R. A. KELSER (*Amer. Jour. Pub. Health*, 30 (1940), No. 8, pp. 866-870).

The use of sodium lauryl sulphate lactose tryptose broth as a primary medium for detection of coliform group, W. L. MALLMAN and C. W. DARBY (*Mich. State Col.*). (*Jour. Bact.*, 40 (1940), No. 1, pp. 143, 144).

Serological reactions and species specificity of some helminths, R. W. WILHELMI (*Biol. Bul.*, 79 (1940), No. 1, pp. 64-90).—The value of the precipitin reaction as a method for determining phylogenetic relationships of helminths has been demonstrated, since this reaction differentiated species and expressed relationships which are in agreement with those derived from morphological comparisons of the species studied.

The presence of a capsule on *Brucella* cells, I. F. HUDDLESON. (*Mich. State Col.*). (*Jour. Bact.*, 40 (1940), No. 1, p. 162).—In the studies conducted, all smooth strains of *Brucella* were found to possess a definite capsule, while dissociated forms did not show a capsule. The size of the bacterial cells plus capsules varied from 1.5 μ to 2.5 μ . Capsular swelling was not demonstrated in the presence of antisera. The technic used for demonstrating the capsule is a modification of the Burri india ink method.

A quantitative study of a protein-nucleate and its components prepared from the *Brucella* group of organisms, and their interaction with *Brucella* specific sera, R. B. PENNELL (*3. Internat. Cong. Microbiol., New York, 1939, Rpt. Proc.*, pp. 791, 792).—Data obtained in connection with the work at the Michigan Experiment Station previously noted (*E. S. R.*, 82, p. 533) are presented.

Furunculosis in Oregon fish, J. N. SHAW and L. SEGHEITI. (*Oreg. Expt. Sta.*). (*Cornell Vet.*, 30 (1940), No. 1, pp. 21-24).—In an investigation of affected native cutthroat fingerlings (*Salmo clarkii clarkii*) from a hatchery at Corvallis, where several hundred had been lost each day, an organism identical with *Bacterium salmonicida* was isolated from lesions on the body. The disease appeared to be more prevalent during hot weather and so far as known occurred only in rearing ponds.

A check-list of the nematode parasites of the domesticated animals in Burma, II, J. BHATTACHARJEE (*Indian Jour. Vet. Sci. and Anim. Husb.*, 10 (1940), No. 1, pp. 119, 120).—In continuation of the check list previously noted (*E. S. R.*, 78, p. 393), nematode parasites of animals identified by the author from collections of the Veterinary Research Laboratory, Insein, Burma, are recorded.

Observations on anaplasmosis in Antigua, B. W. I., L. R. HUTSON (*Trop. Agr. [Trinidad]*, 17 (1940), No. 8, pp. 147, 148).—The occurrence of anaplasmosis in Antigua is reported and confirmed. A clinical case report of this disease in a dairy cow is presented.

Bovine contagious abortion in relation to public health, W. T. ROWLANDS (*Jour. Roy. Sanit. Inst.*, 61 (1940), No. 1, pp. 16-25).

Vaccination for Bang's disease, W. WISNICKY. (Univ. Wis.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 762, pp. 221-229, figs. 3).—A report on the progress of control work and the role of calf vaccination.

Some observations on the eradication and control of Bang's disease, W. N. PLASTRIDGE, L. F. RETTGER, and G. C. WHITE. ([Conn.] Storrs Expt. Sta.) (*Jour. Dairy Sci.*, 23 (1940), No. 8, pp. 755-763).—In work at the station during the period 1925-39 the number of cows' blood samples tested annually for Bang's disease increased from 2,373 to 42,700, the number of herds from 27 to 624, and the number of herds passing one or more negative tests from 4 to 473. The average incidence of infection observed in infected herds at the time of the initial tests was found to be about 25 percent. The average number of suspicious reactors that became positive was 16.6 percent in herds which were negative in the preceding test, 26 in herds in which spread of infection was slow, and 63.6 percent in herds in which spread of infection was rapid. Of 149 infected herds, 64.5 percent required from 1 to 2 tests for eradication, 22.7 required from 3 to 4, and 12.7 percent, more than 4 tests. The principal source of reinfection was found to be association with infected animals, either as the result of adding cows or bulls from untested or infected herds, or of animals breaking into or out of pasture. Association with infected horses or swine accounted for several "breaks," and in some instances available evidence indicated that infection resulted when people went directly from infected to negative herds. It is concluded from available information that, in general, breaks are preventable. In about half of the reinfected herds regular 6-mo. retests detected new infection before it had a chance to spread to more than one or two animals.

A study of an epidemic of brucellosis due to *Brucella melitensis*, I. F. HUDDLESON and M. MUNGER. (Mich. Expt. Sta.). (*Amer. Jour. Pub. Health*, 30 (1940), No. 8, pp. 944-954, fig. 1).—Report is made of the study of a brucellosis epidemic that occurred during the winter of 1938-39 at the Michigan State College, in which 45 individuals developed the clinical form and possibly 49 the subclinical form of the disease. *B. melitensis* was cultured from the blood of 36 of the clinical and 3 of the subclinical cases. No other species of *Brucella* was involved. All possible sources of the infective material responsible for the epidemic are mentioned and discussed. The results of the different laboratory diagnostic tests show that no one test is always sufficient to confirm the diagnosis of clinical brucellosis shortly after onset. The combined results of all the laboratory tests show that active infection and clinical infection are not synonymous. An individual may be infected with *Brucella* and yet never show clinical symptoms of the disease.

Immunity to *Br. abortus* infection, A. D. McEWEN (*Vet. Rec.*, 52 (1940), No. 24, pp. 441-444).—The author is led to conclude that the vaccination of cattle against *Brucella abortus* infection with a living virulent vaccine results in a high resistance to reinfection, and that the vaccinated animals which abort do so because of a vaccination infection and not on account of subsequent exposure to infection.

Paratuberculosis (Johne's disease) of cattle in Assam.—I, Its incidence and epizootology, P. G. PANDE (*Indian Jour. Vet. Sci. and Anim. Husbandry*, 10

(1940), No. 1, pp. 40-62).—In a survey made of the incidence of Johne's disease among government farm animals in Assam, conducted mainly by use of the avian tuberculin test, all classes and breeds of animals and crossbreds were found equally susceptible to the disease. An unusually high incidence was found among calves, but post-mortem evidence of the disease in such young animals has not been obtained.

The control of the chronic form of streptococcic mastitis, R. B. LITTLE (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 762, pp. 212-220).—In two herds under investigation, the chronic form of mastitis due to *Streptococcus agalactiae* was detected through bacteriological examination of the secretion from individual cows and controlled by elimination of all infected animals. One herd has been free from infection for nearly 3 yr. and the other for over 4 yr. In another herd, raised under special precautions, *S. agalactiae* was not detected in the secretion of any cow during a period of 9 yr. In a herd where the infected animals were maintained in the same stable with the normal cows and milked last, new cases appeared throughout the period of observation. The results of this study suggest that the contagious form of mastitis can be more quickly eradicated from a herd when the infected animals are immediately disposed of or segregated from the normal cows.

Familial cerebellar hypoplasia and degeneration in Hereford calves, J. R. M. INNES, D. S. RUSSELL, and A. J. WILSDON (*Jour. Pathol. and Bact.*, 50 (1940), No. 3, pp. 455-461, pls. 4).—Description is given of the clinical and histological features of five examples of familial cerebellar hypoplasia, arrested development, and degeneration in calves. The pathological changes were found confined to the cerebellar cortex. In cattle the condition appears to be restricted to the Hereford breed and is possibly due to a hereditary factor which has emerged as the result of intensive inbreeding.

Two mortalities among sheep due to infection with species of the Salmonella group of bacteria, D. F. STEWART (*Austral. Vet. Jour.*, 16 (1940), No. 4, pp. 169-172).—One of two mortalities resulting from *Salmonella* infection among sheep was found to be due to *S. bovis-morbificans*, the other to *S. typhimurium*.

Gastrointestinal worm parasitism acquired by sheep during the winter season, D. W. BAKER and J. SAWYER (*Jour. Bact.*, 40 (1940), No. 1, pp. 166, 167).—Observations extending over a period of 5 yr. indicated that sheep and goats while stabled during the winter months were parasitized by nematodes of the various strongyloid types as well as by tapeworms. In the experimental work lambs known to be free from intestinal parasites were transferred to a new environment in which the bedding was contaminated by the feces of adult sheep. The work was carried on during cold winter weather, when the only possible source of infestation was from the infested indoor environment. Group A consisted of five 8- or 9-month-old lambs that had been reared parasite-free, with one being held in the laboratory as a control. Group B was made up of 13 lambs born during December, January, and February and transferred to the infested environment immediately after birth. Fecal examinations were made at weekly intervals. Both groups acquired various species of the super-families Strongyloidea and Trichuroidea and tapeworms of the genus *Moniezia*. The first positive fecal examinations were obtained 54 days after birth for group B and 42 days after exposure for group A. The recorded exposure period for group B would appear to be from 14 to 21 days too long, since lambs eat little formed food during early life. These experiments establish that gastrointestinal worm parasites can be acquired by sheep while stabled during the winter months.

A field trial comparing phenothiazine, tetrachlorethylene emulsion, and copper sulphate and nicotine sulphate mixture for the treatment of trichostrongylosis, H. M. GORDON and L. K. WHITTEN (*Jour. Council Sci. and Indus. Res. [Austral.]*, 13 (1940), No. 2, pp. 81-85).—The administration of phenothiazine in doses of 15 gm. for weaners about 5 mo. old and weighing about 20 kg. was highly efficient against *Trichostrongylus* spp. and showed encouraging results against *Oesophagostomum venulosum* and *Chabertia ovina*. "Tetrachloroethylene in doses of 3.5 cc. administered in an emulsion following a dose of copper sulfate was also highly effective against *Trichostrongylus* spp. The after-effects observed following the use of this drug may be of very serious significance when large numbers of sheep are being treated and held in yards and unless a good deal of attention is given to those individuals which become semicomatose and are unable to rise. Under crowded conditions in yards a great many sheep are likely to be suffocated by other sheep falling on them. The mixture of copper sulfate and nicotine sulfate usually prescribed against *Trichostrongylus* spp. gave very poor results. The possible reasons for this are briefly discussed, and further studies on suggested reasons are indicated."

Studies on phenothiazine as an anthelmintic: A comparison of the efficiency of finely and coarsely ground phenothiazine against *Oesophagostomum columbianum*, H. M. GORDON (*Jour. Council Sci. and Indus. Res. [Austral.]*, 13 (1940), No. 2, pp. 85, 86).—In a study of the differences in the anthelmintic efficiency of phenothiazine as related to particle size, a coarsely ground preparation appeared to be less efficient than a finely ground preparation when administered against *O. columbianum* in sheep.

The anthelmintic efficiency of Lentin (Merck) against *Oesophagostomum columbianum*, H. M. GORDON (*Jour. Council Sci. and Indus. Res. [Austral.]*, 13 (1940), No. 2, pp. 87-90).—In the experiment reported, Lentin, a choline derivative (aminofornyl- β -hydroxyethyltrimethylammonium chloride), administered in doses exceeding those recommended by manufacturers against *Strongylus* infestation in sheep was not an efficient anthelmintic for use against *O. columbianum*, *Haemonchus contortus*, or *Trichuris ovis*. Its use was attended with fatal toxic effects, 6 of the 22 sheep died, and a seventh recovered after administration of atropine. These results, obtained in the field, confirm those of other trials carried out under laboratory conditions with sheep in pens and receiving dry feed.

Experiments on the recovery of sheep nematode larvae from pastures, G. P. KAUZAL (*Jour. Council Sci. and Indus. Res. [Austral.]*, 13 (1940), No. 2, pp. 95-106, figs. 2).—A description is given of the technic which has given the best results in the recovery of sheep nematode parasites from pastures. An illustration of the apparatus employed is included. In principle, the isolation relies upon the fact that larvae migrate laterally as well as in a vertical direction from the soil.

The use of oil of citronella for the protection of lambs against blowfly strike, F. G. LENNOX and D. L. HALL (*Jour. Council Sci. and Indus. Res. [Austral.]*, 13 (1940), No. 2, pp. 65-73, fig. 1).—Report is made of studies in which turntable trapping experiments demonstrated the repellency of oil of citronella to blowflies. Insectary tests with a pure population of the Australian sheep blowfly *Lucilia cuprina* showed that the application of solutions of the oil to the fleece surrounding attractive areas on sheep reduced the fly oviposition on these areas. When applied to the tail and purse of lambs at "marking" (tailing and castration), 5- or 10-percent concentrations of the oil in an aqueous soft-soap solution significantly reduced the proportion of animals struck during the subsequent period of healing.

Castration of boars under chloroform anesthesia, W. L. BOYD and H. C. H. KERNKAMP. (Minn. Expt. Sta.). (*North Amer. Vet.*, 21 (1940), No. 5, pp. 287, 288).

Diseases of swine, C. NEIVA (*Moléstias dos suínos*. São Paulo: Rothschild Loureiro & Co., 1940, pp. 279, figs. 32).—The affections and parasites of swine met with in Brazil are dealt with in a practical way. Lists of references to the literature relating to the more important are included.

Changes in the dimensions of Balantidium from swine upon cultivation, N. D. LEVINE. (Univ. Ill.). (*Amer. Jour. Hyg.*, 32 (1940), No. 1, Sect. C, pp. 1-7, figs. 2).—In a study made of the dimensions of *Balantidium* from swine before and after propagation in culture 1,900 individuals from 8 pigs were measured. A significant change in both length and length:width ratio was found after cultivation. In 6 strains the mean length:width ratio became smaller, that is, the individuals became more *B. coli*-like, the reduction varying from 0.10 to 0.53 unit. In 1 of these the shift was from *B. suis*-like to definitely *B. coli*-like dimensions. In 2 other strains the protozoa became more slender and *B. suis*-like, the length:width ratios increasing from 0.10 to more than 0.18 unit.

Pulmonary edema in hogs, L. E. STARR. (Ala. Polytech. Inst.). (*Vet. Med.*, 35 (1940), No. 6, p. 359).

Vesicular exanthema of swine, B. B. WHITE (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 762, pp. 230-232, 237, figs. 5).

Results of feeding zinc to pregnant mares and to mares nursing foals, R. GRAHAM, J. SAMPSON, and H. R. HESTER. (Univ. Ill.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 760, pp. 41-47, figs. 5).—Experiments conducted with a view to determining the possible relation of zinc to an affection of suckling colts on a farm located near a zinc smelter at Depue, Ill., are reported. It was thought that zinc from fumes of the smelter plant had been deposited on the grass and that the milk of the mares, feeding thereon, contained amounts sufficient to poison the colts. Thus far, no experimental evidence has been obtained through feeding zinc lactate to six pregnant mares or to mares nursing foals, over a period of 2.5 yr., to show that the fatal illness of two colts was due to zinc poisoning. Zinc in the amounts of 54 and 540 gr. of zinc sulfate, respectively, fed daily to pregnant mares and mares nursing foals failed to induce symptoms in either the mares or the suckling foals. These preliminary results of zinc feeding are in agreement with the findings of Thompson, Marsh, and Drinker (*E. S. R.*, 57, p. 195).

Studies with equine streptococci.—I, A survey of beta-haemolytic streptococci in equine infections, P. L. BAZELEY and J. BATTLE (*Austral. Vet. Jour.*, 16 (1940), No. 4, pp. 140-146).—Four hundred and fifty-seven strains of group C Lancefield streptococci (β -hemolytic), recovered from 415 cases of serious and typical equine diseases, were examined by colony morphology, serology, and biochemical reactions. These strains have been classified broadly into a scheme that may be incorporated into the group plan of Lancefield. There was a complete agreement between the serological and biochemical reactions of the types found. The epidemiology of the strains is discussed briefly.

Host range of equine encephalomyelitis: Susceptibility of the North American cottontail rabbit, jack rabbit, field vole, woodchuck, and opossum to experimental infection, J. T. SYVERTON and G. P. BERRY (*Amer. Jour. Hyg.*, 32 (1940), No. 2, Sect. B, pp. 19-23).—Observations made of the susceptibility to infection by the virus of equine encephalomyelitis are reported for these animals, all of which have natural habitats in close proximity to equines during the time of year when equine encephalomyelitis occurs. In the limited ex-

perience, the opossum was refractory to infection by both the eastern and western types of the virus. The field vole was shown to have about the same order of susceptibility as the guinea pig, mouse, or Richardson ground squirrel. The woodchuck was less susceptible than any in the foregoing group of animals, but brain-to-brain passages of the virus were readily made, and the results suggest that the field vole and woodchuck may act in nature as reservoir hosts for the disease. The least susceptible of the animals tested were the wild rabbits, and although both genera (*Sylvilagus* and *Lepus*) gave definite evidence of infection following intracerebral inoculation, the virus could not be maintained by brain-to-brain passage. Nineteen references are listed.

A study of birds and mosquitoes as hosts for the virus of eastern equine encephalomyelitis. W. A. DAVIS (*Amer. Jour. Hyg.*, 32 (1940), No. 2, Sect. C, pp. 45-59).—Studies conducted with 17 species of mosquitoes revealed that 5 native to Massachusetts, namely, *Aedes vexans*, the salt-marsh mosquito, the brown salt-marsh mosquito, *A. atropalpus*, and *A. triseriatus*, and a laboratory strain of the yellow-fever mosquito could transmit the virus of eastern equine encephalomyelitis from infected birds or mammals to other animals. No transmissions were obtained with mosquitoes of other genera (*Culex*, *Mansonia*, and *Anopheles*). It is deemed likely that most mosquitoes of the genus *Aedes* can serve as vectors of the virus in the laboratory but that in nature the importance of the different species is determined by ecologic factors, including the feeding habits of the insects, their flight range, abundance, and perhaps seasonal variations. If mosquitoes are the natural vectors of equine encephalomyelitis, *A. vexans* was probably the most important vector of the infection in an epidemic that occurred in New England in the summer of 1938, a study of which is said to have supported the postulate of Ten Broeck (*E. S. R.*, 83, p. 819) that birds act as reservoir hosts for the virus of equine encephalomyelitis. Experimental evidence showed that birds (English sparrows, pigeons, cowbirds) could be infected with virus by the bite of infected mosquitoes, and that infected birds may serve as a source from which mosquitoes may become infected. These results do not, of course, prove that birds are the natural reservoir of equine encephalomyelitis, but added to the epidemiologic studies it is deemed likely that they do constitute a reservoir from which mosquitoes become infected with virus which they, in turn, pass on to horses, human beings, birds, or other animals. Thirty-nine references are included.

Indication of the presence of the virus of equine encephalomyelitis in brain of ground squirrel. R. GWATKIN and T. MOORE (*Canad. Jour. Compar. Med. and Vet. Sci.*, 4 (1940), No. 3, pp. 78-82).—Examination made during the summer of 1939 of the brains of 127 Richardson ground squirrels (*Citellus richardsoni*) by intracerebral inoculation of guinea pigs with 1:20 of brain suspension of western virus resulted in the finding of 10 brains that were contaminated, causing the death of injected animals.

Anaphylactic reactions following the use of chick embryo equine encephalomyelitis vaccine. W. R. WOLFE and B. F. TRUM ([*War. Dept. U. S.*], *Off. Surg. Gen., Vet. Bul.*, 34 (1940), No. 3, pp. 226-228, fig. 1).—Report is made of reactions of an anaphylactic nature that occurred in 3 horses and a mule out of the 1,014 horses and mules at Fort Robinson, Nebr., vaccinated with chick embryo vaccine against equine encephalomyelitis.

A simple and practical test for the diagnosis of osteoporosis in horses. V. D. RATNAM (*Indian Jour. Vet. Sci. and Anim. Husb.*, 10 (1940), No. 1, pp. 115, 116, pl. 1).

Canine rabies vaccination: An experimental study of the efficacy of the single subcutaneous injection method with phenol treated vaccine. C. N.

LEACH and H. N. JOHNSON (*Amer. Jour. Hyg.*, 32 (1940), No. 2, Sect. B, pp. 46-53).—Natural resistance of unvaccinated dogs to artificial intramuscular inoculation with massive doses of street rabies virus was demonstrated. Of 105 vaccinated dogs, 24.8 percent died of rabies after test virus inoculation, while 55 percent of 120 control animals succumbed to the disease. The mortality among control animals was significantly higher than that observed among vaccinated dogs. It is concluded from this study that a single subcutaneous vaccination with phenol-treated vaccine affords some protection against subsequent experimental exposure to rabies street virus. Thirteen references are listed.

Preventing poultry diseases, M. W. EMMEL. (Fla. Expt. Sta.). (*Fla. Grower*, 48 (1940), No. 9, p. 14).

[**Mortality among laying fowl**], F. B. HUTT. (Cornell Univ.). (*Harper Adams Util. Poultry Jour.*, 24 (1938-39), No. 11, pp. 395-399).—The mortality in 2 New York State laying tests that commenced in 1931 was 22.4 percent of 9,893 birds entered. Of the 1,922 cases passed upon, 38.4 percent were due to neoplasms, 25.3 to disorders of reproduction, 11.2 to prolapse of oviduct, 5.9 to kidney diseases, 3.4 to impactions, alimentary tract, 2.4 to internal hemorrhage, and 13.4 percent to other causes.

A technique for the intravenous inoculation of chick embryos, E. A. EICHHORN. (U. S. D. A.). (*Science*, 92 (1940), No. 2385, pp. 245, 246, fig. 1).—Description is given of a simple technic developed for the intravenous inoculation of chick embryos. Employing this technic, there had been 32 passages from egg to egg in series at the time of writing, and the mortality rate due to hemorrhage in faulty manipulation had been approximately 30 percent. There is thought to be no reason why this mortality rate cannot be considerably reduced with improved technic.

Preliminary report on the propagation of the fowl-leucosis virus on chick embryos by intravenous inoculation, W. J. HALL, C. W. BEAN, and M. POLLARD. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 762, p. 247).—The authors, using the intravenous technic described by Eichhorn, as above noted, obtained marked lesions in the embryos which became infected through inoculation. "Chick embryos 11 days of age were inoculated intravenously with 0.05 cc. of heparinized leukemic chick blood. Daily examination of blood smears from the inoculated embryos was made after a few days of incubation. The appearance of increasing numbers of hemocytoblasts in the peripheral blood indicated the onset of leucosis. The disease developed in the embryo in 6 to 8 days after inoculation, at which time the embryo became morbid or died. Embryo infection was confirmed in every case by inoculation of susceptible chicks with embryo blood. These chicks then developed typical cases of leucosis in about the same time as those inoculated with leukemic chick blood. Approximately 3.5 percent of embryos inoculated with leucotic chick blood developed leucosis. Two groups of embryos came down with leucosis when inoculated with second-passage embryo blood."

The effect on the growth-rate of young chickens of infections of the tapeworm *Hymenolepis carioca*, G. W. LUTTERMOSER. (U. S. D. A.). (*Helminthol. Soc. Wash. Proc.*, 7 (1940), No. 2, pp. 74-76).—The feeding of 1,000 cysticercoids of *H. carioca* to each of twenty 2- to 4-week-old Rhode Island Red chicks did not seem to retard their growth rate when kept on a well-balanced diet.

Tests with miscellaneous substances for the removal of tapeworms from chickens, P. D. HARWOOD and J. E. GUTHRIE. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 762, pp. 248-253).—A review is presented in connection with 51 references to the literature, and experiments conducted with 223 substances and 27 mixtures as anthelmintics for the removal of tapeworms from

chickens are reported. Of the materials tested, only lead arsenate exhibited any promise as a poultry taeniocide, and in carefully controlled tests in which chickens experimentally infected with *Raillietina cesticillus* were used, it was found that lead arsenate in effective doses is too toxic to be recommended for general use for this purpose. The details of the experiments conducted are given in tables.

A preliminary note on the efficiency of phenothiazine against some poultry helminths, F. H. S. ROBERTS (*Austral. Vet. Jour.*, 16 (1940), No. 4, pp. 172-174).—The administration of phenothiazine in the commercial form known as Thiox was tested against certain poultry helminths at dose rates of 0.4 gm. per pound body weight, 1 gm. per pound body weight in a single dose, and 1 gm. per pound body weight divided into three equal portions and administered on 3 successive days. "At all these dose rates the drug was ineffective against *Cheilospirura hamulosa*, *Raillietina tetragona*, and *Hymenolepis carioca*. A dose rate of 1 gm. per pound body weight in a single dose gave a moderate efficiency against *A[scaridia] galli* (56.2 percent) and indicates that better results may be secured with a higher dose rate. The drug appears to have a promising anthelmintic action against *H[eterakis] gallinae*. There are, then, indications from these trials that phenothiazine may prove of some value against *A. galli* and *H. gallinae* if used in large doses and given in the food, a line of treatment to be investigated in the near future."

The toxicity of various copper compounds and mixtures for domesticated birds, E. M. PULLAR (*Austral. Vet. Jour.*, 16 (1940), No. 4, pp. 147-162, figs. 2).—When copper preparations were fed in varying amounts to fowls, the minimum lethal doses determined, expressed in grams per kilogram live body weight, were as follows: Single crystal of copper sulfate 0.9, powdered copper sulfate from 0.3 to 0.5, copper sulfate in a 4-percent solution from 1 to 1.5, copper sulfate when mixed with twice its weight of sodium chloride from 0.3 to 0.5, and copper carbonate 0.9. The copper sulfate in the dry residue of bordeaux mixture was only feebly toxic, and that in bordeaux mixture solution was completely nontoxic for fowls. The question of the availability and absorption of copper is discussed in the light of these results.

On the resistance of chickens to the intestinal nematode *Ascaridia lineata* (Schneider) following immunization, L. L. EISENBRANDT and J. E. ACKERT. (Kans. Expt. Sta.). (*Amer. Jour. Hyg.*, 32 (1940), No. 1, Sect. D, pp. 1-11).—In the two experimental lots of chickens reported upon, consisting of nine sub-groups, it was shown that White Leghorn chickens do not readily develop an immunity to the intestinal nematode *A. lineata* following intracardial injections of sterile extracts of this nematode. In some instances, however, a parenteral immunity apparently affected the intestinal nematodes, since three of the nine groups of chickens artificially immunized were significantly protected against *A. lineata*. "An artificially acquired general body immunity, as evidenced by the many positive precipitin ring tests made from the serums of the injected chickens, usually, but not always, failed to protect the host from *A. lineata*. In six of nine groups of chickens, the nematodes were not significantly shorter than those in the control chickens. The intestinal nematode *A. lineata* failed to stimulate chickens to develop an acquired general immunity. This was substantiated by the fact that all serological data were negative for the noninjected control birds. The type and the quantity of antigen and the age at which the injections of antigen were initiated did not play important roles. Titers for the positive precipitin tests were low. They were not correlated with the length or the numbers of *A. lineata* in the particular host involved."

A list of 24 references to the literature is included.

Some observations on the viability of Doyle's disease virus of fowls under different conditions, S. G. IYER (*Indian Jour. Vet. Sci. and Anim. Husb.*, 10 (1940), No. 1, pp. 81-87).—Results of experiments conducted with reference to the viability of the virus of the so-called Doyle's disease of fowls under laboratory conditions, with a review of the literature on the subject, are presented. The virus used in the tests was mostly contained in organs such as the liver and spleen. After aging at room temperature of about 17° C., it remained viable for 21 days. At 37° the virus did not die after 24 days but was inert after 31 days. Saline emulsion of buccal swabs from fowls dead of the experimental disease gave variable results. It remained viable at 37° for 3 days but was found to be dead after 4 days. Exposure to direct sunlight for 1 hr. had no lethal effect on the virus.

Successful cultivation of avian plasmodia in duck embryos, F. WOLFSON (*Amer. Jour. Hyg.*, 32 (1940), No. 2, Sect. C, pp. 60, 61).—In the study reported, three species of *Plasmodium*, namely *P. cathemerium*, *P. elongatum*, and *P. lophurae*, were successfully cultivated in duck embryos. This is the first report known of the successful cultivation of any species of the genus in bird embryos.

Sinusitis in turkeys, L. HART (*Austral. Vet. Jour.*, 16 (1940), No. 4, pp. 163-168, fig. 1).—A description is given of a disease which appears to be specific for turkeys and is characterized by inflammation of the infraorbital sinuses. "Although in the field it behaves like a highly infectious disease, experimentally it has been possible to transmit it only by direct injection of exudate into the sinus. Infection by contact, ocular and nasal instillation, and atomization gave negative results. The time elapsing between injection and the appearance of symptoms varied from 3 to 12 days. The causal agent was not determined, but appears most likely to be a filtrable virus, although two attempts to pass it through an Elford collodion membrane were unsuccessful. The causal agent persisted in vivo for 11 mo., the maximum period tested. Sinus content produced the disease after being held in glycerine saline for 14 days at 36° C., but not after being held for 2 mo. After being held in saline at 36° for 14 days it failed to produce the disease. The disease was set up by injection into each sinus of 1 cc. of a 1 in 10,000 dilution of exudate. Birds which had recovered from one attack were immune to reinfection, but attempts to produce immunity artificially were unsuccessful. Injection into affected sinuses of small amounts of 2 to 5 percent silver nitrate solution appears to be the best and cheapest method of treatment, providing it is carried out in the early stages and care is taken that the solution does not enter the subcutaneous tissues."

Post-mortem autodigestion of the intestinal mucosa of the turkey, L. E. ROSENBERG. (Univ. Calif.). (*Stain Technol.*, 15 (1940), No. 2, pp. 53-56, figs. 7).

A note on the development of acquired immunity in avian malaria, R. HEGNER (*Amer. Jour. Hyg.*, 32 (1940), No. 1, Sect. C, pp. 24-26, fig. 1).—In a study made of a canary infected with the Hartman strain of *Plasmodium cathemerium* the rate of destruction of malaria parasites was found to increase progressively and rapidly during the rise in the number curve. There is no sudden appearance of resistance at the crisis. Infections in monkeys and man appear to be similar to those in birds in this respect.

Apoplexy in a canary, A. J. DURANT and H. C. McDUGGLE. (Mo. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 762, pp. 265, 266, fig. 1).

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Indiana Station] (*Indiana Sta. Rpt.* 1939, pp. 13, 34-38, 39-41, 42-45, 77, 78, figs. 5).—This report notes work on electric pig brooders, and a study of the use and practicability of

electric heat for warming drinking water for livestock, both by T. E. Hienton and J. M. Fore; mechanical refrigeration of eggs, by Hienton, Fore, and E. R. Menefee; use of electric energy in brooding, by Hienton and Fore; precooling of fresh fruits in refrigerator cars, by Hienton and K. I. Fawcett; electric soil sterilization, by Hienton and J. B. Greiner; codling moth control with electric traps, by G. E. Marshall and Hienton; plow trash shields, by R. H. Wileman; Canada thistle and similar weed-control implements, by Wileman and O. C. Lee; low corn-cutting demonstrations, and rubber tires for tractors and farm implements, both by Wileman; seed-corn drying, by Wileman and A. J. Ullstrup; poultry-house ventilation, by I. D. Mayer and C. W. Carrick; and combined harvester thresher, atmospheric corrosion of wire and wire products, experimental dairy barn, field ensilage harvesting, and power-driven manure spreader, all by Mayer.

Range improvement through conservation of flood waters.—A report of progress, O. W. MONSON and J. R. QUESENBERRY. (Coop. U. S. D. A.). (*Montana Sta. Bul. 380 (1940), pp. 20, figs. 16*).—This bulletin reports data on the measurement of the actual run-off from small watersheds, a determination of the extent to which this run-off can be recovered and used, and an investigation of the possibilities of range vegetation by the conservation and use of such run-off water. As a means for run-off measurement, a 4-ft. Parshall flume was placed at the mouth of a coulee receiving the run-off from about 2 sq. miles of watershed. This flume was equipped with an automatic water-stage recorder so controlled by a float as to operate only during actual water flow.

Water passing through the coulee was prevented from following a large gully to the river by an earth dam, or dike, 3 ft. high and provided with five 20-ft. spillways for distribution of the water. In three areas three methods of utilizing this water were tested. The first, described as free flooding, but including the use of two shallow contour ditches to prevent localization of the water in swales and low spots, appeared to be adapted to lands having slopes up to 5 percent. The second control procedure, described as "controlled flooding" and involving a system of dikes at right angles to the slope and almost on the contour, was designed to direct the water back and forth across the slope. Dikes 16 in. high, graded 0.05 percent, and about 1,200 ft. in length were used. Natural revegetation of both dikes and borrow pits is progressing well. Of these experiments it is stated that the method of meandering flooding is adapted to slopes of less than 1.5 percent, but for steeper slopes the contour spreading ditches should be used. On a third area, having a slope of less than 1 percent, a procedure described as ponding or check flooding was tested. Dikes from 12 to 14 in. high backed up the water over strips 100 ft. wide. Contour dikes at contour intervals of 0.8 ft. were provided with riprapped spillways about 100 ft. apart to prevent overtopping. Dikes and spillways were successfully seeded to brome grass. Crested wheatgrass also gave good results and responded well to flood irrigation, though its growth was less heavy than that of the brome grass. This method gave better penetration of the water than did the mere flooding over of the surface, but it concentrated the available water on a smaller area of land.

Winter pasture grazing load on the area treated in these experiments was increased from 200 head, requiring supplementary feeding with hay and cottonseed cake, to 300 head, requiring no hay and but little cottonseed cake. It is believed that the results have more than justified the expense.

Surface water supply of Hawaii, July 1, 1937, to June 30, 1938 (*U. S. Geol. Survey, Water-Supply Paper 865 (1940), pp. IV+122*).—This report presents measurements of stream and ditch flow in the Territory.

Experiments with electric water heaters for dairy farms, J. M. FORE and T. E. HENTON (*Indiana Sta. Bul. 447 (1939), pp. 12, figs. 11*).—The efficiencies of 15 heaters, 11 of the tank type and 4 portable immersion units, were tested under various conditions in the heating of water for cleansing dairy utensils. The average final temperature attained was 174.9° F., as against the 165° to 170° considered necessary for proper washing. The most important single efficiency factor was that of the insulation, the tank heaters showing an average efficiency of 77.7 percent, as compared with the 62.8 percent average efficiency of immersion heaters operated in uninsulated pails. Of the immersion heaters, 2 used in uncovered, uninsulated pails showed an average efficiency of 77.85 percent. The same 2 heaters in pails placed in heat-insulating materials in a box and provided with an insulated cover operated at an average efficiency of 88.5 percent. Immersion heaters used in uninsulated water containers were more efficient when of 1 kw. or greater wattage.

Electric water heaters of from 3- to 15-gal. capacity are practical for use on Indiana dairy farms producing bulk milk where electric service is available. Five of the tank-type heaters, equipped with heating elements of 2,000 w. or more, heated 5 gal. of water from tap temperature to 170° in less than 1 hr. Three immersion heaters and 1 small tank heater heated 3 gal. of water to the same temperature in less than 1 hr. Such heaters may be connected before milking is started to provide from 3 to 5 gal. of hot water when milking is finished. Of the tank heaters of low wattage (from 250 to 1,000), 3 equipped with thermostats required more than 1 hr. to heat water to 170°. These heaters, because of the thermostat control, are operated continuously. They will supply from 8 to 15 gal. of hot water when needed.

AGRICULTURAL ECONOMICS

[Papers and notes on agricultural economics] (*Jour. Farm Econ.*, 22 (1940), No. 3, pp. 533-620, 633-646, figs. 2).—Included are the following papers: Time Preference and Conservation, by A. C. Bunce (pp. 533-543) (Iowa Expt. Sta.); Supply Schedules—"Long-Time" and "Short-Time", by R. L. Mighell and R. H. Allen (pp. 544-557) (U. S. D. A. and Univ. Ky.), having for its purpose "to re-examine the supply-schedule concept and to indicate some of the bridges to be built between the earlier supply-response studies and the type of long-time response study that seems needed for long-range price forecasting and long-time planning"; Training and Recruitment of Agricultural Economic Personnel—IV, A Training Program, by T. Cooper (pp. 558, 559) (Univ. Ky.), V, For Public Service, by J. D. Black (pp. 560, 561), VI, An Administrator's View, by F. F. Hill (pp. 562-566) (Cornell Univ.), and VII, The Government Service as a Career, by C. F. Sarle (pp. 567-569) (U. S. D. A.) (*E. S. R.*, 83, p. 834); Dr. Schultz on Farm Management Research, by J. D. Black (pp. 570-580), being comments on the paper entitled Theory of the Firm and Farm Management Research (*E. S. R.*, 82, p. 400); Part-Time Farming Research, by L. A. Salter, Jr., and L. F. Diehl (pp. 581-600) (U. S. D. A.), analyzing 24 research reports to ascertain certain aspects of part-time farming and to assist in the orientation of future research; Trading in Wheat and Corn Futures in Relation to Price Movements, by P. Mehl (pp. 601-612) (U. S. D. A.), a study of the relationship between daily trading of various classes of traders and between their trading and daily price changes of Chicago wheat and corn prices, August 1937 to June 1938; and Economic Phases in Soil Erosion Control, by P. E. McNall (pp. 613-620) (Univ. Wis.).

The following notes are included: Suggestions for a Sample Census of Agriculture in the West, by M. Clawson (pp. 633-637) (U. S. D. A.); Social Aspects

of Land Use in Delaware, by R. O. Bausman (pp. 637-640) (Univ. Del.); and Financing of Agriculture in Russia, by V. Katkoff (pp. 640-646) (Univ. Calif.).

[Abstracts of papers on agricultural economics] (*Assoc. South. Agr. Workers Proc.*, 41 (1940), pp. 41-43, 46-48, 94, 95, 106-108, 120-128, 130-132, 164, 165, 166, 167, 168-178, 208-211, 220-225).—Included are abstracts of papers presented at the forty-first annual convention of the Association of Southern Agricultural Workers at Birmingham, Ala., February 7-9, 1940, on agricultural adjustment, land-use planning, land classification, farm labor and tenancy, lease provisions, marketing different farm products, farm enterprises, farm and forest cooperatives, forest management, soil conservation, etc.

[Investigations in agricultural economics by the Indiana Station, 1938-39] (*Indiana Sta. Rpt. 1939*, pp. 81-85, 103, figs. 3).—Brief statements of findings are included for studies of economy of pastures and land use on different soils, both by F. V. Smith; profitable farm practices in central Indiana, economical farm power, and economy of combines, all by J. C. Bottum; successful farms in northwestern Indiana, movements of feeder livestock, and farm buildings, all by L. S. Robertson; costs and returns on intensive crops in northern Indiana, by Robertson and M. G. Smith; crop returns on different soils, by Bottum and F. V. and M. G. Smith; motortruckes, by T. K. Cowden; costs of farm machinery, by O. G. Lloyd and E. L. Butz; landlord-tenant relations, by Lloyd and J. R. Hays; and marketing eggs and the retailing of eggs in Indianapolis, both by E. R. Menefee.

Current Farm Economics, [August 1940] (*Oklahoma Sta., Cur. Farm Econ.*, 13 (1940), No. 4, pp. 77-106, figs. 10).—In addition to the usual review of the agricultural situation and tables on prices, etc., the following articles are included: How Land-Use Planning Operates in Oklahoma, by H. A. Miles (pp. 83-89) (U. S. D. A.) (E. S. R., 83, p. 689); Guideposts for Farmers' Analysis of Hog Prices, by G. P. Collins (pp. 90-98); and The Principle of the Graduated Land Tax, by R. T. Klemme (pp. 99-103).

Foreign Agriculture, [August-September 1940] (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr.*, 4 (1940), Nos. 8, pp. 459-507, figs. 16; 9, pp. 511-574, figs. 10).—No. 8 includes articles on Netherlands Agriculture and the War, by P. G. Minneman and C. L. Davis (pp. 459-492), discussing agricultural production and trade, wartime agricultural control measures, and the effects of the World War and the present war, and on The Hog Industry in Argentina, by P. O. Nyhus (pp. 493-507), discussing production, marketing, consumption and trade, and the wartime prospects. No. 9 is an article on Agriculture of the Netherlands Indies, by W. Ladejinsky (pp. 511-574), dealing with physical background, the people and the land, economic welfare, agricultural practices, agricultural production, effect of the world depression on the islands, reconstruction, and the foreign trade.

[Agricultural law] (*Internatl. Inst. Agr. [Roma], Internatl. Bul. Agr. Law*, No. 1 (1940), pp. [2]+114).—This first number includes articles on All-Risk Wheat Crop Insurance in the United States of America Under the Federal Crop Insurance Act of 1938, by R. H. Shields and H. Donoho (pp. 4-19) (U. S. D. A.); The New Romanian Civil Code and Agrarian Legislation, by V. Bulgaru (pp. 19-33); The Dutch Law on Agricultural Leases, by C. M. O. van Nispen tot Sevenaer (pp. 33-46); Emphyteusis in Modern Greek Law, by A. D. Sideris (pp. 47-53); and Review of the Agrarian Jurisprudence of the Italian Court of Cassation, by A. Azara (pp. 53-68); notes on Agrarian Law in Italy (Legislation, Science, and Teaching), by P. Germani (pp. 69-80), and The Evolution of the Right of Landownership in Yugoslavia (pp. 80-82); and abstracts of the Act of December 26, 1939 [Spain] setting up bases for the colonization of large

extensions of land, the act [Italy] providing for the colonization of the large landed property in Sicily, and measures [Switzerland] against speculation in land overindebtedness.

The farmer in the groupistic regime, H. C. TAYLOR (*Jour. Land and Pub. Util. Econ.*, 16 (1940), No. 3, pp. 253-261, figs. 2).—The groupistic struggle in the United States of industry, labor, and agriculture is discussed.

"The approach to the solution of this problem would seem to lie in the substitution of intergroup cooperation for intergroup conflict, the substitution of statesmanship economics for groupistic economics, the substitution of the general welfare as the goal instead of seeking to benefit one group at the expense of another. . . . This calls for a political economy which will encourage balanced abundance and parity real incomes for comparable services. It is a function of government to respond to this need by discouraging selfish groupistic policies and by developing a truly national economic policy."

Accounting for farm costs: A proposed approach, J. W. DAVULT (*Thesis, Columbia Univ., New York, 1939, pp. 151*).—This doctoral thesis is "an attempt to examine the nature of farm costs and their allocation with reference to the general farm from a theoretical economic and accounting point of view, and to suggest a method of approach similar to factory cost accounting procedure." The valuation of farm real estate, farm personalty, departmentalizing the farm, and the allocation of farm costs are discussed.

The economic history of live stock in Ireland, J. O'DONOVAN (*Dublin: Cork Univ. Press; London and New York: Longmans, Green and Co.* [1940], pp. [4]+460, [figs. 12]).—The principal topics treated in this book are livestock in Ireland to 1845, the industry since the famine, and State schemes for the improvement of livestock in Ireland.

Possibilities for cattle income, R. T. BURDICK (*Colorado Sta. Bul.* 460 (1940), pp. 37).—Included in this analysis of factors affecting income are tables showing (1) the effect of death losses with different percentages of calf crop upon number of heifers or steers remaining at the end of one or more years per 100 cows in the breeding herd; (2) upon number of heifer calves saved at the end of first year for replacements; (3) upon number of cows for sale; (4) upon percentage change in sale weight on 375-lb. base for calves and 700-lb. base for yearlings; (5) with different percentages of calf-crop replacement and death losses, (a) the possible number of calves and yearlings available for sale and (b) the pounds of calf, yearling, and cow sales from 100 breeding cows; (6) size of herd to maintain 100 breeding cows and pounds and value of calf, yearling, and cow sales when heifers enter the herd at 2 and 3 yr. of age; (7) effects of sale price on income from cow sales; and (8) cost per 100 lb. of beef with different first-year costs and production.

Corn in the development of the civilization of the Americas, L. O. BERCAW, A. M. HANNAY, and N. G. LARSON (*U. S. Dept. Agr., Bur. Agr. Econ. Bibliog.* 87 (1940), pp. IV+195).—A selected and annotated bibliography including over 400 references.

Cotton production in the United States: Crop of 1939, H. J. ZIMMERMAN (*Washington: U. S. Bur. of the Census, 1940, pp. II+37*).—Tables show the United States production of cotton and linters by years from 1899 to 1939 and by States the production of cotton and linters and cotton ginned to specified dates 1936-39; average gross weight of several kinds of bales and number and gross weight of square bales 1937-39; number of ginneries 1939 and quantity of cotton, exclusive of linters, ginned 1936-39 by counties; and cotton ginned to specific dates.

Flax-management practices in Imperial Valley, with world statistics, W. SULLIVAN, H. L. LANDERMAN, and G. A. CARPENTER (*California Sta. Bul.* 641 (1940), pp. 38, figs. 5).—A brief history of flax in California is given. Analysis is made of the cost and input factors in the Imperial Valley and the processing, marketing, etc., of flax and flax products. An appendix includes world flax statistics.

An analysis of peanut-cotton-hog farm businesses in a depression year, F. L. UNDERWOOD (*Virginia Sta. Tech. Bul.* 67 (1940), pp. 103, figs. 4).—Records for 1932 were obtained by the survey method for 699 farms in southern Nansemond County. An analysis is made of the receipts, expenses, profits, capital, land use, crops, farming practices, prices received for peanuts and cotton, factors affecting crop yields, numbers and value of livestock, hog production and disposal, pork prices, factors affecting hog production, the effect on income of rates of production, index of prices, labor efficiency, size of business, combination of enterprises, personal factors, etc.

The average income available for the use of capital and operator's labor was —\$25, and the average labor income —\$220. The unfavorable price situation and unfavorable weather during the year were the most important factors affecting the general level of income. Variations in prices for products sold, in amounts of productive work per man, and in production rates of crops and livestock, particularly hogs, were the most important factors affecting the income of different farms. Variations in prices were due chiefly to quality and volume of products. Labor efficiency generally was associated with size of business, but large capital investment tended to offset the advantages of relatively large business. Relatively high production of crops and hogs was profitable if obtained economically. Due to the general situation size of business was inversely related to income. Increased peanut acreage was profitable if yields were high and quality good. The addition of hogs was the most profitable way to increase size of business. Increased corn production was profitable only through conversion into pork. Increased cotton acreage was associated with reduced income. Personal factors were important only in so far as they were associated with sound farm management. Of the total income for the farms, 34.6 percent was products used by the household, and on over one-fourth of the farms such products constituted 50 percent or more of the total income. As the proportion increased all important measures of farm business efficiency, including labor earnings, declined. "The outstanding effect of the depression was to make improvements in rates of production and labor efficiency cost more than they were worth at prevailing prices for farm products unless such improvements could be achieved with little or no cash outlay, either by reorganization of the farm layout or by the addition of hogs to the business."

Economics of flue-cured tobacco farming, W. L. GIBSON, JR. (*Virginia Sta. Tech. Bul.* 66 (1940), pp. 135, figs. 3).—This study was a repetition in less detail of the study previously noted (E. S. R., 81, p. 857) to determine the effects of the A. A. A. program begun in 1933 upon farm operations and farm income and to study the farm organization from the standpoint of a different price level and different weather conditions. For 1936, 535 records were used in the main analysis. The weather conditions in 1936 were excellent for tobacco, while those in 1933 were relatively unfavorable. The average price for tobacco in 1933 was \$13.67 per 100 lb., while that in 1936 was approximately twice as much. Analyses similar to those in the previous study were made, and findings for the 2 yr. are compared.

The total average capital investment per farm in 1936 was \$6,718, an increase of 43 percent from 1933. Total receipts averaged \$1,860, nearly double those

in 1933. Farm expenses averaged \$945 in 1936, average total farm labor income was \$567, and the average operator's income was \$444 plus \$482 worth of properties. Landlords return averaged 8.3 percent. Croppers averaged \$409 above their expenses plus \$278 for properties. The average size of farm increased 11.3 acres from that of 1933. The acreage of tobacco was reduced 1 acre per farm, that of corn 1.3 acres, and that of wheat 1 acre. The acreage of hay was increased from 4.3 to 11 acres, that of open-permanent pasture from 8.6 to 14 acres, and the number of animal units per farm from 6.03 to 6.76. Farms normally producing high yields of good quality tobacco reduced their acreage in tobacco less than the average. Farms not cooperating with the Soil Conservation Service made little change in land use during the period. Increased erosion reduced size of farm business by reducing acres of crops grown, especially tobacco, and shifting from intensive crops to those of an extensive nature. Rye as a cover crop for tobacco lands and green manure crops on other lands increased. Significant increases occurred in the use of manure on tobacco lands, of commercial fertilizers on both tobacco and other lands, and of lime. The most important business analysis factors determining labor income in order of importance were tobacco price, productive-man-work units, production index, and work units per man.

Estimated gross cash income from the sale of agricultural products from the farm and from Agricultural Adjustment Administration payments for Ohio farms, by counties—1939, P. P. WALLRABENSTEIN and J. I. FALCONER (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 130 (1940), pp. [1]+11*).—This continues the series (E. S. R., 83, p. 406).

Fields of current State planning board activity, C. W. ELIOT (*Natl. Resources Planning Bd. Cir. 8, rev. (1940), pp. [2]+77*).—The current State planning board activities are classified according to function.

Relationship of character of farming units to land management in two townships in Indiana, J. R. HAYS. (Coop. U. S. D. A.), (*Indiana Sta. Bul. 450 (1940), pp. 20, figs. 7*).—For Deer Creek Township, Cass County, in the northern part of the State, an analysis is made of the size and tenure of operating units; location of tracts in relation to the farmstead; changes in ownership and operators since 1915, and the relationship of physical characteristics and land use to the changes and of distance from farmstead to size of fields, physical characteristics, land use, etc.; and the effects of division of farm units on land management. In Johnson Township, Knox County, in the southwestern part of the State, analysis is made of size, tenure, and location of tracts.

In Deer Creek Township only 55 percent of the operating units consisted of a single tract under one ownership, 25 percent of from 2 to 4 separately located tracts, and 25 percent involved from 2 to 4 separate owners. In Johnson Township less than 50 percent of the operating units consisted of 1 tract under a single owner, 46 percent of the farms consisted of from 2 to 6 separate tracts, and 40 percent involved from 2 to 5 owners. In Deer Creek Township the ownership of 15 percent of the units and the operators of 25 farms had not changed since 1915. The ownership of 85 percent of the units had changed from 1 to 8 times. On 4.5 percent there had been more than 10 different operators. Where operators changed most frequently the tracts on the average were smaller and less productive and had a higher percentage of cultivated lands and small grain. Little difference existed in the cropping program on the tracts at different distances from the farmstead, but about 5 percent more of the land was in cultivated and grain crops and less in woods, waste, and idle lands on distant tracts than on the farmsteads. The home tracts received more lime and manure. Rented por-

tions of part-owned farms had 6 percent more of the land in cultivated and small grain crops and 11 percent less in sod and open permanent pasture and received less manure and slightly less lime than owned portions.

Land-ownership patterns in relation to land types in Dickinson County, Michigan, I. F. SCHNEIDER (*Michigan Sta. Quart. Bul.*, 23 (1940), No. 1, pp. 46, 47).—This survey revealed a marked change in the types of landownership between the years 1916 and 1937. "If the present trend continues, it is reasonable to assume that more than 75 percent of Dickinson County will have passed into State ownership and administration within the next 20 yr."

Farm organization and management in the Colebrook area, H. C. WOODWORTH and A. HANGAS (*New Hampshire Sta. Bul.* 322 (1940), pp. 40, figs. 21).—The data for this project, initiated in 1933, were obtained by a fieldman who made notes on the methods used in field operations and chore work, collected input and output data and financial records, and mapped farms, and from the financial statements for 38 farms for the year ended November 1, 1934. The area and its agriculture are described. Analysis is made of the financial reports, the dairy and field operations, labor requirements, and seasonal distribution for different crops and dairying. Methods of working out revised plans for operation of the farms are discussed and illustrated.

The experimental agricultural conservation program in Licking County, Ohio: A study of the results in 1939, F. L. MORISON. (Coop. U. S. D. A.). (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul.* 129 (1940), pp. [1]+23).—In 1938 the U. S. D. A. Agricultural Adjustment Administration initiated an experimental agricultural conservation program in Licking County based on a method of measuring the rate of soil improvement or deterioration developed by the Ohio Experiment Station and Ohio State University. The results in 1939 of 258 farms in the county are compared with those on 240 farms in 6 adjoining counties where the regional program was used. An appendix shows the productivity factors assigned to each acre or unit of practice in the Licking County program. Data are included regarding the two sets of farms for the years 1935-39, inclusive, and the changes to be made in the 1940 Licking County program.

Forty-two of the farms in Licking County and 83 in the adjoining area did not participate in the programs in 1939. On 127 and 141 farms, respectively, the acreages of corn were within the 1939 acreage allotments, and on 89 and 16 farms, respectively, the allotments were exceeded. Reduction of corn acreage was made on 98 and 96 of the participating farms, respectively, in the two areas. Payments averaged \$63 per farm for the participating farms in Licking County and \$111 on the participating farms in the adjoining areas. The productivity balances in 1937, 1938, and 1939 on the farms in Licking County and in the adjoining counties were: Participating farms within the 1939 corn allotments —0.74, —0.62, and —0.45, and —0.75, —0.58, and —0.49; participating farms with more than the 1939 corn allotment —0.77, —0.67, and —0.67, and —0.50, —0.64, and —0.45; and nonparticipating farms —1.01, —1.08, and —1.19, and —0.78, —0.75, and —0.57. In both areas the percentage of farmers receiving payments increased with size of farm. In general, farms with low yields complied to a lesser extent with the corn allotments than did those with higher appraised yields. From 1938 to 1939 owners and tenants related to owners reduced the acreages of corn and wheat 6.5 but increased other depleting crops 3.2. Tenants not related to owners reduced wheat and corn 4.4 and increased other depleting crops 4.6.

Crop rotations practiced in Tennessee types of farming areas III, XI, and XIV, C. E. ALLRED, B. H. LUEBKE, and B. A. FRANKLIN (*Tennessee Sta., Agr. Econ.*

and Rural Sociol. Dept. Monog. 116 (1940), pp. [1]+11+27, figs. 11).—Based on crop histories for Crockett and Overton Counties, 1932–36, and Roane County, 1935–39, the crop rotations in the three types-of-farming areas are discussed.

Farming possibilities in a problem area of the East Tennessee Valley.—A preliminary report, C. E. ALLRED, H. J. BONSER, R. G. MILK, and J. D. RUSH. (Coop. U. S. D. A.). (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 114* (1940), pp. [1]+VI+53, figs. 7).—This preliminary report is based on the study of existing farm units comprising 3,581 acres in Roane County plus a few farms in Anderson County. The topography; markets; population; resources; land use; farm organization; investments; receipts, expenses, and income; family incomes and expenses; social contributions and costs; the possibilities of the area; and the possible systems of profitable farming are discussed.

Basic data on [9] Tennessee Counties, R. G. MILK. (Coop. U. S. D. A.). (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monogs. 102-A* (1940), pp. [2]+9; 102-B, pp. [2]+10; 102-C, pp. [2]+9; 102-D, pp. [2]+7; 102-E, pp. [2]+6; 102-F, pp. [2]+8; 102-G, pp. [2]+7; 102-H, pp. [2]+8; 102-I, pp. [2]+6).—Maps, reports, aerial photographs, surveys, and statistical and research data are listed for and relate to Roane, Jefferson, Claiborne, Coffee, Giles, Bledsoe, Henry, Hardin, and Humphreys Counties.

The Northern Great Plains (*Washington: Govt., 1940, pp. [2]+44, figs. 4*).—The work of the Northern Great Plains Committee, appointed by the Federal Government in 1936, is described. The problems of the area, its rehabilitation through irrigation and dry-land readjustments, and the work of rehabilitation by States and local communities are discussed. The findings and recommendations of the National Resources Planning Board and lists of its publications are included.

Type-of-farming areas in Saskatchewan, R. A. STUTT (*Sci. Agr., 20* (1940), No. 9, pp. 526–531, fig. 1).—The objectives of this study were to define the types of farming and determine the boundaries of each area.

Extended functions for institutional landowners, C. L. STEWART (*Jour. Land and Pub. Util. Econ., 16* (1940), No. 3, pp. 357–362).—Some basic principles for the control of corporations owning or operating farm real estate and for the relationship between institutional owners and tenants are suggested and discussed.

Capital rationing, uncertainty, and farm-tenancy reform, T. W. SCHULTZ. (Iowa Expt. Sta.). (*Jour. Polit. Econ., 48* (1940), No. 3, pp. 309–324).—The purpose of this contribution is to formulate certain basic features inherent in tenancy reform having a direct bearing on the combination of resources of the farm and consequently upon the cost structure in order to point out fundamental economic effects following a change in the system of tenure from tenancy to ownership. Two conclusions regarding farm-tenure reform are: (1) Changing tenants to encumbered owners reduces materially the returns of farmers who have limited assets, and (2) unforeseeable windfalls and losses due to changes in prices, interest rates, and technology make ownership, especially when the property is heavily encumbered, a much greater gamble for the farmer than renting.

Crop insurance—an experiment in farm-income stabilization, J. C. CLENDENIN (*Jour. Land and Pub. Util. Econ., 16* (1940), No. 3, pp. 277–285).—This is a description and discussion of the operation of the crop insurance plan for wheat and the present and future problems.

“The wheat crop insurance venture may at this stage be called promising but unproved. Several more experimental years are needed to prove the salability of the insurance and its capacity to bear an expense-money loading.

Possibly the project will require some expense-money assistance from the Government indefinitely; if so, we need to discover how much is necessary and whether the social stability obtainable is worth its cost."

Homestead tax exemption in the United States, M. T. OLCOTT (*U. S. Dept. Agr., Bur. Agr. Econ., Econ. Libr. List 15 (1940), pp. 22*).—Seventy-two selected references, chiefly for the period January 1927 to October 1940, are included, grouped by States and as general.

Agricultural finance in the United States, [I], II, H. W. TORGERSON (*Jour. Land and Pub. Util. Econ., 16 (1940), Nos. 2, pp. 196-206, fig. 1; 3, pp. 318-324*).—"The purposes of this article are to present a general picture of American agricultural finance today and to discuss certain current problems in the Federal program of agricultural financing."

Preliminary report on local public finance situation in Sheridan County, Montana, S. W. VOELKER. (Coop. U. S. D. A. et al.). (*Montana Sta. [Mimeog. Cir. 21] (1940), pp. [3]+56, figs. 2*).—The present situation is analyzed, and possible solutions to the tax problem are outlined.

Advantages and disadvantages of Government price control, R. W. BARTLETT. (Univ. Ill.). (*Ind. State Dairy Assoc. Ann. Rpt., 50 (1940), pp. 80-88*).—This is a discussion of Government price control, with special reference to milk.

Price fixing by government in foreign countries, 1926-39: A selected list of references on direct price fixing of agricultural products by foreign governments, A. M. HANNAY (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog. 86 (1940), pp. VIII+631*).—This is a selected list of over 1,800 references. The general references are arranged alphabetically under the country and the laws for each country, classified by products, and listed chronologically. General treatises on price control and purely theoretical discussions of price fixing and references to the international wheat agreement of 1933² are omitted, and attention is called to a brief article containing the text of the final act of the Conference of Wheat Exporting and Importing Countries³ and an analysis of the difficulties inherent in the application of a controlled international wheat price by Taylor (*E. S. R., 74, p. 117*). No attempt was made to include price fixing due to the present war in Europe.

Belgian rural cooperation: A study in social adjustment, E. J. ROSS (*Milwaukee, Wis.: Bruce Pub. Co., [1940], pp. XIII+194, [fig. 1]*).—The object of this book is to analyze the crisis in Belgian agriculture at the end of the last century, to compare present conditions with the conditions then, and to draw conclusions regarding the changes, which are due largely to the adoption of cooperation. Part 1 describes the physical and cultural setting in sections on the physical environment, Belgian agriculture today, and the Belgian people. Part 2 deals with the crisis of the last century. Part 3 discusses the means taken to solve the agricultural difficulties, including action taken by the government, the work of private cooperatives, and the role of the clergy, and shows how the development of the cooperatives represents an adjustment to the basic life patterns of Belgium and the Belgian people and also how the principles of cooperation have been modified by these conditions. Part 4 compares the conditions before and after the development of agricultural cooperatives. A bibliography is included.

The elements of marketing, P. D. CONVERSE and H. W. HUEGY (*New York: Prentice-Hall, 1940, 2. ed., rev., pp. XVIII+823+89+XVI, [figs. 13]*).—In this revision (*E. S. R., 63, p. 783*), more emphasis is placed on marketing economics

² *Jour. Min. Agr. [Gr. Brit.]*, 40 (1933), No. 8, pp. 716-718.

³ See pp. 718-720 of citation in footnote 2.

and policies, important material that has become available is included, and the treatment of the parts dealing with market institutions and marketing of farm products is condensed. Cost and efficiency of marketing, income and its distribution, field warehousing, factoring, increasing and decreasing costs as applied to retailing and wholesaling, relation of volume of sales and location to expenses of retail stores, supermarkets, ABC labeling, classification of goods, Government regulations, etc., are treated more completely. In addition to part 1 dealing with the meaning and cost of market distribution, the consumer, and the development of marketing methods, and part 7 conclusions, the material is presented in parts dealing with functional and commodity approaches, market institutions, commodity marketing, merchandising, and prices and competition.

Transportation of farm products in central Indiana by commercial truckers, C. M. HARDIN and T. K. COWDEN (*Indiana Sta. Bul.* 446 (1940), pp. 34, figs. 7).—This second bulletin in the series (E. S. R., 83, p. 264) is based on interviews with 161 commercial truckers specializing in the transportation of farm products. Analysis is made of the annual expenditures for operation, the effects of miles traveled and age of truck on the costs, the returns to operators per load and per mile, and the rates and returns for livestock, grain, and supplies.

The average 1½-ton truck included in the study was driven 24,112 miles per year at a cost of 4.2 ct. per mile. The average operator of 1 truck had a labor return of \$917. Operators of 2 or more trucks had an average return of \$1,159 as compared with \$3,657 for semitrailer operators. One-truck operators hauled an average of 409 loads per year. The average trip was 37 miles, the average load 2.7 tons, the average receipts per load \$5, and the average return per hour of labor approximately 40 ct. Receipts per mile averaged 9.1 ct. and cost including labor 8 ct., leaving a profit of 1.1 ct. Approximately 45 percent of the tonnage was livestock, 28 percent grain, hay, and straw, 7 percent coal, 5 percent lime, 3 percent fertilizers, and 12 percent miscellaneous commodities. Receipts for return loads constituted only 4.1 percent of total receipts. Such receipts are an important item in profits since they involve but little additional cost, but recent legislation is discouraging return loads by placing additional restrictions on operators hauling manufactured goods.

Trend of motor transportation rates for livestock in Ohio, G. F. HENNING and E. B. POLING (*Ohio Sta. Bimo. Bul.* 206 (1940), pp. 152, 153).—Included are tables showing the indexes, simple average and weighted average, of trucking rates to Cleveland, Columbus, and Cincinnati by years 1929-39 for hauls of 0-49.9 and 50-99.9 miles for cattle, calves, hogs, and sheep.

Markets and prices for New Hampshire berries, L. A. DOUGHERTY (*New Hampshire Sta. Bul.* 321 (1940), pp. 52, figs. 15).—"This study was undertaken in order to bring together more facts concerning the small fruit industry in New Hampshire. It deals principally with markets, methods of sale, prices, and opportunities for growers of small fruits in New Hampshire. Some data are also included on varieties, yields, and returns. The more complete utilization of local markets and possible outlets for surplus berries, if expansion should occur, are also given consideration." The data were gathered through questionnaires and direct contacts with producers, retail stores, hotels, camps, etc.

An analysis of dealers' sales of milk and cream in the New York market, 1933-38, C. J. BLANFORD. (Coop. U. S. D. A.). ([*New York*] *Cornell Sta. Bul.* 735 (1940), pp. 24, figs. 44).—The fresh milk and fresh cream receipts are analyzed to determine consumers' response to price changes, business conditions, seasons, etc., during a period of business depression and recovery. The

New York City market; grades of milk and types of packages; milk and cream receipts; trends in sales of grade A and grade B milk and heavy cream; seasonal, day-of-the-week, and holiday variations in sales; and the variations due to price changes and business conditions are discussed.

Changes of 1 ct. per quart in the price of grade B milk had only a slight effect on total sales. A 1-ct. change in the price of half pints of heavy cream had only a slight effect on the total sales, but changes of 2 or 3 ct. caused material changes in sales. During the period there was no change of over 1 ct. in the price of milk on retail routes. On two occasions the price at stores declined rather sharply and there was a marked increase in sales at stores, without much change in sales on retail routes. The relationships between milk and cream sales and business activity, as measured by the *New York Times Index* or department-store sales in New York and Brooklyn, were not as close as might be expected. Milk receipts lagged about 10 mo. behind the *New York Times Index* and about 5 mo. behind department-store sales. Cream receipts lagged about 10 mo. behind department-store sales.

Knoxville wholesale fruit and vegetable market.—I, Buyers and buying problems, C. E. ALLRED, B. H. LUEBKE, and W. S. CRAWFORD (*Tennessee Sta. Agr. Econ. and Rural Sociol. Monog. 115 (1940), pp. IV+34, figs. 9*).—The market agencies for fruits and vegetables in Knoxville, the buying by retailers, the purchases of out-of-town buyers, and the needs of the wholesale and retail buyers in order to meet customers' demands are described.

Cooperative marketing of Ohio potatoes by the Ohio Farm Bureau Cooperative Association, C. W. HAUCK. (Ohio Expt. Sta. et al.). (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 132 (1940), pp. [2]+14, pls. 3*).—The data were gathered primarily from 535 potato growers in 21 counties and 38 of the 129 dealers who had purchased potatoes from the association during the years 1934-35 through 1939-40. The grades of potatoes sold, important outlets, and prices received in 100- and 15-lb. bags, 1936-37 through 1939-40, are analyzed. The modified program adopted by the association for 1940-41 is discussed.

Two-thirds of the growers were affiliated with the Farm Bureau, but 56 percent had not sold potatoes at any time through the Bureau. Of the growers, 61.5 percent believed the Farm Bureau marketing program had been beneficial and 7 percent that it had been detrimental. Of growers replying regarding marketing methods, 211 favored pooling and 105 individual sales, 166 preferred that the Bureau take full responsibility to make sales, 160 that the grower take full responsibility, and 35 favored joint responsibility. Of those answering the questions as to marketing practices, 97 percent favored the Farm Bureau handling potatoes for growers not affiliated with it, 78 purchases for storage, 97 purchases to supply the trade if local growers could not supply the demand, and 89 percent purchases from other States to insure a longer business period. With one or two exceptions, the dealers had high regard for the Farm Bureau. Two objections were raised—(1) the use of the "grower's grade" due to lack of definiteness of specifications, and (2) the inability of the association to guarantee a continuous supply of potatoes. Nearly 60 percent of the potatoes sold were U. S. No. 1. Chain stores took 54.4 percent of the potatoes. In 1936-37, 91 percent were sold in 100-lb. bags and 1 percent in 15-lb. bags; in 1939-40 the sales were 50 and 46 percent, respectively. The differential in price received in favor of 15-lb. bags was 30 ct. in 1938-39 and 33 ct. in 1939-40.

Survey of farmers' selling and purchasing cooperatives in Tennessee, 1938.—A preliminary report, C. E. ALLRED and B. D. RASKOFF (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 113 (1940), pp. [1]+111+28*).

figs. 6).—This preliminary report on a study in cooperation with the T. V. A. describes the development and the reasons for organization and discontinuance in the State of the two types of cooperatives.

Of 922 cooperatives organized since 1874, 102 were active in 1938, of which only 11 were organized prior to 1919. The chief reasons for going out of business reported by 305 associations were inefficient management, inadequate educational program, inability to readjust with change in agricultural conditions, consolidation or reorganization, no economic need for the association, lack of a definite credit policy, improper financing, inadequate accounting records, overinvestment in fixed assets, dishonest management, inclement weather, fire, and disease.

Periodicals issued by farmers' marketing and purchasing associations (*Farm Credit Admin.* [U. S.], *Coop. Res. and Serv. Div., Misc. Rpt. 5, rev. (1940)*, pp. [4]+23).—This is a list of publications issued or sponsored by marketing or purchasing associations, official organs of such associations, and general organizations sponsoring farmers' cooperatives. The publications are grouped by commodities.

Prices of beef cattle, L. ROBERTSON and M. P. MITCHELL (*Indiana Sta. Bul. 445 (1940)*, pp. 22, figs. 26).—Charts are included and discussed showing the relationships of beef cattle prices and general price level, general business conditions, beef cattle production and purchasing power cycles, classes and grades, seasonal variation, condition of western ranges, size of corn crop, past margins of profit, and changes in consumer demand.

Farm sales of Ohio milk through different outlets.—I, Columbus area: Delaware, Fairfield, Franklin, Licking, Madison, Pickaway, and Union Counties, C. G. McBRIDE and R. W. SHERMAN (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 131 (1940)*, pt. 1, pp. [2]+30, figs. 11).—This study is based on a survey of all farms with three or more dairy cattle. The changes in market outlets 1903-40, the status of manufacturing outlets, transportation facilities, sanitary controls by health boards, cooperative marketing, and types of farming are discussed.

Receipts, utilization, and prices of milk and cream in Maine milk control areas, G. F. DOW (*Maine Sta. Bul. 399 (1940)*, pp. [4]+73-183, figs. 17).—Federal and State milk control and the Maine milk control areas are described. The receipts and distribution of milk and cream in the State; the seasonal, day-of-the-week, and holiday variations in distribution; the surpluses; and the prices of milk and cream, including allocation of retail prices between producers and distributors, effect of size and location of markets, effects of price changes and business conditions on consumption, etc., are analyzed. An appendix includes the Maine milk control law, rules and regulations of and forms used by the control board, and references on legal aspects of milk control.

What becomes of the consumer's dairy dollar? T. K. COWDEN. (Purdue Univ.). (*Ind. State Dairy Assoc. Ann. Rpt., 50 (1940)*, pp. 69-79, fig. 1).—This is mainly a summarization of State and Federal studies as to the percentages of consumer's expenditures for different purposes, different dairy products, and for different items in the costs of producing and distributing dairy products.

Price of coffee in Puerto Rico from 1900 to 1938, J. J. SERRALLÉS, JR., and M. VÉLEZ, JR. (*Puerto Rico Univ. Sta. Bul. 54 (1940)*, pp. [2]+24, figs. 7; *Span. abs.*, pp. 22-24).—Data for approximately 30,000 coffee purchase transactions were obtained from 14 exporters, 9 dealers, 2 farmers, and 1 coffee roaster in 12 towns. The area planted to coffee, the production, exports to different countries, and legislation affecting the price of coffee are discussed. Tables and charts are included and discussed showing the monthly average Puerto Rican

farm price of coffee; the monthly variations in periods of stable, increasing, and declining prices; and the relation of farm prices to Puerto Rican production and exports, to world production of mild and all coffee, to prices of Latin-American coffee in the New York City market, and to wholesale commodity prices in the United States and of the purchasing power of coffee to that of other commodities in the United States. A Spanish summary is included.

Crops and Markets, [August–September 1940] (*U. S. Dept. Agr., Crops and Markets, 17 (1940), Nos. 8, pp. 157–184, figs. 2; 9, pp. 185–208, figs. 4*).—Crop and market reports of the usual types are included.

RURAL SOCIOLOGY

[Abstracts of papers on rural sociology] (*Assoc. South. Agr. Workers Proc., 41 (1940), pp. 38–40, 44, 45, 73, 74*).—Included are the following abstracts of papers presented at the 1940 convention of the Association of Southern Agricultural Workers: Marginality Among Farm People, by W. E. Garnett (pp. 38, 39) (Va. Expt. Sta.); Causes of Marginality in Farm People, by C. E. Allred (pp. 39, 40) (Univ. Tenn.); The Mobility of Farm Population, by O. D. Duncan (pp. 44, 45) (Okla. A. and M. Col.); and Human Relations in the Changing Conditions of Southern Agriculture, by H. Hoffsommer (pp. 73, 74) (La. State Univ.).

Alabama rural communities: A study of Chilton County, I. T. SANDERS and D. ENSMINGER. (Coop. U. S. D. A.). (*Ala. Col. Bul., 33 (1940), No. 1A, pp. 80, figs. 26*).—This is an analysis of the rural communities of an Alabama county.

The situation and prospects of the population in the Black River settlement, Louisiana, T. L. SMITH and S. E. GRIGSBY (*Louisiana Sta. Bul. 319 (1940), pp. 42, figs. 4*).—Conclusions reached by the authors were: The minute family farms of this settlement of 490 families in a distress area are incapable of producing more than a subsistence livelihood as long as the backwaters of the Mississippi, Red, and Black Rivers are allowed to destroy the crops. The living conditions as reflected by the shabbiness of the houses, the smallness of the homes in comparison to the size of the family, lack of screening, and primitive sanitation, cannot be expected to rise above the simplest standards so long as the inhabitants depend upon the land as their primary means of income. Apparently the families in this area are habitually on, and oftentimes below, the economic margin.

The changing school population and its implications, J. F. THADEN. (Mich. Expt. Sta.). (*Mich. Acad. Sci., Arts, and Letters, Papers, 25 (1939), pt. 4, pp. 629–640*).—The author shows that a rapid change in the character of the school population is taking place—a decrease in the elementary grades and an increase in the secondary school. In Michigan, enrollment in the elementary divisions dropped from 838,790 in 1930 to 691,544 in 1938, a decrease of 17.6 percent.

The population of New Mexico: Its composition and changes, S. JOHANSEN (*New Mexico Sta. Bul. 273 (1940), pp. 56, pl. 1, figs. 17*).—Conclusions reached by the author were: Topographical and climatic features have been important forces in the settlement of New Mexico. Population has grown from slightly over 60,000 in 1850 to 528,687 in 1940. The greatest increase took place between 1900 and 1910. The average number of persons per square mile in 1930 was only 3.5 compared with 41.3 for the United States as a whole, but varied from 0.5 person per square mile in Catron County to 37.4 in Bernalillo County. In 1930, approximately three-fourths of the population resided in rural areas, but the proportion of rural people in the total population declined at each census enumeration between 1880 and 1930. The major part of the population growth

has resulted from increase in the number of persons born in the State. The racial elements of New Mexico are the Anglo-Americans, the Spanish-Americans, and the Indians. The proportion of single males was less in 1930 than in 1880, while the proportion of single females increased slightly. Between 1850 and 1930 the average size of New Mexico families decreased from 4.6 to 4.1 persons. Urban families are the smallest and rural farm families the largest. The illiteracy rate declined rapidly between 1880 and 1930, but in 1930 was 13.3—more than 3 times the rate for the United States. New Mexico had the highest birth rate of all the States in 1936 and a rate nearly twice as high as for the United States. The death rate was exceeded only by that of one other State. New Mexico also had the highest infant mortality rate of all the States, more than twice that of the United States. The Indians constituted nearly 7 percent of the total population of New Mexico in 1930, concentrated in a few counties in the northwestern portion of the State. Few Indians live in urban centers. The illiteracy rate among the Indians is much higher than that for the total New Mexico population.

Selective factors in migration from a New York rural community, A. A. GESSNER. (Coop. U. S. D. A.). ([*New York*] *Cornell Sta. Bul.* 736 (1940), pp. 55, figs. 8).—Supplementing an earlier study by Hoag (E. S. R., 46, p. 386), "this bulletin states the findings regarding migration and the factors associated with it for 339 former students enrolled in Belleville Union Academy between the years 1919 and 1938. Forty-nine percent of them have taken up residence outside the district and another 5 percent are attending school outside the district. Almost one-fifth of the whole group are now city dwellers, and almost 40 percent of the migrants moved to cities. . . . More women than men have left the area, and a larger proportion of the female migrants than of the male migrants went to cities. Fifty-two percent of the migrants and 44 percent of the nonmigrants came from the upper halves of their classes. . . . If the selective process which has affected the migrations of the older members of the group continues to operate in the same way upon the younger members, the selection of migrants on the basis of scholastic ability will eventually be much greater for this group. . . . Twelve percent more of those who have left than of those who remained had training beyond high school. Twenty-four percent more of those now in cities than of those in rural areas had training beyond high school. Seven percent more of the village-reared than of the farm-reared students have left the district. The proportion of village-reared in cities is twice that of farm-reared. Half the men were in agriculture. Three-fourths of the women were in domestic occupations, including homemaking in their own homes. The men who remained in the community remained to follow agricultural pursuits to a large extent. Sixty-eight percent of those who left went into nonagricultural occupations. The occupations of fathers and sons were closely related in the case of the agricultural occupations."

Movement of people from North Dakota farms continues, J. P. GREENLAW and R. NOVAK (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 1, pp. 11-14, fig. 1).—The authors show that during 1939 there was a net migration of 3,000 persons away from North Dakota farms, and offer suggestions concerning possible adjustments.

A survey of standards of life of New Zealand dairy-farmers, W. T. DOIG (*New Zeal. Dept. Sci. and Indus. Res. Bul.* 75 (1940), pp. 113, figs. 7).—A description of the standards of life of these dairy farmers and their families.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

The role of the land-grant college in governmental agricultural programs, J. A. VIEG ET AL. (*Iowa State Col. Bul.*, 38 (1938), No. 2, pp. 14).—This report

was prepared by a committee of the faculty of Iowa State College as an attempt to clarify Federal-State relationships in agriculture.

Federal-State relationships in agriculture.—II, Education for action programs in agriculture, J. A. VIEG ET AL. (*Iowa State Col. Bul.*, 38 (1939), No. 28, pp. 15).—This report, prepared by the committee referred to above, is a further study designed as a basis for cooperation between the land-grant college and the National Government.

Some social science courses required by agricultural colleges, 1939, C. E. ALLRED and B. D. RASKOFF (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 112* (1940), pp. [1]+II+32).—The number of quarter-hours of social science required for graduation with majors in each of 10 major fields of study in 48 United States colleges of agriculture ranges from none in 2 colleges to 39 in 1 college, 35 colleges requiring 9 hr. or more. Of the required courses, 2 are in general economics, 13 in agricultural economics, 5 in sociology, 4 in history, 4 in political science, 2 in psychology, and 2 in philosophy. Four colleges require from 4 to 9 quarter-hours of social science but permit unrestricted electives. Of the 48 colleges, 35 require 1 or more courses in agricultural economics; 29 require 1 or more courses in general economics; 10, 1 or more in sociology; 6, 1 or more in political science; 5, 1 or more in history; and 2 require courses in psychology and philosophy. Social science requirements by major fields of study are heaviest for majors in agricultural business, agricultural administration, agricultural economics, and agricultural education.

Teaching conservation in elementary schools, E. G. BATHURST (*Fed. Security Agency, U. S. Off. Ed. Bul. 14* (1938), pp. V+125, pl. 1, figs. 17).—"The purpose of this bulletin is to aid teachers in the selection, adaptation, and organization of materials for the teaching of conservation in grades 1 to 7 or 8." The principles of organization are discussed, with a suggested curriculum plan. Sources of help for teachers are listed, and teacher's preparation, teaching plan, and the daily schedule are discussed. Special emphasis is placed on the curriculum unit and presentation of suggestions appropriate for rural and urban pupils of different ages.

A functioning program of home economics, I. SPAFFORD (*New York: John Wiley & Sons; London: Chapman & Hall, 1940, pp. XIII+469*).—"This book is for the administrator, curriculum worker, or teacher within or without the field of home economics who in rebuilding the curriculum would draw into it the best that each field has to offer." The several chapters deal with the meaning of home economics, the schoolman's attitude, home-life education, building a dynamic program of education, the administrator and the home economics program, and home-life education in elementary, junior high, and senior high schools, for adults at college level, and for professional students in college.

Personnel administration and personnel training: A selected list of references, M. BENTON and H. L. BUCKARDT (*U. S. Dept. Agr., Soil Conserv. Serv. Bibliog. 2* (1940), pp. [2]+IV+59).—Included is a list of bibliographies and over 430 annotated references.

FOODS—HUMAN NUTRITION

[Foods and nutrition studies by the Indiana Station] (*Indiana Sta. Rpt. 1939, pp. 9, 21, 22, 92, 93*).—This report summarizes the progress of work on vitamin A requirements and values and the estimation of carotene; the relation of color and composition to culinary quality of Indiana potatoes grown in muck and other soil types, by G. Redfield; the utilization of pork products,

including studies of the effects of freezing storage on palatability, cooking losses, and tenderness, by R. Jordan and O. D. Collins; continued studies (E. S. R., 81, p. 736) on hydrogenated lard, by Jordan and Collins; and mineral losses in cooking vegetables in salted water.

Making white and whole wheat bread with three types of yeast and hard wheat flour, E. J. THIESSEN (*Wyoming Sta. Bul.* 242 (1940), pp. 32, figs. 3).—The experimental work reported was concerned with the development of good formulas for home-made bread, the baking of white bread with hard-wheat flour by the long and short process, and the baking of whole-wheat bread, using similar processes and yeasts as for the white bread. Consideration was given to variations in ingredients (including differences in granulation and composition in the case of whole-wheat flours), in methods of mixing, and in fermentation and handling of the dough; and to baking, cooling and storing, and staling of the bread. The fermentation values of yeasts in various forms and for different periods of storage were also studied, with the observations that more consistent results were secured with quick acting, dry granular yeasts than with the dry cakes in which preliminary sponges were made; that both dry and compressed yeast stored in air-tight containers were active over long periods when stored at low temperatures; and that compressed yeast was active over a period of several months if kept frozen. The Wyoming hard-wheat flour was found to yield bread of good quality when fermented and baked under standard conditions; in the case of whole-wheat flours better bread was obtained with the finely granulated product than with the more coarsely granulated flours.

In practical application of the experimental studies formulas are given for white and whole-wheat breads, with directions for handling the dough and baking. Common defects in bread and their causes and the scoring of bread are considered.

The gluten mesh, C. O. SWANSON. (Kans. State Col.). (*Northwest. Miller*, 201 (1940), No. 1, Sect. 2, pp. 3a, 20a, figs. 4).—Dough properties are discussed in terms of the behavior of dough structure, which is pictured as an intricately woven gluten network, enmeshing starch granules in particular and having a film of moisture adsorbed on protein and starch granules. The behavior of dough in baking is considered from the standpoint of the intrinsic character of the protein material and of the substances which make up its environment; these are the substances naturally present in the flour and the substances that are added in the baking formula.

Research on the utilization of agricultural products in California, W. V. CRUESS. (Univ. Calif.). (*Chem. and Indus.*, 58 (1939), No. 33, pp. 773-778).—This paper was presented as an address before the food group of the Society of Chemical Industry (Great Britain), May 10, 1939.

Studies of the nutrition values in prunes, A. F. MORGAN. (Univ. Calif.). (*Calif. Fruit News*, 101 (1940), No. 2699, pp. 10, 11).—A brief general statement is given concerning recent and current studies on the nutritive value of prunes.

A study of quality and retail prices of Ohio packed vegetables, C. W. HAUCK (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul.* 123 (1939), pp. [25], figs. 2).—A total of 65 No. 2 cans each of Ohio-packed corn and tomatoes, representing 43 brands of corn from 23 packers and 35 brands of tomatoes from 25 packers, was purchased on the open market, coded, and submitted to the U. S. Department of Agriculture for quality scoring. Averages of quality and price were then computed for each commodity, packer, city, and type of store; and relationships between quality and price calculated.

The corn ranged from 5.5 to 15 ct. a can, with an average of 8.43 ct., and the tomatoes from 5.5 to 14 ct., with an average of 8.2 ct. Corn averaged 6.52

ct. a can in corporate chain stores and 9.87 ct. in independent stores (including voluntary chains), and tomatoes averaged 6.36 and 9.77 ct., respectively. The quality scores also varied widely, the corn scoring from 61 to 95, with an average of 75.4, and the tomatoes from 43 to 93, with an average of 76.2. The differences in quality were considerable between poorest and best samples packed by certain packers even under the same label. There was no appreciable difference between the average scores of samples bought in chain and in independent stores.

As determined by simple comparisons and by statistical analyses, price alone was wholly unreliable as an index of quality for both corn and tomatoes, although as the prices increased there was a slight tendency for quality also to increase. There was a strong tendency for prices of both commodities to cluster at various traditional levels, with wide variations in quality at each of these levels. Fully informative labeling is recommended as holding promise to sellers and buyers alike.

Palatability and color of potatoes bought on a retail market, R. M. GRISWOLD. (Mich. Expt. Sta.). (*Food Res.*, 5 (1940), No. 3, pp. 281-290).—In the interest of simplifying potato testing for culinary quality and consumer preference, a study was undertaken to determine possible relationships among palatability factors as graded by judges and between these factors and color measured objectively. The potatoes used in judging were "old" potatoes grown in Michigan, Maine, and Idaho and purchased in 10-lb. or 1-pk. lots, 50 from each source, on the retail markets of Detroit between the middle of February and the middle of May 1937. The cooking and sampling methods were essentially those of Wright et al. (*E. S. R.*, 75, p. 565), and the grading chart for scoring a modification of the score card used by these investigators and the meat-judging chart of the National Cooperative Meat Project. The scoring was done by an experienced committee of four or five judges. The cooked samples were riced for determining the color when cold in a Lovibond tintometer.

The subjective scores for mealiness showed highly significant positive correlations with other desirable palatability factors, thus indicating the feasibility of considering mealiness alone in subjective ratings. Correlations between boiled and baked potato scores were highly significant both for mealiness and "general conclusion," indicating that if a potato of the type used in the experiment is of good quality when boiled it is likely to be of good quality when baked. The color data showed significant correlation with the judges' scores for palatability, indicating that a comparatively white potato will probably be scored higher by a judging committee than a darker potato. Palatability increased with price of the samples tested and declined with prolonged storage.

Preserving the dietetic value of frozen foods, E. M. CHACE. (U. S. D. A.). (*Jour. Amer. Dietet. Assoc.*, 16 (1940), No. 1, pp. 34-38).—The various stages in the process of preparing frozen-pack vegetables and fruits from the selection of strains to the marketing of the frozen product are outlined, with the steps which must be taken to insure preservation of quality.

Why eat frozen pack fruits and vegetables? N. TODD HUNTER. (Wash. Expt. Sta.). (*West. Frozen Foods*, 1 (1940), No. 4, pp. 3, 4).—This nontechnical discussion of the importance of fruits and vegetables in the diet contains data from a previously published study of the vitamin C content in peas (*E. S. R.*, 81, p. 313) in illustration of the necessity of research into factors influencing the nutritive value of fruits and vegetables during and subsequent to freezing for the frozen-pack industry.

Practical food inspection, I, II, C. R. A. MARTIN (London: H. K. Lewis & Co., 1940, 2. ed., vols. 1, pp. VII+316, figs. 138; 2, pp. VII+275, figs. 58).—Volume 1

of this work, of which the first edition was published in 1932 (E. S. R., 70, p. 242), deals with meat inspection and volume 2 with fish, poultry, and other foods.

The forty-fourth report on food products and the thirty-second report on drug products, 1939, E. M. BAILEY (*Connecticut [New Haven] Sta. Bul. 437 (1940)*, pp. 451-485).—This annual report (E. S. R., 82, p. 274), summarizing the results of examinations of foods and drugs for the calendar year 1939, presents data on the proximate constituents of many samples of cereal breakfast foods (corn, oat, rice, rye, wheat, and miscellaneous), together with notes and occasional data on various other products, including beverages, fats and oils, flavoring extracts, maple sirup, meat products, and milk and milk products. A summary of inspection experience for the past 5 yr. in regard to vitamin D milk indicates that 90 percent of all samples examined fully or substantially met the vitamin D unitage claimed.

Buying beef by grade (*U. S. Dept. Agr., Misc. Pub. 392 (1940)*, pp. 8, figs. 7).—The United States official grades of beef, Prime, Choice, Good, Commercial, and Utility, based on characteristics (marbling, texture, grain, and color) considered the best indicators of quality, are described, with brief indications as to the use of the grade stamp and the way to obtain graded beef. Cutter and Canner, the lowest grades, are seldom sold in retail meat shops.

The influence of technic on the composition values of identical diets, J. E. HAWKS, M. M. BRAY, J. M. VOORHEES, B. VELEY, C. CARLSON, and M. DYE. (*Mich. Expt. Sta.*). (*Jour. Amer. Dietet. Assoc.*, 16 (1940), No. 5, pp. 416-419).—To determine the factors responsible for variations in the composition of identical diets, analyses were made of 212 diets, divided in three series and weighed under slightly different conditions, dried to constant weight at 60° C. and analyzed for nitrogen and calorie values. Precautions were taken to obtain homogeneous samples of the individual foods used and to minimize moisture losses while weighing out the samples. The analytical values, reported as to range and variability, indicated that the least variations occurred when the diets were weighed at one time from the same sample of food on a fairly accurate torsion balance. The results were only slightly less constant, however, when the samples were weighed at 3-day intervals, using fresh supplies of the perishable foods, when trip balances were used in place of torsion balances, or when the size of the samples saved for analysis was decreased.

A dietary study of the middle-class Chinese and Mohammedans in Sungpan, L. T. CHENG and H. C. KU (*Sci. Soc. China, Biol. Lab. Contrib., Zool. Ser.*, 13 (1939), No. 8, pp. [1]+91-99).—This study represented a 7-day winter survey of 16 Chinese and 28 Mohammedan families in Sungpan in northwestern Szechwan Province. It is concluded that the dietaries were adequate except in vitamin C.

School lunches using farm surpluses, R. S. CARPENTER and F. W. YEATMAN (*U. S. Dept. Agr., Misc. Pub. 408 (1940)*, pp. [1]+VI+48).—This publication, prepared primarily for the directors of school-lunch programs where surplus foods made available by the Surplus Marketing Administration are used, presents menu patterns of six types with a number of concrete menu suggestions for each pattern, together with recipes and suggested variations.

The influence of the nitrogen content of the diet on the calorie balances of pre-school children, J. E. HAWKS, J. M. VOORHEES, M. M. BRAY, and M. DYE (*Mich. Expt. Sta.*). (*Jour. Nutr.*, 19 (1940), No. 1, pp. 77-89, fig. 1).—The data on calorie balances given in this paper, together with those on nitrogen utilization discussed in an earlier report (E. S. R., 79, p. 707), were obtained

in two long-continued balance studies on five preschool children. These children received in the first period a diet containing 3 gm. of protein per kilogram per day and in the second a diet furnishing 4 gm. per kilogram per day. The calorie values of food, urine, and feces for 3-day collection periods were determined by means of the oxycalorimeter. The results, together with the calculated absorption and retention (in terms of total calories and percentage of intake), are reported for each child for the individual collection periods.

A comparison of the average intake values with the average retention values for the separate balance periods showed that small diet fluctuations were reflected in the retention values regardless of the level of protein intake. On the higher protein diet, however, the proportion of the intake calories retained (averaging from 88.0 to 91.4 percent in the several periods) was somewhat less than on the medium protein diet (89.9-92.7 percent of intake calories retained), due apparently to increased nitrogen elimination in feces and urine. This corresponded to an increase from 7.3 to 12.0 percent in the average proportion of the intake calories eliminated. Thus, subtracting 10 percent from the intake values to care for excretory losses does not always give accurate results. Although the change from the 3- to the 4-gm. protein diet reduced the actual number, as well as the percentage, of the intake calories available for body needs, at the same time it also produced greater weight gains in the children. Because of the constancy of the level of calorie utilization over the several balance periods it appeared that preliminary periods were unnecessary before the high protein diet.

Dry skim milk in low cost diets, E. P. HUNT. (U. S. D. A.). (*Child Devlpmnt.*, 10 (1939), No. 4, pp. 241-268, figs. 4).—This study, undertaken to appraise the dietary effects of dried skim milk supplements in low-cost diets deficient in milk products, was conducted over a period of 141 days, the measurement of nutritional effects being limited to consideration of increments of stature. The sample consisted of 213 preschool Negro boys who ordinarily received no more than 1 cup of fluid milk or its equivalent per day. These children, comparable as to body measurements, age, and family living conditions, were divided on a geographic basis into a control group of 101 children and a demonstration group of 112 children. Children from the control group received the equivalent of from 0 to 360 gm. (median 90 gm.) of dried skim milk per day, while those in the demonstration group received from 310 to 1,220 gm. (median 820 gm.). The children were given physical examinations at the beginning and the end of the study.

Measured-diet records which gave an indication of the frequency of use of various classes of foods were obtained for all children. That these were fairly accurate was checked by comparison with quantitative-diet records obtained for a sample of 11 demonstration and 6 control children, and used to calculate the daily nutritive value of the diets of the two groups. The range and the median intake reported for these two groups with respect to Ca, P, Fe, protein, calories, and vitamins A, B, and G indicated, as was to be expected, superiority of the demonstration diet in all nutrients except iron; this superiority was especially evident when the dried skim milk supplements were sufficient to increase the daily milk supply to the equivalent of 820 gm. or more of fluid skim milk. Growth in stature during this period of approximately 4 mo. was more homogeneous and somewhat greater for the 4-year-old demonstration group than for the corresponding series of the control group.

Obesity in childhood.—I, Physical growth and development of obese children, H. BRUCH (*Amer. Jour. Diseases Children*, 58 (1939), No. 3, pp. 457-484, figs. 14).—A study of 102 obese children from 2 to 13 yr. of age was concerned

with their physical growth and development, weight at birth and early development, growth in stature, and skeletal and sexual maturation. The findings compared with results obtained in studies of normal children indicated that growth in stature of the obese children, although in excess of the average normal, was still in harmony with the height development of children who mature early. The skeletal maturation was normal or advanced. The high weight of the obese child was considered only an exaggeration of a normal trend, since the weight of normal children who mature early is significantly higher than that of children who mature later. The menarche in obese girls occurred early, before 10 yr. in some cases, and more than 50 percent of the boys between 11 and 14 yr. of age showed evidence of approaching or attained puberal development. The intensive growth and early maturation as observed in the obese children was considered due to the growth-promoting effect of abundant nutrition rather than the result of hypothyroidism and hypopituitarism.

Proteins and other nitrogenous constituents of water melon seeds (*Citrullus vulgaris*), P. S. KRISHNAN and T. K. KRISHNASWAMY (*Biochem. Jour.*, 33 (1939), No. 8, pp. 1284-1290).—Watermelon seeds, important as a potent source of urease and of some nutritional importance in regions where they form an article of diet, were examined along conventional lines to ascertain the nature of their protein constituents and of the nonprotein and nonextractable nitrogenous material. The shell-free seeds, containing 5.5 percent moisture, 3.8 ash, 5.5 ether extract, and 5.4 percent nitrogen, were ground and defatted by acetone extraction, the defatted material being exhaustively extracted with water, 10 percent NaCl, and 0.2 percent NaOH in succession. The several extracts and the unextracted nitrogenous material were subjected to further study, the results, showing the nitrogen distribution, being reported in each case.

The nitrogen of watermelon seeds was found to be made up of "glutelin, 9.4 percent (extractable 1.6 percent, not extractable 7.8 percent); globulin, 73.2 percent; water-soluble protein, 6.3 percent; proteoses, 3.5 percent; peptones, 1.1 percent; material precipitable by phosphotungstic acid, 0.1 percent; simpler substances not precipitable by phosphotungstic acid, 1.6 percent." The globulin in crystalline form and the glutelin were isolated in pure form and their most important amino acids determined. Independent determinations of arginine and histidine bore out the accuracy of the values for these amino acids obtained by the nitrogen distribution method. The seeds did not contain canavanine or citrulline, either free or combined, and only traces of free arginine were found.

New creatinine standard for basal metabolism and its clinical application, N. B. TALBOT, J. WORCESTER, and A. STEWART (*Amer. Jour. Diseases Children*, 58 (1939), No. 3, pp. 506-511, fig. 1).—In an extension of previous work (E. S. R., 80, p. 848), data on creatinine excretion were obtained on additional normal subjects, including 14 boys from 5 to 6 yr. of age, 16 boys from 7 to 14, and 22 girls from 6 to 14 yr. of age. Caloric output was also determined. By statistical methods, it was shown that the correlation between creatinine and caloric outputs was as good as that between caloric output and weight. The standard as formulated for boys is expressed by the equation caloric output = 0.657 creatinine excretion + 822, and for girls, caloric output = 0.657 creatinine excretion + 739. It is considered that the creatinine standard is as accurate as the weight standard for normal children and of greater accuracy for those that are abnormal, since the creatinine excretion is related to muscle mass rather than metabolic rate. Application of the standard in a study of children with thyroid disorders showed that the creatinine excretion was independent of the rate of metabolism.

Assessment of the level of nutrition: A method for the estimation of nicotinic acid in urine, L. J. HARRIS and W. D. RAYMOND (*Biochem. Jour.*, 33 (1939), No. 12, pp. 2037-2051, figs. 9).—The method described depends upon the cyanogen-bromide-aromatic amine reaction, but with the use of *p*-aminoacetophenone in place of aniline, as employed by Swaminathan (*E. S. R.*, 80, p. 131) and Bandier and Hald (*E. S. R.*, 82, p. 586), and with special features as noted in the following description:

"The urine is heated with NaOH to convert any amide into the acid, and neutralized. The specimen is divided into four portions. One is kept as blank and to the other three are added 0, 20, and 40 μ g. of nicotinic acid. The solutions, which must be protected throughout from the light, are warmed with CNBr, cooled, treated with *p*-aminoacetophenone, allowed to stand, and acidified, and the three color intensities measured in a Pulfrich photometer with S 47 filter, comparing with the blank to which no CNBr has been added. For any given specimen the depth of color varies with the pH, with the concentration of salts, and possibly with other factors, but the three readings always lie on a straight line and by extrapolation to zero the content of nicotinic acid can be accurately determined." Recoveries of nicotinic acid in aqueous solution amounted to 105 and 104 percent and added to urine to 98 percent.

Guinea pigs and dogs on a nicotinic acid-free diet showed progressive decrease in excretion to 0 values with the development of symptoms of deficiency. Rats, although showing increased output of nicotinic acid with increased intake, continued to excrete nicotinic acid on a deficient diet. In tests on three normal adult male subjects the nicotinic acid excretion values ranged from 3.1 to 6.2 mg., but with heavy smoking the output of one subject rose from 5 to 7.3 mg., and with heavy smoking in connection with increased intake of nicotinic acid and marmite to values of 9.8, 12.6, and 10 mg. A patient with diagnosis of anorexia nervosa excreted 2.5 and 2 mg. of nicotinic acid in two tests and one with pellagra 1.8 and 2.9 mg. before and 4.6, 4.8, and 10 mg. during treatment.

The effect of choline on the ability of homocystine to replace methionine in the diet, V. DU VIGNEAUB, J. P. CHANDLER, A. W. MOYER, and D. M. KEPPEL. (Cornell Univ.). (*Jour. Biol. Chem.*, 131 (1939), No. 1, pp. 57-76, figs. 5).—In growth studies undertaken to test this theory, rats given methionine alone as a supplement to the cystine-methionine-free diet grew well, others receiving homocystine lost weight or showed no gains, and others receiving both homocystine and choline chloride grew well. In other tests rats receiving cystine alone lost weight and this was not checked by choline chloride. In repetition of the experiment with rats from a different stock the results were corroborated in general but with less uniformity in response. This was traced to the presence of a small amount of choline, 1.4 percent, in ryzamin-B. It was also found that the tikitiki and milk extract used in the experiment noted above in which growth was secured with homocystine contained approximately 1 percent of choline. The amounts of the ryzamin-B and of the tikitiki-milk concentrates used were calculated to supply 0.35 and 3.5 mg., respectively, of choline per rat per day. In further studies in which choline was removed from the ryzamin-B without loss of enough vitamin B₆ for curative effect, the best growth was secured with homocystine and choline in addition to the basal diet at a level of 1.25 percent. Analysis of livers of animals on the basal diet plus methionine, homocystine, or homocystine plus choline chloride showed high fat content on homocystine, but on homocystine plus choline a low content similar to that on methionine. These results indicate that the administration of choline enables the rat to utilize homocystine for growth purposes in lieu of methionine. It may be, therefore, that choline makes possible the *in vivo* methylation of homocysteine to methionine.

In the preliminary studies with other related compounds and other methyl derivatives it was found that betaine was similar to choline in permitting growth on a diet with homocystine as the sole sulfur-containing amino acid.

The calcium content of gastric juice, J. B. KIRSNER and J. E. BRYANT (*Amer. Jour. Digest. Diseases*, 6 (1939), No. 10, pp. 704-706, fig. 1).—The calcium content was fairly well correlated with the H-ion concentration of the gastric juice as determined in a series of 70 patients and 5 dogs. The calcium averaged 2.06 mg. percent in 36 patients with gastric juice at a pH between 1.49 and 1.91; 2.12 in 17 cases with a pH range between 2 and 2.94; and 4.54 mg. percent in 12 patients with a pH between 3.05 and 8.38. Fasting gastric juice and that obtained following an Ewald test meal contained more calcium than histamine stimulated secretion. The gastric juice calcium in 1 pregnant dog was considerably higher than in man, while the calcium content of fundic pouch juice in 4 dogs was comparable to that of human gastric juice.

The effect of orange juice on calcium assimilation, C. S. LANFORD (*Jour. Biol. Chem.*, 130 (1939), No. 1, pp. 87-95).—Paired groups of young growing rats were maintained for 60 days on a basal diet of ground whole wheat and whole milk, the experimental group receiving in addition 5 cc. of orange juice per rat per day. Gain in total body calcium (calculated as the difference between the calcium content of the experimental animal and the average for controls analyzed at the beginning of the feeding period) as compared with calculated calcium intake indicated that the proportion of the dietary calcium stored by the animals on the supplemented diet was about 8 percent greater than the proportion stored by the control animals on the basal diet alone. "This improved assimilation of the dietary calcium was noted in every instance, and was of unquestionable significance by the usual statistical criteria."

The red blood cell as a source of the iron and bilirubin of the blood plasma, G. BARKAN and B. S. WALKER (*Jour. Biol. Chem.*, 131 (1939), No. 2, pp. 447-454).—According to Barkan and Schales,⁴ there accompany hemoglobin in the circulating erythrocytes two compounds that are intermediate in the transformation of hemoglobin to bilirubin. These carry the "easily split off" blood iron and consist of globin and pseudoheme, the pseudo compound differing from the true one by an opening of the porphyrin ring, probably at the α -methene bridge. The compound in which iron exists with a valence of 2 is designated as α -pseudohemoglobin and the similar compound with trivalent iron is designated as α -pseudomethemoglobin. By the loss of iron and globin these compounds are converted to bile pigment, the final product being bilirubin.

This concept demands that there be a simultaneous transfer of iron and of bilirubin from the red cells to the plasma. The present paper, designed to study this relationship, reports the results of simultaneous determinations of iron and bilirubin in human blood plasma before and after a period of incubation with its own red cells. Freshly drawn samples of human blood containing an anticoagulant were divided into two portions, the plasma being separated out by centrifuge at once in the one sample and after 6 hr. at 37° C. in the other sample. Iron and bilirubin were determined in the plasma by methods noted. In 30 human blood specimens examined an increase of both iron and bilirubin was noted in 18 cases; in 3 there was an increase of bilirubin only; in 4 of iron only; and in 5 no increase was observed. The values reported in detail for 10 of the cases showing increases in both iron and bilirubin indicate that the two constituents were never strictly equivalent, although of the same order of magnitude. The molar increase of bilirubin was usually less than that of iron, due probably to the formation of intermediates. The rate of transfer

⁴ Hoppe-Seyler's Ztschr. Physiol. Chem., 253 (1938), No. 3-4, pp. 83-104.

to the plasma was variable, and the observed increase was inadequate to account for more than a small fraction of the daily production of bile pigment.

In a series tested for bilirubin only no increase was observed in 5 out of 32 normal blood specimens, while among 30 specimens from clinical cases no increase was detected in 14. It was shown also that increase in the plasma bilirubin occurred only in the presence of red cells. The concept of a specific enzyme for the conversion of hemoglobin to bilirubin was refuted in that the presence of quinine or cyanide (enzyme poisons) did not influence the rate of increase of iron or bilirubin.

Iron and copper versus liver in treatment of hemorrhagic anemia in dogs on milk diets, D. V. FROST, V. R. POTTER, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (*Jour. Nutr.*, 19 (1940), No. 2, pp. 207-211).—Mature litter mate collies subjected to repeated hemorrhages superimposed upon an exclusive milk diet from birth were thus brought to an anemic state such that the low hemoglobin level (6-7 gm. per 100 cc.) was maintained with but slight increase over a subsequent 4-week period without therapy. At the end of this period the dogs received daily for a 4-week period one of the following supplements to the milk diet: 100 gm. of whole dried liver furnishing 100 mg. of iron and 3 mg. of copper; iron and copper salts in amounts to furnish 30 and 3 mg. of the respective elements; 30 mg. of iron alone; or 30 mg. of iron for 4 weeks, followed by this amount of iron plus 3 mg. of copper for an additional 4 weeks. With the first two supplements hemoglobin regeneration was optimal; with the iron alone hemoglobin regeneration was slight (only about one-third that with liver or with iron and copper); when the copper was added to the iron supplement at the end of the 4-week period, hemoglobin regeneration was trebled in the succeeding 4 weeks. Only about 16 percent of the iron was utilized to build hemoglobin when iron alone was fed, but two to three times this amount was so used in the two instances where copper supplemented the iron.

The results support the conclusions that whole milk with iron and copper can successfully meet the demand for blood-forming elements occasioned by severe blood loss; that copper is needed with the iron for hemoglobin regeneration; and that with a whole milk diet hemoglobin regeneration is no more rapid with liver therapy than with the iron and copper treatment.

Further evidence of sex variation in the utilization of iron by anemic rats, L. OTIS and M. C. SMITH. (Univ. Ariz.). (*Science*, 91 (1940), No. 2354, pp. 146, 147).—Six litters of young rats made anemic by a 5-week depletion period on a slightly modified Elvehjem and Kemmerer (E. S. R., 67, p. 90) technic were reduced to hemoglobin levels of 2.9-5.4 gm. per 100 cc. of blood. Six male and six female rats sacrificed at this stage averaged 0.015 mg. of Fe per gram of rat, the values for the female rats being no greater than those of the males. The remaining animals were sacrificed and analyzed after a 6-week period in which they received supplements of FeCl₂ furnishing from 0.05 to 0.30 mg. of Fe daily. Gains in weight and in hemoglobin, and Fe content of the body expressed as average total milligrams per rat and as average milligrams per gram are reported for the males and females separately at the various levels of supplement. For the same Fe intake the female rats always showed a higher amount of Fe per gram of rat, and at the lowest level of Fe fed the females retained more Fe than the males in spite of their smaller size. These results were further checked by comparing results with animals that had made equal weight gains; the female rats made greater hemoglobin gains and showed greater Fe retentions than the male rats, both at the 0.05 and 0.2 mg. level of Fe intake. These results support the previous findings (E. R. S., 78, p. 281) that there is a true difference in the way male and female rats utilize iron, and that it cannot be explained by a difference in the weights of the two sexes.

The influence of certain constituents of the diet upon the absorption of lead from the alimentary tract, S. L. TOMPSETT (*Biochem. Jour.*, 33 (1939), No. 8, pp. 1237-1240).—The effect of high- and low-calcium diets on the absorption of lead was studied in experiments with adult white mice fed the experimental diet with supplements of lead acetate (0.05, 0.10, 0.50, and 1.00 mg. of lead per mouse per day) for a period of 14 days, the lead absorption being finally determined by analysis of the entire animal. The lead content of control and test animals and of the unsupplemented diets (which furnished only 0.002 mg. of lead per mouse per day) was determined by the method previously noted (*E. S. R.*, 84, p. 8). The data, reported as total absorption and as absorption per 100 gm. of body weight at the several intake levels of lead, indicate that the absorption of lead was low with the high-calcium diet but high upon the low-calcium diet. In the latter case the absorption increased with increases in the amount of added lead. Although large amounts of lead were absorbed on the low-calcium diet, there was considerable variation between animals receiving the same amounts of lead.

The addition of olive oil (1 cc. per mouse per day) or of cod-liver oil (3 drops per mouse per day) to the low-calcium diets had no effect on the lead absorption. Apparently there was no specific action of the vitamin D and no influence of the fat through the formation of insoluble, hence nonabsorbable, lead soaps in the intestinal tract.

Studies in lead mobilization, S. L. TOMPSETT and J. N. M. CHALMERS (*Brit. Jour. Expt. Pathol.*, 20 (1939), No. 5, pp. 408-417, figs. 10).—Ten cases involving either clinical plumbism or increased lead absorption were studied with reference to the effects of high- and low-calcium diets on the level of blood lead. The high-calcium diets furnishing 2.7 mg. of calcium per day (and sometimes supplemented with intramuscular injections of calcium gluconate) produced a fall in blood lead, whereas the low-calcium diets furnishing 0.13 gm. of calcium per day produced a rise in blood lead either with or without the simultaneous administration of NH_4Cl . The excretion of lead in the two cases studied did not parallel the increase in blood lead. It is considered, therefore, that the deleading process should be undertaken only with adequate laboratory control, since the process may result in a shift of lead to the soft tissues and blood without compensatory increase in excretion. This shift of lead to the soft tissues upon a low-calcium diet was demonstrated in mice given low- and then high-calcium diets following experimentally induced plumbism. Analyses of the skeleton and soft tissues of animals sacrificed at intervals in the experiment showed about 60 percent of the lead to be in the soft tissues, with 40 percent in the skeleton after the period on the low-calcium diet; after the period on the high-calcium diet about 78 percent of the lead was found in the skeleton and 22 percent in the soft tissues. A shift to a second period of low-calcium intake effected a decrease in skeletal lead, accompanied by an increase of the element in the soft tissues. Analytical data are also presented on the lead content of various bones and organs of the one patient who succumbed to lead poisoning.

Oxalic acid in foods and its behavior and fate in the diet, E. F. KOHMAN (*Jour. Nutr.*, 18 (1939), No. 3, pp. 233-246, figs. 3).—Total solids, oxalic acid (anhydrous), and calcium as percentage of fresh substance are reported for a large number of fruits and vegetables. The procedure employed for insuring solution of the total oxalate content and the method of determination (precipitation as CaC_2O_4) are outlined. Almost all of the samples analyzed contained at least traces of oxalate, but only a few foods, namely, spinach, Swiss chard, New Zealand spinach, beet tops, lambsquarters, poke, purslane, and rhubarb, had a high oxalate content (about 10 percent on a dry basis). Of the 53

samples of spinach, including most commercial and many experimental varieties grown in various sections, none was free of oxalate. The samples averaged on a dry basis 9.02 percent (maximum 12.6 and minimum 4.5 percent) anhydrous oxalic acid. Calcium in these same samples and on the same basis averaged 1.25 percent (maximum 2.50 and minimum 0.44 percent). California-grown spinach was found to average lower in calcium than Maryland-grown spinach.

To compare the availability of calcium from greens of high and low oxalate content, feeding experiments were conducted with young rats. The greens at levels to supply about 60 percent of the total dietary calcium were added to a basal diet relatively low in calcium but permitting good though not maximum growth and bone formation. Spinach was used as the green high in oxalate, and turnip greens, mustard greens, kale, and collards as greens with negligible oxalate content. On the diet supplemented with spinach, reproduction was impossible, the bones were extremely low in calcium, tooth structure was disorganized, and the dentin poorly calcified. With the other greens excellent animals were produced and their bodies per unit of weight contained four times as much calcium as the bodies of the rats receiving spinach. Apparently, therefore, the spinach not only supplied no available calcium, but also rendered unavailable much of the calcium from other foods. Considerable of the oxalate from the spinach appeared in the urine (with a tendency to carry calcium with it), but much more appeared in the feces.

The antineuritic value of parboiled rice: A comparison with unmilled raw rice. I. A. SIMPSON (*Inst. Med. Res., Fed. Malay States, Bul. 4 (1939), pp. [1]+15, figs. 6*).—The parboiled rice was prepared by soaking unhusked rice, heating it with water on a slow fire until the grains burst, drawing off the water, and drying in the sun. This dry rice, from which the husks may be readily removed by winnowing, is then milled.

In feeding tests with rats the parboiled rice, whether overmilled or undermilled, compared favorably in antineuritic value with samples of undermilled raw rice. These results suggest (1) the possible retention of pericarp by the endosperm after milling, due to increased toughness of these layers, or (2) the absorption by the starchy kernel of vitamin B₁ soaked out from the pericarp.

Some factors producing individual differences in dark adaptation. L. R. PHILLIPS (*Roy. Soc. [London], Proc., Ser. B, 127 (1939), No. 848, pp. 405-424, figs. 3*).—The factors studied were the diameter of the pupil, coloring, visual acuity, and age. The first three were studied in a group of male medical students, all aged approximately 20 yr. and 8 mo., who had received regular doses of vitamin A totaling 100,000 units during the 6 days previous to the examination. The effect of age was studied on 26 subjects of both sexes whose ages ranged from 17 to 70 yr., with an average of 30 yr. and 6 mo., selected as being on a diet furnishing sufficient vitamin A. The dark adaptation tests were made by the apparatus developed by Lythgoe and Phillips,⁵ and the pupils were photographed for diameter measurements on infrared plates by an infrared flash after 2 min. of light adaptation and at the completion of dark adaptation.

From data secured from 40 subjects in the first group, the various factors were correlated in turn with the times taken from the onset of darkness to see each of the selected brightnesses of the test patch, designated as perception times. Significant correlations were obtained for pupil diameter in the light with perception time for 15 out of 17 test patch brightnesses, and confirmed by the significance of the regression of time on pupil diameter in the light for the whole of the data, indicating that a comparatively large pupil in the light produces a retardation in dark adaptation. The correlation of pupil diameter

⁵ Jour. Physiol., 91 (1938), No. 4, pp. 427-436, figs. 2.

in the dark with perception times for 6 selected test patch brightnesses was not significant. This was attributed to the existence of a significant correlation between pupil diameter in the light and in the dark. When the data were corrected for differences of pupil diameter in the light, a series of negative correlation coefficients was obtained which increased with the duration of dark adaptation, showing that a comparatively large pupil diameter in the dark tends to decrease perception times.

Correlations were insignificant for general coloring and visual acuity (within the limits tested) with original or corrected perception times. A significant negative correlation was obtained for pupil diameter in the light, with age. The mean pupil diameter in the dark, 6.86 mm., was significantly lower than the mean of the group (7.44 mm.). "Some part of the retardation of dark adaptation with age is, therefore, due to a small pupil diameter in the dark. The remainder must be assumed to be due to changes in the retina with increasing age."

Experimental vitamin A deficiency in man and the value of "adaptometry" [trans. title], W. v. DRIGALSKI (*Ztschr. Vitaminforsch.*, 9 (1939), No. 4, pp. 325-330; *Fr., Eng. abs.*, p. 330).—Visual adaptation tests, using the Birch-Hirschfeld photometer, were conducted on a normal healthy adult man who subjected himself over a 72-day period to a diet deficient in vitamin A. The tests were carried out according to the original procedure described for this instrument, with readings at 5- and 10-min. intervals after exposure to bright light. At the beginning of the study readings were taken every third day, later every second day, and at the last as often as three times a day. The results led to the conclusion that "subnormal dark adaptation does not necessarily indicate vitamin A deficiency, but normal dark adaptation is only found when vitamin A is adequately provided."

The vitamin A requirement of man, I, II [trans. title] (*Klin. Wchnschr.*, 18 (1939), Nos. 38, pp. 1269, 1270; 40, pp. 1318, 1319).—Two papers.

I. *The healthy adult*, W. v. Drigalski.—This study, conducted by the method outlined above on a healthy adult subjected to vitamin A deficiency, indicated that the optimal vitamin A requirement of this subject was about 5.9 mg. (9,800 International Units) daily. There was a wide zone between faint hypovitaminosis and severe deficiency, due to the body's great capacity for vitamin A storage. The vitamin A stores lasted several months, although slight deficiency became evident very early.

II. *Pregnant and nursing women and diseased subjects*, W. v. Drigalski and H. Kunz.—In this study, conducted on a number of subjects receiving controlled institution diets of known vitamin A content, the daily vitamin A requirements, expressed as milligrams of β -carotene, were found to be 7, 11, and 20 in 3 women in late pregnancy; 5, 10, and 7 in 3 nursing women; and 4, 5, and 6 in 3 subjects with cirrhosis of the liver.

Vitamin A and carotenoids in the liver of mammals, birds, reptiles, and man, with particular regard to the intensity of the ultraviolet absorption and the Carr-Price reaction of vitamin A, H. B. JENSEN and T. K. WITH (*Biochem. Jour.*, 33 (1939), No. 11, pp. 1771-1786).—Determinations were made of the amounts of vitamin A and carotenoids in the liver in 8 human subjects and in 33 different mammals belonging to 21 species, 41 birds belonging to 36 species, and 4 reptiles of 2 species. The variations between species were considerable, and there was no simple proportionality between the amount of vitamin A and carotene in the food ingested and the concentration in the liver. The majority of the livers contained no carotene, although it was present in considerable amount in the liver of certain beasts of prey and birds, as well as in the Herbivora. In no instance was vitamin A₂ demonstrated.

Apart from the interest in the vitamin A content of the various livers, the study was particularly concerned with the relation between the extinction coefficients of the Carr-Price reaction and the ultraviolet absorption, since this relationship must be established for each source of vitamin A if the Carr-Price results are to be expressed in International Units. Most of the livers, therefore, were subjected to a detailed spectrographic analysis in the ultraviolet range, a detailed determination of the absorption of the Carr-Price reaction for three different spectral filters, and an estimation of the carotenoids, including microchromatography. The technics employed are described in detail, and the results are tabulated to show the extinction coefficient $E_{1\text{cm.}}^{1\%}$ (1 gm. liver in 100 cc.; 1 cm. layer thickness) of vitamin A at 328 $m\mu$, the Carr-Price reaction with filters S 59, S 61, and S 66.6 in the Pulfrich photometer, and certain ratios of the extinction values. The absorption curves are described briefly.

For livers showing a typical absorption curve, it was found that the relation between the extinction of the Carr-Price reaction with filter S 61 and vitamin A absorption at 328 $m\mu$ had a fairly constant value of 2.60-2.75, with a coefficient of variation of 10-15 percent. The conversion of the extinctions measured with S 61 in the Carr-Price reaction into I. U. per gram of liver is calculated, therefore, from the formula $B_{1\text{cm.}}^{1\%} \text{ S 61} = 2.60-2.75$, corresponding to about 1,600 I. U. per gram (or if the amount of vitamin A is expressed in micrograms by the formula $B_{1\text{cm.}}^{1\%} = 4,100-4,400$ for the Carr-Price reaction of the pure vitamin A with S 61).

Biological standardization of vitamin-A, P. TAINSH and H. WILKINSON (*Chem. and Indus.*, 58 (1939), No. 48, pp. 1051, 1052).—This preliminary note indicates that the accuracy of the biological assay of vitamin A may be influenced by the nature of the basic diet. It is pointed out that with the diet (slightly modified to introduce 5 percent of agar agar) given in the British Pharmacopoeia, 1932, Addendum, 1936, young rats supplied with 40 International Units of β -carotene (following depletion of the vitamin A reserves of the liver) excrete a carotenoid in the feces; that this is not excreted if 40 I. U. of vitamin A are supplied in place of the β -carotene; that the carotene-fed animals have larger liver reserves of vitamin A than the vitamin A-fed rats; and that the growth responses are smaller on the β -carotene than on the vitamin A supplement. Using the diet described by Morgan (*E. S. R.*, 73, p. 721), however, the carotenoid excretion is not observed, nor is there a difference in vitamin A liver stores or growth rates between rats receiving supplements of vitamin A and those receiving β -carotene. Inclusion of coconut cake meal in the Pharmacopoeia diet gives results comparable with those on the Morgan diet. The differences in physiological response result in marked differences in apparent potency of a given vitamin A preparation assayed against the international standard β -carotene, the relative potencies varying between ratios of 1:1 for the Morgan diet to 2 or more: 1 for the modified Pharmacopoeia diet.

The vitamin A content of "light white" casein, M. K. MAITRA and T. MOORE (*Biochem. Jour.*, 33 (1939), No. 10, pp. 1648-1651).—Light white casein (sodium caseinate) extracted with cold ether or ethyl dichloride yielded about 0.4 percent of fat; subsequent extraction with hot alcohol gave an additional yield of about 1 percent, while direct extraction with hot alcohol alone gave a yield of about 2 percent. Colorimetric estimations on the unsaponifiable portion of these extracts indicated the presence of carotene and vitamin A in the alcoholic extracts. Assuming all the yellow of the alcohol extract to be carotene, the vitamin A of the fat was estimated at about 50 International Units per gram; taking the fat content at the round figure of 2 percent, the value of 1 I. U. per gram was ob-

tained as the approximate total vitamin A activity of the casein. This value was borne out by biological tests in which the light white casein was found to contain enough vitamin A to promote slow growth in rats depleted of the vitamin when included in the diet at the level of 20 percent.

The vitamin A content of cheese, A. W. DAVIES and T. MOORE (*Biochem. Jour.*, 33 (1939), No. 10, pp. 1645-1647).—A sample of English Cheddar cheese was found by biological tests to have a potency of approximately 7.5 International Units per gram, as was to be expected from the milk fat content (about 33 percent). This value corresponded very well with the total vitamin A activity (6-9 I. U. per gram) calculated from the values obtained by colorimetric estimation of vitamin A and carotene content. Colorimetric determinations on other full-milk cheeses, namely, Camembert, Cheshire, Empire red, Empire white, Gruyère, and Stilton, gave similar results. Lower values were found for cheeses of lower fat content, such as Dutch Edam and Danish blue.

Vitamin B₁ content of eight varieties of beans grown in two localities in Michigan, E. KELLY, K. S. DIETRICH, and T. PORTER. (Mich. Expt. Sta.). (*Food Res.*, 5 (1940), No. 3, pp. 253-262, figs. 2).—Eight varieties of beans (*Phaseolus vulgaris*) grown in two localities in Michigan in 1936 (with one exception) were tested during the spring of 1937 and the spring and summer of 1938 for their vitamin B₁ content in the dried ground state by the Chase-Sherman rat-growth method with controls on three levels of vitamin B₁, as both the clay adsorbate and crystalline thiamin hydrochloride, for construction of curves of response for interpretation of the growth data on three levels of the beans. The values obtained were not identical for the two curves of response, but were of the same order of magnitude and showed the same differences between varieties and communities. Blue Pod and Robust varieties ranked highest and Kidney, Yellow Eye, and Cranberry varieties lowest, with the Great Northern, Michelite, and a variety designated as 1200-1 of medium value. The extreme range, as determined from the curve of response to thiamin hydrochloride, was from 2.9 International Units per gram (Blue Pod) to 1.0 I. U. per gram (Yellow Eye). It is noted that even the varieties with the lowest value are comparable with whole wheat, certain nuts, and egg yolk in vitamin B₁ content. No significant differences in values for the same variety grown in the two localities were obtained, although a number of varieties were slightly higher in the Fowlerville area (light to medium sandy loam) than in the Romeo district (heavy sandy loam).

Observations on the liver filtrate factor of the vitamin B₂ complex, T. F. MACRAE, A. R. TODD, B. LYTHGOE, C. E. WORK, H. G. HIND, and M. M. EL SADR (*Biochem Jour.*, 33 (1939), No. 10, pp. 1681-1687).—The portion of an aqueous extract of liver extractable by phenol and not adsorbed on small amounts of charcoal (and containing about one-third of the amount of the filtrate factor present in whole liver extract) served as the source of the liver filtrate factor. From this there was prepared a concentrate representing the deproteinated amylic alcohol extract of a fuller's earth eluate. The concentrate as such, or purified by further adsorption and elution using fuller's earth, was used in the various tests. The rat-growth method previously described by Edgar et al. (*E. S. R.*, 82, p. 297) was used, with slight modification, for determining filtrate factor activity. The following results of the various tests are quoted from the author's summary:

"Liver filtrate factor is not precipitated by salts of lead, mercury, silver, quinine, or brucine, but is precipitated from alcoholic solution by barium hydroxide. The factor is not adsorbed even on exhaustive treatment with fuller's earth; it is, however, adsorbed by large amounts of norite charcoal.

Amyl alcohol and ether extract the factor from acidified solutions. By combination of several methods of concentration a material has been obtained containing the rat day dose of the vitamin associated with about 180 μg . of dry matter. On acetylation liver filtrate factor yields a product easily extractable from aqueous solution by chloroform and possessing only feeble activity; mild hydrolysis of this material gives a product having biological activity comparable with that of the starting material. Treatment of a liver filtrate factor concentrate with diazomethane does not appreciably affect the biological activity."

Maintenance nutrition in the pigeon: Further evidence for the presence of dietary essentials in yeast and liver and their relation to vitamin B₆. C. W. CARTER and J. R. O'BRIEN (*Biochem. Jour.*, 33 (1939), No. 11, pp. 1810-1815).—Evidence is presented to show that the pigeon requires in addition to aneurin and riboflavin a fuller's earth eluate and a fuller's earth filtrate factor, both of which are present in yeast and liver and may be prepared by the methods described. The eluate fraction was found to have marked weight-restorative action, the effect being maximum when supplemented by the filtrate fraction. Crystalline vitamin B₆ (in daily doses of 40 μg .), although less active than the eluate fraction, served in place of it to supplement the weight-restorative action of the filtrate fraction. This supplementary relationship with the filtrate fraction was not exhibited by aneurin or riboflavin.

The filtrate growth factor B_w [trans. title], H. KRINGSTAD and G. LUNDE (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 261 (1939), No. 3, pp. 110-124, figs. 7).—In investigations concerning the vitamin B complex, sugar was the carbohydrate of preference in the basic diet since starches appeared not to be completely free of the B factors. For the basic diet in vitamin B₆ investigations casein purified by repeated precipitation and washing was found preferable, but for studies on the other B factors fish protein was used, since it appeared to carry sufficient vitamin B₆. Fuller's earth adsorption did not give a sharp separation of the B factors in yeast, since the B₆ was not quantitatively removed from faintly acid (pH=5-6) solutions, while from more acid solutions (pH=1) other factors were also adsorbed and compounds toxic to the rats (weakened by avitaminosis) were also found. Vitamin B₆ was quantitatively precipitated with phosphotungstic acid but not by mercuric acetate. The latter reagent failed also to precipitate the filtrate growth factor B_w. Since this factor (at pH=1) could not be extracted with ether, it is apparently not identical with the chick antidermatitis factor. It is considered that the B complex apart from the known factors B₁, B₂, B₆, and nicotinic acid must contain the following: The chick antidermatitis factor (factor 2 of Jukes), the filtrate growth factor (B_w) of Kringstad et al., which is probably identical with the factor W of Elvehjem et al., the antigray hair factor (B_x of Lunde and Kringstad), and possibly other factors.

The newer knowledge of vitamin C in health and disease, E. N. TODHUNTER, (Wash. State Col.). (*Jour. Amer. Dietet. Assoc.*, 16 (1940), No. 1, pp. 1-11).—Recent developments in vitamin C research of particular interest to the dietitian are reviewed.

A note on the vitamin C content of some dried, sugared, and salted Chinese vegetables and fruits, L. T. CHENG and H. TAO (*Sci. Soc. China, Biol. Lab. Contrib., Zool. Ser.*, 13 (1939), No. 7, pp. [1]+87-90).—Vitamin C, determined by a modification of the iodometric titration method of Szent-Györgyi and checked by the 2,6-dichlorophenolindophenol method, is reported in milligrams per gram for 27 dried, salted, or sugared fruits and vegetables obtained from Chinese markets. Comparative analyses of a number of fruits and vegetables in the fresh state are also presented. The data indicate that the

vitamin C was completely destroyed in many of the preserved products. Only traces remained in most of the others, the highest value, 0.176 mg. per gram, being that for salted turnip.

The vitamin C (ascorbic acid) content of ten varieties of watermelons, R. E. CLEGG and G. H. SATTERFIELD. (Univ. N. C.). (*Jour. Amer. Dietet. Assoc.*, 16 (1940), No. 1, pp. 39-42).—The watermelons tested were purchased on the Raleigh, N. C., market as ripe or nearly ripe specimens and were analyzed within 2 days after purchase, using 15-gm. samples cut from the center and the red edible portion $\frac{1}{2}$ in. under the rind. The Lyman, Schultze, and King modification (E. S. R., 78, p. 7) of the Bessey and King titration procedure was used. Values are reported as high, low, and average for each variety.

The portions next to the rind were much more uniform in ascorbic acid content than the heart portions, the averages ranging from 5.31 mg. percent for Cannon Ball to 6.49 mg. percent for Stone Mountain. The averages for the heart sections ranged from 6.37 mg. for the Tom Watson (S. C.) to 10.04 mg. percent for Stone Mountain. The extreme range in values for the heart portion of a single variety was from 7.28 to 13.70 mg. percent for Georgia Rattlesnake. No consistent relationship was evident between the size and shape of the melon and its ascorbic acid content. Samples of flesh and juice from preserved and pickled melon rind gave low values, the highest being 1.31 mg. percent for the juice of pickled rind.

Ultraviolet irradiation and vitamin C metabolism, C. W. JUNGBLUT and R. R. FEINER (*Jour. Lab. and Clin. Med.*, 25 (1939), No. 3, pp. 263-269).—Prolonged ultraviolet irradiation (mercury-vapor lamp) of albino guinea pigs, rabbits, and rhesus monkeys failed to produce any evidence of erythema on the skin; nor was the vitamin C content of the brain, liver, spleen, and adrenal gland decreased by this treatment, as judged by comparison of the analytical values with those determined on control animals receiving no irradiation. The production of a superficial burn on the skin of guinea pigs by the local application of heat was followed, however, by a drop in the vitamin C content of these tissues. From these results and findings cited from the literature, it is concluded that excessive doses of radiant energy apparently cause a derangement of vitamin C metabolism only to the extent that they are capable of producing injury to the tissues.

Investigations into the excretion, absorption, and storage of ascorbic acid in guinea pigs [trans. title], O. J. BROCH (*Ztschr. Vitaminforsch.*, 9 (1939), No. 4, pp. 309-325, fig. 1; *Fr. Eng. abs.*, p. 324).—Guinea pigs weighing 200-400 gm. were used for this study, the animals having been maintained on a basal diet supplied with orange juice until the time of the experimental period. Following the various experimental periods, the ascorbic acid content of the organs (adrenals, spleen, liver, and upper small intestines) was determined by dichlorophenolindophenol titration of a 1.5-percent trichloroacetic acid extract of the tissue. The scorbutic state of the animal was judged from the histological appearance of a stained section of the fixed decalcified root of the incisor, the degree of scurvy being judged according to the scheme of Key and Elphick (E. S. R., 67, p. 189).

In one experiment in which ascorbic acid in doses of 2, 4, 5, or 10 mg. per day was administered orally for 6-17 days, the ascorbic acid content of the adrenals, spleen, and intestine appeared to vary with the intake. With increasing doses even up to 100 mg. daily, the amount stored in these organs scarcely increased above the upper limiting values on the lower doses.

In another experiment the animals were placed on a scorbutic diet after a 7-day saturation period in which 10 mg. of the pure vitamin was administered

daily. It was found that the body stores were depleted at first rapidly, then more slowly, and by the eighth or tenth day the teeth showed the first definite signs of scurvy. At this stage the adrenals contained 0.12-0.15 mg. of ascorbic acid per gram.

The reducing power of the urine, as determined by the dichlorophenolindophenol titration method, was negligibly affected by the oral intake of very large doses (50, 100, or even 1,000 mg.) of ascorbic acid, but injection was followed by measurable excretion of the vitamin. This observation was confirmed biologically by administration of the urine of these test animals to scorbutic guinea pigs.

With small doses of ascorbic acid (2 mg. daily for 14 days), the amount stored in the organs was found to be the same regardless of whether the dose was administered orally or by peritoneal or subcutaneous injection. On the other hand, a single large dose (100 mg.) administered after 12 days on a scorbutic diet resulted in marked storage in the organs if the dose was administered subcutaneously but in only slight storage if given orally.

Changes in the acidity of the gastrointestinal tract as effected by sodium bicarbonate (0.2 gm. in water daily for 14 days) appeared not to interfere with the absorption of small doses (5 mg.) of ascorbic acid. Nor was the absorption disturbed by changes in motility as effected by castor oil (1 cc. for 14 days).

Animals infected with tuberculosis showed no increased usage of ascorbic acid during the incubation period, but usage increased with the development and severity of the clinical symptoms. Hunger induced in test animals by a 5-day period without food was found to have no effect on the storage by the organs of ascorbic acid subsequently administered orally in a 5-mg. dose.

Creatine metabolism in muscular dystrophy due to vitamin E deficiency and its treatment with tocopherol [trans. title], F. VERZÁR (*Ztschr. Vitaminforsch.*, 9 (1939), No. 3, pp. 242-251; *Fr., Eng. abs.*, p. 250).—In these experiments, presented in some detail, a control group of four adult rats on an ordinary mixed diet and an experimental group of three animals on a vitamin E-deficient diet were observed as to physical signs and the urinary excretion of creatine and creatinine. The rats deprived of vitamin E for several months developed muscular dystrophy and also a marked creatinuria. At this stage administration of large doses (100 mg. daily) of *dl*- α -tocopherol quickly effected a return to normal, the creatinine excretion falling in 1 day from the daily total of 1.4-2.2 mg. to the normal excretion of about 0.5 mg. per day. In vitamin E-deficient animals with muscular dystrophy the creatine : creatinine ratio varied from 40 to 130 percent; upon tocopherol treatment this ratio was promptly reduced to the normal level of about 5 percent.

The curative factor (vitamin H) for egg white injury, with particular reference to its presence in different foodstuffs and in yeast, P. GYÖRGY (*Jour. Biol. Chem.*, 131 (1939), No. 2, pp. 733-744, fig. 1).—Egg white injury evidenced by the appearance in 5-7 weeks of specific dermatitis of a seborrheid desquamative type was consistently produced in albino rats on a diet composed of 300 gm. of commercial Chinese egg white, 370 gm. of cornstarch, 150 cc. of peanut oil, 50 gm. of salt mixture (McCullum 185), 30 cc. of cod-liver oil, and 100 cc. of an alcoholic extract of yeast prepared by the method of Sherman and Sandels (*E. S. R.*, 66, p. 92). This diet was used in all but a series of earlier experiments in which a similar diet was found to produce consistent reactions in 1,343 rats (792 males and 551 females), only 60 of the group being refractive. As judged by the rate of onset of symptoms in the 1,283 responsive animals, male rats were more susceptible to injury than the females, and suscep-

tibility for all animals decreased progressively with increase in initial experimental weight. A change in the nature of the commercial (German) yeast extract necessitated for subsequent work the modification of the diet used for these earlier studies.

The distribution in foodstuffs of the factor protective against egg white injury and previously designated as vitamin H (E. S. R., 78, p. 895) was studied by the rat curative method. A "rat day dose" was used as the basis of comparison, and the unit was defined as the daily dose of the food or concentrate which in 4 weeks effects complete cure of the egg white injury. Liver, kidney, yeast, and to a lesser extent cow's milk were found to be the main sources of vitamin H. In experiments with rats water extracts of yeast or extracts prepared with fat solvents were not curative of the dermatitis, indicating the insolubility of the vitamin in water or fat. Autolysis of yeasts at 37° C. in the presence of water and toluene yielded autolysates which, in terms of yeast, did not differ materially from the original titer values. The presence of chloroform (an enzyme poison) in contrast to toluene was detrimental to the autolytic liberation of vitamin H from yeast. These results suggest that vitamin H is part of a compound of higher molecular weight insoluble in water or fat and that the vitamin can be liberated from the compound by autolysis; yeast appears to possess the ferment necessary for this liberation.

Attempts to isolate the factor (vitamin H) curative of egg white injury. P. GYÖRGY, R. KUHN, and E. LEDERER (*Jour. Biol. Chem.*, 131 (1939), No. 2, pp. 745-759).—Fresh liver or a liver powder representing the dry residue remaining after removal of liver extract was used as the source of vitamin H in these isolation experiments. Fresh liver, unlike yeast, did not yield vitamin H upon autolysis, but proteolytic digestion of liver with pepsin or papain but not with trypsin served to liberate the vitamin. With fresh liver papain was not as effective as pepsin, but with liver powder satisfactory results were obtained with papain digestion, particularly after preliminary autolysis of the powder and discard of inactive break-down products with the filtrate. Hydrolysis of fresh liver or kidney under normal or high pressure did not liberate the vitamin, but in the presence of acid (H_2SO_4 or HCl) liberation was effected under high pressure. Liver powder, when autoclaved with or without acid for 1 or 2 hr. at about 200° C. gave very good yields of the vitamin. Further concentration from the hydrolysates was accomplished by extraction with acetone, methanol, or ethyl alcohol.

Vitamin H was precipitated quantitatively from crude concentrates by phosphotungstic acid, although large amounts of the acid were needed. Preliminary concentration of the vitamin by adsorption on charcoal and elution with a mixture of water, pyridine, and methanol, followed by hydrolysis of the eluate with 4 percent H_2SO_4 gave a solution from which precipitation with phosphotungstic acid was more effective. This precipitate was decomposed with barium hydroxide. Gold chloride successfully precipitated the vitamin from eluates, particularly after preliminary precipitation with phosphotungstic acid. The gold was removed with H_2SO_3 rather than H_2S , since various sulfides (Au, Cu, Pt, but not Pb) adsorbed the vitamin. A large number of miscellaneous precipitants also tested gave negative results. In various preparations obtained by precipitation following adsorption and elution, the concentration of the vitamin was such that one rat day dose contained 0.5 mg. of organic dry residue, corresponding to 75-100 mg. of the original liver powder. Further chemical purification of these concentrates lowered the rat day dose in special experiments to from 30% to 40% of organic dry residue. Water solutions of these preparations were inactivated by treatment with formaldehyde, nitrous acid, benzoyl chloride, and ketene.

Papain digestion or hydrolysis under pressure were successfully applied to yeast autolysates, although the residue of organic solids was always higher in these preparations of the vitamin than in the corresponding products obtained from liver.

Physicochemical properties of the factor (vitamin H) curative of egg white injury, T. W. BIRCH and P. GYÖRGY (*Jour. Biol. Chem.*, 131 (1939), No. 2, pp. 761-766).—By means of electro dialysis experiments, using concentrates of varying degrees of purification but containing a low concentration of electrolytes, it was found that the factor (vitamin H) curative of egg white injury in rats had an isoelectric point between pH 2 and 4, the actual value appearing to be between pH 3 and 3.5. Thus the factor is an amphoteric electrolyte exhibiting acidic properties. "Attempts at precipitation by means of various alkaloids were not successful. The sodium salt of vitamin H is soluble in absolute ethyl alcohol, while the addition of $\text{Ba}(\text{OH})_2$ or of $\text{Ca}(\text{OH})_2$ renders the active principle insoluble in ethyl alcohol."

HOME MANAGEMENT AND EQUIPMENT

Use of time in its relation to home management, J. WARREN [*New York Cornell Sta. Bul.* 734 (1940), pp. 98, figs. 14].—Records were obtained from more than 500 farm families in Genesee County, New York, interviewed in the spring of 1936. Forty-seven households were also interviewed during the summer, fall, and winter to study the effect of season. The material, together with information on family composition and household equipment, is summarized in numerous tables and discussed at length.

On an average 63 hr. per week were used for homemaking, of which 52 hr. was used by the homemakers themselves. Care of the house and food preparation accounted for two-thirds of the time. In households where there were children the homemaker used more time for homemaking and less for sleeping and leisure than in other households. "The care of a child less than 1 yr. of age seemed to require about 1,000 hr. a year over and above the homemaking time required for an adult, in addition to the extra time used for washing." Other phases, including the effects of help, work loads, labor saving devices, labor efficiency, liking for the various activities, financial status, farm and other work, and community activities are also considered.

A study of consumer purchases (*Vermont Sta. Bul.* 463 (1940), pp. 22, 23).—This progress report summarizes the results obtained in an analysis of the village housing data in the consumer purchases schedules for the State (E. S. R. 82, p. 716).

[**Equipment studies by the Indiana Station**] (*Indiana Sta. Rpt.* 1939, pp. 91, 92).—Progress is reported in continuation of studies (E. S. R., 81, p. 749) on refrigeration in the farm household (including adequate refrigeration for "frozen food" products), by G. Redfield and T. E. Hinton; and on small electric mixers (and mixer motors), by Redfield.

A study of electric roasters, P. B. POTTER and E. C. NEALE (*Virginia Sta. Bul.* 325 (1940), pp. 30, figs. 10).—The six roasters, representing popular makes and models, are described (with illustrations) briefly as to construction and accessories. Results of performance tests on the unloaded roaster and of selected cooking tests are reported.

The roasters were of low wattage (1,320). This was of advantage in that it permitted operation on a single house circuit without the need for special wiring, but of disadvantage in requiring a longer period for heating to the required cooking temperature. The performance tests showed that this preheating required from 20 to 40 min. Four of the six roasters showed satis-

factory thermostatic control. In general there were no important differences in performance among the several roasters of different makes.

Actual cooking tests, standardized as to general procedure in preliminary trials, showed that baked goods were more successfully produced in the bottom baking positions of the roaster near the source of heat, that the cooking of vegetables and the roasting of meat were slightly more successful than the baking of cakes and pastries, that a basic meal (meat, vegetables, puddings, and biscuits) sufficient for eight persons could be successfully prepared at one time, and that canning operations were limited to certain low-temperature products. The cost of operation per meal or per product compared closely to that of the electric range, but in many cases may be less due to the smaller size of the appliance that has to be heated and put into operation.

MISCELLANEOUS

Statistical methods for medical and biological students, G. DAHLBERG (*London: George Allen & Unwin; New York: Interscience Pubs.*, [1940], pp. 232, figs. 13).—This is an elementary introduction to the methods used to ascertain the significance of biological data. The methods are illustrated throughout by examples drawn from medical and biological research.

Methods of statistical analysis, C. H. GOULDEN (*New York: John Wiley & Sons; London: Chapman & Hall*, 1939, pp. VII+277, figs. 15).—An explanation of the principles of statistical analysis and its application with particular reference to agricultural problems.

Analyzing data for relationships, F. A. HARPER ([*New York*] *Cornell Sta. Mem.* 231 (1940), pp. 14, figs. 2).—This memoir deals only with two of the problems, (1) moving averages where both factors are irregular and (2) the method of reducing effects of interserial associations.

Fifty-second Annual Report of [Indiana Station], 1939, J. H. SKINNER, H. J. REED, ET AL. (*Indiana Sta. Rpt.* 1939, pp. 142, figs. 38).—The experimental work not previously referred to is mostly noted elsewhere in this issue.

Fifty-third Annual Report [of Vermont Station, 1940], J. L. HILLS (*Vermont Sta. Bul.* 463 (1940), pp. 31).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Bimonthly Bulletin, [September 1940], edited by W. C. PALMER (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 1, pp. 23, figs. 2).—In addition to several articles noted elsewhere in this issue and the customary abstracts, this number contains Research and a North Dakota "Live-at-Home" Program, by H. L. Walster (pp. 2, 3); and North Dakota Farm Prices, by W. L. Ettesvold (p. 22).

NOTES

California University and Station.—Three buildings recently completed on the Davis campus include a \$325,000 library-administration building, a \$60,000 irrigation laboratory, and a \$165,000 chemical laboratory.

Dr. Carl L. Alsberg, since 1937 director of the Giannini Foundation of Agricultural Economics, died November 1, 1940, aged 63 years. Dr. Alsberg was born in New York City, graduating from Columbia University in 1896 and receiving the M. D. degree from the College of Physicians and Surgeons in 1900. After 3 years' further study at the Universities of Strasbourg and Berlin he became instructor in biochemistry at Harvard University, and in 1908 was appointed chemical biologist in the U. S. D. A. Bureau of Plant Industry. From 1912 to 1921 he served as Chief of the Bureau of Chemistry, and from 1921 to 1933 was director of the newly established Food Research Institute and dean of graduate study in Stanford University.

Dr. Lindsay A. Crawford, assistant professor of agricultural economics and assistant agricultural economist in the station and the Giannini Foundation, resigned, effective January 1, to become assistant secretary of the Berkeley Bank for Cooperatives of the U. S. D. A. Farm Credit Administration.

Recent appointments include Dr. Dorothy S. Thomas, director of research in social statistics at the Yale University Institute of Human Relations, as professor of rural sociology in the College of Agriculture and rural sociologist in the Giannini Foundation and the station; Dr. H. R. Josephson, assistant forester in the California Forest and Range Experiment Station, as assistant professor of forestry and assistant forest economist; and Dr. C. M. Rick as instructor in truck crops and junior geneticist.

Connecticut State Station.—A two-story brick office and laboratory building has been completed at the Tobacco Substation at a cost of about \$75,000.

Kansas College and Station.—C. K. Otis has resigned as instructor in agricultural engineering and assistant in agricultural engineering investigations.

Maine Station.—Dr. Raymond Pearl, head of the department of biology from 1907 to 1918 and since 1923 associated with the biological, biometrical, and statistical work of Johns Hopkins University, died November 17, 1940, aged 71 years. A native of New Hampshire, he was graduated from Dartmouth College in 1899 and received the Ph. D. degree from the University of Michigan. He served as instructor in the latter institution from 1912 to 1916 and in the University of Pennsylvania from 1906 to 1907. He was also associated with many other institutions as special lecturer or consultant. In recent years he had been especially interested in population studies, and he was the author of a long list of articles on this and other subjects, including *Modes of Research in Genetics, 1915*; *The Nation's Food, 1919*; *The Biology of Population Growth, 1925*; and *The Natural History of Population, 1938*.

Mississippi College and Station.—Frank J. Welch has been appointed professor and head of the department of agricultural economics.

Nebraska University and Station.—Recent appointments include Dr. M. W. Felton as instructor in plant pathology and assistant plant pathologist and Dr. Lester E. Hanson as instructor in animal husbandry.

Ohio Station.—H. R. Moore, associate in rural economics, resigned November 15, 1940. Dr. Byron T. Shaw and W. A. Junnila have been added to the staff as assistants in agronomy and agricultural engineering, respectively.

MARCH 1941

No. 3

AGRICULTURE AT THE PHILADELPHIA MEETINGS OF THE A. A. A. S.

The meetings held in Philadelphia from December 27, 1940, to January 2, 1941, under the auspices of the American Association for the Advancement of Science were inevitably of much interest to agricultural research. Approximately 225 sessions were held by this organization and its associated societies, and the total number of papers and addresses presented was 2,164. Perhaps half of these were of rather direct significance to agriculture.

The American Association is now in its ninety-third year, but its origin and early development were linked almost exclusively with the general sciences. Not until 1915 was specific recognition accorded by the organization of a section on agriculture. At that time this event was discussed in these columns as follows: "Time was, and not so long ago, when agriculture as a subject had no place in an association of sciences and would not have received an invitation. The man who should attempt to present a strictly agricultural topic before such an association would have been out of place, because there was so little basis for a thorough scientific treatment, and because agriculture as a subject of general interest to science had not yet won its way. The change which has come is, therefore, a twofold one. It applies to the remarkable scientific advancement of the subject itself, which finds few parallels, as well as to a change of attitude on the part of men of science. Agriculture has earned a place among the sciences, and having earned it has been recognized and formally admitted into the fellowship of the sciences."

The quarter century which has gone by since these words were written has been notable for a striking expansion in agricultural research funds, facilities, and programs. The Purnell Act of 1925 and the Bankhead-Jones Act of 1935 have increased the annual Federal expenditures throughout the stations from \$1,440,000 to \$6,848,750. Meanwhile the income of the stations from non-Federal sources has risen from \$3,826,383 to \$14,367,999, so that their total revenues for the fiscal year ended June 30, 1940, were \$21,216,749 as compared with \$5,286,383 for 1915. Their personnel engaged in the work of administration and inquiry has increased from 1,857 to 4,593. During the same period there has been also much development in the research

work of the U. S. Department of Agriculture and to a lesser extent in that of other agricultural research agencies.

Under these circumstances it should not be surprising to find the stations and Department generously represented on the programs and in positions of influence. This was of course particularly true for those sections and organizations of direct relation to agriculture, such as the American Society for Horticultural Science, the American Phytopathological Society, and the American Association of Economic Entomologists. The broad extent of the relationships, however, is indicated by the inclusion in the program of the American Physical Society of a paper on Soil Studies with Radioactive Phosphorus—The Phosphate Fixation of Soils, from the Hawaii Experiment Station; in Section I, Psychology, of A Study of Experimentally Induced Shifts in Food Preferences, from the University of Connecticut; in Section N, Medical Sciences, of Petroleum Products for Mosquito Control, from the New Jersey Experiment Stations; in the Society of American Foresters on Seasonal Trends in the Moisture Content of Soils Beneath Forest and Grass Vegetative Covers, from Cornell University; in a symposium on anthropology and modern life of a discussion of Anthropology in Program Planning, by Dr. J. S. Provinse of the U. S. D. A. Bureau of Agricultural Economics; and in the American Association of Scientific Workers of a paper on The Scientist and Agricultural Policy in a Democratic State, by Dr. C. E. Kellogg of the Soil Survey.

In the field of botany, 111 research contributions were presented before the American Phytopathological Society. Of these, 63 came from 25 experiment stations and 21 from the U. S. Department of Agriculture. To the Botanical Society of America, the land-grant colleges and experiment stations in 21 States supplied 53 of the 150 papers and the Department 23. To the American Society of Plant Physiologists, 13 stations contributed 26 and the Department 1 of its 65 papers. The colleges and stations also contributed 4 of the 24 papers listed before the Mycological Society of America and 3 of the 17 before the Sullivant Moss Society. These figures are exclusive of duplication in joint sessions, and many of the Federal contributions were cooperative with the States.

Of 64 research papers listed before the Association of Economic Entomologists, 36 were identifiable with the colleges and stations and 11 with the Department. In addition there were a panel discussion of extension methods and a symposium on present-day entomological instruction, in which these agencies extensively participated. There were also 14 papers from the colleges and stations and 4 from the Department on the program of the American Society of Parasitology and 19 and 1, respectively, in the American Society of Zoologists.

Over 300 papers were prepared for the American Society of Horticultural Science. Of these 230 were from the colleges and stations, 66

from the Department, and 11 from other sources. Of 27 papers on the program of the Potato Association of America, 22 were from the colleges and stations and the remainder from the Department.

The single session of Section O, Agriculture, was held jointly with the Sections on Botanical Sciences and Chemistry. Taking the form of a symposium on the Liebig Centenary, it presented nine papers dealing with developments in the field of agricultural chemistry since the publication in 1840 of Liebig's Organic Chemistry in the Application to Agriculture and Physiology. These papers discussed in turn the influence of Liebig on the mineral nutrition of ordinary plants, by Dr. Burton E. Livingston of Johns Hopkins University; the humus theory and the role of humus in plant nutrition, by Dr. S. A. Waksman of Rutgers; the promotion of agricultural chemical research, by Dr. H. R. Kraybill of Purdue; leaf analysis as a means of diagnosing the nutrient status of crops, by Dr. W. Thomas of the Pennsylvania State College; the chemistry of soils, by Dr. R. Bradfield of Cornell; proteins, by Dr. H. B. Vickery of Connecticut [New Haven] Station; mineral fertilizers, by Dr. H. A. Curtis of the University of Missouri; and from the U. S. Department of Agriculture animal nutrition, by Dr. P. E. Howe, enzymes and fermentation, by Dr. A. K. Balls, and the law of the minimum, by Dr. C. A. Browne, chairman of this symposium.

Special mention should be made of the eighteenth annual award by the American Association of the \$1,000 prize for a notable contribution to science selected from the papers presented at the meetings. This award was bestowed upon Drs. D. R. Hoagland and D. I. Arnon of the California University and Station for their paper on The Availability of Nutrients With Special Reference to Physiological Aspects. The paper, a contribution from the division of plant nutrition and the department of horticulture, dealt with a study carried out under two Bankhead-Jones projects of the California Station.

One of the most significant features of the Philadelphia meetings, as of most similar gatherings in recent years, was the large number of joint sessions and conferences and symposia. Among these may be mentioned the joint symposia of the American Association of Economic Entomologists and the Entomological Society of America on breeding of cultivated plants resistant to insect attacks; that of the Genetics Society of America, the Botanical Society of America, and the American Association for Horticultural Science on theoretical and practical aspects of polyploidy in crop plants; that on potato ring rot held under the auspices of the Potato Society of America and the American Phytopathological Society; that of the Liebig Centenary, already referred to; that of the American Phytopathological Society and the American Association of Economic Entomologists on plant quarantines as barriers in interstate trade; and that of the American Society for Horticultural Science, the American Society of Plant Physiologists, and the

Botanical Society of America on present concepts of ion availability in plant nutrition.

These meetings, with many others, reflected the very real interest in cooperative effort which prevails today. There were many indications that the great body of research workers who take seriously their responsibility to agriculture and to the public which supports them is increasingly recognizing the necessity for group attack in working out practical solutions for the complex problems facing the farmer. Furthermore there seemed to be more enthusiasm for and greater satisfaction coming out of such teamwork. It would appear that research workers are learning rapidly how to work together.

Workers' conferences appear essential to the most successful progress of joint undertakings. They plainly promote mutual understanding, appreciation, and friendliness. This results in freer and franker discussion and in more critical and constructive analysis of methods and conclusions. Attention is kept focused on the major practical objectives. There is voluntary coordination of effort and a distinct attempt is made by the group to arrange for attack on all essential factors that may affect the success of recommended practices in the hands of the farmer. The effectiveness of carefully planned and conducted scientific work comes out in such conferences in contrast to the hazy results of poorly planned and conducted experiments. After such gatherings each man present undertakes to do a better job than before and his sense of responsibility is definitely increased. The result is more rapid progress and work of better scientific quality and greater practical value from the use of research funds.

The Philadelphia sessions were especially productive in the furtherance of these objectives.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations by the Idaho Station] (*Idaho Sta. Bul.* 236 (1940), pp. 55-57).—These are reported upon under the heading of utilization of agricultural byproducts, by M. Aslett, H. Beresford, L. M. Christensen, E. Graham, and G. Taylor, and were concerned mainly with various uses of products from cull potatoes.

A spectrographic study of the distribution of mineral elements in sugar cane, S. S. BALLARD (*Hawaii. Planters' Rec.* [*Hawaii. Sugar Planters' Sta.*], 44 (1940), No. 3, pp. 183-186).—Spectroscopic evidence shows the dry-leaf cane to contain the highest concentrations of several trace elements. The data suggest that the behavior of some major elements in migrating from dying leaves to the living portion of the plant is shared by iron, manganese, sodium, and strontium. Chemical data on the distribution of five major elements are also included to give a more complete picture.

A qualitative color test for the montmorillonite type of clay minerals, S. B. HENDRICKS and L. T. ALEXANDER. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 6, pp. 455-458, fig. 1).—The identification of montmorillonite is important in problems of soil genesis. Organic diamines that oxidize into highly colored forms in the presence of the clay mineral montmorillonite can be used as a qualitative color test. Organic matter interferes with the test, and soils to be tested should be treated with hydrogen peroxide. The treatment is not necessary on horizons that have small amounts of organic matter. Kaolinite clay minerals and other inorganic fractions did not react to the test.

Iron content of bread and bread ingredients, C. HOFFMAN, T. R. SCHWEITZER, and G. DALBY (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 8, pp. 454, 455, fig. 1).—In an attempt to find a simple and accurate method of ashing that would obviate any volatilization of iron salts, it was found that sodium hydroxide solution added to the sample before ashing prevented the loss of iron. By the method given, 1 gm. of sample (or more if iron content is low) in a high-quality silica ashing dish is thoroughly mixed with 1 N NaOH (electrolytic), using 5 cc. per gram of sample, dried in an oven at 100° C., and ashed in an electric muffle at low redness. The thiocyanate colorimetric method is used for final determination of the iron, the iron standards being prepared from iron wire of highest purity. Data reported for control and recovery experiments indicate that this "alkaline ashing procedure insures complete recovery of added iron, whereas dry ashing without added caustic gives erratic results." Data on the iron content of bread and bread ingredients (flours, wheat germ, bran, oatmeal, cornmeal, yeast, molasses, commercial egg yolk, raisins, and honey) are reported and compared in some cases with values reported in the literature.

Riboflavin in liver extract, G. E. SHAW (*Quart. Jour. Pharm. and Pharmacol.*, 12 (1939), No. 3, pp. 541-549).—The assay method presented, with notes on the various steps in the procedure, involves preliminary chloroform extraction of an acetone solution of the diluted liver extract to remove interfering fluorescing ma-

terials; this extraction is facilitated by preliminary acidification of the solution. After separation of the chloroform and the aqueous-acetone phases, the acetone is removed from the latter phase by vacuum evaporation at a temperature of 30°–40° C., the remaining aqueous solution is made alkaline to phenolphthalein with 1 N NaOH, and then exposed in a shallow dish to unfiltered ultraviolet irradiation for a suitable time. The irradiated solution, made acid with acetic acid, is extracted with chloroform, and the fluorescence of a 10-cc. aliquot of this extract is compared with that of 10 standard dilutions of riboflavin likewise irradiated in alkaline solution and extracted with chloroform. The procedure described estimates the total riboflavin content. In a separate study the instability of riboflavin to nitric acid was shown.

Synthesis of vitamin K₁, A. A. KLOSE and H. J. ALMQUIST. (Univ. Calif.). (*Jour. Biol. Chem.* 132 (1940), No. 1, pp. 469, 470).—The method of synthesis of 2-methyl-3-phytyl-1,4-naphthoquinone (vitamin K₁) previously announced (E. S. R., 83, p. 585) is presented here in detail. This synthetic preparation, as well as one prepared by another method by Doisy and a natural preparation by Doisy all gave similar assay values, varying from 56,000 to 61,500 cc. of the reference standard per gram by the chick assay method of Almquist and Klose (E. S. R., 82, p. 88). The synthetic preparations also showed about the same intensity of color reaction (E. S. R., 83, p. 14) as the natural vitamin. It is considered probable, however, that the synthetic vitamins contain a small amount of cyclized vitamin K₁.

A simple specific precipitation test for cow's milk, A. GNOSSELIUS (*Arch. Disease Childhood*, 15 (1940), No. 83, pp. 171–176, figs. 2).—The precipitin serum used in this test is prepared by intravenously injecting 5 cc. of cow's milk into rabbits five times on alternate days and then, 4 days after the last injection, completely bleeding the rabbits. The test is conducted by centrifuging the milk to be tested and then transferring 2 or 3 loopfuls of the undiluted fat-free milk to a slide, adding 1 or 2 drops of the test serum, and mixing. In a positive test precipitates are quickly formed, while in a negative test the fluid remains homogeneously turbid and no flocculation occurs. The reaction has proved a rapid method for detecting admixtures of cow's milk with human milk.

Detecting cow-goat milk mixtures, J. C. MARQUARDT. (N. Y. State Expt. Sta.). (*Jour. Milk Technol.*, 3 (1940), No. 3, p. 144).—The simple test described is based on the fact that goat's milk will give a casein precipitate with ammonium hydroxide at certain temperatures, while cow's milk will not precipitate with like treatment. The addition of as little as 1 percent of goat's milk to cow's milk can be detected by the test.

A rapid colorimetric method for the determination of lactic acid in milk, B. HEINEMANN (*Jour. Dairy Sci.*, 23 (1940), No. 10, pp. 969–972).—Steps involved in the described method are precipitation of fat, lactose, and protein with copper sulfate and calcium hydroxide, filtering, adding concentrated sulfuric acid to the filtrate, heating, cooling, and adding veratrole. A red color develops on standing, which is in proportion to the amount of lactic acid present.

The determination of pH in milk and whey by means of colour indicator paper, L. SEEKLES (*Jour. Dairy Res.* [London], 11 (1940), No. 1, pp. 79–83).—Data are presented to indicate that lyphan paper M25 can be used for pH measurements in milk and whey within a pH range of 5.4 to 6.6 with only a slight error. In very acid milk paper of the L series was successfully used. Lyphan paper could not be used with alkaline milk or whey.

The measurement and significance of pH values in cheesemaking, J. G. DAVIS and C. C. THIEL (*Jour. Dairy Res.* [London], 11 (1940), No. 1, pp. 71–78).—The application of the colorimetric dilution method for the determination of pH values in cheese making is described.

A note on a simple and accurate viscosimetric form of rennet test, C. W. KING and E. M. MELVILLE (*Jour. Dairy Res. [London], 11 (1940), No. 2, pp. 184-186, figs. 3*).—The apparatus is described and illustrated.

A new method for the detection of neutralized cream, including a comparison with other methods, D. J. HANKINSON and E. O. ANDERSON ([*Connecticut*] *Storrs Sta. Bul. 234 (1939), pp. 73, figs. 25*).—This method for detecting neutralizers in cream, based chiefly on pH and buffer measurements, depends on the use of a heavy metallic ion contained in uranyl nitrate for the preparation of a protein and fat-free serum. The filtrate thus obtained is subjected to determinations of pH, NaOH titer, and HCl titer. Dividing the HCl titer by the NaOH titer, the buffer ratio is obtained. The final application of the test depends on the fact that the relationship of pH to buffer ratio is increased by neutralization and decreased by souring. Correction tables and formulas to be used in determining the final readings are presented. This new method detected cream which had been neutralized as little as 0.025 percent regardless of the percentage of serum, composition of the serum, or acidity of the cream before neutralization. The results of a detailed comparison of the new method with other methods of detecting neutralized cream are also included.

Tests show juice yields that may be obtained from Colorado sour cherries, W. E. PYKE, G. JOHNSON, and L. R. BRYANT (*Colo. Farm Bul. [Colorado Sta.], 2 (1940), No. 4, pp. 13-15*).—Yields of juice from Montmorency and English Morello cherries grown under several combinations of culture are shown. For the Montmorency variety the data indicate results from plats irrigated and mulched, irrigated but not mulched, mulched but not irrigated, and neither irrigated nor mulched, and for English Morello cherries results from an irrigated but not mulched plat. Weight of the fruit, of the pulp, of the pressed juice, and of the filtered juice is given, together with percentages of pressed and of filtered juice on the basis of the pulp and the refractive index of the filtered juice as determined at 20° C.

Commercial production of table wines, M. A. AMERINE and M. A. JOSLYN (*California Sta. Bul. 639 (1940), pp. 143, figs. 21*).—This bulletin discusses in detail methods for the production of wines of from 11 to 14 percent alcohol content, both of the "vin ordinaire" and of the choice or fancy quality, red-wines and white wines, and both sweet and dry types. Statistics concerning the production and consumption of wines and their nature and composition are first taken up, followed by sections on the various phases of production from choice of suitable grapes to the stabilization of the wine, its preparation for the market, and the disposal of the byproducts.

New uses of cotton pulp, F. C. VILBRANDT. (Va. A. and M. Col.). (*Chron. Bot., 6 (1940), No. 5, pp. 97-100*).—A brief record of volume and nature of cotton consumption by pulp industries, a summary of researches on chemical pulp, and a bibliography relating to cotton processing.

AGRICULTURAL METEOROLOGY

The foundation of American meteorology by the United States Army Medical Department, E. E. HUME (*Mil. Surg., 87 (1940), No. 2, pp. 89-118, figs. 14*).—This is a historical account on the origin and development of meteorological records and studies in the United States, beginning with the first official meteorological records in America made on the order of James Tilton, Surgeon General of the Army, who on April 2, 1814, directed hospital surgeons to record the weather.

A method of comparing climatic conditions in different localities, C. A. SHULL. (Okla. A. and M. Col. et al.). (*Okla. Acad. Sci. Proc., 19 (1939), pp.*

111, 112).—The method consists in a mathematical computation of the equilibrium forces which would exist in dry organic matter when it had reached dynamic water equilibrium with the environment. The only instrument needed is a sling psychrometer, and the necessary data are the dry bulb temperature and the relative humidity of the air. The equation used for the calculation is given.

The climate of the South, J. B. KINCER (*Mfrs. Rec.*, 109 (1940), No. 10, pp. 63–65).—A general discussion, including temperature, frost and the growing season, precipitation, snowfall, and brief miscellaneous comments relative to the southern United States.

A micro-climate recorder, A. KROGH (*Ecology*, 21 (1940), No. 2, pp. 275–278, figs. 5).—In the apparatus described and illustrated the motor is the clockwork of a wrist watch, mounted in a special box and wound with a key. The hour-hand axle projects into a separate compartment where it carries the disk on which the recording instruments are mounted. The temperature recorder is a bimetallic spiral and the moisture recorder a human hair. The levers are provided with very fine vertical writing points tracing lines on a smoked glass plate.

A discussion of the application of a climatological diagram, the hythergraph, to the distribution of natural vegetation types, A. D. SMITH. (Utah State Agr. Col.). (*Ecology*, 21 (1940), No. 2, pp. 184–191, figs. 11).—Weather data were collected for eight vegetation types, viz, southern desert shrub, sagebrush, boreal forest, deciduous forest, short and tall grass areas of North America, Russian steppe, and Argentina pampas. The resulting figures indicated a definite pattern for each vegetation type studied. This was expressed in the shape of the figure or the clockwise or counterclockwise direction exhibited by following the successive months of the year. Using this normal hythergraph pattern as an index the data showed that the Illinois prairie area is in the deciduous forest climax rather than true prairie. Likewise, the Albuquerque, N. Mex., region would seem to be properly regarded as semidesert grassland rather than short grass—a classification made by many phytogeographers. Were climatic data to be secured from stations located with a view to interpreting as nearly as possible the conditions to which vegetation is subject, it is believed that the diagrams shown would delimit broad natural vegetation units. There are 21 references.

Tree-rings as a record of precipitation in western Nebraska, H. E. WEAKLY. (Nebr. Expt. Sta. coop. U. S. D. A.). (*Tree-Ring Bul.*, 6 (1940), No. 3, pp. 18, 19).—A preliminary report.

Climatic chronology in some coast redwoods, E. SCHULMAN (*Tree-Ring Bul.*, 6 (1940), No. 3, pp. 22, 23).

Problems in dating rings of California coast redwood, E. FRITZ. (Univ. Calif.). (*Tree-Ring Bul.*, 6 (1940), No. 3, pp. 19–21, figs. 2).—A note describing several anomalies in growth rings of California redwood (*Sequoia sempervirens*) which must be considered by the tree analyst in dating past climatic events.

Compression wood and the recent chronology in Mesa Verde firs, A. E. DOUGLASS (*Tree-Ring Bul.*, 6 (1940), No. 3, pp. 23, 24, fig. 1).—Photographs showing features important in correct interpretations of ring series in Douglas fir are presented, with notes.

Tree growth beside a rain gauge and thermometer, C. J. LYON (*Ecology*, 21 (1940), No. 4, pp. 425–437, figs. 3).—Using mature trees of six species in a New Hampshire valley forest and plotting mean ring widths against calendar years, a tested trend line for each permitted calculation of yearly deviations for periods of about 70 yr. Correlation coefficients proved significant among most

of the evergreens and between oak and larch. For the full growth records, white pine, Scotch pine, and red oak gave significant, positive correlation coefficients with the rainfall of certain periods of the year, but Austrian pine, Norway spruce, and European larch showed no consistent agreement with precipitation records. The daily mean temperatures by months were compared with the annual growth rates in the same way, with little agreement between growth increments and temperatures of the growing season, but all the conifers gave significant positive correlations between growth of the year and the temperatures of March and April before growth had started. The temperature effect is interpreted as indirect, controlling growth in later months by determining the amount of water received by the soil from melting snow and from the March and April precipitation. A delayed effect of April air temperatures on soil temperatures of May is also possible. In general, the results of this analysis emphasize the importance of water supply as controlling growth rates in northern trees. Specific conclusions were reached for the water supply relations of each species used, but white pine was outstanding for its sensitivity to the water available to the roots.

Atmospheric ammonia as the primary source of nitrogen to plants, G. INGHAM (*So. African Jour. Sci.*, 36 (1939), pp. 158-163).—The author claims to have shown that current theories regarding the restoration of nitrogen to the soil by nitrogen-fixing bacteria are entirely inadequate. The theory here introduced is a modification of Liebig's original theory that ammonia is derived from the air, and asserts that not only is ammonia brought down by the rain but that it is also directly absorbed from the air by the organic and inorganic colloids in the surface soil. This theory is believed to supply a reasonable explanation of the fact that a soil may lose annually 100 lb. of N per acre in drainage and by crop removal without suffering a corresponding loss of organic matter. It is also believed to show why fallowing has substantially the same effect on crop production as an application of a nitrogenous fertilizer.

Influence of forest cover on wind velocity, W. L. FONS. (U. S. D. A. and Univ. Calif.). (*Jour. Forestry*, 38 (1940), No. 6, pp. 481-486, figs. 5).—A study in three common types of cover, grassland, brush, and even-aged ponderosa pine, of variation in wind velocity as influenced by height above ground and by vegetation showed the shapes of wind-velocity-distribution curves to be distinctly different in each type. Wind velocities at any two heights bore a linear relation to each other. The linear slope and intercept are dependent on temperature difference between the two levels and on the height of the lower level above the ground surface. Wind velocity decreased at the top of the crowns and remained nearly constant in the canopy zone.

Origin and destructive power of hurricanes, J. P. FINLEY (*New York: Weekly Underwriter*, 1939, pp. [11, figs.] 8).—This is a general discussion, profusely illustrated by tables and charts, including suggestions to private and commercial interests as to how losses may be greatly lessened by more alert and intelligent use of available information.

The effects of the 1938 hurricane on the apple industry of Connecticut, H. A. ROLLINS. (Conn. State Col.). (*Conn. Pomol. Soc. Proc.*, 48 (1938), pp. 55-63, figs. 7).—A general survey of the situation.

Aftereffects of the New England hurricane on fruit trees, H. A. ROLLINS. (Univ. Conn.). (*Amer. Fruit Grower*, 60 (1940), No. 10, pp. 11, 18, 19, figs. 4).

Studies of frost penetration, H. U. FULLER (*Jour. New England Water Works Assoc.*, 54 (1940), No. 3, pp. 275-281, figs. 6).—Records are presented of frost penetration in gravel v. clay, the relation between air temperatures and frost,

various curves setting forth different phases of the study, and a frost chart for the period December to May as worked out for the Portland, Maine, area.

Facts and fancies about Florida freezes, E. S. ELLISON (*Citrus Indus.*, 21 (1940), No. 7, pp. 5, 12, 13).—A semipopular analysis of the Florida freeze of 1940, with comparisons.

SOILS—FERTILIZERS

[**Soil investigations by the Idaho Station**]. (Partly coop. U. S. D. A.). (*Idaho Sta. Bul.* 236 (1940), pp. 23, 24, 38, 39, 40, 41).—The influence of barnyard manure and shallow tillage on soil and water losses and the influence of the lime content of the soil on chlorosis were studied by G. O. Baker. Coniferous timber soil was investigated by W. V. Halversen, J. M. Hale, and W. G. Hoge. Studies on the clay fraction are reported upon by L. E. Ensminger, and the influence of irrigation upon movement of lime and salts by L. M. Christensen, Baker, and M. R. Kulp, who have also completed alkali land reclamation investigations.

An improvement in lysimeter design, E. F. WALLIHAN. (Cornell Univ.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 5, pp. 395–404, figs. 3).—Pyrex glass cylinders 12 in. in diameter and 30 in. deep with round bottoms having a 1-in. hole for installation of a tensiometer for drainage were used to obtain conditions more nearly like those in the soil in situ than are obtained in the common lysimeter, which does not have drainage conditions similar to those in the lower layers of the soil because the soil is separated from the external tension forces. With the lysimeter described, it is possible to apply tensions similar to those found under ordinary cropping or fallow conditions.

Soil survey of Iowa: Franklin County, R. W. SIMONSON ET AL. (Coop. U. S. D. A.). (*Iowa Sta. Soil Survey Rpt.* 79 (1940), pp. 84, figs. 36, map 1).—In addition to the survey data already recorded in the Federal soil survey report (E. S. R., 79, p. 301), there are included results of experiments on the management of the soils of this county.

Natural land divisions of Santa Cruz County, California: Their utilization and adaptation, R. E. STORIE (*California Sta. Bul.* 638 (1940), pp. 56, pl. 1, figs. 29).—The importance of an accurate inventory of soil productivity and present land utilization according to natural land divisions in the development of a program of best land use for Santa Cruz County is emphasized. This county has a total area of 435 sq. miles and lies about 60 miles south of San Francisco. About 11 percent of the county is valley land. The Santa Cruz Mountains, extending to an elevation of about 3,000 ft., comprise almost 74 percent of the county.

The system employed in classifying land into natural groups and divisions is essentially as follows: The different physiographic divisions are indicated by letters, the letters having the following meanings: A, the alluvial fan and flood plains; B, the flatter basinlike land; C, the low terrace land; D, the high terrace land; and E, the upland or mountainous land.

For determining land utilization of the various soil groups, the natural land division map was superimposed on a land-use map prepared from an earlier survey. The author's index for rating the agricultural value of soils (E. S. R., 70, p. 157) was applied to the soils in the county. Productivity ratings of the various soils were established from the yield records obtained from various agricultural agencies and from farmers. Information on the basic factors presented above was considered in the preparation of the data on each soil type according to the natural land divisions of the county. This information is presented in tabular form. In addition, the data are summarized

and are presented in a colored map of the county, indicating the natural land divisions, soil productivity, and general characteristics of the soil in each area.

Solution concentration as a possible factor influencing soil aggregation, H. E. MYERS and H. E. JONES. (Kans. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 9, pp. 664-668).—Changes in salt concentration of the soil solution have been previously suggested by Conrad (E. S. R., 71, p. 14) as having an effect upon soil aggregation. Using calcium nitrate or sucrose at rates of 1,000 or 2,000 lb. per 2,000,000 lb. did not bring about a significant increase in the degree of aggregation of the pulverized clay-quartz or H-colloid-quartz system. Further, the stability of naturally occurring soil aggregates was not increased by the above treatment. Slight increases in the degree of aggregation of natural soil aggregates are explained by probable increase in microbial activity.

Sorption by clays, T. N. JEWETT (*Soil Sci.*, 50 (1940), No. 3, pp. 163-173, fig. 1).—The mechanism of water-vapor uptake by soils and clays in relation to the physical and chemical composition of the clay is considered. The author points out that the kaolinite and montmorillonite clay types react differently toward water because of a difference in specific attraction for water. When sorption by soils is studied, it is suggested than an organic liquid (toluene) as well as water be used. Soil colloids of low silica contents were found to sorb similar amounts of water and toluene, while those with high silica: sesquioxide ratio sorb more water than toluene.

Some effects on cane quality produced by different soils, R. J. BORDEN and L. R. SMITH (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 44 (1940), No. 3, pp. 187-200).—Cane was grown in large concrete tubs of the two markedly different soils Makiki and Manoa. In the first two crops the Manoa soil gave larger yields of cane, but the Makiki soil gave a better cane quality, its juice yield in percentage of the cane being higher. In the third crop, however, the Manoa soil gave both higher cane yields and higher juice yields, basis of the cane. The initial pH values were 7.2 in the Makiki and 5.4 in the Manoa soil. After the third crop these values had changed to 5.6 and 4.8, respectively. The authors do not definitely attribute the change in their results to the change in pH value but consider that there may have been some connection.

Numerous analytical data are given.

Water and soil conservation experiments at Spur, Texas, R. E. DICKSON, B. C. LANGLEY, and C. E. FISHER. (Coop. U. S. D. A.). (*Texas Sta. Bul.* 587 (1940), pp. 67, figs. 36).—This bulletin reports upon work on Miles, Abilene, and associated soils, subject to an average annual rainfall of between 20 and 21 in. (extreme variation, from 11.09 to 38.08 in.), of which annual precipitation about 80 percent falls during the growing season.

Level terraces having ends open were found to be much more efficient in conserving water than terraces with 3-in. slope per 100 ft. along the terrace, and to cause an appreciable increase in crop yields. Level terraces with ends closed so as to hold all the water that falls gave an average increase in crop returns for 12 yr. of \$6.21 per acre per year over those obtained by the old conventional practice of running the rows with the slope. By diverting the run-off water from a 1,200-acre watershed onto a 120-acre sirup pan terrace system the water for use by crops on the system has been increased approximately 16 percent, and crop yields have shown a marked increase.

Seventy percent of the rainfall during 1937, 1938, and 1939 was evaporated from fallowed plats of Abilene clay loam soil. Tillage and cropping practices that may increase the rate and amount of penetration of water are being studied with a view to increasing the amount of available water by decreasing

evaporational opportunities. Solid contour listing of native grass pastures resulted in a deeper penetration of soil moisture, an increase in available moisture, and a threefold increase in forage production. A close relationship exists between the available water in the soil at planting time and the yield of lint cotton. Seasonal rainfall, although a highly significant factor in determining crop yields, apparently is of less importance than moisture stored in the soil prior to planting time.

40-Day loss: 14-tons soil per acre, T. N. JONES. (Coop. U. S. D. A.). (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 9, p. 2, fig. 1).—The author presents a brief report of the effects of rainfalls of from 0.11 to 8.58 in. on erosion-measurement plats ranging in slope from 2.5 to 12.5 percent, the soil being Houston clay, the crop cotton in contour rows. The proportion of the rainfall lost as run-off ranged for the 40-day period from 0 to 81 percent. The total soil loss from the 12.5-percent slope was nearly 14.82 tons, from the 7.5-percent slope 14.14 tons, and from the 10-percent slope nearly 11.78 tons. It is pointed out that the rains of the largest total quantity do not always cause the greatest soil and water losses, the determining factors being apparently the rainfall intensity and the moisture content of the soil at the beginning of the rain.

Farms the rains can't take, K. DAVIS. (Coop. Wis. Expt. Sta.). (*U. S. Dept. Agr., Misc. Pub. 394* (1940), pp. II+14, figs. 8).—Some results of erosion measurements and control experiments carried out at the Upper Mississippi Valley Erosion Substation, near La Crosse, Wis., are here recorded. Recommendations for control and prevention measures of the usual type are based upon these results.

As indicating the seriousness of the problem in the upper Mississippi Valley region, it is noted that farmers of Minnesota, Wisconsin, Iowa, and Illinois farm more than one-half of the grade-1 farm land in the United States and a large share of the grade-2 land. The soil-erosion surveys show nearly one-half of the entire area of these four States to be seriously eroded, more than 13 million acres of formerly productive farm land having lost most of their topsoil and become severely gullied.

Soil defense in the Pacific Southwest, G. K. RULE and R. W. NETERSTROM (*U. S. Dept. Agr., Farmers' Bul. 1848* (1940), pp. [4]+55, pl. 1, figs. 36).—This publication deals with erosion and its control in California and Nevada, being mainly concerned with measures of defense that are now being employed on farms and range land within project areas of the Soil Conservation Service and in areas where members of C. C. C. camps have been assigned to erosion-control activities. The last section deals with a new procedure whereby farmers may cooperate legally through soil conservation districts in a more appropriate use of the land.

Soil treatment suggestions are result of study in subirrigated San Luis Valley, J. W. TOBISKA (*Colo. Farm Bul. [Colorado Sta.]*, 2 (1940), No. 4, pp. 4-6).—Conditions in the area named approach those of solution culture in an inert supporting medium, the soils being coarsely sandy and adapted to the practice of supplying irrigation water from below the surface. High yields have been obtained, but salinity and alkalinity have appeared at some points. Soil solution from the bad spots should be analyzed before treatment is attempted. Fertilizers free from chlorides and from sodium salts should be used where chlorine and sodium compounds are already present in high concentrations. Alkalinity is to be dealt with by means of organic fertilizers, sulfur, or gypsum. Ammoniated phosphates increased the yield and quality of potatoes where nitrogen and phosphate deficiencies had been found. Ammonium sulfate is preferred to nitrates. Calcium and magnesium deficiencies should be

met by applying the sulfates of these elements rather than limestone or dolomite, unless the alkalinity is less than that indicated by pH 7.5. Conditions in the utilization of these sandy soils by irrigation from below approach those of water culture sufficiently closely that too high a concentration of the soil solution is to be avoided when possible. In any event, the solution should contain the mineral nutrients in proper ratio or balance.

The nitrogen, organic carbon, and pH of some southeastern Coastal Plain soils as influenced by green-manure crops, R. D. LEWIS and J. H. HUNTER. (U. S. D. A. and Ga. Coastal Plain Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 8, pp. 586-601, figs. 4).—Greenville, Norfolk, and Tifton sandy loam soils, on which varying amounts of vegetation from different crops were grown and returned to the soil, were studied to determine the effect of various systems on the carbon and nitrogen relationships in the soil. The comparisons consisted of winter green manure, winter and summer green manure, summer green manure, winter cereal and summer legume, winter cereal and summer legume (without fertilizer), permanent kudzu, Bermuda grass sod, and cash crop rotation with summer legumes. The organic matter was either increased or maintained under all the systems, while the total nitrogen was increased in all cases. It is indicated that it is not necessary to build up the soil nitrogen and carbon contents to high levels to insure the production of good crops, but that it is important that the green-manuring system followed maintain the soil organic matter.

The authors conclude that "more than one green-manure crop in succession results in higher nitrogen and carbon than one crop per year, but the added gain is not sufficient to justify the loss incurred by tying up the land for the time required. The most economical system for using green manure seems to be one in which the most important cash crop follows the green-manure crop."

The vertical distribution of total and dilute acid-soluble phosphorus in twelve Iowa soil profiles, R. W. PEARSON, R. SPRY, and W. H. PIERRE. (Iowa Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 9, pp. 683-696, figs. 2).—Samples from 12 soil profiles representing 11 soil series of the Prairie, Planosol, and Gray-Brown Podzolic groups which occur in Iowa were analyzed for total phosphorus, dilute acid-soluble phosphorus, and pH. Total phosphorus was found to decrease with depth to a minimum in the lower A or upper B horizons, and to increase below the zone of the lower A and continue to increase until the C horizon, which was found to have the greatest amount in most cases. The dilute acid-soluble phosphorus was found to follow a trend similar to that for total phosphorus in 9 out of the 12 profiles studied. Increases in availability with depth were not found to be correlated with differences in pH.

Significance of adsorption, or surface fixation, of phosphorus by some soils of the Prairie group, W. H. METZGER. (Kans. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 7, pp. 513-526).—Soil samples from various horizons of virgin soil profiles and from cultivated fields were studied for phosphorus fixation. Treatment with oxalate indicated more oxalate retained than phosphorus released. The free oxides of aluminum and iron were found to have an important effect on phosphorus fixation. This effect was true even in the pH range of from 5.0 to 6.0. Extraction of the soil samples with buffered H₂SO₄ did not materially alter the base-exchange capacity of the samples but reduced the phosphorus fixing capacity from 12 to 78 percent.

Calcium-potassium-phosphorus relation as a possible factor in ecological array of plants, W. A. ALBRECHT. (Mo. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 6, pp. 411-418, fig. 1).—The relation of climatic factors to the development of the soil and the resultant effect on the supply of calcium,

potassium, and phosphorus available for plant growth is considered in relation to the probable effect on the ecological array of plant species. Since phosphorus is generally the limiting factor in most soils, consideration is given to the calcium-potassium relationship in the ecological array. The effect of precipitation on the soil development, as measured by decrease in exchange capacity, is considered. A calcium : potassium ratio is suggested for a better understanding of plants in relation to soil development and fertility.

Oxidation-reduction potential of arsenate-arsenite systems in sand and soil mediums, C. M. KEATON and L. T. KARDOS. (Wash. Expt. Sta.). (*Soil Sci.*, 50 (1940), No. 3, pp. 189-207, fig. 1).—Treatments of orchard soils to overcome the toxicity of arsenic residues indicated a relationship between the oxidation-reduction potentials of the soils treated and the condition of plant growth. Investigations are reported on the effect of iron, aluminum, and colloidal clay content and the oxidation-reduction potentials of arsenate-arsenite systems under different soil conditions. The addition of ferric oxide caused an increase in the redox potential. Alumina produced no effect on oxidation or reduction. High soil colloidal content was accompanied by low potential and small percentage oxidation. It is suggested that arsenic-poisoned soils be treated with some mildly oxidizing agent capable of arsenic fixation. Iron oxide is suggested because of its beneficial effect.

Qualitative studies of soil micro-organisms, III, IV (*Canad. Jour. Res.*, 18 (1940), Nos. 2, Sect. C, pp. 42-53; 4, Sect. C, pp. 129-135, fig. 1).—Further work in this series (E. S. R., 82, p. 448) is reported.

III. Influence of plant growth on the character of the bacterial flora, A. G. Lochhead.—Qualitative investigations of the bacterial flora of the rhizosphere of red clover, mangels, oats, tobacco, corn, and flax were made to determine the effect of the various crops on the type of organisms present. Comparisons were made with control soils. Bacteria in the rhizosphere were found to show greater physiological activity than the bacteria of the soil away from the plant. The "rhizosphere effect" in relation to resistance and susceptibility of plants to soil-borne diseases is indicated.

IV. The rhizosphere in relation to the nutritive requirements of soil bacteria, P. M. West and A. G. Lochhead.—Bacteria were isolated from the rhizospheres of two varieties of flax and two varieties of tobacco. One of the flax varieties was resistant and the other susceptible to wilt, while one of the varieties of tobacco was resistant and the other susceptible to black root rot. One hundred representative bacteria were isolated from each plant. The bacteria in the rhizosphere were found to have more complex nutritive requirements than those in the control soils. Bacterial types that are dependent for their growth upon a supply of thiamin, biotin, and amino nitrogen were found to develop in the root zones. The root effect on bacterial development was also noted with young seedlings. Because of this more favorable development, it is suggested that the roots may excrete certain amounts of these stimulative substances. The rhizosphere effect was more marked with the susceptible varieties of flax and tobacco than with the resistant varieties. The presence of increasing amounts of organic matter in the soil was found to depress the rhizosphere effect.

Fertilizing value of spent phosphate catalyst, G. S. FRAPS. (Tex. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 7, pp. 542-544).—The fertilizer value of spent phosphate catalyst, used in the manufacture of gasoline from petroleum, was determined by pot experiments and chemical analyses. The phosphoric acid of the catalyst was found to have an availability to plants similar to that of superphosphate.

Neutral vs. acid fertilizers, C. DORMAN (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 9, p. 8).—Adding about 500 lb. of dolomitic limestone to each ton

of an otherwise acid-forming 4-8-4 fertilizer cost about 30 ct. per acre, practically eliminated soil acidification, and increased the seed-cotton yield by about 90 lb.

Nature and liming value of quenched calcium silicate slag, W. H. MACINTIRE, L. J. HARDIN, S. H. WINTERBERG, and J. W. HAMMOND. (Tenn. Expt. Sta. et al.). (*Soil Sci.*, 50 (1940), No. 3, pp. 219-237, pls. 2, figs. 3).—Laboratory and pot culture investigations on the liming value of a relatively new type of quenched slag, originating as a byproduct from rock phosphate reduction furnaces, are reported. The byproduct slag is largely calcium silicate having a low phosphate content and is not to be confused with "basic slag." With tests involving six soils and using leguminous and nonleguminous crops, 100-mesh slag proved superior to limestone at ordinary rates. Response was especially good in phosphorus-deficient soils, indicating that at rates of application for liming purposes the slag also supplied P_2O_5 for plant growth.

No harmful effects resulted when applications of 5, 10, 20, and 40 tons per acre of 20- to 60-mesh and 100-mesh slag were made. It is concluded by the authors that slag between 4 and 35 mesh can be used safely and advantageously at rates up to 10-ton $CaCO_3$ equivalent per 2,000,000 lb. of soil.

Manganese, copper, and magnesium contents of some commercial fertilizers, C. E. MILLAR and W. S. GILLAM. (Mich. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 9, pp. 722-725).—Recent advancements in plant nutrition have shown that small quantities of certain elements are necessary for normal plant growth. The most practical way of correcting these deficiencies is by applying small amounts of the desired element with the fertilizer. Since fertilizers may contain certain quantities of these elements, the authors attempted to determine whether these amounts would be adequate for normal plant growth by analyzing 11 commercial fertilizers of the 2-12-6 grade for copper, manganese, and magnesium. These elements were found to be present in most of the samples, but the amounts found were never large. Due to the fact that the usual rate of fertilizer application is quite small, the crop must depend very largely upon the soil for these elements.

Factors influencing availability of boron in soil and its distribution in plants, B. WOLF. (N. J. Expt. Stas.). (*Soil Sci.*, 50 (1940), No. 3, pp. 209-217, pl. 1, fig. 1).—Sassafras and Dunellen sandy loams were studied in the greenhouse to determine the response to boron, the effect of different treatments on boron availability, and the distribution of boron in plants. With the Sassafras sandy loam, boron-deficiency symptoms occurred at pH approaching 7 and became more severe with increasing pH. The percentage of boron in the plant tops decreased with increasing pH. Magnesium hydroxide caused greater reduction in availability of soil boron than did the hydroxides of calcium, sodium, or potassium. From 5 to 10 lb. of borax per acre was sufficient to eliminate boron deficiency from the Dunellen sandy loam, while application of 20 lb. were found to be toxic. Increased applications caused increased boron consumption.

The elimination of differences in investment in the evaluation of fertilizer analyses, W. B. ANDREWS. (Miss. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 7, pp. 495-502, fig. 1).—A method is presented whereby it is possible to eliminate differences in investment in the evaluation of fertilizer analyses so that it is possible to determine which fertilizer analysis will give the largest return per dollar invested. Factory-mixed and home-mixed fertilizers were compared by determining the increase in yield of seed cotton from an application of 600, 1,200, 1,800, and 2,400 lb. per acre of a 4-8-4 fertilizer. By plotting increases in yield per acre against rate and cost of fertilizer and constructing a line of best fit, it was possible to determine the relation of one factor to the other. For the expenditure of a definite

amount of money for 4-8-4 fertilizer, 26 percent more fertilizer was obtained when fertilizers were home mixed.

Commercial fertilizers, H. R. KRAYBILL ET AL. (*Indiana Sta. Cir.* 256 (1940), pp. 88, fig. 1).—In reporting the 1939 inspection analysis data, this circular also shows, together with other related information, the tonnage in Indiana of low- and high-grade fertilizers from 1915 to 1939, inclusive. Use of complete fertilizers containing 20 or more units of plant food per ton, first recorded for the year 1927, increased to more than four times as much in 1930, dropped sharply in 1931 and in 1932, and rose steadily from 1933 to 1939 when the figure was more than one-fourth greater than the previous (1930) maximum.

AGRICULTURAL BOTANY

A contribution toward a bibliography of Oregon botany, with notes on the botanical explorers of the State, K. W. HUGHES (*Thesis, Oreg. State Col., Corvallis, 1939*, pp. [3]+93).—This annotated bibliography is arranged under the botanical explorers of Oregon, ecology, food and drug plants, paleobotany, systematic botany, and a miscellaneous list.

Synthesis of thiamin by excised roots of maize, J. E. McCLARY. (Univ. Mo.). (*Natl. Acad. Sci. Proc.*, 26 (1940), No. 9, pp. 581-587).—Though efforts to improve an aqueous solution of mineral salts and glucose for growing excised corn roots by adding known growth factors or various extracts were unsuccessful, these roots were maintained in a medium consisting of mineral salts, 5 percent glucose, and 1.5 percent agar for 115 days through 18 transfers without appreciable decrease in their elongation. Thiamin was synthesized in significant amounts by excised roots growing in this solution. Evidence presented seems to indicate that the physical conditions of the media were probably the limiting factors for growth in an aqueous medium and under certain conditions in the agar medium.

Response of excised tomato roots to β (-4-methylthiazolyl-5)-alanine, W. J. ROBBINS (*Plant Physiol.*, 15 (1940), No. 3, pp. 547-552, fig. 1).—In the solution culture experiments reported the growth habit and general morphology of the roots in solutions containing the amino acid were much the same as those of roots under a thiamin thiazole regimen, although the amino acid was as satisfactory. *Phycomyces* and *Staphylococcus aureus* have been reported as unable to use the amino acid appreciably, but the author considers this difference in response of excised roots and micro-organisms to be apparent only, since he found the amino acid effective with *Phycomyces* if enough were supplied—the amounts being of the order of 1,000 times those of the vitamin thiazole required to produce the same effect. No difference for *Phycomyces* was found between the effects of the amino acid filtered sterile and that heated in the autoclave. It would seem that the amino acid is much more available to the tomato root than to *Phycomyces*, and a similar difference appears to exist in the relation of these organisms to thiazole. This difference in sensitivity may be associated with the slower growth and smaller total growth of tomato roots as compared with *Phycomyces*, or it may be due to some fundamental difference. A theoretical discussion of the possible bases for the results obtained is included.

Auxithals synthesized by some filamentous fungi, L. H. LEONIAN and V. G. LILLY. (W. Va. Expt. Sta.). (*Plant Physiol.*, 15 (1940), No. 3, pp. 515-525).—Of the six organisms tested for ability to synthesize biotin, thiamin, and the two moieties of thiamin, *Rhizopus suinus* and *Fusarium niveum* proved capable of synthesizing biotin and thiamin from pure dextrose, amino acids,

and inorganic salts. *Phytophthora erythroseptica* was unable to grow without an external supply of thiamin but synthesized biotin. *Phycomyces blakesleeanus*, when furnished pyrimidine and thiazole, linked them together to produce thiamin. *Pythiomorpha gonapodioides*, supplied with pyrimidine, elaborated its own thiazole and linked it with the pyrimidine to form thiamin. *Mucor ramannianus* synthesized thiamin when the medium contained thiazole, producing its own pyrimidine. The last three species synthesized biotin, as shown by the growth of biotin-requiring fungi in the presence of mycelial extracts or media in which these species had been grown. *M. ramannianus* produced less biotin and thiamin than the other five fungi, but when both thiazole and pyrimidine were added to its medium instead of thiazole alone, the resulting mycelium supported good growth in organisms requiring either thiamin or its moieties. Most of the thiamin is stored in the fungus mycelium, only traces of it passing into the medium. Appreciable amounts of pyrimidine and thiazole, however, diffuse out. The same applies to biotin, except that comparatively larger amounts find their way into the medium.

Effect of extracts of *Phycomyces* upon its development, W. J. ROBBINS (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 559-564, figs. 6).—Earlier studies (E. S. R., 83, p. 461) led to the assumption that one or more growth substances in addition to thiamin favor spore germination, growth, and reproduction in *P. blakesleeanus*. In this study, mycelial extracts affected the germination of the spores and at least the early growth of the mycelium in a medium of minerals, sugar, asparagine, and thiamin. Such extracts of various ages increased in effectiveness with the age of the mycelium and then decreased, exhibiting some correlation with the growth rate of the mycelium from which the extracts had been prepared. No uniform results were secured on the effect of the extracts on gametic reproduction. Their effect on spore germination and growth is explained by assuming that growth substances other than thiamin are concerned in the development of this fungus. The unidentified substance (or substances) is referred to as factor Z.

Effect of potato extracts on growth of *Phycomyces*, W. J. ROBBINS and K. C. HAMNER (*Bot. Gaz.*, 101 (1940), No. 4, pp. 912-927, figs. 3).—The evidence obtained confirmed previous reports that germination, early growth, and gametic reproduction in *Phycomyces* may be stimulated in cultures containing potato extract. Increasing amounts of the extract up to a certain limit may increase growth and reproduction, while amounts beyond it induce decrease in growth and zygote formation. Indications were that potato extract contains at least two factors influencing *Phycomyces* development—one factor (Z_1) adsorbable on charcoal and freed from it in the presence of ammoniacal acetone, and the other (Z_2) not adsorbable to any great extent on charcoal and remaining in the filtrate. Either factor produced some stimulative effect on development, but a combination of the two was far more effective than either alone. The Z_1 factor may be identical with biotin. No correlations of the Z_2 factor have yet been found. Comparisons are made with the effects of the antigrey factor obtained by Morgan and Simms from yeast noted on page 419.

Specificity of nicotinic acid as a growth factor for isolated pea roots, J. BONNER (*Plant Physiol.*, 15 (1940), No. 3, pp. 553-557, fig. 1).—The ability of 23 substances chemically related to nicotinic acid to replace it as a growth factor for isolated pea roots was determined. Among those tested, only substances yielding nicotinic acid by simple hydrolysis proved active.

Root stimulation in sugar cane (*Saccharum officinarum*) with special reference to the effects of ethyl alcohol, H. F. CLEMENTS and E. AKAMINE. (Hawaii Expt. Sta.). (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 482-487, figs. 4).—

Following pretreatment with a solution of ethyl alcohol a very marked increase of root production in sugarcane planting material was noted. At favorable temperatures the phosphate ion was as effective as alcohol in this respect, especially in sets naturally containing small amounts of phosphate. At marginal temperatures, however, phosphate proved ineffective. It is suggested that the alcoholic stimulation is due to its ready availability as a high-energy-containing food.

Plant growth in culture solution and availability of ions adsorbed on permutit and aniline black, F. S. SCHLENKER. (R. I. Expt. Sta.). (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 525-529, figs. 5).—The work here detailed was devised to test the availability of adsorbed ions to plants growing in fluid media, two compounds capable of adsorbing inorganic ions being used, viz, permutit, which adsorbs cations by base exchange, and Demineralite, which adsorbs anions as acids. The anion and cation complexes were mixed to simulate various solution formulas noted in solution culture literature and then suspended in water. From evidence derived from actual plant growth it was shown that these adsorbed ions became available under the test conditions and could be used to promote good plant growth. Comparisons of development in solution culture and in the adsorbed solutions tended to indicate a more satisfactory growth in the latter, but the data are considered too few for definite conclusions. "The proposed solution culture technic offers a degree of flexibility not found in the usual solution culture methods."

Transmission spectrograms of leaf extracts, F. F. FERGUSON, W. S. DELOACH, and L. W. WEBB, JR. (Va. A. and M. Col. et al.). (*Plant Physiol.*, 15 (1940), No. 3, pp. 559, 560, figs. 2).—The transmission spectrogram of a denatured alcoholic solution of leaf extracts is presented.

The mineral composition of the alcoholic extract of potato leaves and its relationship to crop yields, C. E. BEAUCHAMP (*Plant Physiol.*, 15 (1940), No. 3, pp. 485-502, figs. 3).—Increments of K in the fertilizer resulted in marked increases in yields, whereas those of N and P produced none. The field yields of potatoes correlated well with the total percentage of plant food nutrients found in the alcoholic extracts of the leaves. A low total percentage of nutrients in the dry matter of the alcohol leaf extract always resulted in low, and a high percentage in high, yields. Increase of K in the fertilizer resulted in an increase of its percentage in the alcohol leaf extract and, in turn, a higher yield. The lowest percentage of K in the leaf extract occurred in the control plats, followed by the minus-K plats. Yields exhibited the same sequence. Minus-K plats showed a higher K content in the leaf extract than did the controls, indicating that added N and P alone stimulated the plant to absorb more K from the soil. The percentage of P in the alcoholic leaf extract was not correlated with the amount applied in the fertilizer, but showed a marked parallelism with the amount of K present in the alcohol-soluble portion of the leaves. The percentage of P in the alcoholic leaf extract was always low when the K content in the leaf was also low, irrespective of the amount of P in the fertilizer. The percentage of N in the alcohol leaf extract presented no correlation with the K content of the fertilizer. The percentages of both Ca and Mg in the leaf extracts showed an inverse relation to that of K, displaying a tendency to increase as the latter decreased and vice versa. The percentage of total nutrients in the mineral portion of the leaf extract varied directly with the fertilizer treatment. In control and minus-K plats this value was lower than in plats receiving complete fertilizers. The potato yield was apparently correlated with the mineral composition of the dry alcoholic extract of the leaves. Both quantitative and qualitative relationships were shown, since the highest-yielding plats exhibited a high mineral content and practically a definite ratio among the three major fertilizing nutrients. The lower-yielding plats showed a lower mineral content, and the ratio in which the fertilizing elements

were present departed from that found in the highest-yielding plats. There are 25 references.

Some aspects of mineral nutrition in relation to Bison flax, E. A. HELGESON, T. H. HOPPER, and D. TAYLOR. (N. Dak. Expt. Sta.). (*Plant Physiol.*, 15 (1940), No. 3, pp. 503-514, figs. 3).—Using a pure line of Bison flax grown to maturity in selected Shive type 1, three-salt nutrient solutions under constant renewal technic, and recording the temperature, humidity, and light conditions, results indicated the following: Final growth in height of top was relatively constant over a wide range of nutrient salt proportions. Fairly large amounts of KH_2PO_4 resulted in relatively early maturity, the time being modified inversely by the N content of the solutions. Relatively large amounts of oven-dry material were obtained with high KH_2PO_4 solutions. The other constituent salts of the various solutions showed no uniform relation to the oven-dry weight produced. The greatest seed production usually occurred in solutions containing the higher portions of KH_2PO_4 , but other nutrient constituents showed no definite relation in this respect. The heaviest seeds were obtained from plants growing in nutrients high in KH_2PO_4 . There was no marked variation in amount of oil produced when the composition of the solution was varied over a rather wide range. Oils from seeds produced in cultures relatively high in KH_2PO_4 possessed higher iodine numbers than those from cultures low in this salt. The production of plants grown on constantly renewed nutrient solutions exceeded that of field-grown plants in height of tops, weight of seeds, average protein content of seeds, and iodine number of the oil. The average oil yields of the test plants about equaled those of field-grown plants.

Methods of sap expression from plant tissues with special reference to studies on salt accumulation by excised barley roots, T. C. BROYER and D. R. HOAGLAND. (Univ. Calif.). (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 501-511, figs. 5).—In studying salt accumulation by root cells, two general methods for recovery of tissue fluids from barley roots were compared, viz, hydraulic expression of prefrozen tissues and direct expression from fresh tissues, with subsequent re-expression of press cakes after freezing. Study of successive increments of expressed fluid from fresh root tissues indicated that an admixture of fluids from different regions of the tissue had occurred. Present methods are deemed inadequate to permit the separation of fluids derived from protoplasm and from vacuoles or other aqueous phases. The most satisfactory procedures for salt accumulation studies as applied to complex tissues are those giving the largest yields of expressible fluids. Studies on the accumulation of electrolytes by excised barley roots subjected to various procedures for expressing fluids led to conclusions consistent with those previously presented (E. S. R., 76, p. 457). No method of sap expression used gave any evidence that mineral solutes can be absorbed against a concentration gradient, except when conditions of aerobic metabolism prevail.

The use of indicator plants in locating seleniferous areas in western United States.—III, Further studies, O. A. BEATH, C. S. GILBERT, and H. F. EPPSON. (Univ. Wyo.). (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 564-573, figs. 8).—Continuing these investigations (E. S. R., 81, p. 634), the present study, including plants in localized areas of eight States, shows a definite trend toward segregation of the seleniferous Astragali into certain generic groups, whereas other prominent indicator plants, such as species of *Stanleya*, *Xylorrhiza*, and *Oonopsis*; exhibited no such alinement. The Se-bearing Astragali thus far studied fall into 6 of the 29 phylogenetic groups of the Jones classification, but this is not taken to mean that other groups may not later be found to contain as many or more species with this specialized development. A new field for study was opened up by the discovery that *Castilleja chromosa* from the Tertiary in

Fremont County, Wyo., gives a high Se value. Since it is parasitic on the roots of a wide variety of hosts, some of which are Se absorbers, further work is necessary to determine whether this and related species can accumulate Se from the soil directly, through the roots of other plants, or both.

Soil samples collected in Stoddard County, Mo., contained Se in significant amounts, but none of the lists of native plants seen contained any of the recognized indicator plants. Near Dryden, Tex., a soil sample from the Upper Cretaceous gave 3.5 p. p. m. of Se, but no indicator plants were observed on the outcrops. Either a new group of indicator plants may be present where these Se-bearing rocks are exposed, or factors not yet known may adversely affect Se absorption. Earlier findings on the seleniferous character of the Dakota and Morrison formations over a large area were confirmed. Absorption of Se is a specialized function limited to certain plants belonging to widely separated genera. There is also a large group of plants which are incapable of absorbing it directly from the soil, even though some of them can take it up after it has been converted into a more readily available form. Not all the factors influencing this conversion are as yet well understood. There are 20 references.

Integration of climatic and physiologic factors with reference to the production of sugar cane, H. F. CLEMENTS. (Hawaii Expt. Sta.). *Hawaii. Planters' Rec.* [*Hawaii. Sugar Planters' Sta.*], 44 (1940), No. 3, pp. 201-233, figs. 13).—Using $\frac{1}{4}$ -acre plats of variety 31-13S9 in two localities, an attempt was made to correlate sugarcane growth with external and internal factors. Complete weather and compositional records were compiled, and the marked differences in yield obtained at the two places is explained on the basis of differences in sunlight intensity. Growth at Kailua, calculated by means of a formula involving growth at Waipio and the ratios of leaf areas, crop densities, and sunlight intensities, proved very close to the observed growth. It was demonstrated that, since climatic factors so markedly affect growth, the fertilizer requirement of a given crop is determined largely by them. Because of the complexity of the problem, an attempt was made to establish indexes within the plant which could be followed during its growth. The primary index is the total sugar content of the young leaf sheaths. If growth is below normal for the conditions of atmospheric energy this index will rise; if above normal it will fall. In either case the following secondary indexes may be consulted for causes: Moisture level—determined as the dry weight of the young leaf sheaths (percentage green weight), and therefore expressed inversely; nitrogen level—determined as the percentage composition (dry weight) of the young leaf blades; and levels of other soil materials, such as P and K, which may also be followed through analysis of the young leaves. Corrective measures for the various abnormalities of the primary index are suggested.

Storage of root reserves in Rhodes grass, H. WEINMANN (*Plant Physiol.*, 15 (1940), No. 3, pp. 467-484, figs. 5).—*Chloris gayana* was grown under controlled conditions in pots receiving different fertilizer treatments and harvested at three maturity stages. In the well-fertilized plants significant increases in the root system occurred after the time of flowering and during seed formation, when aerial growth had ceased. During this period, considerable amounts of sugars, hydrolyzable carbohydrates, N, P, and K were lost from the shoots and largely recovered in the roots. Besides translocation from the shoots, N and mineral elements also accumulated in the roots to a certain extent by simultaneous absorption from the soil. The duration of absorption varied, however, for different elements, and also for plants grown under different nutritional conditions and hence reaching different stages of physiological maturation. The relative amounts of dry matter and

constituents present in the roots increased in most cases considerably during fall, indicating a continuous storage in the roots with approach of maturity. Abnormally developed and immature remaining deficiency plants showed in part a correspondingly abnormal behavior with respect to root storage and absorption. There are 20 references.

Criticism of a recent paper on the pectic content of plant materials, Z. I. KERTESZ. (N. Y. State Expt. Sta.). (*Plant Physiol.*, 15 (1940), No. 3, pp. 565, 566).—This refers to an article by Elwell and Delm (E. S. R., 82, p. 580).

Further observations on the response of various species of plants to length of day, H. A. ALLARD and W. W. GARNER (*U. S. Dept. Agr., Tech. Bul.* 727 (1940), pp. 64, pl. 1, figs. 26).—Continuing the studies on the effects of photoperiodism (E. S. R., 80, p. 597) on many wild and cultivated plants, representing many families, the shortest daylight exposure used was 10 hr., then beginning with 12 hr. the daily light period was increased by $\frac{1}{2}$ -hr. steps to the full day length of Washington, D. C., which is nearly 15 hr. on June 21. In the main, the study deals with time of flowering, heights attained, and character of growth for the different photoperiods, the data being presented largely in tabulated form. Each plant is classified according to its behavior, whether a day-neutral, short-day, long-day, or an intermediate-day type. In some cases this classification is only tentative, owing to limited data, and may need modification with further study. Indeterminate or day-neutral plants are defined as those which flower more or less readily in response to all lengths of day. Short-day plants are those which flower readily on the shortest exposure but cease flowering or do so less readily when the day-length has been sufficiently increased. Long-day plants are those which flower readily on relatively long days but cease to do so or show delayed flowering with shortened days. Intermediate plants are those with a definite zone of flowering, on either side of which flowering ceases or is less favored, because the days are either too short or too long. In the long-day and the short-day groups there appear to be all degrees of flowering response to length of day, ranging from complete inhibition when a critical point is reached to merely delayed or sparse flowering above or below a certain optimum length of day.

Assimilation and respiration of excised leaves at high concentrations of carbon dioxide, R. LIVINGSTON and J. FRANCK. (Univ. Minn. et al.). (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 449-458, figs. 15).—The photosynthesis and respiration of *Hydrangea otaksa* leaves were not completely stopped by CO₂ concentrations as high as 20 percent. The effects of such high concentrations are strongly influenced by "internal factors" not directly controllable. Depression of the assimilatory rate by 20 percent CO₂ was much greater during the dormant than during the vegetative period. Physiologically young leaves were more tolerant of high concentrations than were old leaves, and their tolerance was increased by "sugar-feeding" and by starving them. The photosynthetic rate in 20 percent CO₂ usually increased on prolonged illumination. Leaves could frequently be induced to tolerate high CO₂ concentrations by starting them in 2 or 5 percent CO₂ and increasing it by progressive small steps without interrupting illumination. Leaves so conditioned assimilated in 20 percent CO₂ at about half their maximum rate. In one test a leaf was conditioned to synthesize in 50 percent CO₂ at ± 15 percent of its maximum rate. At constant intensity and for the concentrations studied, the conditioned rate is a linear function of the CO₂ concentration. The depressant effect of concentrated CO₂ is greater at high than at low light intensities. There was some evidence that a leaf which had been conditioned to high CO₂ concentrations was less able than an ordinary leaf to photosynthesize at low concen-

trations. This effect occurred only after the leaf had been induced to assimilate rapidly in high CO₂ concentrations; it was not produced by simple exposure to this medium.

Measurement of the respiratory quotient of plant tissues in a constant gaseous environment, A. ULRICH. (Univ. Calif.). (*Plant Physiol.*, 15 (1940), No. 3, pp. 527-536, figs. 3).—The author describes a simplified apparatus for determining simultaneously the CO₂ evolved and the O₂ absorbed by plant tissues under a constant gaseous environment. This permits the introduction of Reiset absorption towers for absorbing CO₂, and the O₂ absorbed by the plant tissues is replaced electrolytically by a generator operating automatically by a mercury manometer. The amount of current passing through the generator is measured by a coulometer in series. This method was successfully used in studying respiration in excised roots in order to gain further information on organic acid metabolism as related to the absorption of cations and anions.

The influence of the microscope on botany during the last hundred years, F. W. JANE (*Jour. Roy. Micros. Soc.*, 60 (1940), No. 1-2, pp. 45-49).

On the staining of plant tissues, D. A. JOHANSEN (*Chron. Bot.*, 6 (1940), No. 2, pp. 30, 31).—A review of recent advances.

Rapid staining methods in plant histology, R. S. McLEAN and E. J. IRELAND. (Univ. Fla.). (*Jour. Amer. Pharm. Assoc.*, 29 (1940), No. 7, pp. 318-321).—This is a preliminary report on two staining methods for plant material, both involving the flaming of the primary stain, a technic long used in bacteriology.

Improved smear methods for rapid double staining, P. N. BHADURI (*Jour. Roy. Micros. Soc.*, 60 (1940), No. 1-2, pp. 1-7, pl. 1).—Technic for plant material.

Treatment of cassava (*Manihot utilissima*) with colchicine.—I, A preliminary note on polyploidy shown by differences in size of stomata [trans. title], E. A. GRANER (*Jor. Agron.*, 3 (1940), No. 2, pp. 83-98, figs. 2; *Eng. abs.*, p. 97).

The effects of colchicine upon the division of the generative cell in *Polygonatum*, *Tradescantia*, and *Lilium*, O. J. EIGSTI (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 512-524, figs. 66).—Using material prepared by the slide cultural technic and whole mounts of stylar tissue, mitoses of the generative cells were studied. *Lilium* and *Polygonatum* have a distinct generative cell in the pollen tube, whereas it was not possible to differentiate a cytoplasmic sheath around the generative nucleus in *Tradescantia*. Normal mitosis is compared with that under colchicine treatment. The latter inhibited chromosome movements during the division of the generative cell in a way similar to that of chromosomal movements in mitosis of other tissues. When colchicine was present no metaphasic plate stages appeared, the nuclei were not equatorially divided, both daughter chromosomes moved into the same nucleus, the chromosomal cycle was continued, and the total chromosome number did not exceed the diploid. The mitotic cycle was arrested in early metaphase by colchicine, which precluded later metaphase, anaphase, and the formation of equatorial nuclei. The total effect involved the interaction of the responses to colchicine of two mitotic processes, viz, the mitotic cycle was inhibited, and the chromosomal cycle continued as usual in a regular mitosis. Thus the nuclei which formed in the treated pollen tubes were cytogenetic entities unlike other nuclei formed in normal mitoses. Physiological effects of colchicine were enlargement of the pollen tube, increase in the width of the tube wall, decrease in percentage of bursting of pollen tubes, and branching of pollen tubes. Vermiform nuclei in microgametes may be seen in pollen tubes studied from stylar tissue. Because of its specific inhibitory action on the mitotic cycle and its retarding action on the

chromosomal cycle, colchicine is considered a valuable aid in studying chromosomal morphology concerned with the number, size, configuration, and karyotype. Chromosomal fragments appeared more often in treated than in untreated pollen tubes. There are 46 references.

Further studies on zonal structure and growth of the shoot apex of *Cycas revoluta* Thunb., A. S. FOSTER. (Univ. Calif.). (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 487-501, figs. 12).—The author here describes the results of a study of the shoot apex of large individuals of *C. revoluta*, a continuation of earlier investigations on the seedling apex (E. S. R., 81, p. 764).

Development of the foliage leaves of *Taxodium distichum*, G. L. CROSS (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 471-482, figs. 47).—"The general anatomy of the mature foliage leaf of *T. distichum* is described briefly, and the remainder of the paper is devoted to a description of some of its outstanding histogenetic features."

The genus *Myriangium* in North America, J. H. MILLER. (Univ. Ga.). (*Mycologia*, 32 (1940), No. 5, pp. 587-600).—A taxonomic study of this group of plectomycetous fungi which occur on scale insects parasitizing various woody plants, including a key to the four North American species of *Myriangium* (one new combination).

***Mollisia tetrica*, *Peziza sejournei*, and the genera *Phaeociboria* and *Pycnopeziza*,** H. H. WHETZEL and W. L. WHITE. (Cornell Univ.). (*Mycologia*, 32 (1940), No. 5, pp. 609-620).—A systematic study of these fungi, including new taxonomy.

Heterothallism in *Ceratostomella multiannulata*, R. W. DAVIDSON. (U. S. D. A.). (*Mycologia*, 32 (1940), No. 5, pp. 644, 645).—On the basis of monosporous cultures, the heterothallism of this fungus was demonstrated.

A new species of *Pistillaria* on rice straw, R. E. REMSBERG. (Cornell Univ.). (*Mycologia*, 32 (1940), No. 5, pp. 667-670, fig. 1).—*Pistillaria oryzae* n. sp. is described.

"Mutations" in *Aspergillus niger* bombarded by low voltage cathode rays, R. M. WHELDEN (*Mycologia*, 32 (1940), No. 5, pp. 630-643, figs. 4).—This reports a study of several variant strains induced by bombardment of spores in vacuo by low-density beams of low-velocity electrons, comparable in their density and range to the secondary electrons released in spore tissues under X-ray bombardment. The changes in pigment, morphology, and cytology are described.

Lethal and dissociative effects of X-rays on bacteria, S. HABERMAN and L. D. ELLSWORTH. (Ohio State Univ.). (*Jour. Bact.*, 40 (1940), No. 4, pp. 483-503, figs. 6).—This study indicated that the lethal effects of X-rays depend on the number of bacteria present at any given time, and more on the wavelength emitted than on the intensity once the rays completely bathe the bacterial suspension. The killing effect on *Staphylococcus aureus* was greater for the hard than for the soft rays. Dissociation was induced in *S. aureus* and *Serratia marcescens* by X-rays, actively proliferating cells showing the greater tendency. The kind and number of variants resulting from X-ray irradiation could not be predicted, and often no changes were observed.

Efficiency of energy utilization in the growth of bacteria, O. RAHN. (Cornell Univ.). (*Growth*, 4 (1940), No. 1, pp. 77-80).—"The maximal efficiency of energy utilization in growth is of the same magnitude in the vertebrates, insects, and bacteria studied. The greater efficiency of yeast under the conditions of commercial manufacture may be due to careful selection of the strain as well as to perfect control of optimal conditions. One Calorie of food produced in pigs 0.036-0.073 gm. solids=0.2-0.4 Calorie, in trout 0.035-0.068 gm.=0.18-0.31, in cockroaches 0.082-0.083 gm.=0.34-0.35, in molds 0.125-0.145 gm.=0.58-0.7, in

yeast 0.135-0.25 gm.=0.6-1.1, in colon bacteria 0.075-0.181 gm.=0.34-0.81, in bacilli 0.028-0.053 gm.=0.13-0.24, in pseudomonads 0.048-0.05 gm.=0.21-0.22 Calorie."

Relation between food concentration and surface for bacterial growth, H. HEUKLEKIAN and A. HELLER. (N. J. Expt. Stas. et al.). (*Jour. Bact.*, 40 (1940), No. 4, pp. 547-558, figs. 2).—Under the experimental conditions described, *Escherichia coli* made no growth in glucose and peptone concentrations of 0.5 and 2.5 p. p. m. Addition of glass beads permitted considerable growth, this effect being noticeable up to 25 p. p. m., beyond which the bacterial numbers with and without the beads were about the same. The population of stream water was similarly affected by adding clean sand and by aeration and agitation. Stirring of sewage likewise resulted in an increase of bacterial numbers. Adding stones covered with biologically active slime to surface waters failed to prevent bacterial increase but considerably reduced its magnitude. Surfaces enable bacteria to develop in substrates otherwise too dilute for growth, development taking place either as attached bacterial slime or colony growth. Once a biologically active slime is established on surfaces, the rate of biological reaction is greatly accelerated.

GENETICS

Studies of a telocentric chromosome in maize with reference to the stability of its centromere, M. M. RHOADES. (U. S. D. A.). (*Genetics*, 25 (1940), No. 5, pp. 483-520, pls. 3, figs. 3).—Corn plants hyperploid for a telocentric chromosome consisting of the short arm of chromosome 5 produce an occasional secondary trisome. The supernumerary chromosome of the secondary trisomes consists of two short arms of chromosome 5 attached to a median centromere. Use of mutant genes lying in the telocentric chromosome showed that it was involved in the formation of the secondary chromosome. The frequency with which secondary trisomes were found when plants hyperploid for the telocentric chromosome served as pollen parents was 0.46 percent, but used as female parents only 0.22 percent. Pollen hyperploid for either one or two short arms of chromosome 5 rarely functions successfully in competition with haploid grains. It was suggested that the secondary chromosome arises at meiosis from a transverse division of the centromere of the telocentric chromosome, and that it is occasionally incorporated into the generative nucleus during the first microspore division. The vegetative nucleus would be haploid and pollen tube growth normal, but the two sperm would transmit the secondary chromosome. The telocentric chromosome apparently undergoes structural changes in somatic cells. Production of secondary or isochromosomes at meiosis from the telocentric chromosome and its loss and modification in somatic tissue show that a terminal centromere is unstable. Such a telocentric chromosome would tend to be eliminated by natural selection.

Cytogenetic studies of divergent meiotic spindle formation in *Zea mays*, F. J. CLARK. (Conn. [New Haven] Expt. Sta. et al.). (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 547-559, figs. 6).—The recessive factor in corn described as arising after ultraviolet treatment of pollen causes fibers of the first meiotic spindle to diverge instead of converge at the polar regions of the spindle figure. The chromosomes at anaphase I follow the diverging paths of the spindle fibers, and few to many small nuclei are formed at telophase I, each incorporating from one to several chromosomes. The multinucleate condition of telophase I introduces a multispindle formation in the second meiotic mitosis, and consequently from four to many spores are produced from a single micro-

sporocyte, each spore containing from one to several small nuclei embracing one or more chromosomes. Small nuclei so produced do not degenerate or become pycnotic. Spores with at least a complete set of chromosomes distributed among several small nuclei can develop normally. Within a single microspore, the prophase of the first microspore division is initiated simultaneously in each of the separate nuclei. The method is described whereby the multinucleate condition may return to a uninucleate condition following the first division in the microspore.

Chromosome numbers and meiosis in the genus *Carex*, H. A. WAHL. (Pa. State Col.). (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 458-470, figs. 64).—The chromosome numbers of 107 species and 5 hybrids of the genus were investigated, the haploid numbers forming an aneuploid series ranging from 13 to 56. A type of meiotic behavior is described in which the first meiotic division is considered as an equational division and the second as reductional. If this conclusion is further substantiated, the Cyperaceae will have been shown to have three features unique in the plant kingdom. These are the disintegration of three potential microspores from each tetrad, the aneuploid series of chromosome numbers, and the behavior of homologous chromosomes at meiosis. Whether there is a causal relation between these three features is a problem to be decided by future investigation.

Determination of the chromosome numbers of *Solanum* species in the vicinity of Buenos Aires [trans. title], E. L. RATERA (*Buenos Aires Univ., Inst. Génét. [Pub.]*, 1 (1940), No. 6, pp. 7, pl. 1).

Inheritance of resistance of H-44 and Hope wheats to stem rust, R. F. PETERSON (*Jour. Hered.*, 31 (1940), No. 6, p. 272).—The author calls attention to early work on the genetics of rust resistance in these wheats.

Cattle-breeding in Tanganyika Territory and some developmental problems relating thereto, M. H. FRENCH (*Empire Jour. Expt. Agr.*, 8 (1940), No. 29, pp. 11-22, fig. 1).—The importance of better environmental conditions for the improvement of native zebus by crossing with Shorthorn, Friesian, and Ayrshire bulls, as well as those of other breeds, is stressed. The excellence of the first cross was not maintained in subsequent generations without continued grading on account of the unfavorable environmental conditions other than nutrition. Slightly higher temperatures and respiration rates were associated with the higher grades.

Genetics and range sheep improvement, J. E. NORDBY. (U. S. D. A.). (*Sci. Mo.*, 51 (1940), No. 4, pp. 310-320, figs. 6).—The application of genetic principles to the improvement of range sheep at the U. S. Sheep Experiment Station and Regional Sheep Breeding Laboratory at Dubois, Idaho, involves the development of inbred strains of special superiority for definite uses and testing them frequently for their transmitting qualities, as determined by progeny performance. Consideration must be given to the ability of individuals in perpetuating their own line and for use in crossing with other lines and strains.

The effect of an early lethal (t^0) in the house mouse, S. GLUECKSOHN-SCHOENHEIMER (*Genetics*, 25 (1940), No. 4, pp. 391-400, pl. 1, figs. 6).—Comparative studies of the histological development of lethals caused by the homozygous condition of the three pairs of alleles pertaining to tail condition (E. S. R., S2, p. 33) indicated that the $t^0 t^0$ embryos cannot be distinguished until about 5 days after fertilization. Development of the homozygote stops, and it dies on the seventh day and resorption sets in. The TT homozygote develops until the eleventh day, when it dies. The effects of the two alleles T and t^0 on the notochord and mesoderm suggest action on two different structures. Since

both have the same origin and the t^0 gene precludes the formation of the notochord because of its early influence, it is impossible to determine if both would act on the same tissues.

A dwarf mutation in the rabbit: The constitutional influence on homozygous and heterozygous individuals, H. S. N. GREENE (*Jour. Expt. Med.*, 71 (1940), No. 6, pp. 839-856, pls. 3, figs. 4).—The dominant dwarf mutation in Polish rabbits previously noted by Castle (E. S. R., 62, p. 323) produces other abnormalities of the skull. In the homozygote it is lethal. A second type designated as semidwarfs was also described, slightly larger than the dwarfs and with the bones of the calvarium almost completely calcified at birth. Interbreeding dwarf transmitters produced 1,321 progeny, of which 305 were dwarfs and 33 semidwarfs. Interbreeding of semidwarfs produced 6 normals, 11 semidwarfs, and 6 dwarfs. The best hypothesis to explain this situation seemed to be that semidwarfs were genetically heterozygous for the dwarfing factor and homozygous for the diminutive factor. The primary effect of the dwarfing gene is an inhibition of the secretory functions of the pituitary.

Variation in mouse embryos of 8 days gestation, E. ALLEN and E. C. MACDOWELL (*Anat. Rec.*, 77 (1940), No. 2, pp. 165-173, pls. 2).—The somites of 95 embryos from ♀s killed 8 days after mating showed marked variations, even in the same litter. The somite counts ranged from 0 to 8, and were independent of litter size and number and position in the uterus.

Are differences in size between parts of the body due to general or specific factors? J. I. COHEN (*Natl. Acad. Sci. Proc.*, 26 (1940), No. 8, pp. 524-526).—Referring to studies by Castle and by Sumner (E. S. R., 50, p. 823) pertaining to the inheritance of size in rabbits, the author suggests by an analysis of the measurements of 164 ♂ and 106 ♀ psychotics and 50 normal ♂s that the size of body parts could best be determined by two major growth reactions, one governing magnitude of all physical dimensions and the other governing proportions in growth and circumferential measurements. Analyses of the variance in 14 measurements confirmed this conclusion.

Five years of breeding for high and low percentage of thick albumen in the eggs of Rhode Island Reds, C. W. KNOX and A. B. GODFREY. (U. S. D. A.). (*Poultry Sci.*, 19 (1940), No. 5, pp. 291-294, figs. 2).—Beginning in 1932 with fowls laying eggs with an average of 50 percent thick albumen (E. S. R., 79, p. 527), selection of lines for high and low percentages demonstrated the heritability of this condition. The average percentage of thick albumen was increased to over 60 percent in the high line in 1937 and 1938 and decreased to about 47 percent in the low line in the same time.

Further studies of the interrelationships of cellular characters in Columbidae, M. R. IRWIN and L. J. COLE. (Wis. Expt. Sta.). (*Genetics*, 25 (1940), No. 3, pp. 326-336).—Using methods previously employed in studies of the antigens in the Pearlneck and ringdove and hybrids between them (E. S. R., 83, p. 182), the authors made similar studies of the Pearlneck and Senegal and their hybrids and backcrosses. Agglutination reactions showed that several of the species-specific characters of the Pearlneck not in the ringdove were also present in the Senegal. Evidently, each species (Pearlneck, Senegal, and ringdove) possesses antigens specific to its own species and shares other antigens with the other two species, singly and jointly. Two cellular characters, and possibly a third, seemed, from the segregation in the backcross, to differentiate Pearlneck from Senegal.

Applications of reproduction physiology to livestock breeding, F. F. MCKENZIE. (Mo. Expt. Sta. and U. S. D. A.). (*Growth*, 3 (1939), No. 3, pp. 277-293, figs. 8).—Observations made on reproductive behavior and oestrous cycles of a large group of ewes, sows, cows, goats, and mares are reported.

The duration of oestrus and the intervals between the cycles are tabulated. Reference is made to the use of the pregnancy test in mares and the progress of inducing ovulation artificially in the larger animals as it occurs in mice and rats in the pregnancy test. Fertility of ♂s was lowered by high temperatures, too frequent services, and, presumably, by environmental influences.

The chemistry and cytology of the sperm membrane of sheep, W. W. GREEN. (Minn. Expt. Sta.). (*Anat. Rec.*, 76 (1940), No. 4, pp. 455-473, pl. 1).—Through the use of ram sperm collected by methods previously described by Comstock (E. S. R., 82, p. 36), the membrane of the sperm was found to furnish a new cytological measure of sperm quality. The number of vesicles in the membranes over the anterior portion of the sperm head was reduced with aging and frequent ejaculation. A correlation of 0.7 was found between the number of vesicles present and the rate of glycolysis.

Effects of low environmental temperature on the reproductive organs of male mammals with annual aspermia, L. J. WELLS and M. ZALESKY. (Univ. Mo. et al.). (*Amer. Jour. Anat.*, 66 (1940), No. 3, pp. 429-447, pl. 1, fig. 1).—Continuing the studies of sperm formation in the ground squirrel (E. S. R., 81, p. 499), the authors investigated the effects of exposure of ♂s to controlled temperatures of from 4° to 18° C. Treatments begun at 4° during the mating season continuously maintained sperm production and large accessory reproductive organs for more than 12 mo. Low-temperature treatments begun during the aspermatic interval hastened the time of appearance of spermatozoa only slightly. The gonadotropic potency failed to regress, in the main, in ♂s kept at low room temperature. Temperature seemed to affect the activity of the reproductive organs through its influence on the activity of the pituitary gland.

The experimental modification of the oestrous cycle in the ferret by different intensities of light irradiation and other methods, F. H. A. MARSHALL (*Jour. Expt. Biol.*, 17 (1940), No. 2, pp. 139-146, pl. 1).—Acceleration of the oestrous cycle of adult ♀ ferrets was correlated with the degrees of light intensity to which they were exposed. Ultraviolet irradiation, in addition, usually kept the ♀s in heat for a longer period. Examination of the ovaries of such animals showed the presence of luteal cells, which suggested the luteinization of follicles without rupturing, yet normal ovulation usually occurred only after coitus. Irradiated ♀s went off heat soon after being placed with ♂s, presumably as a result of copulation. Irradiation of ♂ ferrets caused descent of the testes in December, and they remained in the scrotum until the next autumn.

The time and sequence of preovulatory changes in the cat ovary after mating or mechanical stimulation of the cervix uteri, A. B. DAWSON and H. B. FRIEDGOOD (*Anat. Rec.*, 76 (1940), No. 4, pp. 411-429, pls. 2).—The preovulatory development and changes in the follicles, including maturation of ova, in 13 cats is described.

A complete unequal twin in a teratomatous tumor of a Belgian hare, G. C. KENT, JR. (*Anat. Rec.*, 77 (1940), No. 2, pp. 193-196).—An anatomically complete and evidently normal rabbit fetus completely encysted in the abdominal region of its dam and a second fetus with early arrested development in the same cyst are described.

Incomplete posterior duplication of the body (dipygus) in an albino rat, H. L. RATCLIFFE and H. D. KING (*Anat. Rec.*, 77 (1940), No. 1, pp. 49-56, figs. 4).—An anomalous mouse was described in which the anterior portion of the animal was normal but there was a doubling of the hind legs and displacement of some of the visceral organs.

Germ cell migration in relation to asymmetry in the sex glands of hawks, A. J. STANLEY and E. WITSCHI. (La. State Univ. et al.). (*Anat. Rec.*, 76

(1940), No. 3, pp. 329-342, figs. 3).—Differences in the location and migration of gonads in species of hawks are noted and described.

Bioelectric potential as indicator of ovulation in the hen, M. ALTMANN. (Cornell Univ.). (*Science*, 92 (1940), No. 2389, pp. 338, 339).—Tests of the bioelectric potential difference between the sides of the abdomen were made on two laying hens with a D. C. millivoltmeter. There was a violent rise in the P. D. at the time when ovulation must have occurred, which ranged from 25 to 40 min. after laying, and normal levels were reached 2 hr. later.

Reproductive cycles in animals with special reference to the bat, M. J. GUTHRIE. (Univ. Mo.). (*Growth*, 3 (1939), No. 3, pp. 261-275, figs. 6).—It is pointed out that breeding seasons occur in cycles which are differently related to season in the several species. Some animals, like birds, breed as the days increase in length, whereas others, like sheep and deer, breed as the days get shorter. Changes in the amount of light will modify the seasonal behavior and breeding seasons. Endocrine interrelationships played a pronounced part as also, presumably, did food. The bat in its reproductive cycle was found to show marked seasonal variations in the percentage of differentiated cells in the hypophysis. The differentiated cells are low in the early summer, when the secretion is presumably high; but the number increases to a peak in July and August, when secretion must be lower. The numbers of small follicles in the ovaries remained about the same throughout the year, but there was an increase in the number of large follicles in late fall. The whereabouts of bats in the wild during early pregnancy is unknown, and, although copulation may occur in the fall, ovulation does not occur until spring. On account of the variable growth of the oöcytes in cycles and the long period of submaximal oestrous response to hormones, the bat is deemed a valuable animal for a study of factors conditioning reproductive cycles.

Artificial insemination in livestock breeding, W. V. LAMBERT and F. F. MCKENZIE. (Coop. Mo. Expt. Sta.). (*U. S. Dept. Agr. Cir.* 567 (1940), pp. 68, figs. 24).—Descriptions are given of advantages, limitations, and uses of artificial insemination for breeding livestock, with special reference to the practice with horses, cattle, sheep, swine, and other animals. There is appended a bibliography of 76 citations.

[**Artificial insemination of sheep and dairy cattle**], D. E. BRADY, E. M. GILDOW, D. L. FOURT, and F. C. FOUNTAINE (*Idaho Sta. Bul.* 236 (1940), pp. 10, 13, fig. 1).—Electrical stimulation of rams for semen collection and artificial insemination of ewes were found successful, resulting in 16 conceptions after 22 inseminations. There was an average of 2.83 inseminations per conception in dairy cattle.

Harmonic interrelations between reproduction, mammary gland growth, and lactation, C. W. TURNER. (Mo. Expt. Sta.). (*Growth*, 3 (1939), No. 3, pp. 323-336, figs. 5).—Reference is made to the interrelation of hormones in reproduction, lactation, and growth of the mammary gland. Methods are described for assaying the pituitary hormones, including mammogen (the duct growth factor), lactogen (milk secretion factor), thyrotropic hormone, and carbohydrate and fat metabolism hormones, as well as studies on the effects of the pituitary secretion on the adrenals and thyroids.

Electrophoretic homogeneity of pregnant mare serum gonadotrophin, C. H. LI, H. M. EVANS, and D. H. WONDER. (Univ. Calif.). (*Jour. Gen. Physiol.*, 23 (1940), No. 6, pp. 733-739, figs. 3).—By the use of methods previously described for the purification of the lactogenic hormone (E. S. R., 83, p. 184), a highly potent extract of pregnant-mare serum was prepared. The molecular weight of the hormone was estimated to be 30,000. Acetylation by ketene

(E. S. R., 82, p. 323) suggested the essentiality of free amino groups for the biological activity of this hormone.

Growth-stimulating effect of testosterone propionate, H. S. RUBINSTEIN and M. L. SOLOMON (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 442, 443).—Small doses (0.05 mg.) of testosterone propionate given daily for from 26 to 80 days of age caused significantly greater weight and body-length increases as compared with the controls and in contrast to the depressing effects of larger doses (E. S. R., 82, p. 324).

Opossum pouch young as experimental material, C. R. MOORE and D. BODIAN (*Anat. Rec.*, 76 (1940), No. 3, pp. 319–327, fig. 1).—Snout-rump length, weight, measurements, and various observations were made on 248 pouch young opossums. Applications of androgen in lanolin to pouch young from 3 to 35 days or more of age were well tolerated, but oestrogens were very toxic. Subcutaneous injections were tolerated after the fifteenth day. Gonadectomy operations were performed after the twentieth day, but with difficulty.

The effect of the ovary and of urinary estrogens on the growth of hair in the rabbit, C. K. HU and C. N. FRAZIER (*Anat. Rec.*, 77 (1940), No. 2, pp. 155–164).—Study was made of the effect of maturity, sex, and oestrinization on the appearance of hair and hair growth on shaved areas of Chinese albino rabbits. Variations were noted between animals and even in different locations on the same animal. Before sexual maturity, hair growth occurred about the same in both sexes; but after maturity, hair grew more rapidly in ♀s than in ♂s and was delayed with the removal of the ovaries. Oestrinization of ♂s induced more rapid hair growth than occurred in the normal animal.

Direct action of estrone on the mammary gland, W. R. LYONS and Y. SAKO. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 398–401, figs. 6).—Rubbing one of the nipples of 2-month-old ♂ rabbits with 3 International Units of oestrone in sesame oil for 5 days per week for 5 weeks caused duct growth in the treated gland but no growth in the gland on the other side, which had been treated with oil alone. More rapid proliferation followed treatment with 3 I. U. than with 0.3 I. U. per dose. Thus the oestrone is deemed mammary stimulating.

The relation of the estrogenic hormone to the formation and maintenance of corpora lutea in mature and immature rats, C. MERCKEL and W. O. NELSON (*Anat. Rec.*, 76 (1940), No. 4, pp. 391–409, pls. 2, fig. 1).—Treating mature rats daily with oestrone, if started when the rats were in oestrus, initiated dioestrus for about 3 weeks, presumably by suppressing pituitary hormones. The corpora lutea regressed, and the oestrin exerted a direct effect on the sex accessories. A single large dose of oestrone to mature ♀s in oestrus initiated a dioestrus period of about 2 weeks and then a return of the regular oestrous cycles. Continuous oestrus was induced in immature ♀s, the ovaries were devoid of corpora lutea, and the follicles were small. It was not clear whether the luteinizing hormone was released, since preformed corpora lutea were not present in the ovaries.

Quantitative studies of cell types in rat hypophysis following administration of antigonadotropic serum, J. C. FINERTY, H. S. KUPPERMAN, and R. K. MEYER. (Univ. Wis.). (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 551–553).—Daily treatment of 21 ♀ rats from 10 to 20 days of age with 0.5 cc. of antigonadotropic hormone from rabbits injected with sheep pituitary extract caused a marked increase in the basophile and a decrease in the chromophobe cells of the pituitaries as in castrated animals. Ovarian weight was retarded to 5 mg. when the treatment ceased, but increased to 20 mg. 5 days and 59.7 mg. 10 days later.

Maintenance of pregnancy in castrate rats by means of progesterone, I. ROTHCHILD and R. K. MEYER. (Univ. Wis.). (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 402-404).—Although abortion was not prevented in pregnant rats castrated on the fourth day of gestation when less than 1 rabbit unit of oestrone was administered per day, pregnancy was maintained until the twenty-first day of gestation with 1 or 2 rabbit units of progesterone.

The experimental shortening of delayed pregnancy in the albino rat, C. K. WEICHERT (*Anat. Rec.*, 77 (1940), No. 1, pp. 31-47, pls. 3).—The gestation period of litters following immediately after parturition varied from 22 to 36 days, evidently depending on the number of young suckled from previous litters. The corpora lutea of lactating rats on the twenty-first day of gestation were definitely smaller when litters of large numbers were being suckled than when fewer young were suckled. Although small doses of progesterone did not accelerate development, implantation was hastened by Antuitrin-S and by large doses of progesterone for from 7 to 8 days after insemination, and living fetuses were found on the twenty-first day. The action of suckling may stimulate the production of prolactin in the hypophysis and inhibition in the secretion of gonadotropic hormones and thus control nidation.

The effect of picric and flavianic acids on the potency of the follicle-stimulating anterior pituitary hormone, H. JENSEN and S. TOLKSDORF (*Jour. Biol. Chem.*, 132 (1940), No. 2, pp. 519-526).—The gonadotropic effects of extracts of sheep pituitary were augmented in their effects on ovarian weights and follicle development in immature ♀ rats by tannic acid. Only a slight effect was produced on a highly purified follicle-stimulating preparation, but tannic acid markedly stimulated the effect of a purified luteinizing hormone. Precipitation of the preparation with picric or flavianic acid did not injure the follicle-stimulating potency, and support was not given to the reversibility of the actions.

The effect of testosterone propionate on the sex-life of the female rat, J. R. GROOME (*Jour. Expt. Biol.*, 17 (1940), No. 2, pp. 164-167).—Female rats 55 and 74 days of age were given eight daily injections of 500 γ of testosterone. Oestrus was delayed, with the uteri undergoing a cycle of pseudopregnancy after mating. The pseudopregnancy was terminated with pregnancy, and young were born from 34 to 56 days later. Control litters were born after from 23 to 26 days.

Effects of testosterone propionate on female roller canaries under complete song isolation, F. M. BALDWIN, H. S. GOLDIN, and M. METFESSEL (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 373-375).—Female roller canaries in complete song isolation were induced to bring forth malelike song after about 15 days of daily injection with 2.5 mg. of testosterone propionate.

Relation between volume of vehicle and chick comb response to androsterone, E. KLEMPNER, F. HOLLANDER, and R. T. FRANK (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 631-633).—Reduction of the volume of sesame oil in which androgen was supplied to the combs of chicks was found to stimulate comb growth more than larger doses of the vehicle. A mean improvement of 67.9 percent in comb weight was produced with 0.02 cc. as contrasted with 0.05 cc. of the vehicle. Similar results were obtained with doses of from 1 to 50 γ of the androgen. More than 1,000 birds were used in the tests.

Improvement in chick comb response to androsterone obtained with alcohol as vehicle, E. KLEMPNER, R. T. FRANK, and F. HOLLANDER (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 633-636).—The weights of the combs of baby chicks treated with androgen in alcohol averaged 155.7 percent heavier than with different doses of the hormone in a sesame oil vehicle. The improvement was ascribed to the more rapid evaporation of the alcohol, less loss

in spreading to less responsive areas, and more rapid absorption. The experiments were conducted with 318 treated and 220 control chicks.

Effect of volume used for injection in micro-assay of prolactin, R. W. BATES and O. RIDDLE (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 505-509).—By the stimulation of the crop gland of pigeons with 0.5 cc. containing 0.125 γ in each of two injections, as much response was obtained as that from two injections of 0.05 cc. containing 0.5 γ of prolactin each. Thus, with the more dilute solution, only one-fourth as much prolactin was required for minimum stimulation as when there was less dilution. Similar effects of dilution were obtained when the total dose was administered in a single injection. No simple explanation seemed apparent for the dilution effects.

FIELD CROPS

[**Research with field crops in Idaho, 1939**], K. H. KLAGES, G. O. BAKER, C. A. MICHELS, C. I. SEELY, W. E. COLWELL, R. S. SNYDER, J. L. TOEVS, R. F. JOHNSON, R. E. KNIGHT, and W. A. MOSS. (Partly coop. U. S. D. A. et al.). (*Idaho Sta. Bul.* 236 (1940), pp. 20-22, 23, 41, 57, 58-60, 61-63, 65, 66, 67-71, figs. 6).—Agronomic experimentation at the station and substations, again (E. S. R., 81, p. 638) reported on briefly, included breeding work with winter and spring wheat, corn, and *Phalaris tuberosa*; variety tests with winter and spring wheat, corn, alfalfa, forage grasses, and pasture mixtures; promotion of germination of peas by chemical treatments; effects of nurse crops with clover and alfalfa; effects of ammonium sulfate applications on the hay and seed yields of orchard, smooth brome, crested wheat, meadow fescue, and tall oat grasses in solid and row plantings; a seeding test with flax; fertilizer trials with alfalfa, wheat, and potatoes; influence of legumes and manure on yield and protein content of wheat; a comparison of storing potatoes in boxes and in bulk; costs of clearing cut-over land; and control of bindweed by cultivation and sodium chlorate, and tests of borax on alfalfa and as a herbicide. The behavior of new varieties resulting from breeding work including Idaed spring wheat, Lemhi wheat, a hardy selection of bulbous canary grass, a dwarf crested wheatgrass, and Michels grass is also noted.

[**Crop production in Maryland**] (*Md. Agr. Soc., Farm Bur., Rpt.*, 24 (1939), pp. 161-172, 174-176, 244-248).—This paging includes the following papers (with discussions): Lespedeza in Maryland, by W. B. Kemp (pp. 161-165); Pasture Fertilization, by R. P. Thomas (pp. 165-170); Seed Certification in Maryland, by A. O. Kuhn (pp. 170-172); and Results of Hybrid Field Corn Demonstrations (pp. 174-176), and Problems in Making Hay (pp. 244-248), both by J. W. Magruder.

[**Farm crops research in Mississippi**] (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), Nos. 9, pp. 1, 2, 3-6, 8, figs. 5; 10, pp. 1, 2, 3-6, 7, 8, figs. 13).—Brief reports of progress are made from current research in the following articles:

No. 9.—Fall-Planted Clovers Merit Attention for Pasture, Hay, Seed, by H. W. Bennett (pp. 1, 2); Oat Production in Mississippi, by R. Kuykendall, J. Pitner, J. F. O'Kelly, J. L. Anthony, and C. D. Hoover (pp. 3-6) (E. S. R., 82, p. 475); and Expanded Production of Oats and The Value of Winter Legumes, both by C. Dorman (p. 8).

No. 10.—Familiar Sweets [Sweetpotatoes] May Yield Starch, Food, Meal, Silage, or Hay, by C. Dorman (pp. 1, 8); High Yielding Varieties of Soybeans Which Mature Seed Crops Early or Medium or Late Enable Growers To Extend Harvest Period, by H. A. York (p. 2); Delta Yields of Wheat and Barley (p. 2), and Oat Variety Yields at Stoneville (p. 7), both by P. W. Gull; and Sweetpotato Plant Production, by W. S. Anderson (pp. 3-6).

Crop sequence studies in northwestern Ohio, R. M. SALTER and J. G. LILL. (Ohio Expt. Sta. and U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 8, pp. 627-630).—Sugar beets, corn, oats, soybeans for seed, and soybeans for hay, grown on Brookston clay every year under each of several crop sequence conditions, were harvested, 1936-39. Corn yields appeared to be influenced the most by the nature of the preceding crop; oats and sugar beets showed a lesser yet marked influence; whereas soybeans, either for hay or seed, were affected only slightly and fluctuated least in yield association with seasonal variations. Except for the soybean crops, the yield when any one crop followed itself was the poorest or nearly poorest obtained among the different sequences. An arrangement which would give the greatest total advantage for the rotation as a whole, although possibly soil-depleting, is soybean hay, corn, soybean seed, sugar beets, and oats.

Legumes for crop production in the Yazoo-Mississippi Delta, R. KUYKENDALL (*Mississippi Sta. Bul.* 345 (1940), pp. 27, figs. 10).—Experiments with winter and summer legumes, 1930-39, included variety and seeding tests, methods and dates of turning, and comparisons of their value for soil fertility at the Delta Substation and elsewhere in the Delta. Hairy vetch, results indicated, should be planted at the rate of 25 lb. per acre, Hungarian and common vetch 30, and Austrian Winter peas 35 lb. when planted on beds and at twice these rates when broadcast; giant bur-clover (unhulled) from 10 to 15 bu., and California bur-clover 15 lb. per acre. Most winter legumes have done best when sown in October, although unhulled bur-clover seemed best planted in August. According to subsequent yields of seed cotton and amount of nitrogen added to the soil, the legumes gave best results when thoroughly disked and completely covered when bedded, and medium, early, and late turnings differed little in value.

The winter legumes and equivalent commercial nitrogen cost about the same per acre. Hairy vetch equaled about 55 lb. of commercial nitrogen at the substation and usually increased cotton more than did 30 lb. of nitrogen, and in outlying tests was equivalent to from 27 to 45 lb. of commercial nitrogen. Fertilizing cotton following winter legumes, with certain exceptions in 1939, was not profitable. Winter legumes returned an average net profit of from 18 to 40 ct. for each pound of seed planted. California bur-clover was grown to advantage and was superior to other winter legumes in certain fields. Better crops of legumes were obtained in three fields nearest the loessial hills by applying basic slag 500 lb. and potassium chloride 100 lb. per acre, but such treatments were not needed in the west Delta or in the Tallahatchie-Yazoo Basin. Soybeans interplanted with corn did not reduce corn yields the first year and caused an increase of nearly 15 bu. per acre the second year. Beneficial effects of soybeans when followed by cotton continued into the second year. Cowpeas and crotalaria also gave good increases in yields.

Growing winter legumes in Louisiana, F. L. DAVIS, C. G. HOBGOOD, and C. A. BREWER, JR. (*Louisiana Sta. Bul.* 318 (1940), pp. 28, figs. 9).—Annual average increases in yield of from 500 to 600 lb. of seed cotton per acre were obtained on Olivier silt loam at Baton Rouge after turning under Austrian Winter peas, *Melilotus indica*, and the hairy, common, and Hungarian vetches. Besides the increase in the first year, a residual effect from legume green manures resulted in acre increases of from 240 to 300 lb. of seed cotton in the second year and about 200 lb. in the third year. Legume green manures of from 3.5 to 4 tons resulted in larger increases in cotton yield than did 36 lb. per acre of nitrogen from sodium nitrate, which in turn surpassed winter legume growth of 3 tons or less of green matter per acre. Rye and oats as cover crops did not, on the average, appreciably increase the yield of cotton.

Inoculation and fertilizer experiments throughout the State with Austrian Winter peas and common vetch demonstrated that planting these legumes in soil too dry for germination may result in unsatisfactory nodulation and consequent crop failure. Increased growth of winter legumes was produced by superphosphate, by basic slag, and in largest amounts by superphosphate with lime on all soils tested. Application of 500 lb. of basic slag per acre to inoculated vetch and peas doubled the average yield of green matter in 1938-39, and in 1937-38, 330 lb. gave average increases in top growths of 52 and 50 percent, respectively. For both legumes the increase in growth from 225 lb. of superphosphate per acre on all tests averaged 83 percent. Nearly all soils of the interior Coastal Plains seemed to need phosphate fertilization for satisfactory green manure crops.

Recommended methods for growing and turning under Austrian Winter peas and vetch are outlined.

The breeding of herbage plants in Scandinavia and Finland (*Imp. Agr. Bur. [Gt. Brit.], Joint Pub. 3 (1940), pp. 124, figs. 2*).—Contributions on this subject include Herbage Plant Breeding in Sweden, by G. Nilsson-Leissner and F. Nilsson (pp. 15-51) (64 refs.); The Application of Cytology to Herbage Plant Breeding, by E. Åkerberg (pp. 52-61) (28 refs.); Lucerne Breeding in Sweden, by R. Torssell (pp. 62-70) (25 refs.); Improvement of Herbage Plants in Denmark (pp. 71-79), and Some Breeding Experiments With Timothy (pp. 80-92), both by H. N. Frandsen (14 refs.); Selection and Inbreeding in Red Clover and Timothy, by H. Wexelsen (pp. 93-114) (3 refs.); and Red Clover Breeding in Finland, by O. Pohjakallio (pp. 115-120) (7 refs.).

Technique of grassland experimentation in Scandinavia and Finland (*Imp. Bur. Pastures and Forage Crops [Aberystwyth], Herb. Pub. Ser. Bul. 28 (1940), pp. 52, pls. 2, figs. 7*).—Articles in this symposium include Technique Employed in Grassland and Pasture Experiments of the Swedish Grassland and Peat Association, by G. Giöbel (pp. 7-15); Methods for Botanical Analyses, by K. Lundblad (pp. 16-20); Technique of Grassland Plot and Field Trials in Norway: Methods of Pasture Experiments, by B. Sakshaug (pp. 21-27); Technique of Grassland Plot and Field Trials in Norway: Methods of Meadow Experiments, by H. Foss (pp. 28-31); Methods of Grassland Analysis in Denmark, by H. Bøgh (pp. 32-38); The Technique of Experiments With Strains and Seeds Mixtures, by J. Hansen (pp. 39-42); and Methods Used in Pasture Experiments in Finland, by C. A. G. Charpentier (pp. 43-47). The locations of agricultural research stations in these countries are listed and shown on an outline map.

Grassland investigations in Australia (*Imp. Bur. Pastures and Forage Crops [Aberystwyth], Herb. Pub. Ser. Bul. 29 (1940), pp. 107, figs. 2*).—A series of special articles on the Australian environment, plant introduction, plant breeding and selection, northern and southern Australian pastures, and weeds and insect pests is preceded by a brief review of the work of institutions engaged in grassland research. Articles are also devoted to the pasture investigations in the state departments of agriculture and at the Waite Institute. The final part contains 247 abstracts of recent publications on grassland in Australia and an index of genera.

Permanent pastures, R. P. BLEDSOE and O. E. SELL (*Georgia Sta. Bul. 207 (1940), pp. 51, figs. 23*).—Recommendations on practices for permanent pastures, especially for the Piedmont section of Georgia, based on studies at the station, Jonesboro, and Macon, deal with soils; fertility and lime, including the use of limestone, phosphate, and nitrogen; seeds mixtures; seeding and sodding practices and the inoculation of legumes; supplements for permanent pastures;

descriptions, including adaptation, behavior, and merits of individual pasture grasses, clovers, lespedezas, and other legumes; weed control; grazing and management; the cost of establishment and maintenance; and the care of livestock on pastures. Appended tables show the composition of winter clovers in early and late spring and as affected by phosphates and limestone; composition of Bermuda grass, limed, unlimed, and fertilized; available P_2O_5 at three depths in soil growing four clovers and receiving several rates of phosphate and lime; and dry matter yields of Bermuda-lespedeza pasture variously fertilized and limed on Cecil soil.

Studies of pasture management, M. F. ABELL (*New Hampshire Sta. Bul.* 326 (1940), pp. 24, figs. 2).—Surveys on 256 farms throughout New Hampshire revealed that the available open pasture could furnish only about three-fifths of the total of about 196,500 acres needed for the livestock on hand. From 20,000 to 25,000 acres of brush pasture must be cleared, and this and the good present open pasture must be fertilized. Harvesting crops to feed to dairy cows during the pasture season instead of improving the pastures appeared uneconomical, as the several ways of producing summer green feed were all more expensive than pasture. While rowen furnishes cheap pasturage, close grazing may injure later hay crops. Farms with some improved pasture fed more grain, silage, and green feed than farms with no improved pasture. Ensiling grass and clover helped to avoid losses from poor curing of hay during wet periods and furnished a satisfactory supplement to late summer dry pastures. The average pasture season of 144 days was shorter than possible under a proper improved pasture program. The poorer hay land where available offers an excellent means of obtaining permanent pasture and at less cost than by clearing brush from land.

The kind of brush present on pastures may serve as criteria of soil fertility. For example, juniper, sweetfern, sheep laurel, and hardhack among the shrubs and clubmoss, wintergreen, cinquefoil, ladies' tobacco, and yarrow with poverty and sweet vernal grasses grow on the poorer soils. Some shrubs, as sweetfern, if in nearly pure stands also indicate in general a light soil not well suited for improvement. Heavy stands of hardhack or meadowsweet usually signify a soil high in moisture-holding capacity, with good pasture possibilities when improved. A mixed stand of brush usually found on a good pasture soil marks some improvement in soil fertility, or a step up from the juniper level.

Of the three methods of brush removal studied under a wide range of conditions, pulling required about 100 hr. per acre, cutting 80, and burning about 60 hr. and, respectively, were about 95, 60, and 85 percent effective the first year. With most kinds of brush, the methods are about equally effective by the beginning of the third year. Sweetfern, blueberry (low-bush), sheep laurel, and blackberries have been very persistent. Blueberry and sheep laurel are too difficult to pull and too short or hard-stemmed to cut, and seasonal conditions prevented burning twice a year as a control. When grazing was permitted after brush removal and fertilizing, the new brush growth, particularly of gray birch, was made more palatable by fertilizer and was browsed by cattle; hardhack, meadowsweet, and high-bush blueberry were browsed less, and sweetfern, sheep laurel, or low-bush blueberry practically not at all. Moss covered a rather high percentage of the plats but was not a serious deterrent to improvement. Sodium nitrate materially reduced the amount of moss, but improvement has come faster with applications of lime, superphosphate, and potash. The high labor requirement in removing brush makes it desirable to clear only a small area each year, probably from 2 to 5 acres, depending on the kind and the amount of brush. The pasture improvement and fertilization programs are outlined.

Management—a cure for overgrazed range, A. B. NIELSON. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 8, pp. 602-606).—The relative rates of recovery of the key species, bluebunch wheatgrass (*Agropyron spicatum*) and Idaho fescue (*Festuca idahoensis*), under proper management and protection, were studied in southeastern Washington. Bluebunch wheatgrass has begun growth from 10 days to 2 weeks earlier on moderately used pastures than on those overgrazed in the previous spring. Improper management has reduced the yield of the better forage and also exposed the soil to serious erosion. A carrying capacity per 100 surface acres estimated at 96 animal unit months was revealed on virgin bunchgrass range, 70 on moderately overgrazed range, and only 11 on severely overgrazed range. Properly managed range under a deferred and rotation system of grazing increased 43 percent in forage density and 112 percent in carrying capacity in 2 yr. Bluebunch wheatgrass which had been overgrazed severely increased about 19 times in forage yield under 2 years' protection from grazing. Protection for 1 yr. of a range in better condition brought an increase of 3.44 times in forage yield of the grass the next season.

Lawn experiments, F. A. WELTON and J. C. CARROLL (*Ohio Sta. Bul.* 613 (1940), pp. [1]+43, figs. 18).—The lawn practices recommended were based extensively on experiments since 1927 concerned with seedbed preparation, seeding, soil treatments, cultural operations including mowing, influence of rainfall on growth, grass species, and lawn in shade. The standard mixture used consisted of Kentucky bluegrass three parts by weight, redtop one part, and white clover one-fourth of one part.

For use in establishing new lawns on subsoil brought to the surface in building operations, well-rotted manure proved better than other materials, and cinders improved the physical condition of the soil more than did sand, slag, surface soil, or coarse limestone. Liberal application of a 10-6-4 fertilizer on all treated subsoils after the first winter resulted in fair turf at the end of 3 yr., but after fertilization ended the turf declined in appearance. Well-rotted manure also gave best results for improvement of fertile surface soil, while addition of black soil was not helpful. It was found desirable to seed from August 20 to September 20 or defer it until very late fall or early spring and to plant at least 3 lb. of the standard mixture per 1,000 sq. ft.

Maintenance studies indicated that the value of lime depends on soil reaction and the kind of grass desired. Kentucky bluegrass and white clover thrive on alkaline, neutral, or only slightly acid soil, while fescues and bents tolerate a rather acid condition. Steamed bone has favored the development of good turf, its action being slow but cumulative in effect. Since its neutralizing value is about 10 percent, it may be used to maintain a sward of Kentucky bluegrass and white clover. Better lawn appearance resulted from monthly and bimonthly applications of ammonium sulfate than those made in spring once a year. A 10-6-4 fertilizer gave as dense a stand as ammonium sulfate and a better root system. Inorganic nitrogen carriers gave a more vigorous immediate but a less prolonged growth than organic carriers, and nitrogen appeared sooner and in greater quantity in sap of grass treated with inorganics. Fertilization affected both quantity and quality of grass.

Kentucky bluegrass contained on the average nitrogen 3.37 percent, phosphorus 0.38, and potassium 1.77 percent, and from May through September removed from 1,000 sq. ft. 2.28, 0.24, and 1.17 lb., respectively, of these elements. Three creeping bents removed on the average 5 lb. of nitrogen.

Definite gains resulted from returning clippings to the lawn and from one rolling in early spring when soil conditions were suitable. Frequent mowing was not beneficial, and mowing as late as November 1 instead of stopping September 15-October 1 resulted in less vigorous grass the next year. Close mow-

ing (0.5 in.) contrasted with high mowing (2 in.) resulted in an increase in growth of grass, a decrease in root development, and in more crabgrass. New fall seedlings were improved by mulches of peat or well-shaken wheat straw but were injured by maple leaf mulches. Established lawns receiving annual fall mulches of maple and oak leaves showed injury in the fourth year. A light top dressing of compost each fall failed to result in better appearance. With artificial watering (E. S. R., 73, p. 603), from 8,000 to 10,000 gal. of water per 1,000 sq. ft. per season were needed on Wooster silt loam soil.

Kentucky bluegrass is more widely adapted and grown than any other of the few grasses deemed suitable for lawns in Ohio. To bring a creeping bent lawn to perfection usually requires more than ordinary care. For use under trees, Chewings fescue, probably due to its more extensive and deeper root system, proved far superior to rough-stalked meadow grass. Wood meadow grass was of little value.

[Reports of the seventh and eighth Alfalfa Improvement Conferences], H. L. WESTOVER. (U. S. D. A.). (*Alfalfa Impr. Conf. Rpts.*, 7 (1939), pp. [2]+41, figs. 2; 8 (1940), pp. [2]+53, fig. 1).—The report of the seventh conference, held in New Orleans, La., November 22, 1939, includes statements from experiment stations actively participating in the breeding program—California by B. A. Madson, Colorado by R. M. Weihing, Kansas by C. O. Grandfield (U. S. D. A.), Michigan by E. E. Down, Nebraska by H. M. Tysdal (U. S. D. A.), New Jersey by H. B. Sprague, New York by C. H. Myers, and Wisconsin by R. A. Brink and W. K. Smith, and by T. M. Stevenson in Canada. A symposium on The Increase and Distribution of New Alfalfa Varieties was led by L. F. Graber (Univ. Wis.), and the topic was discussed from the seed producing standpoint by E. R. Jackman (Oreg. Sta.), the seed consuming standpoint by R. D. Lewis (Ohio Sta.), from the State viewpoint by R. I. Throckmorton (Kans. Sta.), the seed certification viewpoint by R. D. Mercer (Mont. Sta.), and from the Federal standpoint by H. L. Westover. A paper entitled Some Observations at Aberystwyth, Wales, by D. W. Robertson (Colo. Sta.), is also included.

Papers (with discussions) presented at the eighth conference at Fort Collins, Colo., July 8 and 9, 1940, were *Lygus* Damage in Alfalfa in Relation to Seed Production, by J. W. Carlson (pp. 2-9), Problems Related to Breeding Alfalfas for Resistance to Black-Stem Disease, by M. L. Peterson (pp. 9, 10), Artificial Inoculation of Alfalfa To Determine Susceptibility to Bacterial Wilt, by F. R. Jones (pp. 10-15), and Discussion on Yield of Self Fertilized Lines of Alfalfa, by H. M. Tysdal (pp. 38-51) (all U. S. D. A.); Laboratory Studies of Hard Seeds of Alfalfa, by A. M. Lute (pp. 15, 16), and Germination Studies in Alfalfa, by R. M. Weihing (pp. 16-18) (both Colo. Sta.); and Alfalfa Breeding, by T. A. Kiesselbach (pp. 19-38) (Nebr. Sta.).

Alyceclover, R. MCKEE (U. S. Dept. Agr., *Bur. Plant Indus.*, 1940, pp. 2).—A tabloid description of Alyceclover (*Alysicarpus vaginalis*) and its adaptation, cultural needs, and uses.

About this new Alyce clover, W. E. STOKES. (Fla. Expt. Sta.). (*South. Seedsman*, 3 (1940), No. 11, pp. 7, 18, figs. 3).—Alyceclover, grown in Florida on a rapidly increasing acreage and making good growth in other Southern States, has been used to advantage for pasture, hay, and soil improvement. The author comments on its cultural and fertilizer requirements, hay and seed production, chemical composition, and disorders.

Cotton Research Congress, June 27-29, 1940, Waco, Texas ([*Waco, Tex.*, 1940], pp. [438], figs. [13]).—Papers presented included Cottonseed Oil—Old and New Uses, by J. S. Abbott; Shift in Cotton Production, by D. A. Banded; Possible Methods for Increasing the Consumption of Cotton and Cotton By-Products, by C. A. Basore and A. R. Macormac; Mechanization and Its

Relation to the Cost of Producing Cotton in Texas, by C. A. Bonnen, Land Classification—Inventory and Characterization of Our Land Resources in Relation to Cotton Production, by W. T. Carter, The Purpose of This Congress, by A. B. Conner, Cost of Producing Cotton in Five Areas in Texas, by P. H. Czarowitz, A Review of the Recent Developments in Cotton Breeding as Related to Yield and Quality, by D. T. Killough, Cottonseed as a Source of a New Type Flour, by C. W. McMath, Factors Related to Low Cost Ginning, by W. E. Paulson, and Economic Significance of Cotton Insect Control, by F. L. Thomas (all Tex. Expt. Sta.); Development of the Chemical Cotton Cellulose Industry, by W. F. Bowld; The World Cotton Situation, by W. L. Clayton; The Cotton Industry of Texas, Its Importance and the Significance of Recent Trends and Shifts in Cotton Acreage, Yield, and Quality by Regions, by A. B. Cox; Economic Significance of Cotton Disease Control, by A. A. Dunlap, W. N. Ezekiel, H. E. Rea, C. H. Rogers, and P. A. Young; Some Suggestions for New Chemical Research on Cotton and a Review of Recent Developments, by E. K. Everett; Ginning and Packaging Practices in Relation to Quality and Value of Cotton, by F. L. Gerdes, Aid Given by the Department of Agriculture in Expanding the Consumption of Cotton, by G. B. Hill, A New Research Attack on the Cotton Problem, by H. G. Knight, The Technology of the Cottonseed Crushing Industry, by K. S. Markley and D. F. J. Lynch, The Place of Cotton in Farming Systems in Texas, by Type-of-Farming Areas, by B. H. Thibodeaux, and The Significance of Cotton Fiber Properties With Respect to Utilization, by R. W. Webb (all U. S. D. A.); Cotton in Relation to Other Textile Fibers, by M. Harris; The Tragic Plight of Cotton and Its Effect Upon the State and Nation, by E. J. Kyle (Tex. A. and M. Col.); Recent Trends in Cotton Finishing, by S. Lenher; Cottonseed Oil—A Typical American Industry, by J. F. Moloney; The Importance of Cotton in the American Economy, by P. Molyneux; Promoting Larger Uses of Cotton Products Through Merchandising Efforts, by C. T. Murchison; Industrial Research Activities of the National Cotton Council, by H. S. Olcott, D. M. Musser, R. F. Nickerson, and L. W. Bass; What About Our Texas Cotton Export Machinery? by R. Roggenbrod; Cotton Standardization in Relation to Yield, Quality, and Income, by J. M. Saunders; New and Expanded Uses for Cotton Lint Through Chemistry, Engineering, and Education, by E. P. Schoch and S. Williams; Changing Cotton Horizons, by V. H. Schoffelmayer; Purchase of Cotton From Growers Strictly on the Basis of Quality, by E. R. Torn; Interstate Trade Barriers and the Cotton Industry, by P. T. Truitt; and The Development of Uses of Cottonseed Feed Products, by A. L. Ward.

Profit from \$100 spent for cotton fertilizer, W. B. ANDREWS (*Mississippi Sta. Bul. 342 (1940), pp. 19, figs. 2*).—Experimental data on the effects of formulas and rates of fertilizers for cotton on profits obtained in the hill sections of Mississippi are given in detail for several agricultural areas and summarized. Recommendations based on the data and other available information are for limestone uplands 200 lb. each of ammonium sulfate and of superphosphate; Brown loam upland 600 lb. of 4-8-4; all other uplands 500 lb. of 6-8-4 or 450 lb. of 8-8-4; and silt and sandy loam first and second bottoms 600 lb. of 4-8-8 fertilizer. Modifications of the rates and formulas and of the suggested home mixtures are indicated for special conditions. Using 1,200 lb. per acre of 4-8-4 fertilizer, costing \$15.94 when factory mixed and \$12.64 when home mixed, was more profitable than 600, 1,800, or 2,400 lb. on all soils except the Brown loam upland on which 600 lb. was most profitable.

Comments are also made on methods of applying fertilizers, which depend on the rate per acre and the soil; the need of all soils for nitrogen but not necessarily the recommended quantity of phosphorus and potash; the effect of

depression years on the ratio of nitrogen, phosphorus, and potash applied; and the influence of fertilizers on the available lime, phosphorus, and potash in the soil.

Flax production in Georgia, R. P. BLEDSOE and G. D. THORNTON (*Georgia Sta. Cir. 123 (1940), pp. 7, fig. 1*).—Information on production practices for seed and fiber flax, recommended from cooperative experiments, 1937–40, is given on the adaptations of the spring- and fall-sown crop, soils and fertility needs, cultural and harvesting methods, varieties, production costs, and marketing. Although results with flax so far have been promising, the station indicates that the crop is still in the experimental stage in Georgia.

Relative efficiency of the two-dimensional quasi-factorial design as compared with a randomized-block arrangement when concerned with yields of Irish potatoes, E. L. LECLEGG and M. T. HENDERSON. (U. S. D. A. and La. Expt. Sta.). (*Amer. Potato Jour., 17 (1940), No. 10, pp. 279–282, fig. 1*).—The two-dimensional quasi-factorial design of Yates (E. S. R., 76, p. 26; 79, p. 469) for plat arrangement was found to be generally more efficient than a randomized block design when the tests contained 36 or more hypothetical varieties or strains of potatoes.

Twentieth annual report of the Nebraska Potato Improvement Association, edited by H. O. WERNER (*Nebr. Potato Impr. Assoc. Ann. Rpt., 20 (1939), pp. 56, figs. 3*).—Papers presented at the 1939 annual meeting at Gering, Nebr., included Potato Growing and Research in Central Europe, by O. Smith (pp. 13–23) (Cornell Univ.); Vital Methods for Producing Certified Seed Potatoes Under Irrigation, by M. Koehnke (pp. 24–28); Psyllids in 1938 and Outlook for 1939, by T. H. Hankins (pp. 33–35) (Univ. Nebr.); Bacterial Ring Rot of Potato Has Been Found in Nebraska, by J. H. Jensen (pp. 36–38) (Nebr. Expt. Sta.); and The 1938 Potato Season, by H. O. Werner (pp. 47–53).

Experiment with potatoes, F. S. PRINCE, P. T. BLOOD, W. H. COATES, and T. G. PHILLIPS (*New Hampshire Sta. Bul. 324 (1940), pp. 38, figs. 2*).—Potato experiments since 1928 on Worthington silt loam on Jackson farm near Colebrook and since 1933 on Paxton loam on Lane farm near Pittsfield, made in 3-yr. rotations of potatoes (receiving the fertilizers), oats, and hay, dealt with fertilizer and rotation problems. Prince, Blood, and Phillips report that, based on the standard treatment of 1 ton of 4-8-7 fertilizer per acre, omission of potash caused the greatest yield reduction, with phosphorus second and nitrogen third. Phosphorus, when doubled on Jackson farm, caused a greater yield increase than potash or nitrogen, which ranked in order, while on Lane farm stimulation from extra phosphorus and potash was nearly equal. Tests during the second 6 yr. on Jackson farm attribute more stimulation to fertilizer high in phosphorus than with high potash, although a significant increase came when both were doubled. Potatoes grown under high potash tended to be shorter and blockier, while high phosphorus reversed the trend, and this was accentuated by omission of potash. Certain varieties appeared more sensitive to phosphorus variations than others, which might influence the choice of the ratio.

Potatoes fertilized with 1 ton per acre of 4-8-7 fertilizer on Jackson farm averaged 386 bu., 0.5 ton 318, and 1.5 ton 431 bu., while on Lane farm 1 ton of fertilizer increased the acre yield 69 bu. over no fertilizer. Lime in conjunction with a fertilizer omitting potash had a depressing effect on yields. Double-strength fertilizer caused a definite increase in yield over single strength on Lane farm when equal amounts of plant food were provided. Banding fertilizer along the sides of the row gave a slight increase over broadcasting. Magnesium did not affect yields appreciably in either test, and on Jackson farm use of boron did not seem to be warranted. Yields of oats hay on Jackson farm

followed the fertilizer treatments, and yields of oats hay and other hay were influenced favorably by liming.

Fertilizers leaving a strong residual acid reaction failed to perform well on Jackson farm in increasing or maintaining yields, and potato foliage showed symptoms typical of magnesium hunger. On neither farm did lime show stimulation on the potato crops, although on Ireland farm near Greenland an increase in potato yields occurred after green manure of soybeans on limed plats.

That the 3-yr. rotations without organic manures failed to maintain the original organic matter level of the soil was reported by Coates. Jackson farm plats receiving high phosphorus treatment lost least organic carbon, while the loss after omission of phosphorus on Lane farm was more than double that after high phosphorus. Liming increased the organic carbon level on Lane farm and resulted in a smaller decrease than with other treatments on Jackson farm. Aluminum sulfate in equal amounts was slightly more effective than sulfur in reducing scab and changing soil reaction. Plowing under green manure or broadcasting ammonium sulfate to provide part or all of the fertilizer nitrogen is suggested as an economical remedy for overliming.

Quality studies on tubers, reported by Blood and Prince and involving specific gravity tests (E. S. R., 81, p. 864), indicated that fertilizers have had a slight effect upon quality, high phosphorus tending to increase and high potash to decrease the ratings. Wide inherent differences in quality ratings appeared to exist among varieties, some ranking high and others uniformly low. Potatoes well manured before harvest, and especially those grown without set-backs in midseason due to adverse weather, have exhibited high quality, indicating effects of other factors on ratings within a variety. Variations in ratings of tubers grown in the same hill are as yet unexplained.

Potato fertilizer and nutrition studies in 1939, O. SMITH. (Cornell Univ.). (*Amer. Potato Jour.*, 17 (1940), No. 10, pp. 262-275).—Results of investigations published in 1939 and late in 1938 on fertilizers, green manures, cover crops, rotations, soil fertility, soil reaction, and sand and solution culture studies with the potato are summarized, with a list of 79 titles.

The response of potatoes to different sources of nitrogen, phosphorus, and potash, T. R. COX and T. E. ODLAND. (R. I. Expt. Sta.). (*Amer. Potato Jour.*, 17 (1940), No. 5, pp. 105-113).—Potato yields for 1934 and 1939 on permanent plats receiving nitrogen for longer than 40 yr. were higher after ammonium sulfate than after sodium nitrate on well-limed plats, pH 6 or above, but did not differ much on acid (pH 5) plats. In order of yields, 1931-33, the ranking of phosphorus carriers was triple superphosphate, basic slag, superphosphate, ground bone, and rock phosphate. Yields were lower on plats receiving one-half the normal application of P_2O_5 in superphosphate. Increase in the rock phosphate application by one-half produced a yield increase averaging 12.7 percent on plats moderately limed but returned no consistent increase on well-limed soil. Of four potash carriers tested during 5 yr., best results came from potassium sulfate and the poorest from kainit. Potassium sulfate was slightly superior to the chloride, especially at a 200-lb. rate during 2 yr. However, the most economical source currently is high-grade chloride.

Sugar beet culture in Minnesota, J. O. CULBERTSON. (Coop. U. S. D. A. et al.). (*Minnesota Sta. Bul.* 349 (1940), pp. 24, figs. 8).—Cultural methods and field practices involved in producing sugar beets, varieties, fertilizers, soil and climatic needs, and byproducts are described for Minnesota growers.

Experiments at Waseca and other substations revealed progressive decline in yield with delay in planting from April 24 to June 3; higher yields from closer than from wider spacing, although 20×12 and 18×18 in. are more practicable

than closer spacing; increase in average tonnage, 1934-38, from 5.57 to 15.24 tons per acre and of sucrose content from 13.63 to 14.69 percent as stand density increased from 22.2 to 100 percent; and reduction in tonnage from 15 to 10.58 tons per acre and indicated available sucrose from 3,927 to 3,233 lb. per acre as thinning was delayed progressively from the 2- to 12-leaf stages. Evidence on fertilizers indicated that from 40 to 50 lb. of P_2O_5 per acre should be applied in the Red River Valley and from 30 to 40 lb. in southern Minnesota.

[**First, second, and third reports of the Tobacco Institute of Puerto Rico**] (*Tobacco Inst. Puerto Rico Ann. Rpts.*, 1 (1937), pp. 53, pl. 1, figs. 18; 2 [1938], pp. 36, figs. 15; 3 [1939], pp. 50, figs. 12).—Activities of the institute, centered at Rio Piedras, treated in the first and second reports by J. A. B. Nolla and in the third report by C. Esteva, Jr., included breeding work with tobacco varieties for quality, yield, and resistance to black shank, mosaic, and other diseases; interspecific hybridization; tests of varieties of cigar filler and wrapper and bright cigarette tobacco; studies of burning quality; flue- and sun-curing trials; green manure and fertilizer tests; comparison of priming v. stalk-cutting of filler strains; studies of the nicotine contents of the plants of varieties of *Nicotiana rustica* and of their leaves in different growth stages and of different Puerto Rican tobaccos; and comparative analyses of United States and Puerto Rican flue-cured tobaccos. The organization and objectives of the institute (pp. 7-17) and a review of the economic situation of the Puerto Rican tobacco industry, largely cigar filler (pp. 36-53), are set forth in the first report, and the facilities of the institute (pp. 12-20) are described in the third report.

Flue-cured tobacco fertilizer recommendations for 1941, C. B. WILLIAMS ET AL. (Coop. U. S. D. A. and 4 States). (*North Carolina Sta. Agron. Inform. Cir. 127 (1940)*, pp. [2]+3).—Fertilizer formulas, acre rates, and sources of plant food are recommended by the Agronomy Tobacco Work Conference held at Blacksburg, Va., August 8, 1940, for flue-cured tobacco and for plant beds on average soils in Virginia, North Carolina, South Carolina, Georgia, and Florida.

The effect of temperature and relative humidity, during and after curing, upon the quality of white Burley tobacco, R. N. JEFFREY (*Kentucky Sta. Bul. 407 (1940)*, pp. 353-383, figs. 6).—Experiments in curing Burley tobacco in air-conditioned chambers determined that good leaf can be cured at temperatures from 60° to 90° F. provided the relative humidity is about the optimum of 65 to 75 percent. Too high a relative humidity tended to produce darker tobacco, and Burley cured at too low a relative humidity often was mottled, with yellow areas predominant at medium temperatures, red areas at high temperatures, and a green cast or green spots, especially at low temperatures. A relative humidity of 77 percent appeared undesirable when held for as long as a week. Comparison of effects on quality of constant temperature and moisture conditions v. normal diurnal fluctuations showed that the conditions in the barn may be allowed to fluctuate between day and night provided the average conditions are near optimum. This decreases the expense of control. Split tobacco lost weight faster during curing than tobacco not split but tied to the sticks, but did not differ consistently in quality.

The curing chambers were also used to study effects of air conditions after curing, but before stripping, on the quality of the tobacco. Cured tobacco evidently should not be exposed to a relative humidity above 75 percent for longer than needed to bring the leaf into ease for stripping or damage may occur. The rate of damage increases rapidly as relative humidity rises. The moisture content of cured Burley rises slowly as the relative humidity is increased up to about 70 percent and at an increasing rate toward higher humidities. This phenomenon may be related to the optimum relative humidity for curing and the maximum safe relative humidity after curing. Temperature did not appear

to affect significantly the moisture content of the tobacco so long as the relative humidity remained constant. Although some decrease in pliability is noted at low temperatures, most of the difference in feel of tobacco results from change in relative humidity. It is stated that the feel of cured tobacco can be used satisfactorily in applying the results reported if one becomes accustomed to its relationship to relative humidity. Use of heat in a tobacco-curing barn as a means of reducing the relative humidity is deemed practicable because of the relationship between temperature and relative humidity and the wide optimum temperature range as compared with the narrow optimum humidity range.

Seed inspection in Kentucky, 1939-1940, W. A. PRICE, E. C. VAUGHN, E. DEEN, H. TILSON, A. MCDANIEL, K. FRIED, M. MORTON, and M. L. LITTELL (*Kentucky Sta. Regulat. Ser. Bul. 25 (1940), pp. 32*).—Purity and germination percentages and, when present, excessive quantities of noxious weed seed are reported for 553 official samples of agricultural seed obtained from dealers during the year ended June 30, 1940.

Variations in the dormancy of seeds of the wild oat, *Avena fatua*, E. H. TOOLE and F. A. COFFMAN. (U. S. D. A.). (*Jour. Amer. Soc. Agron., 32 (1940), No. 8, pp. 631-638*).—Individual plant samples of wild oats, collected in 10 localities in the western half of the United States, had an average germination of 13.8 percent in 14 days at 20° C. when tested at once and 64.5 percent when tested again from 9 to 11 mo. later. Marked differences were found in the proportions of dormant seeds of wild oats from different localities, and plants from any given locality varied widely in dormancy. Examination of plants from 6 localities for morphologic characters showed more variation in some localities than in others. Association between dormancy and morphologic characters was not evident.

The control of weeds, edited by R. O. WHYTE (*Imp. Bur. Pastures and Forage Crops [Aberystwyth], Herb. Pub. Ser. Bul. 27 (1940), pp. 168, pls. 26, figs. 9*).—This symposium on the prevention and eradication of weeds on agricultural land by cultural, chemical, and biological means comprises papers on Investigations Relating to Weed Control in Western Canada, by T. K. Pavlychenko (pp. 9-26) (22 refs.); Chemical Analyses as an Aid to Classification of Poisonous Plants, by R. H. F. Manske (p. 27); The Farm Weed Problem in America, by L. W. Kephart (pp. 28-37); Principles of Chemical Weed Control, by A. S. Crafts and R. N. Raynor (pp. 38-54) (55 refs.); Weed Control in Turf, by J. Monteith, Jr. (pp. 55-67); The Control of Weeds in Germany, by B. Rademacher (pp. 68-112) (49 refs.); Some Australian Weed Problems, by G. A. Currie (pp. 113-130) (17 refs.); The Biological Control of Prickly-Pear in Australia, by A. P. Dodd (pp. 131-143); Pasture Weeds, by E. B. Levy (pp. 144-152); Biological Control of Noxious Weeds of New Zealand, by D. Miller (pp. 153-157); and The Most Important Poisonous Plants of South Africa, by D. G. Steyn (pp. 158-162).

HORTICULTURE

[**Horticultural research by the Idaho Station**], C. A. MICHELS, G. W. WOODBURY, C. F. DIETZ, and L. VERNER (*Idaho Sta. Bul. 236 (1940), pp. 22, 24-27, fig. 1*).—Included are reports of projects relating to the development of new varieties of canning peas, comparison of fall and spring planting of onion bulbs, testing of head lettuce varieties, effect of calcium sprays in reducing cracking of sweet cherries, and the effect of indoleacetic and indolebutyric acids in widening the crotch angles of young fruit trees.

Chemicals in plant production, M. AFANASIEV. (Okla. A. and M. Col.). (*South. Florist and Nurseryman, 49 (1940), No. 26, pp. 26, 27*).—In studies involving potted plants (rooted cuttings and seedlings), repeated applications of

vitamin B₁ in concentrations of 0.01 mg. per liter had no beneficial effect either during the treatment period or in the 3 mo. following. In a second experiment treatment of small plants with vitamin B₁ during the transplanting operation gave evidence of a favorable effect on survival. In a third test with seed of 10 species of trees and shrubs there were indications of a beneficial influence of B₁ in speeding up germination, particularly of red cedar. Among other vitamins used, B₆ gave beneficial results in stimulating root formation of cuttings. American holly responded better to a mixture of indolebutyric and naphthaleneacetic acids than to either acid used alone. Subsequent treatment of cuttings with sugar, 1- to 5-percent solution, gave promising results. Callusing of cuttings before treatment with acid proved highly beneficial in at least one difficult species.

Responses of plant cuttings to treatment with naphthyl acids and their potassium salts in a talc carrier, N. H. GRACE (*Canad. Jour. Res.*, 18 (1940), No. 9, Sect. C, pp. 457-468).—Using a series of talc dusts containing indoleacetic acid and the acids and potassium salts of several members of the naphthyl series of root-stimulating substances, the author found that the higher members of the series compared favorably with naphthaleneacetic acid with respect to most of the responses considered. There were indications that naphthaleneacetic acid or its salt had a greater effect on the number of roots per rooted cutting. Talc alone substantially increased root development and the initiation of new growth by dormant cuttings.

Some effective methods of applying fertilizer, V. F. NETTLES. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 53 (1940), pp. 202-205).—Reviewing the results of experiments with various crops, the author suggests that the placement of fertilizer in bands at each side of and beneath the seed row has usually given better results than placing in the furrow row or broadcast. A comparison of three methods, (1) in the row 10 days before planting, (2) broadcast, and (3) in side bands, showed yields of 180, 176, and 203 bu., respectively, for snap beans. Comparable results were secured with cucumbers and peppers. There was some evidence that in dry or moderately dry periods mixing of fertilizer in the furrow row may reduce the stand and retard development.

The effect of common salt on the yield and composition of certain vegetable crops grown upon muck soil in Michigan, P. M. HARMER and E. J. BENNE. (Mich. State Col.). (*Amer. Chem. Soc. Mtg.*, 98 (1939), *Abs. Papers*, pp. 17F-19F).—Working largely on muck plats on the station farm at East Lansing, the authors found that table beets, celery, Swiss chard, mangels, and sugar beets were markedly benefited by applications of common salt. Turnips, celeriac, and radishes gave profitable increases, and cabbage, kale, and kohlrabi showed a slight improvement with salt. Asparagus, barley, carrots, lettuce, mint, oats, onions, parsnips, potatoes, spinach, and tomatoes were not benefited, and in certain cases were injured. Chemical analyses of the plants indicated that the amount of benefit that any given crop is likely to derive from salt treatment can be measured by the capacity of that crop to absorb large quantities of soda. Annual applications throughout a 7-yr. period produced no undesirable physical effects on the organic soil under study.

Rotation plantings to have year-round supply of "greens," L. R. FARISH (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 9, pp. 7, 8).—Information is presented on the growing of New Zealand spinach, Swiss chard, spinach, kale, mustard, tendergreens, and turnips to provide a succession of green leafy vegetables.

Winter green crops show response to nitrate dressing, L. R. FARISH (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 10, pp. 1, 8).—This is a brief

discussion of the fertility and soil needs of various leafy vegetables, such as spinach, mustard, and tendergreens.

Round Dutch variety, 800 to 1,200 pounds 6-8-4 fertilizer per acre, leads 1939-1940 cabbage tests, Truck Crops Branch Station, J. A. CAMPBELL (*Miss. Farm Res. [Mississippi Sta.], 3 (1940), No. 10, p. 8*).—Of 20 varieties and selections of round-headed cabbage set in the field on February 9 after passing the winter in coldframes, Round Dutch was the earliest-maturing kind that did not shoot prematurely to seed. Copenhagen Market, Golden Acre, and similar types produced a large percentage of bolters, with consequent low yields of marketable heads. A study of fertilizer treatments indicated that the most profitable quantity for cabbage lies between 1,000 and 1,500 lb. of a 4-8-4 mixture plus 200 lb. of nitrate of soda as a side dressing.

Chinese cabbage varieties, their classification, description, and culture in the central Great Plains, J. E. KRAUS (*U. S. Dept. Agr. Cir. 571 (1940), pp. 20, figs. 10*).—Based on a study of 30 varieties and strains grown over a period of 4 yr. at the Horticultural Field Station, Cheyenne, Wyo., a classification key is presented based principally on commercial characteristics, such as head shape and leaf formation. Seven variety groups are recognized, each represented by a distinct type variety. General directions are given for the culture of Chinese cabbage in areas with climatic conditions similar to those of Cheyenne. Methods of harvesting and storing, utilization, and the control of insect and disease pests are discussed.

Sweet corn hybrids, E. S. HABER (*Iowa Sta. Bul. P15, n. ser. 1940, pp. 433-468, figs. 10*).—Stating that not all hybrid sweet corns are adapted to all conditions, the author discusses the development of hybrid corn and describes a number of satisfactory hybrids bred by the station, other public agencies, and commercial firms. Hybrid corns have been found, in general, superior to open-pollinated kinds with respect to yield, uniformity in time of ripening, and uniformity in the size and type of ears. For 3 yr. planting from May 1 to June 15 produced no consistent difference in yields of early to midseason hybrids but June planting of late hybrids reduced yields. The time required to reach maturity is greater with early plantings of a single hybrid, and this fact should be considered by the canner to insure an orderly succession of prime canning ears for the factory.

Useful and ornamental gourds, W. R. BEATTIE (*U. S. Dept. Agr., Farmers' Bul. 1849 (1940), pp. [2]+14, figs. 8*).—Designed to supersede leaflet 36 (E. S. R., 61, p. 449), this paper presents general information relative to groups and varieties, culture, control of pests, the handling and utilization of the crop, and the ornamentation of gourds.

Progress report of tomato variety tests, F. P. ESHBAUGH. (Kans. Expt. Sta.). (*Kans. State Hort. Soc. Bien. Rpt., 45 (1938-39), pp. 159-163*).—Here are presented in tabular form with discussion the results of trials at the Fort Hays, Kans., Substation of a large number of varieties of tomatoes. Owing to blossom abscission in midseason, many of the better-known varieties were relatively valueless, and those which produced little foliage were subject to severe sunburn injury to the fruits.

Time involved in pollen tube extension through style and rate of fruit growth in tomato (*Lycopersicum esculentum* Mill.), W. P. JUDKINS. (Ohio State Univ.). (*Amer. Soc. Hort. Sci. Proc., 36 (1939), pp. 891-894, fig. 1*).—Observations on two lots of fall-grown greenhouse Globe plants, one grown at Wooster (where the temperature during September fluctuated from 65° to 90° F.) and the other at Columbus (where the temperature during October, November, and early December was controlled at about 70°), indicated that an appreciable

number of pollen tubes had penetrated to the ovary at the end of 24 hr. An increasing number of flowers developed into fruits when the styles were not removed until 48, 72, or 96 hr. after pollination. The time required for the pollen-tube growth appeared to increase during the fall and winter as light intensity decreased. This change was accompanied by a progressively lower viability of the pollen.

Production of tomatoes and other vegetables without pollination, F. S. HOWLETT. (Ohio Expt. Sta.). (*Veg. Growers Assoc. Amer. Ann. Rpt.*, 1939, pp. 139-145).—Comparing three treatments—self-pollination, emasculation and pollination, and emasculation followed by treatment with 2 percent indoleacetic acid in lanolin—the author secured the highest percentage of flowers to develop into fruits in the indoleacetic acid-treated lot. The fruits were, however, of small weight, and some showed surface lesions. Experiments with weaker concentrations (0.5, 0.1, and 0.02 percent in lanolin and with indolebutyric acid) showed that indolebutyric acid in a concentration of 0.5 percent produced larger fruits than were secured from self-pollination. There was practically no injury to the fruits. The indolebutyric acid fruits were more meaty and milder flavored and were preferred by some consumers to the softer and more acid fruits resulting from pollination.

Some work with eggplant and pepper showed that satisfactory fruits could be produced in these species with indoleacetic acid, but there were fewer fruits than were secured from self-pollination.

Effect of soil moisture on acid content of tomatoes.—A preliminary report, F. A. LEE and C. B. SAYRE. (N. Y. State Expt. Sta.). (*Food Res.*, 5 (1940), No. 1, pp. 69-72).—Fruits of John Baer, Marglobe, King Humbert, and Golden Queen, taken from plants grown in the greenhouse with abundant and with limited quantities of soil moisture, were affected in acidity by the moisture environment, with dry conditions tending to increase acidity. John Baer and Marglobe were less influenced by moisture than were King Humbert and Golden Queen. Golden Queen had the most acid fruits of the four varieties and was the most influenced by soil moisture changes.

The availability of replaceable potassium to tomatoes on a Sassafras sandy loam, J. B. HESTER and F. A. SHELTON (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 8, pp. 563-569, figs. 4).—The loss of potassium from a 6-in. column of topsoil of Sassafras sandy loam through 6 in. of subsoil is rather small on moderate applications of muriate of potash, even with very severe leaching. K in the acid subsoil was not readily drawn back into the topsoil in this experiment. Replaceable K in a Sassafras sandy loam was a good index of available K to tomatoes. K in the replaceable form appeared to be a more efficient source for tomatoes than muriate of potash when it was supplied in large amounts near the plant roots.

Inspection, certification, and transportation of nursery stock in Kentucky, with a brief report for the year ended June 30, 1940, W. A. PRICE and H. G. TILSON (*Kentucky Sta. Regulat. Ser. Bul.* 23 (1940), pp. 20).—In addition to information as to inspection activities, brief comments are presented with regard to the status of certain outstanding insect and disease pests.

Orchard cover crops: A study of the cost and yield of several varieties, F. P. BAEYERTZ (*Calif. Citrog.*, 25 (1940), No. 12, pp. 400, 401, 407).—Data are presented on the growth and yield of a large number of cover crops that are or could be used in California citrus orchards. The plants were grown in boxes to provide as comparable conditions as possible.

A loop method of dwarfing plants and inducing flowering, F. T. McLEAN (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 2, pp. 123-125, fig. 1).—By bending the slender stem of a sapling into a loop, with the tip pointing upward

and the base and top of the loop intertwined into a loose knot, the author succeeded in bringing a 2-year-old sweet cherry tree into flower. Apparently, looping checked vegetative growth and promoted flowering without interfering seriously with normal metabolism, such as would occur with root pruning or girdling. The chestnut, wistaria, apple, and hemlock were also treated with definite check in the vegetative development.

Combating fruit pests in Kansas, G. A. FILINGER (*Kansas Sta. Cir.* 199 (1940), pp. 45, figs. 21).—Revised to include recent developments (E. S. R., 69, p. 212), this paper contains information relative to various diseases and insects, comparative susceptibility of apple varieties to certain diseases, spray equipment, spray materials, spraying methods and schedules, rodent control, etc.

Comparative cold hardiness of scion roots from fifty apple varieties, N. W. STUART. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 330–334).—Based on the electrical conductivity of exosmosed electrolytes after freezing at 20° F., scion roots of some 50 varieties are arranged in descending order of hardiness. The top 5 varieties were Haralson, Virginia Crab, Milton, Yellow Transparent, and Hibernial, and the lowest 5 were Esopus Spitzenburg, Fallawater, Rhode Island Greening, Roxbury Russet, and Porter. French crab, the standard seedling rootstock, rated low in hardiness. When a temperature of 15° was employed, injury was severe to the roots of all 24 varieties tested. There was nearly twice as much injury at 17.5° as at 20°. In general, scion roots from varieties of recognized hardiness were also hardy.

Control of the pre-harvest drop of Crimson Beauty apples by spraying with plant hormones, D. S. BLAIR (*Canad. Hort. and Home Mag.*, 63 (1940), No. 8, *Growers' Ed.*, pp. 215, 216).—Using two commercial preparations, a 20-percent reduction in dropping was recorded by the Canadian Experimental Farms in tests in a large commercial orchard in Ontario. The author concludes that such sprays offer a practical means of reducing the preharvest drop in Crimson Beauty.

Maturity studies with sweet cherries, D. V. FISHER and J. E. BRITTON (*Sci. Agr.*, 20 (1940), No. 9, pp. 497–503, fig. 1).—As determined at Summerland, B. C., there was, in the 15 days preceding optimum picking maturity of Bing and Lambert cherries, a progressive change in skin color from light to dark red, an increase in the soluble solids of 3 percent, and an increase in weight of 37 percent. There was a close correlation between soluble solids content as measured by the Zeiss refractometer and quality. The size of crop, vigor of the tree, and seasonal conditions all influenced soluble solids content. Skin color was found a reliable index to optimum picking maturity of Bing and Lambert cherries. Skin color and soluble solids were closely correlated in Bing but not so consistently in Lambert. Fruit picked at optimum maturity kept firm and bright in common storage, whereas immature fruits tended to shrivel. A color chart was prepared for the several varieties.

Transplanting shock in peach seedling rootstocks and its effects on size of nursery and orchard trees, W. H. UPSHALL (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 340–342).—Comparing two methods of handling peach seedlings, (1) thinning in the seed row, and (2) transplanting to the nursery row, the author found that in 3 years' trials transplanting caused a very marked depression of growth. At budding time, the transplanted seedlings were smaller and resulted in smaller-sized trees for sale. The fact that size differences tended to disappear following planting in the orchard is explained, in part, by the greater amount of wood removed from the larger trees during pruning. The harmful effects of the early transplanting treatment were more serious on poorer-quality soils.

Growth and development of the embryo and fruit of the peach as affected by ringing and defoliation of the branches, H. B. TUKEY and F. A. LEE. (N. Y. State Expt. Sta.). (*Bot. Gaz.*, 101 (1940), No. 4, pp. 818-838, figs. 4).—Using two varieties—Elberta and Ward Late—with 128 and 142 days from full bloom maturity, respectively, the authors followed the development and chemical changes in twigs, fleshy pericarp, stony pericarp, integuments, nucellus, endosperm, and embryo of fruits on ringed and defoliated branches. Apparently it was possible for an appreciable quantity of some of the substances which comprise the embryo to be derived from the fruit. Under ordinary conditions materials apparently move into both the fruit and the embryo in sufficient amounts to supply the embryo, but when the supply is limited, as by ringing and defoliation, the materials evidently move from the fruit into the embryo. Such a situation may occur in trees of low vigor or those heavily loaded with fruit, with a resulting crop of immature, low-quality fruit.

Maturity and storage studies with peaches, D. V. FISHER and J. E. BRITTON (*Sci. Agr.*, 21 (1940), No. 1, pp. 1-17).—Working with three yellow-fleshed freestone varieties—Rochester, Vedette, and Veteran—the authors found that during the week preceding optimum harvesting maturity the fruits increased in volume from 20 to 40 percent. In addition, there was a change in shape with progressing maturity. Cheek diameter increased more rapidly than did diameter across the suture, thus giving the fruits a more rounded form. Peaches satisfactory for shipment as fresh fruit were rounded in shape, showed yellow shades of skin color, orange-yellow flesh, and a firmness of about 20 lb., as measured by the Ballauf pressure tester. Increase in soluble solids, as measured by the Zeiss refractometer, was not a satisfactory maturity index. The onset of meakiness limited the storage of peaches, becoming evident in most varieties in fruit removed to 65° F. after from 1 to 2 weeks at 40° and after from 2 to 3 weeks at 32°. Delay of from 1 to 2 days at 75° prior to cold storage did not appreciably affect storage life and did improve ultimate quality and juiciness. There was little difference in the duration of good condition after storage in peaches held at 32° or 40°. Peaches held at 65° after picking kept from 10 to 19 days when mature and from 13 to 31 days when harvested in the medium-mature stage. The use of modified atmospheres containing increased carbon dioxide gave discouraging results.

Experience shows raspberries and other brambles should be covered for winter, G. BEACH (*Colo. Farm Bul.* [*Colorado Sta.*], 2 (1940), No. 4, p. 11).—Observing that uncovered raspberries survive Colorado winters without severe injury on an average of only 1 yr. out of 5, the author discusses methods of protection and suggests that proper fertilization will also aid in reducing winter damage.

Cranberry growing in Massachusetts, H. J. FRANKLIN (*Massachusetts Sta. Bul.* 371 (1940), pp. 44, figs. 40).—This comprehensive and well-illustrated paper contains information on production; growth and fruiting habits of the plant; location and preparation of the bogs; drainage; provisions for and the effects of flooding; sanding operations; varieties; control of insect, fungus, and weed pests; harvesting; preparation of fruit for market; marketing and storage; etc.

Recent results of weed control experimentation, C. E. CROSS. (Mass. Expt. Sta.). (*Cranberries*, 5 (1940), Nos. 3, pp. 8, 9; 4, p. 5).—The effects of kerosene, ferric sulfate, ferrous sulfate, common salt, ocean water, sodium arsenate, copper sulfate, and sodium chlorate on different species of weeds occurring in cranberry bogs are discussed, with information as to concentrations, time of application, effect on the cranberry vines, etc.

Many casualties in 5-year test of grape varieties—a few are chosen, C. H. RAGLAND (*Miss. Farm. Res.* [*Mississippi Sta.*], 3 (1940), No. 10, p. 1).—A record

is presented upon the performance of a collection of 60 varieties of grapes planted in the spring of 1936. The outstanding varieties with respect to vigorous growth were Champanel, Lukfata, Muench, Salamander, Lenoir, Marguerite, Lomanto, and R. W. Munson. Of these, Muench, Salamander, and R. W. Munson had the best eating quality. Some 28 kinds died out completely.

Somatic mutation in the vinifera grape.—III, The Seedless Emperor, H. P. OLMO. (Univ. Calif.). (*Jour. Hered.*, 31 (1940), No. 5, pp. 210-213, figs. 2).—Continuing these studies (E. S. R., 76, p. 480), the author points out the scarcity of seedless varieties of grapes and describes a seedless form of Emperor discovered in November 1928 in a commercial vineyard near Visalia, Calif. Up to the present, there have been propagated three clonal generations without any evidence of reversion to the seeded form. A microscopic examination of the ovules revealed the presence of some normal embryo sacs and no degeneration of the nuclei. The pollen of the seedless mutation was as viable as that of the normal form.

Observations on the January 1940 cold injury to tropical and subtropical plants, S. J. LYNCH. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 53 (1940), pp. 192-194).—Records taken following the severe freeze of 1940 showed the Mexican race of avocado to be hardier than the Guatemalan and West Indian races and hybrids. Very little difference in hardiness was noted among mango varieties. The most tender of the tropical fruits under observation were the cashew nut and the Malay apple. The behavior of a large number of species is recorded.

Fertilizer studies with avocados, H. S. WOLFE and S. J. LYNCH. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 53 (1940), pp. 147-149).—In three of four varieties included in the experiment there was an increase in production with an increase in the percentage of N from organic sources up to 66 percent. The undesirability of providing all the N for avocados from organic materials was indicated. In other plots, doubling the N of the fertilizer produced no material increase above the basic treatment. On the other hand, supplemental applications of N at intervals did greatly increase yields of three varieties. An application of Mn proved beneficial in only one of four varieties.

Some preliminary studies of transpiration and carbon assimilation in cacao, D. B. MURRAY (*Trop. Agr. [Trinidad]*, 17 (1940), No. 9, pp. 166-168, pls. 2).—Using the cobalt chloride paper method, but confirming the results by weighing, the author found that the leaf in the field loses water approximately two to five times as rapidly from the lower as from the upper surface. Stomata were found only on the lower surface. Under shade conditions, apparent carbon dioxide assimilation rose rapidly in the morning to a level which was maintained until about 4 p. m., when it declined rapidly. Transpiration rose gradually through the morning to a maximum just after midday. Under full sun, apparent assimilation started at a high level and fell off rapidly between 10 and 11 a. m., and continued at a low level until 3 p. m., when a slight recovery occurred. Transpiration reached a maximum far earlier in the day and was then more than twice that occurring under shade.

A note on the maturation period of cacao pods in Grenada, S. C. COOPER (*Trop. Agr. [Trinidad]*, 17 (1940), No. 9, p. 165).—Records taken on individual pods on trees at 200, 400, and 700 ft. elevations showed that the ripening period of the cacao pod in Grenada ranges between 5 and 6 mo. The months of greatest increment in length and circumference appeared to be the second and third after fertilization, respectively. A lack of seasonal effect on the length of the maturation period was noted.

Quarter century changes in citrus cultural practices, H. J. WEBBER. (Calif. Citrus Expt. Sta.). (*Calif. Citrog.*, 25 (1940), No. 12, pp. 382, 383, 402-405,

figs. 4).—A comprehensive analysis is presented of progress and developments in citriculture, particularly with reference to experimental work.

Preliminary reports on varieties and other factors as influencing cold resistance in citrus, W. W. LAWLESS and A. F. CAMP. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 53 (1940), pp. 120–125, *figs. 3*).—Observations in the station orchards at Lake Alfred indicated that citrus trees withstood the severe temperatures of the 1940 winter better than the less severe temperatures of 1927 and 1934. The increased resistance is attributed particularly to a greater degree of dormancy and also to better condition of the trees as a result of improved fertilizer practices. Rootstocks were also factors in the degree in which they influenced vigor. Among citrus, tangerines were most resistant, followed by Marsh Seedless grapefruit. Pineapple orange suffered more than any other orange or grapefruit. Trees receiving Cu and Mg or, better still, a combination of Cu, Zn, Mg, and Mn had manifestly more resistance to cold than those on a simple NPK treatment. Any deficiency is conceded likely to predispose trees to cold injury, with deficiencies of Cu and Mg of major importance.

Relation of pH to growth in citrus, A. R. C. HAAS. (Calif. Citrus Expt. Sta.). (*Plant Physiol.*, 15 (1940), No. 3, pp. 377–407, *figs. 10*).—The growth of citrus and other subtropical trees in solution cultures was found to be influenced by the pH of the medium. Although tolerating a rather wide range of pH values, the trees made more vigorous growth in acid than in alkaline solutions. When pH was determined accurately, the results obtained with soil and with solution cultures agreed very well with those obtained in the orchard. The author concludes that although trees in California are grown in the field under an irrigated agriculture, they are growing primarily in acid rather than in alkaline mediums and that the acidity of the medium is far greater than assumed previously.

Some effects of soils and fertilizers on fruit composition, B. R. FUDGE and G. B. FEHMERLING. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 53 (1940), pp. 38–46).—Comparing the composition of the fruit of four varieties of citrus grown on sour orange and rough lemon rootstocks, the authors observed that sour orange had consistently produced fruit of higher citric acid, soluble solids, and sugar contents. Differences in skin thickness, specific gravity, and percentage of juice were not significant. Fruit from trees on heavy hammock soils was higher in percentage of juice and total sugars, and lower in percentage of citric acid, than that from trees on light Norfolk soil. The application of certain amendments to trees which had, for about 18 yr., received a so-called complete fertilizer but which were showing deficiencies brought about a marked improvement in composition and quality of the fruit. This was noticed when Cu and Mg compounds supplemented the basic fertilizer in the soil, but where Cu, Zn, Mn, and Mg were all used, either as sprays or soil treatments, the fruit was outstanding with respect to skin color, flavor, and texture and possessed the lowest pH and the highest citric acid, solids, sugars, and vitamin C contents. All three factors—rootstocks, soil, and fertilizer treatment—were involved in the production of high-quality fruit.

Fertilizing citrus trees—tests with Washington navel oranges, J. L. PROVAN and C. E. COLE (*Jour. Dept. Agr. Victoria*, 38 (1940), No. 7, pp. 312–314, 350, *figs. 4*).—Utilizing a commercial grove of 22-year-old Washington navel oranges on rough lemon stock, the authors compared sulfate of ammonia with the same material plus superphosphate and plus superphosphate and sulfate of potash. The results indicated that N was the only effective element, with the trees receiving N alone or combined averaging 445 lb. of fruit in 1938, as com-

pared with 317 lb. for the unmanured controls. No significant differences in the quality of the fruit were recorded.

Progress of granulation of Valencia oranges after picking, J. R. MacRILL (*Calif. Citrog.*, 25 (1940), No. 12, p. 386, fig. 1).—Internal examination of oranges stored under various controlled environments showed a definite increase in the amount and degree of severity of granulation during storage. The most rapid rate of progression in granulation occurred in the blossom halves of fruits. In a later experiment the results of the cutting tests were confirmed by a series of X-ray photographs taken on stored fruits.

Rootstocks for tangelos and other citrus hybrids; and fruit seed content, T. R. ROBINSON. (U. S. D. A.). (*Fla. State Hort. Soc. Proc.*, 53 (1940), pp. 195-199).—Records taken on a 9-year-old planting of tangelo varieties budded in alternate rows on sour orange and Cleopatra rootstocks showed the trees on Cleopatra to be generally the larger, in some cases nearly twice the size of those on sour orange. An examination of the roots showed Cleopatra rootstocks to have a deep taproot and an abundance of crown roots with numerous fibrous roots. Both groups commenced bearing at about the same age, but with yields in favor of the Cleopatra-rooted trees. Rootstock effects were even more pronounced with certain other citrus hybrids, particularly those involving the lime or the kumquat as one parent.

As to quality, fruits produced on Cleopatra rootstocks at least equaled those of the trees on sour orange. There was little difference in size, color, and time of maturity, and no consistent differences in seed content could be attributed to rootstocks. However, when planted in solid blocks, certain of the tangelos were much less seedy than when interplanted with other types of citrus, especially those of the seedy character.

The Pearl tangelo—a new citrus variety, H. B. FROST. (*Calif. Citrus Expt. Sta.*). (*Calif. Citrog.*, 25 (1940), No. 11, p. 346, fig. 1).—A description is presented of a promising tangelo produced by the pollination of the Imperial grapefruit by the Willow Leaf mandarin.

Existence of only one variety of cultivated mangosteen explained by asexually formed "seed," C. L. HORN. (P. R. Expt. Sta.). (*Science*, 92 (1940), No. 2385, pp. 237, 238).—A study of the flowers of two 37-year-old trees growing at Mayaguez, P. R., showed no pollen to be present despite the fact that about half of the fruits had well-developed seeds. Seed formation was evidently asexual, and apparently differed from the nucellar budding observed in mango and citrus fruits. Since descriptions of mangosteen fruits from Java, Malaya, Trinidad, and elsewhere conform precisely with those of the Puerto Rican fruits, the author is convinced that different varieties of this fruit do not exist.

Intermittent light and the flowering of gladiolus and carnation, J. M. ARTHUR and E. K. HARVILL (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 2, pp. 93-103, fig. 1).—Continuing the study (E. S. R., 80, p. 773), the authors report that gladiolus varieties were brought into flower under intermittent light from 500-w. Mazda lamps and that flowering was much more regular than under 200-w. lamps operated continuously for 6 hr. each night. It is believed that the failure to flower under continuous light was due mainly to injury from the intensity of heating rather than to the low intensity of light. This assumption was supported by the fact that mercury lamps furnishing about the same intensity of light as the 200-w. Mazdas, but developing less heat, did not inhibit flowering. Night temperatures averaged about 65° F. under the 200-w. Mazdas, as compared with from 55° to 60° in the house under intermittent light. New corm production proceeded under both short- and long-day conditions, but the

plants did not flower under short-day conditions. Carnations flowered well under intermittent light thermostatically controlled.

Hybrids resulting from controlled pollination of *Lilium sulphureum* with *L. henryi* pollen, N. E. PFEIFFER (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 4, pp. 305-308, figs. 2).—Descriptions are presented of three lilies obtained by crossing *L. sulphureum* with pollen of *L. henryi*. The three plants varied, but all showed definitely the characters of the two parents.

A new race of lily hybrids, A. C. and F. T. McLEAN (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 2, pp. 119-121, fig. 1).—A brief description is given of seedlings resulting from crossing *Lilium tigrinum* and two hybrids of *L. umbellatum* and *L. elegans*. The plants resembled the *L. umbellatum* parent in foliage and growth, but all bore brownish stem bulbils like those of the tiger lily parent. The blooms were intermediate in character.

Continued rose research at Cornell, R. C. ALLEN. (Cornell Univ.). (*Amer. Rose Ann.*, 1940, pp. 63-68).—Of various organic materials incorporated in clay soil, imported peat moss—1:1 of soil—gave the best results in numbers of flowers and in growth. The indications were that a smaller percentage of peat moss would have been equally effective as the amount used. Where five soils were used, namely, gravelly loam, heavy clay, medium clay, muck, and fine sandy silt loam, the addition of peat moss gave good results with all except the last. The poor results with sandy soil are attributed to nitrate depression by the decomposing peat. No difference could be noted whether the roses were planted with the graft unions level with, 4 in. below, or 2 in. above the soil level. Plants not pruned except to remove dead blooms yielded the most flowers, but cutting to the second vegetative bud gave better roses with longer stems.

Texas experimental work, J. C. RATSEK. (Tex. Expt. Sta.). (*Amer. Rose Ann.*, 1940, pp. 114-118).—Herein are discussed the use of fertilizers, value of different understocks, rose breeding, storage of rose plants, and acidification of alkaline soils.

Rosa multiflora and its progeny, C. D. PARIS and T. J. MANEY. (Iowa Expt. Sta.). (*Iowa Acad. Sci. Proc.*, 46 (1939), pp. 149-160).—Stating that *R. multiflora*, introduced into England from Japan in 1781, has played an important part in the production of cultivated roses, the authors present in tabular form a list of varieties that trace back to *R. multiflora* in their parentage.

Progress in thornless roses, N. E. HANSEN. (S. Dak. State Col.) (*Amer. Rose Ann.*, 1940, pp. 79-82).—A brief statement of progress describes five new varieties—Lillian Gibson, Pax Amanda, Pax Apollo, Pax Iola, and Yawa—which are nearly or completely thornless.

Where do the rose roots go? R. C. ALLEN. (Cornell Univ.). (*Amer. Rose Ann.*, 1940, pp. 68-73, fig. 1).—During the third season of growth, Radiance plants on Chenault Multiflora roots were washed carefully from the soil. A total of 43 percent of the roots were below the 16-in. depth, and 3 percent were below the 4-ft. level. The maximum lateral spread from the stem axis outward was 42 in. The data suggest, in part, the reasons for the benefits of deep preparation of the soil. That the top variety influences the understock was shown in 361 roots for Talisman and 193 for Radiance, both grown on Odorata roots.

The rose watering problem, R. C. ALLEN. (Cornell Univ.). (*Amer. Rose Ann.*, 1940, pp. 73-76).—Observing that a vigorous Radiance rose plant may use as much as 30 gal. of water per season in transpiration and that natural precipitation at Ithaca, N. Y., may fail to meet this need, the author supplied plants of five hybrid tea roses with 0, 3, and 8 in. of supplemental water per week. The maximum yield of blooms and greatest growth in inches were recorded on the 3-inch-water plants. The porous-hose method of irrigation proved highly promising.

Ethylene injury to cut flowers in cold storage rooms, D. V. LUMSDEN, R. C. WRIGHT, T. M. WHITEMAN, and J. W. BYRNES. (U. S. D. A.). (*Science*, 92 (1940), No. 2385, pp. 243, 244).—Working with carnations, roses, snapdragons, stocks, and narcissus, the authors found that at 36°, 50°, and 70° F. blooms held in atmospheres free of fruit and of ethylene kept longer than those exposed to these substances. The higher the temperature, the more pronounced was the effect of the gas. The effects on the several species are described. A storage temperature between 33° and 36° was found most effective for carnations.

Holly defoliation prevented by α -naphthaleneacetic acid, J. A. MILBRATH and H. HARTMAN. (Oreg. Expt. Sta.). (*Science*, 92 (1940), No. 2392, p. 401).—Prior to exposure to ethylene gas derived from apples, branches of holly (*Ilex aquifolium*) were sprayed with solutions of α -naphthaleneacetic acid and with water as a check. Despite the presence of free water in the jars, in 48 hr. the holly sprayed with water alone was completely defoliated. Holly sprayed with 0.005 percent of naphthaleneacetic acid did not begin to lose leaves until after 8 days, and that sprayed with 0.01 percent never did shed its leaves, even after blackening.

Effects of dusts containing indolylbutyric acid and oestrone on the rooting of dormant *Lonicera tartarica* cuttings, N. H. GRACE (*Canad. Jour. Res.*, 18 (1940), No. 7, Sect. C, pp. 283–288).—In applications of indolebutyric acid and oestrone, used separately or in combination, the indolebutyric acid increased the number of cuttings rooted, the number and length of roots per cutting, and the mean root length. The average effect of oestrone was generally depressive, with a tendency to offset the beneficial effects of the indolebutyric acid except in the combination of 100 p. p. m. of each, where root length was increased. The number and length of roots and green weight of leaf produced were more sensitive responses for determining the desirable concentration of indolebutyric acid in talc than was the percentage of cuttings to root.

FORESTRY

Disturbance of forest soil resulting from the uprooting of trees, H. J. LUTZ (*Yale Univ. School Forestry Bul.* 45 (1940), pp. [4]+37, pls. 7).—In investigations conducted in or near the Yale Forest near Keene, N. H., and in the Gale River Experimental Forest near Pierce Bridge, N. H., it was observed that the uprooting of trees may result in the mixing of the soil from the upper and lower horizons, usually in a most irregular manner. Measurements of maximum surface soil temperatures on mounds comparable to those caused by uprooting showed significant differences where different slope exposures were compared. The mean maxima were highest on the south, followed in decreasing order by west, level, east, and north positions. These differences influenced the establishment of seedlings. Pore volume in the upper 10 cm. of disturbed soil was significantly higher than that of undisturbed soil. Air capacity of disturbed soil was significantly higher than that of the undisturbed, but no significant difference with respect to water-holding capacity could be established. The rate of infiltration of water into the soil of the mounds was greater than that into undisturbed soil. The surface soil of the mounds tended to be coarser in texture than that of undisturbed areas, with a significantly greater content of particles larger than 1 mm. in diameter. The H-ion concentration of soil from mounds was significantly less than in undisturbed soil, but no differences could be established with respect to exchangeable hydrogen, content of exchangeable bases, or total exchange capacity.

A comparison of forest floors from plantations of the same age and environment, J. KITTREDGE (*Jour. Forestry*, 38 (1940), No. 9, pp. 729–731).—

A study of samples of the forest floor collected from plantations of eight species, all 30 yr. old in 1939 and located east of the campus of the University of California, showed the different species to have had a profound effect. The greatest quantity of forest floor, 24.3 metric tons per acre, was found beneath Monterey pine, followed in descending order by maritime pine, Canary pine, Douglas fir, Monterey cypress, redwood, madrone, and Christmasberry. The differences between species were statistically significant except for Canary pine, Douglas fir, Monterey cypress, and redwood. Species growing naturally on the area tended to have less forest floor than those brought in from distant localities. The annual accumulation of litter was still increasing at the end of the 30-yr. period.

Infiltration capacity of forest soil as influenced by litter, W. M. JOHNSON. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 6, p. 520).—On 12 plats established in each of 3 locations in central Colorado, 6 of each series were left undisturbed. From those remaining, litter and duff were removed by hand with a minimum disturbance of the soil. Water was applied by a sprinkler to all plats until an infiltration rate essentially constant for 15 min. was attained. The average infiltration capacity on the 18 plats where the litter was undisturbed was 1.52 ± 0.16 in. and on the 18 bared plats 0.92 ± 0.10 in. An analysis of measurements of the thickness of the duff, humus, transition layer, and A₂ horizon led to the conclusion that the thickness of the transition layer is the only factor having a significant effect on infiltration. The importance of function of litter in reducing run-off was demonstrated.

Growth substances of doubtful benefit for treatment of pine seeds, R. H. GRUENHAGEN. (Wis. Expt. Sta.). (*Jour. Forestry*, 38 (1940), No. 9, pp. 739, 740).—The treatment of red pine and white pine seeds with talc dust impregnated with known amounts of naphthalenepropionic and indole-3-acetic acids proved of no material value in seed disinfection or in promoting higher germination. Treatments with different concentrations of indole-3-acetic acid in liquid form also proved of no value in increasing germination of the seed of the two pines.

Note on direct seeding in the southeastern Piedmont region, W. E. McQUILKIN. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 9, pp. 734, 735).—Direct seeding studies by the Appalachian Forest Experiment Station in the Piedmont area included loblolly, shortleaf, and Virginia pines, seeded in fall and spring on badly eroded abandoned farm land and on moderately eroded soil supporting a broomsedge cover. The results at the end of the first growing season were promising, but it was too early to draw conclusions.

Increased growth of longleaf pine seed trees at Urania, La., after release cutting, H. H. CHAPMAN and R. BULCHIS (*Jour. Forestry*, 38 (1940), No. 9, pp. 722-726, figs. 3).—Measurements and observations taken in an area which during the period 1901-6 was clear-cut, leaving only a few trees which were of no immediate value for lumber, led to the suggestion that the final cutting of a mature stand of longleaf pine should be heavy, leaving large openings with from four to six well-formed seed trees with crowns averaging 40 ft. in length to each acre. The seed trees may be expected to retard reproduction beneath them, but should during a 40-yr. period develop sufficiently to return a profit in high-grade sawlogs. After 40 yr., the reproduction would be old enough to seed in the blanks left by cutting the old seed trees. The leaving of a few seed trees accomplishes the dual objective, regeneration and the production of some salable lumber.

Control of sprouting from white oak stumps, P. N. JOHANSON and J. G. KUENZEL. (Univ. Calif. and U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 9, pp. 735-737, figs. 2).—Some evidence was secured in southeastern Iowa that covering oak stumps after cutting with slash to a depth of from 1 to 2 ft. would

limit the number of sprouts. A reduction in the number of stimulated dormant buds plus death of etiolated shoots may be the factors responsible for the reduction. Greater depth of slash may become detrimental.

The Kimball maple, E. S. HARRAR (*Jour. Forestry*, 38 (1940), No. 9, pp. 726-728, fig. 1).—A technical description is presented of the Kimball maple, said to be a comparatively rare variety of *Acer macrophyllum*, the bigleaf maple of the Pacific coast. The Kimball maple is readily distinguished from the parental type by its dissected, tropical-like leaves.

Trends of tree migration in Kansas, F. C. GATES. (Kans. State Col.). (*Kans. Acad. Sci. Trans.*, 42 (1939), pp. 127-132, pls. 3).—Stating that over half of the tree species of Kansas show no extension of range during the past 30 to 35 yr., the author cites 3 examples of northward movement. Migration eastward was noted in about 9 species. Some 31 species had made progress westward, moving against the prevailing wind and stream flow. This anomalous situation is ascribed, in part, to the decrease in prairie fires. No cases of real southward migration were reported.

Farm woodlot management in Kansas, L. F. SMITH (*Kansas Sta. Cir.* 201 (1940), pp. 28, figs. 11).—This presentation of general information includes the extent and condition of Kansas woodlots; the growing of new woodlots; sources of planting stock; planting methods; pruning; species; improvement of existing woodlots; protection from overgrazing, fire, and insect, disease, and animal pests; harvesting; mensuration; preservative treatments for timber; etc.

Trees for Washington farms, J. P. NAGLE and E. H. STEFFEN (*Washington Sta. Pop. Bul.* 159 (1940), pp. 48, figs. 23).—General information is presented with respect to the principles underlying the successful establishment and maintenance of tree plantings in the State with particular reference to such items as adaptable species, water requirements, methods of planting, planning of windbreaks, management of farm woodlots, use of trees in combating erosion, and description of species.

The Appalachian fuel moisture scale, G. M. BYRAM. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 6, pp. 493-495, figs. 3).—The author describes a scale for weighing moisture-indicator sticks, which has the advantage of reading directly in terms of wood-stick moisture and eliminates the need of dry sticks weighing exactly 100 gm.

Stumpage and log prices for the calendar year 1938, H. B. STEER (*U. S. Dept. Agr., Statis. Bul.* 71 (1940), pp. 63, figs. 3).—This tabulation of data is presented in the usual manner (E. S. R., 81, p. 47).

DISEASES OF PLANTS

The scientific principles of plant protection, with special reference to chemical control, H. MARTIN (*London: Edward Arnold & Co.*, [1940, 3. ed.], pp. X+385).—The author's stated objects in this edition (E. S. R., 77, p. 793) have been to present to the mycologist and entomologist a detailed survey of the physicochemical factors, to provide the chemist and physicist with means of approach to the biological side, and to supply a book of reference on insecticides and fungicides. Chapters on resistance, environal influences, biological control, weed killers, and the treatment of centers and vectors of infection are also included.

[Papers on phytopathology] (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 332-335).—Abstracts are included on A Regional Study of the Relationship of Potash Treatments to the Development of Cotton Wilt Under Widely Varying Conditions of Soil and Environment, by A. L. Smith (Ga. Expt. Sta. coop. U. S. D. A.); The Development of Wilt in a Wilt-Resistant and in a Wilt-Susceptible Variety of Cotton as Affected by N-P-K Ratio in Fertilizer, by H. B. Tisdale and J. B. Dick

(Ala. Sta. and U. S. D. A.); and A Summary of Recent Seed Treatment Investigations by the Cotton Seedling Disease Committee, by D. C. Neal (U. S. D. A. and La. Sta.).

The Plant Disease Reporter, [November 1 and 15, 1940] (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 24 (1940), Nos. 20, pp. 399-432, figs. 4; 21, pp. 433-450, figs. 5).—These items of interest to phytopathology are included.

No. 20.—Host-parasite check list revision, from *Caesalpinia* to *Carpinus*, by F. Weiss; fruit and vegetable diseases on the Chicago market in 1939, by G. B. Ramsey; incidence of ear rots in the 1939 corn crop, by N. E. Stevens; a survey of cotton boll rot diseases in 1940 and the micro-organisms connected with them, by P. R. Miller and R. Weindling; *Verticillium albo-atrum* wilt of cotton in Texas, by G. E. Altstatt; some hosts of *Verticillium* in California, by K. F. Baker, W. C. Snyder, and H. N. Hansen; two unusual ornamental diseases—wilt of smoke tree due to *Verticillium*, and *Septoria cornicola* leaf spot of flowering dogwood, by T. R. Bender; a dying of beech near Philadelphia, associated with *Phomopsis* sp., by J. M. Walter and C. May; *Fusarium* ripe rot of melons in Connecticut, not associated with *Fusarium* wilt, and some aspects of defoliation of tomatoes in 1940 in Connecticut, both by J. G. Horsfall, J. W. Heuberger, and A. D. McDonnell; blackberry dwarf in boysenberries and youngberries, by S. M. Zeller and J. A. Milbrath; leaf variegation or June yellows appearing in the Bellmar strawberry, by G. M. Darrow and J. B. Demaree; rusts on small grains in Oklahoma, by K. S. Chester; and brief notes on *Sclerotium rolfsii* on flax in Texas and *Alternaria* stem canker of *Antirrhinum*.

No. 21.—Cotton diseases in Texas in 1939, by W. N. Ezekiel and A. A. Dunlap; potato ring rot in Washington, by G. A. Huber; nut diseases in the Pacific Northwest in 1940, by P. W. Miller; brief notes on dahlia smut (*Entyloma dahliae*) on the Oregon coast, powdery and downy mildews on cucurbits in New York, and charcoal rot (*Sclerotium bataticola*) causing damage to sorghum in Nebraska; and host-parasite check list revision for the genus *Carya*, by F. Weiss.

Plant diseases. (Partly coop. U. S. D. A.). (*Idaho Sta. Bul.* 236 (1940), pp. 49-53, 60, 61, fig. 1).—Brief reports are given (by J. M. Raeder, E. C. Blodgett, D. M. Murphy, W. Virgin, and W. Bever) on studies of the reactions of potato seedlings to viruses, and potato seed treatment (pp. 49, 60, 61); leaf spot of Italian Prune plum; leaf injuries to peach by spray residues, wart disease, and leaf spot due to *Coryneum*; borax treatments of apple trees for drought spot and corky core; development of disease-resistant beans; breeding peas for near-wilt resistance, pea seed treatment, and bacteria causing poor germination; wild tomato resistant to curly top virus; Klondike R-7 watermelon found resistant to wilt in Idaho; physiologic races of wheat bunt and covered smut fungi of barley; and *Rhabdospora* parasitizing bindweed.

Preliminary list of plant diseases in the State of Espirito Santo, Brazil [trans. title], S. GONÇALVES DA SILVA (*Bol. Min. Agr. [Brazil]*, 28 (1939), No. 10-12, pp. 13-24; *Eng. abs.*, p. 24).—A list of diseases and pathogens observed by the Plant Protection Service, 1937-38.

Contributions to the morphology and physiology of the Actinomycetes [trans. title], O. v. PLOTHO (*Arch. Mikrobiol.*, 11 (1940), No. 1, pp. 33-72, figs. 2).—A study of the cultural behavior, morphology, and physiology of 15 strains of *Actinomycetes*. There are 93 references.

The distribution of *Aspergillus niger*, with special reference to Germany [trans. title], A. RIPPEL (*Arch. Mikrobiol.*, 11 (1940), No. 1, pp. 1-32).—The geographical distribution and ecology of this fungus are discussed. Over a page of references is included.

An inhibitor produced by *Diplodia zeae* (Schw.) Lév., G. C. KENT. (Coop. U. S. D. A.). (*Iowa Sta. Res. Bul.* 274 (1940), pp. 653-671, figs. 2).—It is indicated by this study that *D. zeae* in its normal growth produces an endocellular inhibitive substance reducing its own growth by two-thirds on agar to which it has been added. Germination of spores was also greatly reduced. This action was not destroyed by correction of pH or sugar concentration in the solution of the inhibitor, and was retained after moderate dilution with distilled water and after boiling or autoclaving at 15 lb. pressure for 1 hr. The inhibiting action was retained after acid and alkaline hydrolysis and after oxidation with H_2O_2 and potassium permanganate. The inhibitor was nonvolatile, and was not extracted with ether, chloroform, or acetone and only partially so with 80-percent ethyl alcohol. The tests indicate it to be a complex substance liberated from the mycelium after 5-11 weeks in culture and to be present in infected portions of the corn plant.

White perithecia and the taxonomy of *Hypomyces ipomoeae*, W. C. SNYDER. (Univ. Calif.). (*Mycologia*, 32 (1940), No. 5, pp. 646-648).—Starting with monoconidial cultures of *Fusarium javanicum* from cucurbit root and fruit rot, it was shown that the fungus is heterothallic and that perithecial color may be either red or white. The morphology of the two types fell within the limits of *H. ipomoeae*, one differing, however, in whiteness of perithecia and both in pathogenicity. Monascosporous cultures from each perithecial type developed into *Fusarium* colonies representative of the original isolates, and inoculation showed them to be pathogenic to cucurbits, thus confirming their identity with the original isolates. Reciprocal crosses of the two types gave fertile perithecia, the color of which depended on the direction of the cross, and the sex reaction was inherited independently of primordial color. The study indicated that single ascospore cultures belong to two sex-reaction groups and may be described as being self-sterile, intergroup-fertile, intra-group-sterile, and hermaphroditic. The occurrence of both red and white perithecia in the same fungus is particularly significant in its taxonomic relations.

A sexual phenomenon exhibited by certain isolates of *Phytophthora capsici*, W. A. KREUTZER, E. W. BODINE, and L. W. DURRELL. (Colo. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 11, pp. 951-957, figs. 2).—Pairing in the same plate a culture of *P. capsici* from the stem of a wilted pepper with one from decaying cucumber fruit resulted in oospore formation at the junction zone 24 hr. after their hyphae met. This did not occur when pepper isolates or cucumber isolates were paired separately. In the case of any cucumber-pepper isolate pairing, attempts to trace the antheridial and oogonial hyphae to their source thalli failed. Only three of the four cultures studied produced oospores when grown separately, and in such cases they formed only after the isolates had been held in culture for 6-8 mo. Oospores were produced by one pepper isolate on potato dextrose agar only, and by the cucumber isolates on bean pods only. The sizes of these structures were compared, and observations were made as to the influence of certain factors on sporangial production by the isolates studied.

An aberrant strain of *Puccinia helianthi* Schw., A. M. BROWN (*Canad. Jour. Res.*, 18 (1940), No. 10, Sect. C, pp. 513-517, pl. 1).—"The aberrant strain of rust here discussed was first observed in haploid infections arising from germinating teliospores of the *tuberosus* strain of *P. helianthi*. The teliospores occurred on a single leaf of *Helianthus tuberosus*. Teliospores on several other leaves of the same collection were induced to germinate, but their sporidia produced only normal infections. This strain of rust differed from

the parent strain in color, pathogenicity, spore viability, and host range, and was practically intersterile with it. It also differed in urediospore size, shape, and echinulation, and in ability to withstand warm temperatures. It is suggested that these differences were probably due to a mutation in which the loss or gain of chromatin carrying more than one gene was involved."

The production of apothecia of *Sclerotinia sclerotiorum* and *S. trifoliorum* in culture, L. HENSON and W. D. VALLEAU. (Ky. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 10, pp. 869-873, fig. 1).—By the method described for producing apothecia of *S. trifoliorum*, *S. sclerotiorum*, and *Claviceps purpurea*, the sclerotia are placed on 1 percent plain water agar in vials which are then tightly plugged with cotton. The vials may be located under any desired conditions where moisture satisfactory for apothecial development is maintained for 6 mo. or more. Stipes of *S. trifoliorum* were produced after an exposure of 6 days or more at 14° C., while *S. sclerotiorum* required 21 days or more of exposure. Stipes but not apothecia are produced in darkness. There are 18 references.

A new powdery mildew, F. J. SEAVER (*Mycologia*, 32 (1940), No. 5, pp. 649-651, fig. 1).—*Uncinula jaborosae* n. sp. on leaves of *Jaborosa integrifolia* is described.

A further report on the Uredinales of Colombia, F. D. KERN and H. W. THURSTON, JR. (Pa. Expt. Sta.). (*Mycologia*, 32 (1940), No. 5, pp. 621-629).—This further contribution (E. S. R., 82, p. 201) includes data on the genera *Bitzea*, *Chardoniella*, *Mainsia*, *Phakopsora*, *Puccinia* (three new species), *Ravenelia*, and *Uredo*.

Comparative host ranges of six plant viruses, W. C. PRICE (*Amer. Jour. Bot.*, 27 (1940), No. 7, pp. 530-541, figs. 2).—Including plants shown to be susceptible by the author and other workers, "tobacco necrosis virus infected 88 species in 37 families but failed to infect 25 species in 13 of these families and 28 species in 20 other families; tobacco ring spot virus infected 143 species in 40 families but failed to infect 14 species in 13 of these families and 21 species in 16 other families; tomato ring spot virus infected 54 species in 35 families but failed to infect 17 species in 12 of these families and 29 species in 20 other families; cucumber mosaic virus infected 191 species in 40 families but failed to infect 21 species in 12 of these families and 25 species in 19 other families; cucurbit mosaic virus infected 5 species in 1 family but failed to infect 107 species in 52 families; and alfalfa mosaic virus infected 92 species in 28 families but failed to infect 16 species in 12 of these families and 43 species in 28 other families." These results are believed to show that ability of a plant to allow increase of a virus in its tissues is a species characteristic and, with regard to at least 5 of the 6 viruses studied, has little or no relationship to taxonomic position of the plant family. There are 52 references.

A low temperature storage cabinet for the preservation of viruses, F. L. HORSFALL, JR. (*Jour. Bact.*, 40 (1940), No. 4, pp. 559-568, figs. 5).—The large-capacity cabinet described for indefinite storage of unstable viruses contains solid CO₂ and cold gas, maintaining an internal temperature of -76° C.

A laboratory biological assay of tenacity of fungicides, J. W. HEUBERGER. (Conn. [New Haven] Expt. Sta. et al.). (*Phytopathology*, 30 (1940), No. 10, pp. 840-847, fig. 1).—A simple, rapid washing test for fungicide deposits has been developed which comparative tests show to be as effective as other tests in removing such deposits. Details are given for a laboratory biological assay of the relative tenacity of fungicides based on the spore-inhibiting powers of their deposits before and after washing. This method makes possible a nu-

merical rating for tenacity for which the term "tenacity coefficient" is applied. The relative tenacity of several copper compounds has been determined by this method, their order of tenacity closely approximating that reported for similar materials, based on chemical analysis of deposits before and after weathering, in laboratory and field.

Information on insecticides and fungicides, S. B. FENNE (*Va. Agr. Col. Ext. Bul. 150 (1940), pp. 12, fig. 1*).

Problems in the determination of physiologic races of *Ustilago avenae* and *U. levis*, I. W. TERVET. (Minn. Expt. Sta.). (*Phytopathology, 30 (1940), No. 11, pp. 900-913, figs. 4*).—Eleven varieties of oats were inoculated with 17 collections of *U. levis* and 63 of *U. avenae*, principally from the Mississippi Valley basin. Some of the collections were inconstant in ability to attack the same variety in succeeding years, taking 1-2 yr. to attain stability of reaction. In some cases this variation was due to the action of the host variety, on which the chlamydo-spores for inoculum were grown, in exercising a selective effect by increasing certain biotypes of the smut at the expense of others. It is likely that in field studies the varying environment from year to year must tend toward variation in the pathogenicity of a collection. Under field conditions at St. Paul, Minn., 3 races of *U. levis* and 3 of *U. avenae* were distinguished by their pathogenicity on the 5 oat varieties, Anthony, Gopher, Rusota, Iogold, and Black Mesdag. Attempts to build up to greater pathogenicity races of *U. avenae* that but slightly attack Bond and Fulgrain, by repeated increase on these 2 varieties, were unsuccessful. Markton, Navarro, and Nakota have not been attacked by any collection, while D. C. II-22-220 resembles Black Mesdag closely in its smut reactions. There are 22 references.

A new culture medium for germination tests with spores of cereal rusts (*Ustilago avenae*, *U. tritici*, *U. hordei*, *Tilletia tritici*, and *Helminthosporium gramineum*) [trans. title], J. KEIL (*Arch. Mikrobiol., 11 (1940), No. 1, pp. 85-88, fig. 1*).—A medium containing an oats extract is reported to have been successfully used, and the formula is given.

Seedling reactions of wheat varieties to stem rust and leaf rust and of oat varieties to stem rust and crown rust, M. NEWTON, T. JOHNSON, and B. PETURSON (*Canad. Jour. Res., 18 (1940), No. 10, Sect. C, pp. 489-506*).—A study of the reactions to 20 physiologic races of stem rust showed several varieties of the *vulgare* type (McMurachy, Eureka, and several strains from Kenya) to be immune in the seedling stage at 55°-80° F. daily, but this immunity disappeared when the plants were kept constantly at 75°-80°. Certain other varieties and hybrid strains proved rather highly resistant to 8 physiologic races of leaf rust, but none of the *vulgare* varieties tested showed immunity or high resistance to both stem and leaf rust. Tests to determine the resistance of oat varieties to physiologic races of oat stem rust and crown rust prevalent in Canada showed that 4 oat varieties from the cross Hajira × Joannette are resistant to all oat stem races tested, and that certain strains from the cross Victoria × (Hajira × Banner Sel. 524) are resistant to all but one. The last strains and the varieties Victoria and Trispermia proved resistant to the 9 races of crown rust tested.

Smut diseases of cereals [trans. title], R. VANDERWALLE (*Chron. Bot., 6 (1940), No. 2, pp. 33, 34*).—A review of recent advances.

Occurrence of scolecospore-producing strains of *Diplodia zeae* in the United States, H. JOHANN. (U. S. D. A.). (*Phytopathology, 30 (1940), No. 11, pp. 979-981, fig. 1*).—Scolecospore-producing strains of *D. zeae* were found in plated kernels from 179 samples of corn from 14 States. The samples used were almost entirely limited to damaged grain from carload lots arriving at

terminal markets in January and February 1939-40. A small number of the scoleospores have been germinated.

The biological antagonism of *Gibberella fujikuroi* and *Gibberella fujikuroi* var. *subglutinans* to *Trichoderma viride*, with notes on the pathological effects of the latter fungus on maize, E. T. EDWARDS. (Univ. Wis.). (*Jour. Austral. Inst. Agr. Sci.*, 6 (1940), No. 2, pp. 91-100, figs. 3).—At 28° C. corn seedlings derived from grain internally infected or externally inoculated with either of the *Gibberellas* commonly showed an apparent growth stimulation and a higher mean dry weight than controls. These growth differences were not due to the action of any growth-stimulating substance produced by the fungi, but resulted from the deleterious effect of *T. viride* on the seedlings raised from seed free from the *Gibberella* spp. The pathological effects of *T. viride* on corn seedlings are described, and the possible role of this fungus as a plant pathogen is discussed.

Relation of crown rust infection to yield, test weight, and lodging of oats, H. C. MURPHY, L. C. BURNETT, C. H. KINGSOLVER, T. R. STANTON, and F. A. COFFMAN. (Iowa Expt. Sta. coop. U. S. D. A.). (*Phytopathology*, 30 (1940), No. 10, pp. 808-819, fig. 1).—In the severe crown rust epidemic in Iowa in 1938 the coefficient of infection (percentage of infection \times type) showed a higher negative correlation with yield and test weight than did either percentage or type of infection alone, indicating that this coefficient is a slightly better measure. The coefficient of crown rust infection showed a high negative correlation with yield and test weight in all tests at Ames and Kanawha in 1938, and the total correlations between coefficient and yield were all highly significant and ranged from -0.75 to -0.8 . For each unit increase in coefficient of crown rust infection (in the presence of the effect of test weight, date ripe, height, and lodging) yield was decreased an average of 0.21-0.32 bu. per acre, and for each unit increase in the crown rust coefficient alone, yield was decreased an average of 0.4-0.47 bu. per acre. Yield and test weight were highly correlated in all tests. With each pound increase in test weight, yield was increased an average of 0.47-2.39 bu. per acre. Lodging, height, and date ripe were all negatively correlated with yield, i. e., for 1938 the stiffer-strawed, shorter, and earlier varieties tended to average higher yields than the weaker strawed, taller, and later varieties. Breeding for resistance to crown rust is of paramount importance when conditions such as those described are encountered. Similar damage occurred in 1927 and 1935. Such frequent occurrence of epidemics in Iowa emphasizes the great need for and potential value of Boone, Marion, and other new varieties with resistance to crown and stem rusts and loose and covered smuts. There are 15 references.

Physiological studies on the causal fungi of *Sclerotium* diseases of rice plant with special reference to some factors controlling the occurrence of the diseases, S. ENDŌ (*Miyazaki Col. Agr. and Forestry Bul.* 11 (1940), pp. 55-218, pls. 20).—In this monograph (117 references) the author presents the results of his studies on the pathogenicity, and especially the effects on seedling roots, of several sclerotial fungi. *S. oryzae-sativae*, *Leptosphaeria salvinii*, and *Corticium sasakii* proved highly pathogenic, while *S. hydrophilum* appeared to be only weakly so. These four species and *C. rolfsii* overwinter as sclerotia in the soil, while *L. salvinii*, *Helminthosporium sigmoideum irregulare*, *S. oryzae-sativae*, *S. hydrophilum*, and *S. funnigatum* do so in stubble or straw. The symptoms of these diseases are described, and the overwintering of the causal fungi, their cultural characters and physiology, and the influences of various environal factors (e. g., pH, temperature, light, toxic substances, various chemicals, moisture and dryness, and antagonisms of other organisms) on them are discussed in great detail.

The histology of infection of susceptible and resistant selfed lines of rye by the rye smut fungus, *Urocystis occulta*, L. LING (*Phytopathology*, 30 (1940), No. 11, pp. 926-935, figs. 4).—Chlamydo-spores germinated and infected the coleoptiles in both resistant and susceptible selfed lines of rye. A binucleate infection hypha penetrated the epidermal wall directly, after softening, invaginating, and sometimes thickening it. Early infection stages were similar in resistant and susceptible lines. The later mycelial development in susceptible lines was rapid, so that hyphae were in the coleoptilar internode of a seedling 21 days old and in the meristematic region of one 28 days old. In resistant rye, mycelial development was retarded, so that smut hyphae failed to spread to the meristematic region and some of the hyphal segments in the outer layers of the coleoptile became vacuolate. There are 15 references.

Present knowledge of browning root rot of wheat with special reference to its control, T. C. VANTERPOOL (*Sci. Agr.*, 20 (1940), No. 12, pp. 735-749, figs. 2).—This is a comprehensive review (29 references), including work by the author, relating to the field development of the disease due chiefly to *Pythium arrhenomanes* and *P. tardicrescens*, the life cycles of the parasites with special reference to their persistence in the soil, weather influences, the wheat and grass species attacked, modifications of the soil environment affecting the disease, the relation of seed source and quality, and varietal resistance.

Wheat, resistant to rust, adapted to Georgia, found in new Sanford, R. P. BLEDSOE (*South. Seedsman*, 3 (1940), No. 11, p. 14).—A note on the new leaf rust resistant Sanford variety, now ready for distribution.

Further studies on the use of the fixed copper compounds in controlling vegetable diseases, J. D. WILSON. (Ohio Expt. Sta.). (*Ohio Veg. and Potato Growers Assoc. Proc.*, 25 (1940), pp. 75-86).—This is a further survey (E. S. R., S3, p. 511) on this group of fungicides, including data for 1939. A number of these materials are said to give promise for use on tomatoes. Most of the fixed coppers were found to injure carrots in Ohio. Some of the treatments delayed the ripening of muskmelons. As in previous years it appeared likely that few or none of the fixed coppers can be used as substitutes for bordeaux mixture or copper-lime dust on celery, a crop which is not sensitive to bordeaux. Most of the fixed coppers, as well as bordeaux, usually caused some injury to lima and snap beans and are thus not recommended unless foliage diseases are expected to become serious.

Diseases of cucumbers and melons in Indiana, C. T. GREGORY (*Purdue Univ.*, [Agr.] Ext. Bul. 249 (1940), pp. 8, figs. 6).

Cucurbit diseases and rot of tomato fruit caused by *Phytophthora capsici*, W. A. KREUTZER, E. W. BODINE, and L. W. DURRELL. (Colo. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 11, pp. 972-976, fig. 1).—*P. capsici*, cause of wilt or blight of pepper, has been found also to induce rots of cucumber and tomato fruits in the field in Colorado and a wilt of squash and watermelon vines.

Common cabbage and cauliflower diseases in Indiana and their control, C. T. GREGORY (*Purdue Univ.*, [Agr.] Ext. Bul. 250 (1940), pp. 8, figs. 6).

Nutritional deficiency symptoms in cotton, H. P. COOPER. (S. C. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 322-324, figs. 6).—This is a brief discussion of the symptoms in the cotton plant under deficiencies in K, S, Mg, Mn, Fe, B, N, and P, together with the factors influencing their expression and amelioration.

Relation of fertilizers, crop residues, and tillage to yields of cotton and incidence of root-rot, H. V. JORDAN, H. A. NELSON, and J. E. ADAMS. (U. S. D. A.). (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 325-328, figs. 2).—The mortality of cotton plants from *Phymatotrichum* root rot was reduced on Wilson

very fine sandy loam soil by fertilizers in which N dominated, while it was increased by those in which P dominated. Instances of such variations with fertilizer treatments were less numerous on the heavier Wilson soils. The effect of these fertilizers on mortality was even less consistent in tests on soils of the Houston series, where cotton follows cotton. After turning under the second crop of sorghum at different stages of growth, reductions in cotton mortality of considerable size were obtained on soils of the Houston series. Reductions of infestation on Houston black clay soil were also secured by turning under the stalks as soon as the cotton was picked, as compared with the conventional bedding late in winter.

Chemistry and growth of cotton in relation to soil fertility and root-rot, J. E. ADAMS, R. C. WILSON, L. E. HESSLER, and D. R. ERGLE. (U. S. D. A.). (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 329-332).—Data analyzed by variance methods are quoted to show that highly significant reductions in mortality from *Phymatotrichum* root rot were associated with 15-0-0, 9-3-0, and 9-3-3 fertilizers, and highly significant increases with the 0-15-0 ratio of ingredients. In the tests reported, the N contents of root bark samples on August 15 and September 20, and of leaf samples on July 20 and August 15, were affected sufficiently to give highly significant negative values for the correlation coefficient r , between N contents and mortality data. The value of r between the P_2O_5 contents of root bark on September 20 and mortality at a comparable date was positive and highly significant. A highly inverse correlation was found between P_2O_5 and N contents of root-bark samples taken on September 20. These data indicate that the chemical composition of root bark and leaves of cotton, as affected by fertilizer treatment, is correlated with the mortality of cotton on the plats from which the samples were taken. Differences in the incidence of the disease as affected by fertilizer treatment were not as numerous or as outstanding for the soils of the Houston as for those of the Wilson series. The turning under of the stalks as soon as the cotton was picked with bedding later in the season, as compared with the prevailing practice of bedding in December or January, resulted in outstanding reductions in mortality. This appears to be due to an effect on the fungus parasite, abetted by chemical composition.

Cotton seed dusting in relation to control of seedling infection by Rhizoctonia in the soil, S. G. LEHMAN (*Phytopathology*, 30 (1940), No. 10, pp. 847-853).—Nondusted cottonseed and that dusted with 5 percent ethyl mercury phosphate preparation were planted in steamed soil previously inoculated with *R. solani*. Controls were run in noninoculated soil. Counts of total emergence, living seedlings, and disease-free seedlings were made, and the results of statistical analysis are given. Dusted seed showed significantly greater improvement in seedling emergence on infested than on noninfested soil in plantings made soon after inoculating the soil, but not in plantings made several weeks afterward. The percentage of seedlings living after emergence, also the percentage escaping stem infections, were increased by seed treatment in all tests, but the increase was not relatively greater by a statistically significant amount on inoculated than on noninoculated soil. The results are taken to indicate that, so far as final seedling stands are concerned, such dusts applied to cottonseed before planting may be of little, if any, value. However, their protective action against fungi on the seed is unquestioned.

Ohio potato diseases, P. E. TILFORD (*Ohio Sta. Bul.* 615 (1940), pp. [1]+35, figs. 28).—A handbook on the degenerative, leaf and stalk, and tuber diseases and their control.

Potato disease control studies on the Maryland Eastern Shore, R. A. JEHLE (*Maryland Sta. Bul.* 433 (1940), pp. 273-316, figs. 6).—The studies re-

ported strongly favor use of certified seed from reputable growers. For stimulating sprout development on late-grown Irish Cobbler stock, the storage temperature should be raised to 60°-65° F., after January 15 or to 80° for about 2 weeks before planting the stock held in sweetpotato houses, or transferred from unheated storage to brooder houses for about 2 weeks before planting. The virus diseases were not significantly affected by different storage temperatures, but their control was more difficult in Eastern Shore than in Garrett County seed stock. Late Eastern Shore seed proved as good as, or better than, Garrett County seed, but renewal at least every other year was found necessary for producing desirable Eastern Shore seed stock. Tubers from the early Eastern Shore crop may be used for planting the late seed crop if they are cut and soaked 1 hr. in sodium thiocyanate (1-12) and planted immediately, but they are slower in coming up than stored tubers. Yields from stored v. treated spring-grown tubers of different varieties are compared. The difficulty involved in controlling virus diseases in late seed crops from treated spring-grown seed in the Eastern Shore is stressed. Irish Cobblers continue to be recommended as the most profitable variety for the early potato crop and the late seed crop in this region, though other varieties may be grown for special reasons discussed. Spraying or dusting the vines for insect and disease control is recommended to all Eastern Shore growers. Best results may be expected from bordeaux mixture (4-4-50) with calcium arsenate (2 lb.), beginning when the vines are 6 in. high, or earlier if flea beetles or leafhoppers are present. The second application should be made about 2 weeks later, to be repeated at 7- to 10-day intervals until maturity. More frequent applications are needed if insects are numerous or when wet, cool weather favors blight. Where spraying is impractical, dusting with monohydrated copper-lime dust is recommended, and with aphids numerous 0.5 pt. of nicotine sulfate to 50 gal. of spray or an additional dusting with 3 percent nicotine where dust fungicides are used.

Resistance of potato to viruses A and X, components of mild mosaic. E. S. SCHULTZ, C. F. CLARK, and F. J. STEVENSON. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 11, pp. 944-951).—Experience with potato seedling varietal reactions to virus X indicated that on the basis of symptomatology varieties may be classified as symptomless carriers, necrotic, light green and slightly rugose, and faintly mottled, and with respect to virus A as necrotic, light green and rugose, and mottled. For both viruses they may also be grouped as immune, rarely infected, and easily infected. The necrotic reaction of some varieties to virus A by graft infection suggests that such varieties are virus A immune by aphid infection. The parental resistance reaction to either virus is transmitted to a high percentage of the progeny. A higher percentage of virus A- or virus X-resistant progeny results from resistant \times resistant than from nonresistant \times resistant parents. Earleine, Katahdin, and S 24642 are virus A immune by aphid but susceptible by graft infection, and they apparently segregate for resistance and susceptibility in crosses with nonresistant varieties. Progenies of virus X immune \times virus A immune were produced that are immune to both viruses. Since these two viruses and their strains are among the three potato mosaic virus groups responsible for most of the potato mosaic epidemics, varieties immune to both viruses A and X will play an effective role in control of potato mosaic.

Strains of potato yellow-dwarf virus, L. M. BLACK (*Amer. Jour. Bot.*, 27 (1940), No. 6, pp. 386-392, figs. 4).—Seven virus strains isolated differed as to the appearance of the local lesions and the systemic effects produced in *Nicotiana rustica*. Some strains induced milder symptoms in Green Mountain potato than did others, but all caused a rather severe disease on this variety.

Five strains protected *N. rustica* from subsequent systemic invasion by a necrosing strain, whereas the presumably unrelated viruses—potato ring spot, potato vein-banding, cucumber mosaic, and alfalfa mosaic—failed to afford protection. The field strain of the virus is named *Marmor vastans vulgare*. A strain inducing necrotic local lesions in leaves of *N. rustica* is described and named *M. vastans lethale*.

How to treat seed potatoes, J. M. RAEDER (*Idaho Agr. Col. Ext. Cir. 67* (1940), pp. 7, figs. 4).

Wilt of salsify, caused by *Verticillium* sp., K. LONGRÉE. (Cornell Univ.). (*Phytopathology*, 30 (1940), No. 11, pp. 981-983, fig. 1).—A *Verticillium* characterized by production of both torulose hyphae and "sclerotia" was isolated from roots of salsify (*Tragopogon porrifolius*) and its pathogenicity demonstrated.

Sweet potato field diseases in Indiana, C. T. GREGORY (*Purdue Univ., [Agr.] Ext. Bul. 251* (1940), pp. 8, figs. 3).

Soil rot of sweet potatoes in Louisiana, L. H. PERSON and W. J. MARTIN. (La. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 11, pp. 913-926, figs. 6).—Sweetpotato soil rot is increasingly serious, now being present in most of the commercial growing areas in Louisiana, where a number of farms are so infested that production has been abandoned. In heavily infested soil the plants are dwarfed, the leaves are small and pale green to yellow, the root system is poorly developed, and most of the roots are entirely rotten. On mature potatoes, pits or cavities with irregular, roughened margins are formed. Laboratory, greenhouse, and field inoculations with an *Actinomyces* found associated with lesions on roots, underground stems, and mature potatoes produced typical symptoms. This organism is described as *A. ipomoea* n. sp. Though a number of cross-inoculations have been made, no infection has yet been obtained on potatoes with the sweetpotato isolates of *A. ipomoea* or on sweetpotatoes with the potato scab isolates of *A. scabies*. The disease is more severe in seasons of light rainfall and in soils with pH above 5.2. When sufficient sulfur has been applied to the soil to reduce the pH to ± 5 , very effective control of the disease has been obtained. There are 13 references.

Sweet potato storage diseases and their control, C. T. GREGORY (*Purdue Univ., [Agr.] Ext. Bul. 248* (1940), pp. 8, figs. 6).

Clean site, space, drainage, spray, for control of mildew, F. J. LEBEAU (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 10, p. 7).—A note on suggested measures for control of tobacco downy mildew.

Classification and nomenclature of tobacco viruses, W. D. VALLEAU. (Ky. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 10, pp. 820-830).—Eight viruses causing disease in commercial plantings of tobacco are discussed, and those showing no relationship to others are given generic rank, the following new genera being proposed: *Musivum*, ordinary tobacco mosaic virus; *Foliopellis*, etch virus; *Murialba*, cucumber mosaic virus; and *Tractus*, streak virus. The vein-banding virus is given specific rank, coordinate with the cucumber mosaic virus, and tentatively named *M. venataenia* n. sp. The streak virus is removed from Holmes' (E. S. R., 82, p. 632) genus *Annulus* and given generic rank as *Artus*. The family Annulaceae of Holmes is not recognized because based on supposed recovery that does not occur. Strains of viruses, when obviously mutants, should be recognized by laboratory designations rather than by trinomials. Similarities between tobacco streak and potato yellow dwarf viruses are pointed out. The use of serology and protection in classifying viruses is discussed.

Tomato diseases in Indiana, R. W. SAMSON and H. R. THOMAS. (Coop. U. S. D. A.). (*Indiana Sta. Cir. 257* (1940), pp. 35, figs. 27).—A conspectus of tomato diseases and their control.

Occurrence of big bud of tomato in the Pacific Northwest, B. F. DANA. (Oreg. Expt. Sta. coop. U. S. D. A.). (*Phytopathology*, 30 (1940), No. 10, pp. 866-869, figs. 3).—Big bud of tomato occurred very sparingly in the Pacific Northwest during late summers and falls, 1937-39. Marglobe, Dwarf Champion, Bonny Best, and strains of *Lycopersicon* spp. exhibited symptoms similar to those previously described for the trouble. Phloem proliferation is a characteristic which with other symptoms serves to distinguish big bud from curly top. Buds from affected plants transferred the disease to healthy tomato plants, but juice inoculations failed. A disease similar to big bud also occurred on common beans, lima beans, soybeans, alfalfa, sweetclover, carrot, and squash.

Phytophthora infestans on tomato, W. R. MILLS. (Cornell Univ.). (*Phytopathology*, 30 (1940), No. 10, pp. 830-839).—Tomato foliage proved resistant to single swarm-spore cultures of *P. infestans* isolated from potato. During six or seven serial passages of these cultures through tomato foliage, the virulence progressively increased until it was indistinguishable from that of a tomato strain isolated from spontaneously infected tomatoes. During seven passages through tomato foliage, a culture virulent for certain normally immune potato hybrids acquired virulence for tomato equivalent to the tomato strain, while still maintaining its original virulence for the potato hybrids. Potato and tomato strains attacked potato foliage with equal severity, and tomato strains retained virulence for tomato after growing for 3 mo. on potato foliage and 6 mo. on the tubers. No morphological differences could be detected between the two strains, except that potato strains produced slightly smaller sporangia than the tomato strain on tomato leaves. It is concluded that the tomato strain arises in nature as a result of serial passage of the potato strain through tomato foliage. There are 27 references.

Soil fumigation with chloropicrin and carbon bisulphide to control tomato root knot and wilt, P. A. YOUNG. (Tex. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 10, pp. 860-865).—*Heterodera marioni*, *Fusarium lycopersici*, and weeds were usually controlled in soil fumigated with chloropicrin at 300-600 lb. per acre. Root knot was usually controlled in soil fumigated with carbon bisulfide at 1,000-3,000 lb. per acre, but neither tomato wilt nor weeds were controlled by it. As a coating for paper used in covering treated soil, animal glue, casein, and vegetable paste were all adequate and equally effective in delaying the escape of these two fumigants. Wetting the top 2-3 in. of soil with water was almost as effective as covering the soil with glue-coated paper.

Fruit diseases and spray practices, J. M. HAMILTON. (N. Y. State Expt. Sta.). (*Conn. Pomol. Soc. Proc.*, 48 (1938), pp. 94-103).—A general survey of the subject.

Wood decay in apple trees in Minnesota, C. J. EIDE and C. M. CHRISTENSEN. (Minn. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 11, pp. 936-944, figs. 2).—Decay of limited extent at 3 ft. above ground was found in 48 of 50 trees 15 yr. old and extending throughout most of the diameter of the trunk in 12 of 68 trees 22 yr. old. Moderate to slight decay occurred in 44 of the remaining 56 trees. Most trees 30 yr. old or over were thoroughly decayed, rot often extending out to or through the bark over part of the circumference of the trunk appearing in some cases to have weakened or killed the cambium and inner bark. Branch stubs were the chief routes of entry into the tree, while other avenues were crotch cracks, sunscald injuries, and frost cracks. Spread within the tree was facilitated by sunscald, cold injury (blackheart) frost cracks, and other wounds. Ten species of wood-rotting fungi associated with this decay were identified (*Fomes applanatus*, *Trametes malicola*, *T. hispida*, *Polyporus versicolor*, *P. adustus*, *P. resinusus*, *Thlephora* sp., *Schizophyllum commune*, *Pholiota adiposa*, and *Lenzites betulina*), while an equal or probably even greater number were

isolated but could not be identified. No one species or combination of species was found frequently enough to be considered responsible for the major part of the decay. It is believed that rot not only accompanies but may be one of the causes of the early decline of apple trees in marginal regions of production. Prevention and proper care of wounds may increase the bearing life of these trees. There are 18 references.

Propagation of sour cherries by piece-root grafting to avoid spraying seedling stocks for leaf spot, E. A. SIEGLER and J. J. BOWMAN. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 10, pp. 873-876).—Stands of 68 and 58 percent, respectively, were obtained on Early Richmond and Montmorency cherries when their scions were bench-grafted to collar piece-root cuttings of mazzard seedlings. Cuttings taken 3 in. below the collar gave relatively poor stands. In addition to certain theoretical advantages in orchard plantings, the propagation of sour cherries by bench-grafting on mazzard roots would save the nurseryman the expense of spraying the seedlings which is necessary when varieties are propagated by budding on mazzard stock.

The constriction disease of peach, J. W. ROBERTS. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 11, pp. 963-968, fig. 1).—This disease, described by Selby in 1898 (E. S. R., 10, p. 557), has been found to cause minor injury to weakened or previously injured trees in Delaware. Isolates from diseased branches caused the disease when inoculations were made through burned areas around buds. The pathogen, formerly known as *Phoma persicae*, is shown to be a *Phomopsis* apparently belonging to the same species as forms occurring on other fruit trees and classified as a pycnidial form of *Diaporthe pernicioso* by some investigators and of *D. eres* by Wehmeyer (E. S. R., 72, p. 489). The disease appears identical with the one known in Europe as dieback. There are 14 references.

Progress report on investigations of the "X" disease of peach, E. M. STODDARD. (Conn. [New Haven] Expt. Sta.). (*Conn. Pomol. Soc. Proc.*, 48 (1938), pp. 29-33).

Mistletoe on persimmon, I. J. CONDIT. (Calif. Citrus Expt. Sta.). (*Madroño*, 5 (1940), No. 8, p. 272).—*Phoradendron longispicum* was found parasitizing 44 of 205 trees in a variety collection of *Diospyros* spp.

Some nutritional relationships as revealed by a study of mineral deficiency and excess symptoms on citrus, H. D. CHAPMAN, G. F. LIEBIG, JR., and A. P. VANSELOW. (Calif. Citrus Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 196-200, figs. 6).—These studies revealed that potash deficiency leads to the accumulation of excessive amounts of B in lemon trees. Prolonged potash deficiency, as well as prolonged N and Fe starvation and K excesses have brought about the split and corky vein condition in citrus leaves, thought to be one of the characteristic symptoms of B deficiency. Excessive phosphate under proper conditions of pH may cause Fe and Zn deficiency, and early senescence of citrus leaves and a seasonal type of N deficiency have been produced by excessive phosphate in fertilizer tests with bearing orange trees in oil drums. Excessive Zn under various nutrient conditions brought on Fe chlorosis in lemon and orange trees, and a limited number of observations have indicated that slight excesses of Cu may also induce it.

Relations of *Pediculopsis graminum* and *Fusarium poae* to central bud rot of carnations, K. W. COOPER (*Phytopathology*, 30 (1940), No. 10, pp. 853-859).—Reasons are advanced for renaming the "*Sporotrichum* bud rot" of carnations "central bud rot." *F. poae* isolated from grasses produces the typical *Sporotrichum* bud rot of carnations, as Stewart and Hodgkiss indicated (E. S. R. 20, p. 647). The initial size of the bud at the time of infection with *F. poae*

has little effect on the course of the disease, and, in spite of an internal rot of the bud, growth of the calyx seems unretarded for at least 16 days after infection. It is proved that the mite *P. graminum* can and does introduce *F. poae* into carnation buds, producing central bud rot. A type of antagonistic symbiosis exists between the mite and the fungus, for it is clear that the mite can subsist on the fungus alone. There are 23 references.

Chrysanthemum diseases and their control, P. E. TILFORD. (Ohio Expt. Sta.). (*Chrysanthemum Soc. Amer. Bul.*, 8 (1940), No. 4, pp. 15-18).—A brief conspectus, the most important diseases being *Verticillium* wilt, *Septoria* leaf spots, foliar nematode, and *Ascochyta* and *Botrytis* ray flower blights.

Leaf curl and mosaic of geranium, L. K. JONES (*Washington Sta. Bul.* 390 (1940), pp. 19, figs. 7).—Leaf curl and mosaic, important virus diseases of geraniums in Washington greenhouses, are readily transmissible by grafting, but not to geranium, tomato, or tobacco by mechanical inoculation. No insect transmission has been observed, although a low percentage of field dissemination has been recorded. The viruses were not transmitted in the seed or by the knife in making cuttings. The appearance of severe leaf curl symptoms during spring and their masking during summer and winter indicate an influence of cultural and environal factors, but varying temperatures from 50° to 70° F., increasing the day length, and depleting the available K, N, or P failed to affect the appearance of symptoms. Applications of manure water and, to a lesser extent, use of Vigoro or iron sulfate around severely affected plants caused them to outgrow leaf curl symptoms. During a 3-yr. period marked reduction in affected plants was obtained by carefully selecting symptomless plants in the field during summer for fall propagation. Nearly complete control of mosaic and leaf curl was obtained by carefully roguing from a bed of stock remaining in the greenhouse for 3 yr. and making all cuttings from the rogued bed.

Chalaropsis thielavioides, cause of "black mold" of rose grafts, K. LONGRÉE. (Cornell Univ.). (*Phytopathology*, 30 (1940), No. 10, pp. 793-807, figs. 9).—Rose growers and distributors in the Eastern States and around Chicago have been confronted with a heretofore unknown trouble appearing on roses in the grafting frame, resulting in heavy losses of grafts on American-grown stock of *Rosa manetti*. Union between stocks and scions is prevented by mycelial growth over the cut surfaces of the grafts, preventing callus formation and causing death of the scions. A fungus identified as *C. thielavioides* was shown to be the cause, and its morphology and physiology were studied. Depending on conditions, both endoconidia and macroconidia either formed germ tubes or gave rise to new endoconidiophores, which soon produced a new crop of endoconidia. The cardinal points of temperature were 18°-27.5° C., 0°-3.5°, and 30.5°-33°. A culture of *C. thielavioides* from a Chinese elm root showed cardinal temperatures similar to one from rose stems, but grew faster, had slightly larger macroconidia, and failed to penetrate deeply into living rose stems like the strain from rose.

Cephalosporium leaf spot of two aroids, M. B. LINN. (Cornell Univ.). (*Phytopathology*, 30 (1940), No. 11, pp. 968-972, figs. 2).—The symptoms of a leaf spot disease of the two foliage plants *Nephtytis afzelii* and *Syngonium podophyllum albolineatum* are described. Cross-inoculations indicated one species of *Cephalosporium* to be the cause of both, described as *C. cinnamomeum* n. sp. Cuprenox (copper oxychloride) (1-100) gave satisfactory control, and maintaining greenhouse temperature and humidity as low as possible and avoiding the splashing of water on the leaves are recommended as aids.

Angular leaf spot of *Pittosporum*, A. G. PLAKIDAS. (La. Expt. Sta.). (*Mycologia*, 32 (1940), No. 5, pp. 601-608, figs. 4).—*Cercospora pittospori* n. sp. and the angular leaf spot on tobira (*P. tobira*) which it was found to cause are described.

A rust-resistant red cedar, A. BERG. (W. Va. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 10, pp. 876-878, fig. 1).—A record of over 16 yr. on a large number of cedars indicated certain trees to possess a very high resistance to *Gymnosporangium juniperi-virginianae*. Scions from the most promising tree were propagated, and when subjected to heavy infection under controlled conditions they maintained their resistance.

Control of cedar rust with sodium dinitrocresylate, F. C. STRONG and D. CATION. (Mich. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 11, p. 983).—A single spray application (spring, 1940) of 1 percent sodium dinitrocresylate (Elgetol) to rust galls of *Gymnosporangium globosum* and *G. juniperi-virginianae* on red cedar (*Juniperus virginiana*) and to rust lesions of *G. clavipes* and *G. clavariaeforme* on dwarf juniper (*J. communis*) when the telia had started to develop inhibited telial column extension and teliospore germination.

A root-rot of Douglas fir caused by *Poria weirii*, I. MOUNCE, J. E. BIER, and M. K. NOBLES (*Canad. Jour. Res.*, 18 (1940), No. 10, Sect. C, pp. 522-533, pls. 4, figs. 14).—A laminated root rot of *Pseudotsuga taxifolia* (= *douglasi*) was observed in young stands on Vancouver Island, B. C. The decay, the associated sporophore, and the cultural characters of the fungus are described, and comparison with *Poria weirii* reported on *Thuja plicata* indicated a close resemblance in all respects.

Field observations on the dying of pines infected with the blue-stain fungus, *Ceratostomella pini* Munch., F. C. CRAIGHEAD and R. A. ST. GEORGE. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 11, pp. 976-979).—Field notes gave convincing evidence that infection by *C. pini* followed attacks by the southern pine beetle, *Dendroctonus frontalis*.

Fungi associated with *Dendroctonus frontalis* in killing shortleaf pines and their effect on conduction, W. C. BRAMBLE and E. C. HOLST. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 11, pp. 881-899, figs. 5).—Through analyses at various stages of the fungus infection of *Pinus echinata* stems attacked by this bark beetle, it was found that although a complex infection occurred a few primary organisms could be constantly isolated during early stages. Of these, only *Ceratostomella pini* proved capable of killing living pines above 2 in. in diameter at breast height following inoculation into their stems. The possibility that *C. pini* kills the trees by inducing a blockage of the tracheids with resin was indicated.

Observations on *Polyporus circinatus*, C. M. CHRISTENSEN. (Minn. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 11, pp. 957-963, figs. 4).—In a north-western Minnesota area *P. circinatus* was found common on *Picea glauca*, occasionally on *P. mariana*, *Pinus banksiana*, and *Abies balsamea*, and once on *P. resinosa*. Several years' observations indicated that the fungus entered the roots of comparatively young trees and progressed slowly toward the crown and up the trunk. Eventually decay involved so much of the diameter of the main roots and lower trunk that the trees stagnated and later fell or were blown over. The fungus may penetrate outward through the cambium of dying trees. Infection loci occur in the forest, but the reason for this is not known. The morphology and cultural characters of the fungus, and the histopathology of infection are described.

***Morenoella quercina*, cause of leaf spot of oaks**, E. S. LUTTRELL (*Mycologia*, 32 (1940), No. 5, pp. 652-666, figs. 13).—This leaf spot, found on eight

species of red and white oaks, is described, together with the structure, physiology, and host relations of the fungus. The infection causes a decrease in photosynthetic activity of seedlings and young trees, lowering their vitality, but is said to be of no appreciable importance to older trees.

Protocoronospora on Phoradendron flavescens in California, L. DARLING. (Univ. Calif.). (*Madroño*, 5 (1940), No. 8, pp. 241-246, figs. 3).—The author describes a new disease of the mistletoe, *Phoradendron flavescens macrophyllum*, growing on willow and poplars and ascribed to the fungus *Protocoronospora phoradendri* n. sp.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Distribution and variation of pocket gophers (genus *Geomys*) in the southwestern United States, W. B. DAVIS (*Texas Sta. Bul.* 590 (1940), pp. 38, figs. 6).—Report is made of a study of 4 geographic species of pocket gophers (genus *Geomys*), of which there are 20 geographic races, 10 of which are herein described as new. The pocket gopher is a destructive rodent when inhabiting farm and pasture lands, those of this group being partial to sandy or friable soils, the heavy soils acting as natural barriers. The species dealt with, keys to geographic races of which are given, are *G. breviceps*, *G. arenarius*, *G. personatus*, and *G. lutescens*.

A population study of the gray squirrel (*Sciurus carolinensis carolinensis*) in eastern Texas, P. D. GOODRUM (*Texas Sta. Bul.* 591 (1940), pp. 34, figs. 5).—The steady decrease in numbers of the gray squirrel, one of the most important game animals occurring in Texas, particularly in the eastern part of the State, led to the investigation here considered. The report is presented under the headings of methods and materials studied, habitat types, squirrel numbers, ecological factors affecting the population, economic status, habitat improvement and management practices, and squirrels and the Texas game laws. The author concludes that destruction of favorable habitat and improper and inadequate laws governing the shooting seasons have been the primary factors in gray squirrel decrease, and under proper management, as outlined, the squirrel population of the eastern part of the State could be approximately doubled.

The spelling of common names of birds, W. H. CHEESMAN and P. H. OEHSER (*Auk*, 54 (1937), No. 3, pp. 333-340).

Common salt as a curative for cannibalism among game birds in captivity, R. B. NESTLER. (U. S. D. A. et al.). (*Mod. Game Breed.*, 10 (1940), No. 7, p. 5).—Preliminary studies at the Patuxent Research Refuge, Bowie, Md., of cannibalism among quail indicate that a deficiency of common salt in the diet is one of the factors, if not the main factor, leading to the vice. Outbreaks of toe-pecking occurring among mature quail on diets containing no salt to 0.5 percent salt were stopped in 24 hr. by an increase of the salt content to 2 or 3 percent. Even fighting, which differs from cannibalism in many respects, was checked by raising the salt content to 5 or 6 percent for several days. Salt levels of 4 or 6 percent apparently have no deleterious effects on mature quail held during the winter, even when fed for several months.

Bob-white populations as affected by woodland management in eastern Texas, D. W. LAY (*Texas Sta. Bul.* 592 (1940), pp. 37, figs. 13).—The results of a study conducted to determine the factors responsible for the continued decrease of bobwhite quail on certain woodland tracts that has taken place even in the absence of hunting are reported. A study of woodland management was made in a nearly typical eastern Texas county in the shortleaf-loblolly pine-hardwood type. The report is presented under the headings of logging practices

as they affect vegetation, methods of censusing quail, winter foods of bobwhites, effects of timber cutting on quail habitat, quail carrying capacity of woodland, and management of pine woodland for quail. The recommendations for management of quail in such cut-over type woodland include plowing and brush clearing in spots and along tramways, protection from heavy grazing and over-shooting, little or no restocking of quail or control of so-called predators except locally as needed, some burning of slash under certain carefully regulated conditions, optional planting of feed patches, and careful regulation of hunting. Favorable environmental change could be induced by landowners under a rotational system of harvesting timber which favors the interspersing of various timber age classes essential to continuous quail production.

Winter banding of Oklahoma crows, E. R. KALMBACH and S. E. ALDOUS (*Wilson Bul.*, 52 (1940), No. 3, pp. 198-206, fig. 1).—Report is made of the banding of 714 crows in south-central Oklahoma during the winter of 1935-36, which yielded 143 returns during the 3.5 yr. following. Of the 65 crows recovered during the breeding and rearing season (April 1 to August 31), 49 (75 per cent) were killed in the prairie provinces of Canada. The dates and locations of numerous other returns recorded in the States north of Oklahoma indicate that many others of this group of crows may have been on their way to or from Canadian breeding grounds. During this same period of the year not one of the winter-banded crows was recovered in Oklahoma, clearly indicating that winter crow control in Oklahoma can have little or no effect on nesting upland game or insectivorous birds of that State.

The great horned owl and its prey in north-central United States, P. L. ERRINGTON and F. and F. N. HAMERSTROM, JR. (*Iowa Sta. Res. Bul.* 277 (1940), pp. 757-850, figs. 4).—Report is made of the food habits of the great horned owl (*Bubo virginianus*), based in part on data secured largely between the years 1930 and 1935 from 84 horned owl nests, examination of 4,815 pellets and 23 food-containing stomachs, and records of direct predation. The prey types studied were chiefly upland game birds, waterfowl, and fur bearers, although many other forms were observed incidentally.

From a survey of the findings, it is considered doubtful if north-central horned owls and associated predators exert a dominant influence upon populations of prey animals taken. "The predators, even in numbers as great as many may themselves tolerate or can maintain locally, seldom appear to utilize more than a small proportion of the staple foods, i. e., rabbits and mice, conveniently available to them and, as a rule, turn to other mammals or to birds when these temporarily become more available than the prey staples. Overpopulation of habitats by nonstaple prey species has been accompanied by some of the most pronounced rises in representation of these types in diets of such flesh eaters as the horned owl. Crises precipitated by weather, destruction of environment, human activities, etc., were often reflected, as well, by response of predators to increased vulnerability of given prey animals. Predator-prey relationships studied in the north-central region were flexible, and predators did not always respond to apparent changes in availability of prey. Nevertheless, unrelieved basic insecurities of prey populations were often attended by response of some predators sufficient to compensate, at least in part, for lack of utilization by others, and compensatory tendencies in loss rates of prey animals were noted under a wide range of conditions having little evident connection with kinds and densities of predators."

A list is given of 119 references to the literature cited, and the results of family and special phase studies are appended.

Starlings attack cattle in Kansas and other Plains States, W. H. WELLS (*Oölogist*, 57 (1940), No. 7, pp. 76, 77).

Blatchleyana, [I], II (*Indianapolis: Nature Pub. Co., 1930, vol. [I], pp. 77, [pls. 2]; 1939, vol. 2, pp. 46, pls. 3*).—A chronological account of the work of and by W. S. Blatchley is followed by a bibliography of his publications. Alphabetical lists by families, genera, and species of the Coleoptera, Heteroptera, and Orthoptera described by Blatchley with citations, to the original descriptions, also lists of the species and varieties, are included.

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 810–820, fig. 1).—The contributions presented (E. S. R., 84, p. 74) are: *Eufallia unicastata*, a Fungus Eating Beetle New to Puerto Rico, by W. A. Hoffman (pp. 810, 811); Natural Dispersion of *Aphelinus mali* (Hald.), by E. J. Newcomer (p. 811) (U. S. D. A.); Poison Bait for Control of the Strawberry Crown Borer, by P. O. Ritcher (p. 812) (Ky. Expt. Sta.); Fumigation Tests in Open Tobacco Warehouses, by W. D. Reed and P. K. Harrison (pp. 812, 813) (U. S. D. A.); Searching for Entomophagous Insects, by S. E. Flanders (p. 814) (Calif. Citrus Sta.); Parasites of the Pistol Case-Bearer, by E. Gould and G. H. Geissler (pp. 814, 815) (W. Va. Sta.); Observations on Life History of *Aeolus mellillus*, by H. H. Jewett (p. 816) (Ky. Sta.); Effect of Paradichlorobenzene on the Feeding of the Black Carpet Beetle, by W. Colman (pp. 816, 817) (U. S. D. A.); Effect of Methyl Bromide on Apple Maggots in Apples, by P. J. Chapman (p. 817) (N. Y. State Sta. and U. S. D. A.); and Attractiveness to the Japanese Beetle of Mixtures of Commercial Geraniol and Eugenol, by W. E. Fleming and E. D. Burgess (p. 818), Mating Habits of *Scolytus multi-striatus* and the Dissemination of *Ceratostomella ulmi*, by C. H. Hoffmann and C. S. Moses (pp. 818, 819), Effect of Insecticidal Residues in Cured Tobacco on Tobacco Moth Larvae, by J. P. Vinzant and W. D. Reed (p. 819), and Ambrosia Beetle *Xylosandrus germanus* Transmits Dutch Elm Disease Under Controlled Conditions, by W. D. Buchanan (pp. 819, 820) (all U. S. D. A.).

[Work in economic entomology by the Idaho Station], R. S. SNYDER, W. E. SHULL, R. W. HAEGELE, R. A. FISHER, T. A. BRINDLEY, F. SHIRCK, and E. L. TURNER. (Partly coop. U. S. D. A.). (*Idaho Sta. Bul.* 236 (1940), pp. 43–49).—The work of the year reported upon (E. S. R., 81, p. 671) includes work on the loads of arsenic, lead, and fluorine spray residues; the codling moth and its control; biological control of codling moth and San Jose scale; dry lime-sulfur plus oil in scale control; a new mite (*Tetranychus* sp.) on red clover; control of the cabbage maggot in radishes and cabbages; laboratory tests with insecticides for control of *Lygus* insects and with rotenone-containing dusts for control of the pea weevil; other pea weevil control investigations; alfalfa as an aid in reducing wireworm populations; and mechanical protection of tomatoes from beet leafhoppers and a reduction in the population of the pest by the use of a pyrethrum-oil spray.

Entomological progress, II, assembled by C. O. EDDY. (Partly coop. U. S. D. A.). (*Louisiana Sta. Bul.* 323 (1940), pp. 51, figs. 7).—This second group of papers (E. S. R., 80, p. 651) presents the results of station findings on insect pest control in the State as follows: Cryolite as an Insecticide (pp. 3–5), The Corn Silk Beetle (pp. 15, 16), The Mexican Bean Beetle, a New Pest in Louisiana (pp. 37, 38), Recent Information on Sand Wireworm Control (pp. 43, 44), and The Oriental Fruit Moth, a New Peach Pest in Louisiana (pp. 45, 46), all by C. O. Eddy; Cotton Flea Hopper Control in Louisiana (pp. 5–12) and The Use of Wettable Sulphur in Combination With Copper Sprays for Control of Red Spiders on Strawberries (pp. 46–48), both by I. J. Benel; Control of the Boll Weevil, by R. C. Gaines (pp. 12–15); Investigations on the Biology and Control of the Alfalfa Caterpillar (*Colias eurytheme* Bois, by E. H. Floyd

(pp. 16-24); Notes on the Biology and Control of the Three-Cornered Alfalfa Hopper in Louisiana, by L. T. Graham and L. O. Ellisor (pp. 25-28); Present Status of *Trichogramma* spp. as a Parasite of the Sugarcane Borer (*Diatraea saccharalis* (F.)) in Louisiana, by A. L. Dugas (pp. 29-31); The Effect of Lime in Reducing Injury by the Sugarcane Beetle, by J. W. Ingram, W. E. Haley, and L. J. Charpentier (pp. 31-33); Varietal Susceptibility of Cane to Sugarcane Borer Injury in 1937, by J. W. Ingram and L. O. Ellisor (pp. 34-36); Wild Hosts of the Sweetpotato Weevil, by K. L. Cockerham (pp. 38, 39); Observations on Flight of the Sweetpotato Weevil, by O. T. Deen (pp. 40, 41); Overwintering of the Sweetpotato Weevil in the Field, by C. L. Stracener and L. D. Newsom (pp. 41-43); and Contact Sprays, by C. O. Eddy and E. H. Floyd (pp. 48-51).

A survey of the insect pests of cultivated plants in Guam, O. H. SWEZEY (*Hawaii, Planters' Rec.* [*Hawaii, Sugar Planters' Sta.*], 44 (1940), No. 3, pp. 151-182, figs. 16).—Further report is made of the entomological survey of Guam extending from April 27 to November 30, 1936, and previously noted (E. S. R., 76, p. 657). The insect pests found on the various crops, particularly rice, corn, copra, and many kinds of vegetables and fruits, are listed, with notes on their relative importance, habits, and natural enemies. A list of the pests in Guam which do not occur in Hawaii, some 60 in number, arranged according to hosts, is included.

Further notes on the food-plants of Nigerian insects, V. F. D. GOLDING (*Bul. Ent. Res.*, 31 (1940), No. 2, pp. 127-130).—A continuation of the earlier notes (E. S. R., 77, p. 508).

Glass tubes for rearing Phlebotomus and other insects, M. HERTIG (*Science*, 92 (1940), No. 2378, pp. 91, 92, fig. 1).

Proceedings Nineteenth Annual Meeting of the North Central States Entomologists (*North Cent. States Ent. Proc.*, 19 (1940), pp. [1]+91).—A report of the annual meeting held at La Fayette, Ind., in March 1940 (E. S. R., 83, p. 515). Among the contributions reported are the following: Regional and Community Adaptations of Insect Control Measures, by T. H. Parks (pp. 5-7); New or Recently Developed Apparatus for Applying Insecticides, by R. Hutson and E. M. Searls (pp. 9, 10); Clean Summer Fallow Aids Wireworm Control, by J. A. Munro (p. 13); Results With Cucumber Beetle Control Studies, by G. E. Gould (p. 14); The Present Status of Methyl Bromide as a Greenhouse Fumigant, by R. Hutson (p. 16); Application of Biological Control Methods to Greenhouse Problems, by C. C. Compton (pp. 16, 17); The Use of Insecticides in Plants Grown in Nutrient Solutions, by C. R. Neiswander (p. 17); Ever-Normal Granary as an Insect Problem, by A. F. Troyer (pp. 19-21), and by W. P. Flint (pp. 21, 22); Effect of Fumigants on the Germination of Grain, by J. C. Frankenfield (p. 23); Cooperation of Agronomists and Entomologists in Plant Breeding Studies on Resistance and Tolerance to Insects, by A. M. Brunson (pp. 28, 29); Cooperation of Agronomists, Botanists, and Entomologists in Plant Breeding Studies on Resistance and Tolerance to Insects, by R. H. Painter (pp. 29, 30); Suggestions on Plant Breeding for Insect Resistance, by W. A. Huelsen (pp. 31, 32); Suggestions on Breeding Crop Plants Resistant to Insects, by R. M. Caldwell (p. 32); Developments and Methods in Plant Breeding Studies as They Relate to Insect Resistant Crops, by R. A. Blanchard et al. (pp. 33-38); The Brown-Banded Roach [*Supella supellectilium*

(Serv.)]—Life History and Habits, by G. E. Gould (pp. 45, 46); How Long Will Termite Soil Poison Treatments Remain Effective? by G. L. Hockenyos (pp. 46-48); How Long Will Soil Poisons Last? by W. E. McCauley (pp. 48, 49); Leafhopper Control on Apples and Grapes, by G. E. Marshall (pp. 51-53); New Developments in Plum Curculio Control, by S. C. Chandler (pp. 53, 54); Recent Spread of the Fruit-Tree Leaf Roller and Recommended Controls, by H. E. Brown (p. 55); Oriental Fruit Moth Control, by R. B. Neiswander, G. E. Marshall, C. E. Palm, and C. W. Wingo (pp. 56-59); Codling Moth Control, by L. F. Steiner, S. C. Chandler, L. Jenkins, and C. L. Burkholder (pp. 59-67); Protecting Strawberries From Root Worms and White Grubs, by R. B. Neiswander (pp. 67, 68); Observations on Comstock's Mealy Bug in a Midwest Orchard, by M. McCown (pp. 68, 69); and The Brown Dog Tick, by J. J. Davis (pp. 82-84).

Effect of temperature upon the toxicity of stomach poisons, L. O. ELLISOR and C. R. BLAIR. (La. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 760-762).—In the testing work with stomach poisons conducted at 60° and 80° F., fifth instar larvae of the southern armyworm and the velvetbean caterpillar were used. "A total of 16 minimal lethal doses were determined at the two temperatures and with four insecticides, [namely], synthetic cryolite, acid lead arsenate, basic copper arsenate, and calcium arsenate. In all instances except one the insecticides were more toxic at 60° than at 80°. However, the mean survival period was shorter at 80° than at 60°. All the insecticides tested were more toxic to the velvetbean caterpillar than to the southern armyworm except basic copper arsenate, which showed very little difference." A description is given of an improved technic for feeding the caterpillars in determining the minimal lethal dose.

Insecticidal action of extracts of *Veratrum viride*, R. A. FISHER. (Iowa State Col.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 728-734, figs. 3).—*V. viride* contains alkaloids which are very toxic to a number of insects. It is pointed out that perfection of practical methods of extraction may again make this drug economically important as a source of insecticide material. Its standardization should be based upon the fraction of alkaloids soluble in ether and not upon the total alkaloid content, since the fraction of alkaloids insoluble in ether is nontoxic.

Rosin residue emulsion as a sticker for lead arsenate in horticultural sprays, R. L. PIERPONT (*Delaware Sta. Bul.* 221 (1939), pp. 35, figs. 2).—Rosin residue emulsion has been shown to improve the efficiency when included with lead arsenate and various fungicides in representative apple, grape, and peach spray combinations by producing a more even coverage on both foliage and fruit and by increasing arsenical adherence. In experimental spraying of apples, conducted under typical Delaware orchard conditions, when used at the rate of 1 pt. per 100 gal. of spray for the first brood with lead arsenate and various fungicides on a rather complete seasonal succession of apple varieties, it was as effective as menhaden fish oil and certain commercial stickers that have been recommended for the apple spraying programs of Delaware and other States. In general, the addition of rosin residue emulsion to the base sprays resulted in a worth-while increase in clean and marketable fruit and a reduction in worm population. Chemical analyses of fruit samples taken at harvest time have indicated that in some cases the arsenical residue exceeded that allowed by Federal regulations, but the excess was readily removed by washing.

"In experimental spraying of grapes, conducted under typical Delaware vineyard conditions, rosin residue emulsion was used with lead arsenate com-

bined with bordeaux mixture and with Cocosil on Concord variety grapes. When employed at the rate of 2 pt. per 100 gal. of spray in a complete spray program for grape berry moth control, it was more efficient than menhaden fish oil and certain commercial stickers. When used at the rate of 1 pt. per 100 gal. of spray, under conditions identical with those just mentioned, the results compared favorably with those obtained with 1 pt. of menhaden fish oil. In general, the addition of rosin residue emulsion, menhaden fish oil, and the commercial stickers to the base sprays resulted in either an increase in clean berries or clean clusters.

"Rosin residue emulsion can be safely employed as a sticker for lead arsenate in horticultural sprays. The use of this material did not result in any discoloration of or injury to foliage or fruit."

Studies of contact insecticides.—XIV, Penetration of certain liquids through the pronotum of the American roach, W. C. O'KANE, L. C. GLOVER, R. L. BLICKLE, and B. M. PARKER (*New Hampshire Sta. Tech. Bul. 74 (1940), pp. 16, figs. 8*).—In reporting further (*E. S. R., 81, p. 73*), the authors give the results of certain studies designed to measure the rate and amount of penetration of several liquids through a piece of the integument that has been detached from the insect and observed in a specially designed apparatus. A description is given of the apparatus and of the procedure employed, together with the liquids studied. The results of the experiments to date are considered as suggestive and in some ways indicative.

Toxicities of optically active nicotines and nornicotines to *Aphis rumicis*, R. HANSBERRY and L. B. NORTON. (Cornell Univ. and N. Y. State Expt. Sta.). (*Jour. Econ. Ent., 33 (1940), No. 5, pp. 734, 735, fig. 1*).—Toxicity studies in the laboratory of a group of optically active nicotines and nornicotines and of *dl*-nornicotine gave the following order of toxicities against the bean aphid: *l*-nornicotine, *dl*-nornicotine, and *d*-nornicotine were almost equally more toxic than *l*-nicotine; *d*-nicotine was substantially less toxic than *l*-nicotine.

Toxicity of some nitrogenous bases to eggs of *Lygaeus kalmii*, C. F. SMITH. (Iowa State Col.). (*Jour. Econ. Ent., 33 (1940), No. 5, pp. 724–727, figs. 6*).—The work conducted has led to the preparation of concentration-mortality curves for solutions of nicotine, quinoline, piperidine, anabasine, pyridine, and sodium oleate to the eggs of *L. kalmii* (Stål.). The median lethal concentrations obtained were nicotine 0.11 percent, quinoline 0.12, anabasine 0.18, piperidine 0.29, pyridine 19.6, and sodium oleate 2 percent. Nicotine, anabasine, piperidine, sodium oleate, and pyridine did not kill the eggs at once, and development of the embryos continued for several days. In some cases the young bugs were able to emerge from the eggs but died soon after hatching. Quinoline, however, killed the eggs at once.

Supplementary spray materials for use with nicotine peat, L. H. DAWSEY and L. N. MARKWOOD. (U. S. D. A.). (*Jour. Econ. Ent., 33 (1940), No. 5, pp. 717–722, fig. 1*).—In the work reported, bentonite was the most satisfactory sticker used with nicotine peat. It is thought that this may be explained by its fixation of the water-soluble portion of the peat, resulting in the formation of nicotine bentonite. Other factors, not considered, which also favor the use of bentonite include the simplicity with which sprays may be prepared and its comparatively low price. The eight other supplementary materials tested as stickers were petroleum oil, petrolatum, paraffin, menhaden fish oil, cottonseed oil, varnish, rosin residue, and rosin gum. Varnish was equally as effective as bentonite from the standpoint of time-load product, but is more costly and its use resulted in slight injury to rose foliage under greenhouse conditions. Cottonseed oil, fish oil, and petroleum oil appear to be more practical from this viewpoint than does varnish.

Persistence of nicotine on rose bushes sprayed with nicotine sulfate combinations, L. H. DAWSEY and L. N. MARKWOOD. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 722, 723, fig. 1).—In connection with the work above noted, tests were made with certain nicotine spray combinations other than nicotine peat. In addition to the nicotine bentonite sprays above described, nicotine bentonite-soybean oil, nicotine sulfate alone, and nicotine sulfate with molasses were tested. The molasses was worse than no sticker at all, bentonite offered definite advantages, and the addition of soybean oil and bentonite together offered the greatest improvement in the compounding of a useful nicotine sulfate spray.

Tight cribs, carbon bisulphide to curb corn insect damage, C. LYLE (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 9, p. 1).

Report on a survey of the infestation of grain insects, J. W. MUNRO (*London: Dept. Sci. and Indus. Res.*, 1940, pp. VIII+54, [pls. 5], figs. [6]).—Findings based upon field work of the survey, commenced in May 1938 and concluded in June 1939 by a committee of which E. Butler was chairman, are reported.

New records of insects in grain stores, R. HOWE (*Ent. Mo. Mag.*, 4, ser., 1 (1940), No. 911, pp. 73-75, figs. 2).—Attention is drawn to forms of quite widespread occurrence not previously recorded from grain stores in Great Britain, namely, *Eurostus hilleri* (Reit.), *Tinea insectella* F. (*misella* Zell.), and *T. ditella* Pierce & Metc.

Disinsectization of aircraft, C. L. WILLIAMS (*Pub. Health Rpts. [U. S.]*, 55 (1940), No. 23, pp. 1005-1010, pls. 2, fig. 1).—A sprayer that may be operated by compressed air at pressures from 25 to 50 lb. is described and illustrated. A diagrammatic drawing which shows its construction is included.

Strain susceptibility to the European corn-borer and the corn-leaf aphid in maize, L. L. HUBER and G. H. STRINGFIELD. (Ohio Expt. Sta. and U. S. D. A.). (*Science*, 92 (1940), No. 2382, p. 172).—The authors have recently found a differential susceptibility to the corn leaf aphid among corn strains and significant correlations in the degree of strain susceptibility to this aphid and the European corn borer.

Parasites of gall-causing insects, M. NIBLETT (*So. London Ent. and Nat. Hist. Soc., Proc. and Trans.*, 1939-40, pp. 85-89).—This review relates to Ichneumonidae, Braconidae, Chalcididae, and Proctotrupidae which parasitize larvae of gall-causing insects.

The biology of six species of cockroaches which inhabit buildings, G. E. GOULD and H. O. DEAY (*Indiana Sta. Bul.* 451 (1940), pp. 31, figs. 14).—Report is made of the findings obtained in a 5-yr. study of the biology of the following roaches: The American cockroach, oriental cockroach, German cockroach, brown-banded roach, the Pennsylvania woods roach *Parcoblatta pennsylvanica* Deg., and the smoky brown cockroach *Periplaneta fuliginosa* S. Of these, the first three are well known household pests, the fourth, the brown-banded roach, has become an important pest in the United States during the past 10 yr., the woods roach is an occasional pest of homes located near woods, and the smoky brown roach is a potential pest of homes in the North. The findings on the effect of temperature upon the nymphal development of the several species are given in tables, of which there are 12. Twenty-four references are given to the literature cited.

Control of the Mormon cricket by the use of poisoned bait, F. T. COWAN and H. J. SHIPMAN (*U. S. Dept. Agr. Cir.* 575 (1940), pp. 16, figs. 3).—Forty different baits, consisting of different combinations and strengths of carriers, attractants, and poisons, were tested. Standard bran proved to be the best carrier, although under favorable feeding conditions a mixture of 3 parts saw-

dust with 1 part mill-run bran was almost as effective. Liquid sodium arsenite, even in small quantities, acted as a repellent. The results of pan baiting confirmed the data obtained by wing-pen tests and established the optimum feeding temperature at 86° F. Peak feeding was observed to occur most frequently in the morning between the hours of 8 and 10 a. m., with a lesser feeding period after 4 p. m. Crickets fed on bait whenever they were migrating. The bait recommended is 100 lb. of standard bran, 3 lb. of sodium fluosilicate, and 10-15 gal. of water, spread at the rate of 10 lb. (dry weight) per acre while the crickets are migrating.

Poisons in baits for grasshopper control, C. C. WILSON. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 745-749).—The results of field tests conducted from 1924 to 1936 with liquid sodium arsenite, powdered sodium arsenite, paris green, and white arsenic in varying quantities to determine their toxic effect in grasshopper baits are summarized. They were conducted principally in California in locations ranging from 5,000 ft. above to 121 ft. below sea level, embracing grassy meadowlands, alfalfa fields, and practically barren desert. Ten economic species of grasshoppers were involved. The plats ranged in size from $\frac{1}{2}$ acre to 5 acres. The relative efficiency of the poisons was determined by comparing the mortalities in the cages of grasshoppers collected from the poisoned plats. Student's Z test was used in determining the differences obtained in experiments wherein the kinds of poisons and the amounts used were varied.

"Liquid sodium arsenite used at the rate of 1 pt. to 5 pt., paris green at 1, 2, 3, and 4 lb., white arsenic at 1, 2, 3, and 4 lb., and powdered sodium arsenite at the rates of 2 and 4 lb. to 100 lb. of bran were equal in efficacy to 1 qt. of liquid sodium arsenite under conditions prevailing during these tests. Dosages of $\frac{1}{2}$ pt. and 3 qt. of liquid sodium arsenite proved less effective than 1 qt. per 100 lb. of bran, the former being sublethal and the latter repellent. The poisons and dosages per 100 lb. of bran recommended for control of grasshoppers in California are liquid sodium arsenite 1 qt., paris green 2 lb., white arsenic 2 to 3 lb., or powdered sodium arsenite 2 lb."

The use of oil sprays in grasshopper control in British Columbia, E. R. BUCKELL (*Canad. Ent.*, 72 (1940), No. 8, pp. 149, 150).—Oil sprays have proved of value in grasshopper control work on the open ranges of British Columbia under certain conditions, but can only assist and never replace the use of poisoned baits since they can be used only with species that concentrate their eggs in restricted areas, such as the clear-winged grasshopper, or species whose nymphs and adults congregate in patches of weeds, such as *Melanoplus mexicanus mexicanus* (Sauss.). They can be used in cool weather when poisoned baits would not be effective. Oil sprays kill by contact only and are valueless against the eggs in the soil. They have no lasting effect as have poisoned baits, and are effective only on the grasshoppers actually hit by the oil emulsion at the time of spraying.

Review field studies of citrus thrips control, C. O. PERSING, A. M. BOYCE, and F. C. MCCARTY. (Calif. Citrus Expt. Sta.). (*Citrus Leaves*, 20 (1940), No. 5, pp. 7, 30).—A continuation of the contribution noted (E. S. R., 83, p. 523).

Some experiments with certain liquid insecticides in houses infested with the bed-bug (*Cimex lectularius* L.), A. J. MUSGRAVE (*Jour. Hyg. [London]*, 40 (1940), No. 4, pp. 462-473, figs. 5).—Description is given of some field work on the disinfection of empty infested houses by means of liquid insecticides and an experiment with an occupied house. A method of obtaining an estimate of the number of insects killed by the application of such insecticides is given, together with some information as to the number found in houses.

The aliphatic thiocyanate, β -butoxy- β' -thiocyanodiethylether, was tried in four different oil carriers and gave good results as a 3-percent solution (6 percent Lethane). A pyrethrum preparation in a heavy oil carrier also showed promise, and a mixture of the two toxic substances was found to be effective. The methods of applying the insecticides are described. Good results were obtained with an ordinary hand sprayer of the horticultural type, giving a continuous spray. The premises were not sealed, but a few wood fittings were eased or removed.

Leaf hoppers enemies of the Persian walnut, P. C. CRATH (*North. Nut Growers Assoc. Proc.*, 29 (1938), pp. 111, 112).

Bionomics and control of the Indian sugar-cane leafhopper, *Pyrilla perpusilla*, Wlk. (Rhynchota, Fulg.) in the Punjab, K. A. RAHMAN and R. NATH (*Bul. Ent. Res.*, 31 (1940), No. 2, pp. 179-190, pl. 1, fig. 1).

An airplane survey of green bug injury in Oklahoma, F. E. WHITEHEAD and F. A. FENTON (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 762-768, figs. 9).—A survey of green bug injury in Oklahoma by means of an airplane led to the conclusion that an aerial survey constitutes a rapid and inexpensive method of locating infestations in their incipient stages. Spots no larger than a yard in diameter are said to have been located on numerous occasions at a time when the pest could be brought under control.

A new geranium aphid (Homoptera: Aphididae), G. F. KNOWLTON. (Utah Expt. Sta.). (*Ent. News*, 51 (1940), No. 7, pp. 196, 197, figs. 7).—*Capitophorus cefsmithi*, taken on wild geranium in Logan Canyon, Utah, is described as new.

Aphids on citrus, J. R. WATSON. (Fla. Expt. Sta.). (*Citrus Indus.*, 21 (1940), No. 3, pp. 14, 18).

The influence of alfalfa on the abundance of the pea aphid on peas grown for canning in southeastern Washington, R. D. EICHMANN and R. L. WEBSTER (*Washington Sta. Bul.* 389 (1940), pp. 36, figs. 15).—Information concerning the factors which influence the abundance of the pea aphid on peas, prepared for growers, canners, field men, and those interested in the canning pea industry of southeastern Washington, is presented. Aphid occurrence as influenced by alfalfa is first considered, followed by a presentation of the aphid abundance over three seasons and a discussion of the factors limiting its abundance. It is shown that alfalfa grown for hay production under irrigation and in bottom lands at low elevation is the chief factor in maintaining the aphid population, since it serves as the principal overwintering host plant and the first growth in early spring affords a succulent host on which aphids multiply rapidly and attain the initial peak population, and from which they subsequently spread to other hosts. The second hay crop growth and later growths throughout the summer carry low populations that are barely able to survive and which seldom if ever produce migrants. In the fall, hay meadow alfalfa revives somewhat and aphids reappear upon it and build up a population preparatory to overwintering.

It is concluded that the use of alfalfa for soil conservation in the Blue Mountain area is compatible with the canning pea industry so far as the pea aphid is concerned, since as planted for erosion control it does not tend to increase the aphid population. Early peas are in a most attractive stage of growth when aphids migrate from hay meadows, and because of the large fields usually adjacent to hay meadows, the peas provide a more favorable host and a greater influence on aphid abundance than erosion-control alfalfa. Aphid abundance is dependent on abnormal weather conditions, which include early fall rain, mild winters, and moist warm growing seasons, especially in early summer. Some varieties of peas and alfalfa are resistant to aphid infestation. On the whole,

however, true resistance is not as yet combined with other desirable qualities, and this phase of the problem remains with the plant breeders.

Plant lice hibernation habits described—recommended control measures outlined, M. A. PALMER (*Colo. Farm Bul. [Colorado Sta.]*, 2 (1940), No. 4, pp. 6-8).—A practical account of aphids, particularly as relates to reproduction, hibernation, and control.

Peanut oil in derris dust mixtures against the pea aphid, T. E. BRONSON and J. E. DUDLEY, JR. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 736-738).—Greenhouse and field experiments have shown that the addition of a small quantity of crude peanut oil to a derris dust mixture appreciably increases its effectiveness against the pea aphid, and that the greater increases in effectiveness occur, in the greenhouse at least, when the relative humidity is comparatively low.

Tests of rotenone, anabasine, nicotine, and other insecticides against the woolly apple aphid and the apple aphid, M. A. YOTHERS and S. W. GRIFFIN. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 800-803, fig. 1).—The results of tests of insecticides against the woolly apple aphid and the apple aphid, conducted at Wenatchee, Wash., during the period 1931-33, are presented in detail in three tables. It was found that anabasine sulfate and nicotine sulfate at the lowest concentrations tested were about equal in effectiveness against the woolly apple aphid, each giving approximately 97-percent kill when an alkylated naphthalene sulfonate was added as a wetting agent. "The wetting agent alone gave a 58-percent kill. At a concentration somewhere between 1 to 3,200 and 1 to 4,800 of both anabasine sulfate and nicotine sulfate, even with the wetting agent doubled, the mortality of the woolly apple aphid began to fall off from 100 percent. Between the same concentrations, with sodium oleate as a wetter but with the wetter not increased at the 1 to 4,800 concentration, the mortality of the apple aphid also began to fall off from 100 percent. Rotenone proved rather ineffective against the woolly [apple] aphid at concentrations as high as 8 oz. in 100 gal. of water and when used with the same wetters as were employed with anabasine sulfate and nicotine sulfate and other materials. At the maximum concentration of 8 oz. per 100 gal., with 4 lb. of soap, a kill of only 93.5 percent was obtained. . . . Against the green apple aphid, however, rotenone gave 100-percent mortality at a concentration of 3 oz. in 100 gal. and an approximately complete kill at 2 oz. with sodium oleate. Nicotine and anabasine sulfate with accessory agents gave almost complete mortality down to concentrations of 1 to 3,200, and anabasine sulfate gave a 95-percent kill at a concentration of 1 to 4,800. This species is undoubtedly much more susceptible than the woolly [apple] aphid. Proprietary sulfonated petroleum activator, alkylated naphthalene sulfonate, pine tar soap, light medium oil emulsion, and sodium oleate all proved effective as wetting agents against the woolly [apple] aphid. Each possessed a certain lethal value of its own. Medium summer oil emulsion, as used in codling moth control, resulted in only 78.3-percent mortality of the green [apple] aphid. Light medium summer oil emulsion with 1 and 2 lb. of soap in 100 gal. gave mortalities of only 54.4 and 60 percent of the woolly [apple] aphid. In tests with 8 oz. of rotenone and 2 qt. of activator and with the activator alone a positive correlation was shown between the temperature prevailing during the post-spray period and the percent kill obtained."

Insects as vectors of yellow dwarf, a virus disease of onions, H. D. TATE. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 14 (1940), No. 3, pp. 267-294).—In transmission experiments the yellow dwarf virus was transmitted from diseased to healthy onion plants by 48 species of aphids. All tests with in-

sects other than aphids, with 2 doubtful exceptions, gave negative results. A list is given of 16 references to the literature cited.

Studies on the transmission of sugar-beet yellows virus by the aphid *Myzus persicae* (Sulz.), M. A. WATSON (*Roy. Soc. [London], Proc., Ser. B, 128 (1940), No. 853, pp. 535-552*).—In experiments at the Rothamsted Experimental Station the efficiency of the green peach aphid as a vector in transmitting sugar beet yellows virus was found to increase greatly with increasing feeding time on the infected plants.

Biological control of the long-tailed mealybug (*Pseudococcus longispinus*), S. E. FLANDERS. (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent., 33 (1940), No. 5, pp. 754-759, fig. 1*).—An outbreak of the long-tailed mealybug near Downey, Los Angeles County, Calif., in 1933 led to the introduction of three established exotic parasites, namely, *Anarhopus sydneyensis* Timberlake, *Tetraneura peregrinus* Comp., and *Anagyrus fusciventris* (Girault). These parasites are not as yet widely distributed, but *A. sydneyensis* and *T. peregrinus* appear to be effective in maintaining the populations of the long-tailed mealybug at low densities. *A. fusciventris* appears to be of little, if any, importance. Twenty-seven references are given to the literature cited.

The brown elm scale: Description and control, F. A. FENTON (*Oklahoma Sta. Bul. 245 (1940), pp. [6], figs. 2*).—A practical account, with description and directions for control.

Non-arsenical dusts for cauliflower and cabbage worm control on Long Island, H. C. HUCKETT (*New York State Sta. Bul. 695 (1940), pp. 58*).—Report is made of experiments conducted during the season of 1933 to 1938 on Long Island to secure data relative to the comparative merits of insecticides manufactured from the dried roots of rotenone-bearing plants and from the dried flowers of pyrethrum as substitutes for lead or calcium arsenate in the control of worms on cauliflower and cabbage.

In field comparisons of dusts containing powders of derris, cube, and timbo, possessing nearly equal extractive content, there were no significant differences in the protective values of the different treatments at a given rotenone strength as shown by the foliage condition of plants in the respective plots. Dust mixtures formulated to contain 0.5 to 1 percent rotenone were of nearly equal insecticidal value for control purposes. Rotenone-containing dusts were less effective than pyrethrum dusts for checking infestations of the cabbage looper, due principally to greater tolerance exhibited by the larger worms toward toxic effect of rotenone-containing dusts.

Experiments were conducted with grades of pyrethrum powder standardized at 1.25, 0.9, 0.6, and 0.5 percent pyrethrins, respectively, which were diluted where necessary by the admixture of clay or talc to strengths of 0.6, 0.5, 0.4, and 0.3 percent pyrethrins. Dusts formulated at 0.4 to 0.6 percent pyrethrin strength were most effective for purposes of control, optimum strength in this respect depending to some degree on extent of dilution and type of diluent.

In the case of impregnated pyrethrin dusts, proprietary powders were placed on trial that contained a minimum strength of 2 or 0.5 percent pyrethrins. These powders were diluted by the admixture of talc to strengths of 0.3, 0.2, and 0.15 percent pyrethrins. At these strengths the dusts were rarely as effective under field conditions as those of pyrethrum, as formulated. Many of the impregnated pyrethrin mixtures lacked good dusting qualities. However, such dusts were particularly toxic to the cabbage looper in all stages of growth, and some of the mixtures containing a higher pyrethrin strength were capable of affording considerable protection.

Tests were also made of pyrethrum and impregnated pyrethrin dusts containing different diluents, such as clay, talc, air-floated gypsum, sulfur, and

diatomaceous earth. Mixtures containing talc were found to be of greatest practical value as denoted by their effectiveness, dusting qualities, and adaptation to the capabilities of dusting machinery. Clay served to impart excellent dusting qualities to the mixtures, but also was instrumental in reducing the insecticidal value of impregnated pyrethrin dusts, and was considered less desirable than talc for extending the protective efficiency of pyrethrum dusts. Mixtures containing diatomaceous earth, as formulated, were as effective as those containing talc or air-floated gypsum, but owing to the bulky nature of the mixture they could only be used satisfactorily by machines of a puff or bellows type.

Birds eating tent caterpillars, J. K. TERRES. (U. S. D. A.). (*Auk*, 57 (1940), No. 3, p. 422).—Observations on the eating of small eastern tent caterpillars by the black-throated green warbler (*Dendroica virens virens*) in Pennsylvania and the black-capped chickadee (*Penthestes atricapillus atricapillus*) in New York are reported.

Observations on *Cirphis unipuncta* Haworth in Mississippi, E. J. MORAN and C. LYLE (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 768, 769).—A brief summary is given of observations of the life history of the true armyworm in Mississippi, where a destructive outbreak first occurred on oats in the Delta section in 1931.

The armyworm and its control, W. R. WALTON and C. M. PACKARD (*U. S. Dept. Agr., Farmers' Bul. 1850* (1940), pp. [2]+12, figs. 8).—This supersedes Farmers' Bulletin 731 (E. S. R., 35, p. 465).

Investigations on the cotton bollworm, *Heliothis armigera*, Hübner.—III, Relationships between oviposition and the flowering curves of food-plants, F. S. PARSONS (*Bul. Ent. Res.*, 31 (1940), No. 2, pp. 147-177, figs. 8).—A continuation of this study (E. S. R., 84, p. 219).

Two years' results with codling moth sprays, C. L. BURKHOLDER, D. L. JOHNSON, and O. W. FORD. (Ind. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 713-717).—Report is made of control work conducted in a 70-acre orchard of mature apple trees at Bedford, located in the three-brood codling moth belt of Indiana, where a combined attack of late second- and third-brood worms had been very difficult to control from August 10 to harvest. With some spray schedules that had been used in the past the orchard had produced less than 50 percent of fruit free of codling moth injury. When in the experimental work, the details of which are given in five tables, more than four first-brood lead arsenate cover sprays containing oil were applied, severe foliage injury, fruit russet, and reduction in size of fruit occurred, especially on varieties such as Jonathan and Grimes. Good commercial control of the pest had been obtained by a maximum of four first-brood cover sprays, although the success of such a program appears to be dependent upon the size of the codling moth population, pruning to facilitate special coverage of the top third of the tree, and supplementary control measures, particularly packing-shed sanitation. A 15-acre test of factory-mix nicotine-bentonite-oil resulted in good control but required more frequent coverage than was the case with the lead arsenate-oil sprays.

“An effort was made to work out a combination schedule using nicotine-bentonite-oil during the first-brood period of codling moth attack and to follow this by one or two lead arsenate-oil sprays to reduce spraying costs as well as take advantage of the high efficiency of lead arsenate during the latter part of the fruit-development period. Codling moth control was satisfactory with this split schedule and foliage injury was negligible. Lead and arsenic loads were determined before and after spray applications and at harvest, and show the possibilities of producing a heavy and effective lead arsenate film by one spray

applied after the apples have reached a size of 7 to 10 fruits to the pound. Washing tests conducted during two seasons show that a rapid washing treatment at packing-shed temperature resulted in a high percentage residue removal which brought both arsenic and lead loads to tolerance on the fruit from the split-treatment plats."

Influence of road dust upon codling moth control, J. A. CALLENBACH. (Wis. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 803-807, fig. 1).—The work reported indicates that road dust is a detriment to codling moth control in sprayed orchards, and that codling moth injury is uniformly greater the more severe the dust condition. Where dust is deposited in extremely heavy layers the entire benefit of spray applications may be lost. The dust appears to act as a mechanical barrier. "Spray deposits tend to dry in patches, and these patches are in turn broken up into smaller patches by surface increase of the fruit. Dust sticks readily to these deposit areas but not to any extent to smooth unprotected parts of the fruit. Because of the mechanical barrier raised by heavy dust deposits, the larvae are compelled to attempt entry through the unprotected portions of the fruit, and hence are unharmed by the original spray deposits. . . . Dusty fruit is difficult to spray because the dust causes the drops to coalesce and run off without wetting the surface. Therefore, later applications are also rendered ineffective because of the impossibility of applying them properly."

Spur-burrowing habit of codling-moth larvae on pear trees, L. G. GENTNER. (Oreg. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 796-799, figs. 5).—Spur-burrowing in pear fruit spurs by codling moth larvae, first shown to be a habit of this pest in the spring of 1937, is said to be on the increase in the Rogue River Valley of Oregon. The fact that young larvae may burrow into fruit spurs with fruit attached, both during the first- and second-brood periods, points to the possible existence of a spur-burrowing strain of codling moth larvae. There is enough food matter in the spurs to permit the larvae to complete their development and change to adult moths. The habit has been noted chiefly on Bosc and Anjou varieties, and occasionally an injured Bartlett spur is found. The larvae usually enter through a scar left by the separation of a fruit stem from the spur. They may almost completely hollow out the spurs, cutting off the food supply to the fruit and leaves attached to the outer end of the spur. These may turn black and hang until after harvest, or may drop prematurely. No practical control can be recommended, since the natural fruit drop extends over a long period of time, leaving points of entry which do not have adequate spray protection.

Codling moth control: Report on 1938-39 investigations, K. M. WARD and J. L. GROOM (*Queensland Agr. Jour.*, 54 (1940), No. 1, pp. 17-37, figs. 2).—In continuation of investigations at Stanthorpe (E. S. R., 80, p. 802), work was aimed primarily at (1) testing white oil and nicotine sulfate in cover sprays, (2) determining the value of timing cover sprays according to the abundance of adult moths, and (3) examining the possibility of timing sprays on a district-wide basis. In a replicated factorial orchard experiment six spray mixtures were compared under three different timing schedules, the quantities given being made up to 80 gal. with water. The results showed that white oil alone, 1½ gal., and three combinations of white oil and nicotine sulfate, namely, 1 gal. : ¼ pt., ½ gal. : ½ pt., and ¼ gal. : 1 pt., gave as effective control as lead arsenate plus spreader. A fourth combination, 1½ gal. : 1 pt., gave better control than any of the other treatments. The results, generally, supported previous observations and demonstrated that white oil and white oil-nicotine sulfate combinations are safe substitutes for lead arsenate in cover

sprays. The nonarsenical cover sprays greatly reduced foliage injury and left no objectional residues on the fruit. A list of 19 references is included.

Cooperative investigations of the relation between mosquito control and wildlife conservation, E. L. BISHOP (*Science*, 92 (1940), No. 2383, pp. 201, 202).—A brief report on the status of a cooperative investigation.

The external morphology of the immature stages of the bee fly *Systoechus vulgaris* Loew (Diptera: Bombyliidae), a predator of grasshopper egg pods, V. L. BERG (*Canad. Ent.*, 72 (1940), No. 9, pp. 169-178, figs. 6).

Report on the Tabanidae of Delaware, D. MACCREARY (*Delaware Sta. Bul.* 226 (1940), pp. 41, figs. 7).—As certain sections of the State are subjected to enormous numbers of horseflies during the summer months, a study was made of the species present and their distribution and habits, with a view to applying means of control. These flies are of considerable economic importance in the infested areas both from the standpoint of actual feeding and as potential vectors of livestock diseases.

From emergence cages placed in various marshes 8 species were collected. "*Chrysops fuliginosa* emerged from soil that was covered twice daily by tides. *C. callida*, *C. dimmocki*, *C. flavida*, *C. fuliginosa*, *C. lugens*, and *C. obsoleta* emerged from an extremely wet location which was inundated occasionally by heavy rains. Twenty species of Tabanidae were reared from collected larvae or pupae. Pupation records for some are presented, and the plant and water relationships of certain larval habitats are described. Four hundred and twelve specimens were captured in mosquito traps on lighthouses in the Delaware Bay. Ten species were collected in traps which were from 3.2 to 8.4 miles from land. A considerable number of males were collected, indicating that this sex is not so closely restricted to the breeding areas as is generally believed. . . . The feeding of the adults is not confined entirely to the blood of vertebrates. Certain species are attracted to and feed on the products of fermentation. The members of the genus *Chrysops* are more prone to attack man than are those of the other genera present in Delaware. An occasional person will show a decided reaction to their bites, but such occurrences apparently are quite rare. *Tabanus nigrovittatus*, *T. daeckei*, *T. lineola*, *T. sparus*, and *T. pumilus* have all been observed feeding upon man. Livestock, especially those on and nearby the marshes, are severely attacked. . . . Fifty-five species have been collected as adults in Delaware. Two species were reared which were never observed as adults, thus making a total of 57 species known to occur in the State. In addition, 2 varieties and 1 subspecies were collected."

The Amazon fly *Metagonistylum minense*, a parasite of the sugarcane borer, T. E. HOLLOWAY and R. MATHES. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 738-742).—Studies of the Brazilian tachinid fly *M. minense* as a parasite of the sugarcane borer in Louisiana, where its Amazon form was introduced from Puerto Rico in May 1938 and its São Paulo or dry-land form in 1939, are reported. The two forms were found to require exactly the same treatment in the insectary. Nine generations of the former were produced in 1938 and six generations of the latter in 1939 up to December 1. The emergence of the Amazon River form ran from 23.8 to 118.5 percent per generation, while that of the São Paulo form ran from 11.5 to 76 percent, being reduced by the prevalence of mites and scavenger flies. The smaller number of generations in 1939 was also due to these predators, as flies for dissection and inoculation were often not available. In 1938 a total of 3,612 flies were reared and in 1939 the number was 3,217. In the field 1,222 flies were released in 1938 and 1,904 in 1939. Both forms were recovered soon after release and were found to have destroyed a considerable number of borers. The Amazon River form

in 1938 killed from 8.4 to 52.2 percent of the borers in the areas surrounding the spots of release, while in 1939 the São Paulo form was responsible for the death of from 3.3 to 58.6 percent. At harvest time in 1938 Amazon flies were recovered in 6 of 7 fields in which they had been released and in which examinations were made. In 1939 they were found in 11 out of 15 fields in which they were released earlier in the year. One hundred borers which were inoculated with maggots of the dry-land form produced 165 flies, although the average production was much lower. This parasite in both its forms appears to be an efficient and adaptable parasite of the sugarcane borer in regions where the climate is suitable for its development. It is easily reared and is quickly fatal to its host.

Effect of pyrethrum and derris on the black blister beetle, F. F. SMITH and W. N. SULLIVAN. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 807-810).—In field tests on china asters that were invaded by the black blister beetle, sprays containing pyrethrum extracts (pyrethrins 1:10,000 and 1:22,000) killed 68.8 and 42.6 percent of the beetles. "Derris powder and derris extract (rotenone 1:18,000) when added to sprays containing pyrethrins 1:10,000 did not increase the killing effect, but when added to sprays containing pyrethrins 1:5,000 a higher kill was obtained. The most effective spray was one containing pyrethrum extract (pyrethrins 1:5,000) and derris powder (rotenone 1:4,000), which killed 91.6 percent of the beetles. The derris powder when used alone killed 11.1 percent of the beetles. A spreader containing alkylphenylbenzenesulfonic acid was added at the rate of 2 gm. per gallon. . . . By a modified turntable method alcoholic pyrethrum extract diluted to give pyrethrin contents of 1:8,000 and 1:16,000 in water was tested on field-collected beetles. Sodium lauryl sulfate (1:3,000) was added as a spreader. The more concentrated spray killed 77 percent of the beetles on the first application and only 44 percent of the survivors on the second, giving a final kill of 87 percent. The less concentrated spray killed 57 percent of the beetles on the first application and only 28 percent of the survivors on the second, giving a final kill of 69 percent. These tests indicated that the weaker beetles are killed by the first application. The more resistant survivors seemed completely recovered from the first application, but since some of them succumbed to a second treatment the first spray apparently had a residual effect. Moribund adults finally died. No sexual differences in susceptibility or resistance occurred among the beetles."

The search for parasites of white grubs (melolonthids) in Zanzibar, Algeria, Morocco, and France, L. A. MOUTIA (*Bul. Ent. Res.*, 31 (1940), No. 2, pp. 193-210, pls. 4, figs. 5).—Report is made of an extensive survey covering a period of 18 mo., conducted with a view to obtaining parasites of white grubs for furthering control of *Phytalus smithi* Arrow in Mauritius.

The locust leaf miner as a pest of soybean, F. W. POOS. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 742-745, fig. 1).—The locust leaf miner, a beetle first recorded as severely injuring soybeans in southern Ohio in 1912, has become an important pest of this crop as well as of the apple and feeds upon white oak, beech, birch, and hawthorn. Observations of the miner following a severe attack on soybeans at Knoxville, Md., in July 1939 and continued at Arlington, Va., are reported. A hymenopterous parasite reared from the pupae of this insect was determined as *Spilochalcis albifrons* Walsh.

Biology and control of the wheat wireworm (Agriotes mancus Say), W. A. RAWLINS ([New York] *Cornell Sta. Bul.* 738 (1940), pp. 30, pl. 1, figs. 12).—Field surveys made during 1931 and 1932 in upstate New York indicated that wireworm injury was one of the most important of the potato tuber

defects that were found in more than one-half of the tubers examined. Of the three species of wireworms commonly present in potato fields, the wheat wireworm is the most abundant and injurious. The eastern field wireworm and the corn wireworm (*Melanotus* sp.), while not as widespread as the wheat wireworm, are injurious in many potato-producing areas. In a study of the biology and control of the wheat wireworm during the 6-yr. period from 1930 to 1936, the life cycle was found to be from 3 to 4 yr. in length. The eggs are laid in the soil from June to July and hatch in approximately 3 weeks. The wireworms grow to larval maturity in from 2 to 3 yr., followed by pupation from late July through August. The beetles then appear and remain in the pupal cells through the winter. Infestations of wheat wireworms start in grass and sod crops. Potatoes generally follow the sod, and the appearance of the beetles during the third and fourth years of the life cycle occurs simultaneously with the sod crop in the rotation. Potato crops in this rotation are therefore usually infested. Marked reductions in wireworm populations and in resultant damage to potatoes followed elimination of the sod crop from the potato rotation. Continuous use of cultivated crops on infested fields reduced wireworm injury to a minimum after 3 yr. The control of wheat wireworms by short rotations is not due to mechanical action of cultivation but rather to unfavorable conditions for oviposition and survival of the young larvae in cultivated crops. Such short rotations should include crops that can be tilled during the egg-laying period during June and July.

Isolation of *Ceratostomella ulmi* from *Scolytus multistriatus* adults stored at different temperatures, C. S. MOSES and C. H. HOFFMANN. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 8, pp. 701, 702).—In Dutch elm disease fungus isolation experiments with the smaller European elm bark beetle held at 70°, 60°, 40°, 28°, and -10° F., 1 lot from each storage condition was removed and cultured at the end of 30, 60, 90, and 120 days, respectively. "*C. ulmi* was recovered from 100 percent of the beetles cultured immediately as a check. All but 2 beetles of the 10 lots cultured 30 and 60 days after storage yielded the fungus. At the end of 90 days *C. ulmi* was recovered from only 60 percent of the beetles stored at 70° and 58 percent of those stored at 60°. At the end of 120 days the recoveries were 0 and 22 percent, respectively, for these temperatures. The fungus was recovered from all the beetles stored at the lower temperatures for 90 and 120 days. Three additional lots of beetles stored at -10° were cultured at the end of 1, 1.5, and 2.5 yr. Recoveries of *C. ulmi* were 100, 98, and 100 percent (the latter based on 44 beetles), respectively. Any of the storage conditions studied were adequate if the material was not kept beyond 60 days. In all cases, however, cultures of beetles stored at -10° were most satisfactory on the basis of rapidity of coremial development and freedom from contaminants."

Entomological considerations in utilization of insect-killed ponderosa pine, P. C. JOHNSON. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 773-776).—Report is made of the results of experimental logging operations conducted by two lumber companies in northern California during 1935 to salvage timber in trees killed by bark beetles (*Dendroctonus*, *Ips*, and *Melanophila*). A decline of 40 percent in infestation the year following salvage was noted.

The strawberry rootworm as a nut pest, P. A. READIO. (Cornell Univ.). (*North. Nut Growers Assoc. Proc.*, 30 (1939), pp. 78, 79, fig. 1).—The finding that the strawberry rootworm *Paria canella* was causing much injury to the buds of black and English walnuts in May 1939, in some cases destroying practically all of the buds on young trees, is reported. The beetle was said to have been

present for several years and to constitute a real menace to nut production. A review of the literature has shown a variety of nut plants to be attacked, injury having been reported from Connecticut, New York, and Pennsylvania.

Control of the alfalfa snout beetle (*Brachyrhinus ligustici* (L.)), C. G. LINCOLN and C. E. PALM. (Cornell Univ.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 769-773, figs. 6).—A report of experiments with poison baits that have been conducted during the past 4 yr. in an attempt to devise a cheap and effective control for the alfalfa snout beetle (E. S. R., 84, p. 86).

Insecticides for boll weevil control, M. T. YOUNG, G. L. GARRISON, and R. C. GAINES. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 787-792).—Report is made of several insecticides tested for bollweevil control in Madison Parish, La., in 1939. The average quantity of the cryolites, sulfur, and the two calcium arsenate-sulfur mixtures applied at each dusting was approximately 15 lb. per acre. Calcium arsenate resulted in a greater decrease in infestation and a greater increase in yield than either of the cryolites tested. One of the cryolites caused severe burning of the foliage, but when 1 percent of the sticker and spreader Lethane had been added the burning was very light and there was a slight decrease in infestation with a significant increase in yield as compared with cryolite alone. Calcium arsenate and mixtures of calcium arsenate and sulfur were about equal in effectiveness. Calcium arsenate and calcium arsenate plus 5 percent of sticker gave equally good control.

Effect of insecticides used in boll weevil control upon aphids and mirids, R. C. GAINES, M. T. YOUNG, and G. L. SMITH. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 5, pp. 792-796).—Studies in Madison Parish, La., in 1939 of the effect of certain insecticides used for bollweevil control upon aphid and mirid infestations and to determine the injury caused by aphids are reported. The aphids usually increased in numbers following applications of calcium arsenate. "A larger number of aphids was found in plats treated with calcium arsenate containing 10.3 percent of water-soluble arsenic pentoxide by the New York method than in plats treated with calcium arsenate containing 0.5 percent, the number found in plats treated with a calcium arsenate containing 4.6 percent falling between the other two. Sulfur appeared to have little or no effect upon aphid infestations. There was a definite correlation between aphid infestations and yields and between aphid infestations and effectiveness of insecticides against bollweevils in cages. The reduction in yields caused by aphids is of much importance. In one series of tests calcium arsenate was sufficiently effective to control light infestations of the tarnished plant bug and the rapid plant bug without the addition of sulfur to the dusting mixture."

Wintering vs. package bees, J. A. MUNRO. (N. Dak. Expt. Sta.). (*Gleanings Bee Cult.*, 68 (1940), No. 10, pp. 609-612, figs. 3).

Moth pests of honeybee combs, V. G. MILUM. (Univ. Ill.). (*Gleanings Bee Cult.*, 68 (1940), Nos. 7, pp. 424-428, figs. 4; 8, pp. 488-493, figs. 5).

Podalonia (Hymenoptera: Sphecidae) of North and Central America, W. D. MURRAY. (Minn. Expt. Sta.). (*Ent. Amer.*, n. ser., 20 (1940), Nos. 1, pp. 1-44; 2, pp. 45-77, pls. 5).

A revision of the ichneumon-flies of the genus *Campoplegidea* occurring in America north of Mexico, G. S. WALLEY (*Sci. Agr.*, 20 (1940), No. 12, pp. 617-734, pls. 3).—Of the 80 species of ichneumonid parasites of the genus *Campoplegidea* recognized as occurring in America north of Mexico, 37 are here described as new. Members of the genus are solitary, internal parasites of lepidopterous larvae, and the records of species are confined to moths, particularly those of the families Geometridae and Noctuidae and to a lesser extent the Notodontidae, Lasiocampidae, and Tortricidae. The majority of the hosts are forms which feed on the foliage of the common coniferous and deciduous trees.

A new parasite of *Anthrenus vorax* Waterhouse, E. A. BACK. (U. S. D. A.). (*Ent. Soc. Wash. Proc.*, 42 (1940), No. 5, pp. 110-113, pl. 1).—Discovery of the effective parasitization of the furniture carpet beetle *A. vorax* by the bethylid *Laelius voracis* Muesebl. (E. S. R., 82, p. 802) in the District of Columbia is reported.

A new species of *Lissonota* (Hym.: Ichneumonidae), R. A. CUSHMAN. (U. S. D. A.). (*Ent. Soc. Wash. Proc.*, 42 (1940), No. 7, pp. 156-158).—Under the name of *L. inconstans* an ichneumonid parasite of *Melissopus latiferreanus*, whose food plants include Catalina cherry, acorns, filbert nuts, and walnuts in California and Oregon, is described as new.

On some parasites and hyperparasites of *Artona catoxantha*, Hamps., C. FERRIÈRE (*Bul. Ent. Res.*, 31 (1940), No. 2, pp. 131-139, figs. 5).—Eighteen forms of parasitic Hymenoptera of the well-known coconut pest *A. catoxantha* are noted, of which seven species and one variety are described as new.

Note on two egg-parasites of *Antestia lineaticollis*, Stål., C. FERRIÈRE (*Bul. Ent. Res.*, 31 (1940), No. 2, pp. 145, 146, fig. 1).—Two chalcidoid egg parasites of the coffee bug *A. lineaticollis* are noted, *Acroclisoides africanus* being described as new.

ANIMAL PRODUCTION

[Livestock investigations in Idaho], D. W. BOLIN, W. M. BEESON, C. W. HICKMAN, E. F. RINEHART, R. F. JOHNSON, J. L. TOEVS, W. WELLS, D. E. BRADY, J. K. WILLIAMS, E. M. GILDOW, C. E. LAMPMAN, G. C. HOLM, D. R. THEOPHILUS, and E. WOODS (*Idaho Sta. Bul.* 236 (1940), pp. 5-10, 14, 15-19, 41-43, 54, 55, 58, 63-65, figs. 3).—Included are brief progress reports (E. S. R., 81, p. 688) on the effect of stage of maturity on the composition of range forage, particularly of arrowhead balsamroot and bluebunch wheatgrass; the vitamin A value of Ladino clover; the phosphorus content of fall and winter range plants; the phosphorus requirements of growing and fattening steers and lambs, and the adequacy of home-grown feeds in meeting these requirements; a comparison of the rate and efficiency of gains of fattening steers in dry lot in summer v. in winter; the economy of a wintering, pasturing, and dry-lot finishing system for beef calves; the value of sugar beet byproducts in the ration of cattle and sheep; the palatability of concentrate feeds as related to the rate of growth of creep-fed lambs; the influence of frequency of nursing and the number of pigs on the milk production of sows; and differences in the vitamin E requirements of male and female white rats.

From poultry experiments results are noted on selective breeding as a means of reducing poultry mortality, the utilization by hens of carotene supplied in alfalfa hay, the use of white grains in poultry rations, the carotene and vitamin A requirements of poultry, and the value of soybean meal as a protein concentrate in turkey starting rations.

[Livestock investigations in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 9, pp. 1, 2, 7, 8).—The results of recent experiments are presented in articles entitled Wintering Beef Herd on Pasture, by R. H. Means; Vines From Maturing Sweetpotatoes, Ordinarily Wasted, Satisfactorily Made Into Succulent Feed for Stock, by H. W. Bennett and M. Gieger; and Beginnings in Beef Production, and The Place of Dairying, both by C. Dorman.

The nutritive value of the natural pastures of the Union of South Africa, P. J. DU TOIT, J. G. LOUW, and A. I. MALAN (*Farming in So. Africa*, 15 (1940), No. 171, pp. 229-232, pls. 5).—A résumé of the protein and mineral composition and energy values of the prevailing species of herbage in the Union of South Africa, together with a series of maps indicating the character of the natural pastures in various sections of this region.

Mineral supplements for stock: The composition of animal licks, P. J. DU TOIT, A. I. MALAN, P. K. VAN DER MERWE, and J. G. LOUW (*Farming in So. Africa*, 15 (1940), No. 171, pp. 233-248, figs. 11).—A general discussion, with particular reference to the prevailing phosphorus content of pastures in various sections of the Union of South Africa. Practical suggestions are offered on methods of administering phosphorus supplements to livestock.

Phosphates for livestock in Montana, H. WELCH (*Montana Sta. Cir.* 157 (1940), pp. [4], figs. 2).—A brief discussion of the symptoms of phosphorus deficiency in cattle, hogs, horses, and sheep and suggested treatment for this disorder.

Pantothenic acid, B. W. FAIRBANKS and E. CURZON. (Univ. Ill.). (*North Amer. Vet.*, 21 (1940), No. 7, pp. 407-410).—A review, with 33 references.

Effect of nerve section upon development of nutritional muscular dystrophy in young rats, A. M. PAPPENHEIMER and M. GOETTSCHE (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 2, pp. 313-316, figs. 2).—The young rats used in this experiment were subjected to the dietary regime previously found to produce muscular dystrophy (E. S. R., 83, p. 382). The left sciatic nerve of these rats was sectioned at ages varying from 5 to 18 days. A histological comparison of the right and left gastrocnemius muscles of individuals which developed muscular dystrophy revealed that the right side showed the usual intense lesions accompanying this disorder, while the left side (nerve section) showed only the familiar alterations consequent on nerve section. When the operation was deferred until the eighteenth day, nerve section no longer afforded protection. It is concluded that the removal of nerve impulses protects the muscles of young rats from the usual effects of vitamin E deficiency, although the exact mechanism by which the protection is afforded remains to be determined.

Commercial feeds in Kentucky 1939, J. D. TURNER, H. S. SPEARS, W. G. TERRELL, and J. J. ROSE (*Kentucky Sta. Regulat. Ser. Bul.* 24 (1940), pp. 50).—A summary of the inspection and analysis of 1,412 samples of commercial feeding stuffs, together with chemical standards for feeds and regulations to be followed by the trade and other pertinent information, is presented (E. S. R., 82, p. 372).

Inspection of feeds, W. L. ADAMS, T. WRIGHT, JR., and R. L. SWALLOW (*Rhode Island Sta. Feed Cir.*, 1940, pp. 100).—Included in this report are the guaranteed and found analyses of 923 samples of stock, dairy, and poultry feeds and 146 samples of dog, cat, and pet feeds (E. S. R., 82, p. 521).

The fasting metabolism of ruminants, S. MORRIS and S. C. RAY (*Biochem. Jour.*, 33 (1939), No. 8, pp. 1217-1230).—In this contribution from the Hannah Dairy Research Institute data are presented on the nitrogen and mineral metabolism of goats (two lactating, two nonlactating), sheep (four nonlactating), and cows (two lactating) during periods of fast. The daily excretion of urinary nitrogen per kilogram of body weight was 0.06-0.08, 0.12-0.2, and 0.12-0.16 gm., and of fecal nitrogen 6.6, 0.35-0.5, and 0.49-0.8 gm. for cows, goats, and sheep, respectively. In all species, the preformed creatinine tended to diminish slightly during fast, whereas the creatine rose markedly. In purine metabolism a fall in the output of uric acid and allantoin but an increase in that of purine base was evident. Increases occurred in both the protein and nonprotein nitrogen fractions of the blood. The excretion of urinary calcium during fast became negligible, and the urinary phosphorus could be accounted for by the muscular catabolism, indicating that little or no catabolism of osseous tissue occurred in these species in a fast of as much as 12 days' duration.

Soybean meal vs. cottonseed meal, C. W. McCAMPBELL. (Kans. State Col.). (*Cattleman*, 27 (1940), No. 5, pp. 47, 49).—A feeding test of 218 days' duration was conducted comparing cottonseed meal (43 percent protein) and expeller soy-

bean meal (41 percent protein) as protein supplements for fattening steer calves. Steers on the cottonseed meal and soybean meal ration, respectively, consumed an average of 9.54 and 9.43 lb. of corn, 1.5 and 1.5 lb. of protein supplement, and 9.55 and 9.53 lb. of sorgo silage daily, with each receiving 1 lb. of prairie hay per head daily during the last 134 days of the trial. Average daily gains per head were 2.14 and 2.11 lb. The lot fed cottonseed meal was appraised at 25 ct. per hundredweight higher and returned \$2.12 greater returns over feed costs at the prevailing prices than the lot receiving soybean meal.

Results of experiment station's steer feeding tests checked at packing house, I. WATSON (*Colo. Farm Bul. [Colorado Sta.], 2 (1940), No. 4, p. 10*).—Results of a feeding test comparing cottonseed meal, soybean meal, tankage, and a mixture of these three concentrates in equal parts as supplements to ground corn, rolled barley, wet beet pulp, and alfalfa hay indicated that 0.5 lb. per head daily of the mixture was slightly more efficient than 1 lb. of either cottonseed meal or soybean meal on the basis of dressing percentage and slightly better than the soybean meal on the basis of carcass grading. Increasing the rate of feeding the mixed supplement was not profitable. Tankage feeding proved less desirable than any of the other supplements. The addition of potassium iodide (129 mg. per head daily) to the cottonseed meal ration decreased the efficiency of gain, indicating that if an iodine supplement is needed this level is too high.

Federal beef grading (*U. S. Dept. Agr., Misc. Pub. 391 (1940), pp. 15, figs. 8*).—A brief history, prepared by the Agricultural Marketing Service, of the Federal grading of beef and an explanation of the "single standard" for grading and stamping beef as adopted in July 1939. Benefits of beef grading for consumers, retailers, wholesalers, slaughterers, and producers are pointed out.

The effect of a phosphorus deficiency on the protein and mineral metabolism of sheep, S. MORRIS and S. C. RAY (*Biochem. Jour., 33 (1939), No. 8, pp. 1209-1216*).—This contribution from the Hannah Dairy Research Institute describes a series of balance experiments with sheep alternately receiving a low-phosphorus basal diet, basal plus phosphorus supplement, and basal plus calcium and phosphorus supplement. An increased output of urinary nitrogen with a consequent decrease in biological value of the proteins occurred during periods of phosphorus deficiency or when a ration having an abnormally high calcium : phosphorus ratio was fed. Endogenous nitrogen metabolism was diminished, but exogenous nitrogen metabolism was unaffected by phosphorus deficiency. Negative balances for both calcium and phosphorus occurred under phosphorus deficiency feeding. Positive balances for both elements occurred when a phosphorus supplement was fed, while the addition of both calcium and phosphorus (high calcium : phosphorus ratio) generally resulted in positive calcium but negative phosphorus balances. The proportion of total calcium excreted which occurred in the urine rose during phosphorus-deficient periods from 0.5 to 5 percent.

Winter care of ewes for early lambs, profit from flock, H. H. LEVECK (*Miss. Farm Res. [Mississippi Sta.], 3 (1940), No. 10, p. 2*).—Winter feeding practices for the sheep breeding flock are discussed.

Effects of feeding ewe lambs during their first winter, A. C. ESPLIN, M. A. MADSEN, and R. W. PHILLIPS (*Utah Sta. Bul. 292 (1940), pp. [1]+12, fig. 1*).—During each of three winters, three groups of range ewe lambs were fed rations with alfalfa hay, alfalfa and barley, and alfalfa and corn silage, respectively, for a winter period of approximately 6 mo., while a fourth control group was handled in a manner similar to other range sheep. Lambs fed during the winter were returned to the original herd in the spring and subsequently all groups

were handled alike. Those fed during the winter made greater gains during that period than the lambs wintered on the range, but this weight advantage was largely lost during the following summer on the range. Greater yields of unscoured and scoured wool, which was of significantly greater staple length, were obtained from the lambs that were farm fed. Death losses were less in these groups than for the range group. The percentage of ewes lambing at 2 yr. of age, of those alive at breeding age, was 64.7 and 45.5 percent for the farm-fed groups and the range-fed group, respectively.

Factors influencing the growth and development of lambs, with special reference to cross-breeding of Merino sheep for fat-lamb production in South Africa, F. N. BONSMMA (*Univ. Pretoria Pubs., ser. 1, No. 48 (1939), pp. 214, figs. 18*).—Objectives of the extensive investigation reported included studies of factors determining the birth weight of lambs, milk production of sheep in relation to fat lamb production, factors influencing the weight growth, changes in body proportions as influenced by breed and sex, and the comparative values of the carcasses resulting from different crosses. Groups of lambs representing 13 different crosses, including first crosses of Merino, Ryeland, Romney Marsh, Dorset Horn, Border Leicester, and Southdown rams on Merino ewes and second crosses of Ryeland and Southdown rams on certain of the crossbred ewes, were used.

Merino ewes producing crossbred lambs had significantly longer gestation periods and produced heavier lambs than Merino ewes mated to Merino rams. A highly significant correlation was found to exist between weight of ewes and birth weight of lambs. Maiden ewes producing male lambs were significantly heavier than those producing female lambs. Early lambing was conducive to relatively heavy lambs. Crossbred ewes were definitely better milk producers than the Merino ewes. The Border Leicester \times Merino excelled in this respect, followed closely by the other first crosses. Live weight of ewes was highly correlated with milk production, and a positive correlation was observed also between birth weight of lambs and the total milk production of their dams.

The growth rate of all first-cross lambs was similar and superior to that of Merino lambs. Second-cross lambs, in turn, tended to excel first-cross lambs in rate of growth. On the basis of equal birth weights there was no significant difference in the growth of wether and ewe lambs, nor did time of lambing significantly influence growth rate. Birth weight appeared to be closely associated with and indicative of subsequent growth differences. The milk yield of the dams was highly correlated with growth rate of lambs, particularly during the first 5 weeks of life.

The outstanding feature of crossing the Merino with various mutton rams was the improvement shown in mutton quality of the progeny, as reflected by the marked increase in the transverse body dimensions and the increased ratios of transverse to longitudinal and transverse to vertical dimensions, a situation reflected in both the live animal and in the carcass. Increased earliness of maturity, higher dressing percentage, greater size of the eye muscle, and increased thickness of back fat were other significant improvements resulting from the cross-breeding. The Southdown \times Merino produced the best first-cross carcass, followed by the Ryeland \times Merino. The second crosses were definitely superior to the first crosses in carcass quality, with the Southdown \times Dorset Horn-Merino excelling in this respect and the Southdown \times Border Leicester-Merino next in order.

An investigation into the effects of delayed slaughter on export lambs, A. R. CALLAGHAN and D. S. THOMPSON (*Jour. Dept. Agr. So. Austral., 44 (1940)*),

No. 1, pp. 3-18, figs. 5).—Simulating conditions existing at Australian slaughtering plants during the rush season when congested conditions frequently necessitate the holding of lambs for a considerable period before slaughter, 5 lots of lambs (33 per lot) were slaughtered 6, 24, 48, 72, and 96 hr., respectively, after removal from their dams. Dressing percentages based on the mean farm live weights were 54.96, 54.96, 53.72, 52.43, and 51.99 percent, respectively. The loss in live weight of lambs held 96 hr. averaged 11.2 percent, of which 73 percent was from the offal fraction and only 27 percent from the carcass itself. There was no apparent loss of fat covering or bloom of the carcasses due to the delayed slaughtering. It appeared that the loss in weight of the carcass was due primarily to loss of moisture.

Inadequacy of the concentrates commonly used in swine feeding, A. G. HOGAN and S. R. JOHNSON (*Missouri Sta. Res. Bul. 321 (1940), pp. 20*).—Data presented cover the farrowing and weaning records of 44 litters from sows constantly restricted to floored pens and receiving rations made up chiefly of corn, tankage, linseed oil meal, and alfalfa meal supplemented with cod-liver oil (Haliver oil in one instance), and minerals. The trials extended over 7 yr. (8 farrowing seasons). On the average 9 live pigs and 0.5 dead pigs were farrowed per litter, with 47 percent of the pigs born alive surviving to 8 weeks. The response of the sows indicated that the rations were partially inadequate, as manifested by subnormal feed consumption and occasionally by lameness, scanty hair, scaly skins, and unsteadiness when standing or walking. The response of pigs was highly variable from year to year, and also between litters within a season. Some litters were practically normal, but most of them developed characteristic abnormalities, including skin lesions, muscular weakness and incoordination, diarrhea, and collapse, followed by death. Fatty livers and kidneys and hemorrhages were frequently observed on post mortem. These abnormalities are attributed to inadequacy of the ration received by the dams.

Distillery slop for hogs, E. J. WILFORD (*Kentucky Sta. Bul. 408 (1940), pp. 385-399*).—Three feeding experiments were conducted to determine the values of thin, settled, whole, and evaporated distillery slops when fed with and without supplements for fattening pigs. Very slow gains resulted from the feeding of distillery slop (in any form) alone, and such feeding practice resulted in soft or oily carcasses. Supplementing distillery slop with corn at a rate of not less than 1 bu. of corn to 50 gal. of slop materially improved carcass quality. Faster and more economical gains were made when both corn and tankage were fed with the slop. Thin distillery slop could be used best by allowing it to settle for several hours and then discarding about one-third of the volume represented by the supernatant liquid. Thin slop, settled slop, and whole slop were worth about 0.5, 0.75, and 1 ct. per gallon, respectively, when fed with corn at 60 ct. per bushel and tankage at \$65 per ton in the proportions recommended.

The requirements of the pig for vitamins A and D, B. J. SENIOR (*Roy. Dublin Soc., Sci. Proc., n. ser., 22 (1940), No. 22, pp. 229-236, pl. 1, fig. 1*).—In an experiment at University College, Dublin (Baile Atha Cliath), four groups of six pigs each, all fed the same well-balanced basal ration, received supplements as follows: (1) No vitamin supplement, (2) vitamin A (concentrate), (3) vitamin D (sunlight), and (4) vitamins A and D. Rickets occurred in practically all individuals in lots 1 and 2 after about 8 weeks, and the pigs were finally given access to sunlight to prevent death losses. Under this regime they rapidly improved and made good gains. The livers of pigs receiving no vitamin A supplement were practically devoid of vitamin A, while

those of the vitamin A-supplemented pigs were relatively rich in this factor. Pigs in groups 3 and 4 weighed an average of 167 and 213 lb. per head and required 3.3 and 2.88 lb. of grain per pound of gain, respectively, indicating the marked beneficial effect of an adequate amount of vitamin A in the diet.

The minimum requirement of riboflavin for the growing pig, E. H. HUGHES. (Univ. Calif. coop. U. S. D. A.). (*Jour. Nutr.*, 20 (1940), No. 3, pp. 233-238, figs. 2).—Continuing this line of investigation (E. S. R., 81, p. 559), two experiments with growing pigs in which graded levels of riboflavin were added to the purified basal diet indicated that the minimum requirement of riboflavin for young growing pigs lies between 1 and 3 mg. per 100 lb. of pig daily.

The minimum requirement of thiamin for the growing pig, E. H. HUGHES. (Univ. Calif. coop. U. S. D. A.). (*Jour. Nutr.*, 20 (1940), No. 3, pp. 239-241, fig. 1).—Based on growth rate and thiamin storage in the resulting tissue of young pigs receiving graded levels of thiamin as a supplement to a purified basal diet, it appeared that the minimum requirement of thiamin chloride hypochloride is about 1 mg. per 100 lb. of growing pig daily.

Growth and development in the pig, with special reference to carcass quality characters, I-III, C. P. McMEEKAN (*Jour. Agr. Sci. [England]*, 30 (1940), Nos. 2, pp. 276-343, pls. 5, figs. 18; 3, pp. 387-436, pls. 11, figs. 9; 4, pp. 511-569, pls. 14, figs. 4).—Three reports of this investigation are noted.

I. Age changes in growth and development.—In the initial phase of this investigation, male pigs of the same genetic strain reared under uniform conditions were sacrificed at 4-week intervals from birth to 28 weeks of age. Detailed measurements of the whole body and its dissected parts and extensive tissue analyses were made. Complete data are presented for the 13 individuals involved; also illustrations showing body proportions with age and changes in the size and character of certain tissues with advancing age are given. Growth in body proportions exhibited a well-defined anterior-posterior gradient from earlier- to later-developing regions. The major body tissues showed marked differential growth behavior, skeleton, muscle, and fat developing in that order. Within any one tissue the individual anatomical units or regions of the body similarly showed well-defined differential growth relationships. The body organs and offals showed marked heterogenic growth, those parts essential to life processes being well developed at birth. Those organs associated intimately with growth functions grew proportionately more from birth, while those whose function is primarily that of storage of nutrient reserves developed little until the later stages of growth. Form as well as weight of the skeleton was found related to body conformation and meat quality. Increase in the size of the muscle fibers proved sufficient to account for the increase in the mass of this tissue, with no evidence of any increase in the number of muscle fibers during postnatal life. The study as a whole revealed the inadequacy of live weight as a measure of growth in the animal body.

II. The influence of the plane of nutrition on growth and development.—The general plan of this comprehensive experiment involved the feeding of four genetically similar groups of pigs on four planes of nutrition from birth to slaughter weight. Two groups were reared to 16 weeks of age on a low plane, the other two on a high plane of nutrition. After that age one group was continued on the low plane (low-low=L-L) and one on the high plane (high-high=H-H), while one of the low-plane groups was changed to the high plane (low-high=L-H) and one of the high-plane group dropped to the low plane (high-low=H-L). The H-H group attained slaughter weight (200 lb.) at 180 days, the L-H and H-L groups at 240 days, and the L-L group at 300

days. Representative animals in each group were slaughtered and dressed under uniform conditions at 16 weeks of age, and the others when 200 lb. live weight were reached. This portion of the report deals with the effect of the high and low planes of nutrition between birth and 16 weeks. Complete data are presented for the 12 individuals (2 males and 4 females from each plane of nutrition) involved in this phase of the study, with illustrations showing the proportions of the whole body and certain component parts at that age.

The average live weights of pigs on the high plane and low plane of nutrition to 16 weeks were 113 and 37 lb., respectively. The head, ears, neck, legs, and body length were penalized relatively less by inadequate nutrition than were body depth, loin, and hindquarters. Low-plane animals to a large extent retained the proportions of the juvenile, while high-plane individuals approached the conformation of the adult. Of the major tissues, skeleton weight was affected relatively less than the weight of the muscle, which, in turn, was affected relatively less than the total fat. For pigs on the high plane the skeleton was 221, muscle 291, and fat 1,007 percent of the weight of these tissues for the low-plane animals. The effects upon skin, tendon, and glands were slightly less than on the skeleton. The effects upon organs and offals were relatively less than upon either live or carcass weight. Late-developing parts of the body as compared with early-developing parts were penalized proportionately more by undernutrition and encouraged more by an ample supply of nutrients. The same anterior-posterior growth gradient trend was evident here as that noted above under growth changes with age. Size of muscle fiber was greatly reduced by undernutrition and well developed through good feeding. Subcutaneous fat was affected to a greater extent than was intermuscular fat. Regional differences in subcutaneous fat provided a clear-cut example of growth gradients of the type described. Linear measurements on the body surface, due to their relationship to the resistant skeleton, showed a proportionately smaller response to nutrition than internal carcass measures of muscle and fat. Differences in the chemical composition and nature of the muscle and fat tissues supported the hypothesis that the differential response of body tissues to nutrition is due to their differential rates of growth and the consequent prior claim of earlier-developing parts to available nutritive supplies.

III. *Effect of the plane of nutrition on the form and composition of the bacon pig.*—Complete data with numerous illustrations are presented for 20 individuals carried to 200 lb. live weight, including 3 males and 2 females each on the H-H, H-L, L-H, and L-L planes of nutrition, as described above. In body form two distinct types of pigs were produced, the H-H and L-H pigs showing a greater proportionate development of the late-developing body parts while the H-L and L-L groups showed proportionately greater development of the early-developing parts. The amount of skeleton and muscle increased and fat decreased with the following order of treatment—L-H, H-H, H-L, and L-L. The results with this group fully support the hypothesis advanced in explanation of the effects of high and low nutrition up to 16 weeks. It is further evident that as growth proceeds the competitive capacity of late-developing tissues increases even under continued undernourishment, due to the proportionately greater decline in the growth intensity with age of the earlier-developing parts. All tissues showed remarkable recuperative capacity on provision of ample nutrients following undernourishment. The sexes differed markedly in anatomical composition, males being characterized by less bone and muscle and more fat than females.

A second feeding trial like the one described above in all respects, except that beyond 16 weeks all rations were relatively much lower in protein con-

tent, gave results essentially like those obtained at the higher level of protein feeding.

The influence of low and high planes of nutrition on the composition and synthesis of fat in the pig, T. P. HILDITCH, C. H. LEA, and W. H. PEDELTZ (*Biochem. Jour.*, 33 (1939), No. 4, pp. 493-504, fig. 1).—Samples of back fat obtained from pigs on the above-described feeding regimes were taken at 16 weeks of age and when 200 lb. of live weight were reached. A determination of the component acids of these fats indicated that on a restricted diet the deposition of fat is not only slower but the fat produced is softer, due to an increase in the small proportion of linoleic acid present, together with some increase in the proportion of oleic acid. A comparison of the amounts of each component acid in the total fats of the diet with those in the body fats indicated a marked synthesis of the glycerides of palmitic, oleic, and stearic acids. Other minor components may also be synthesized, but linoleic and unsaturated C₂₀₋₂₂ acids in the body fat are derived only from ingested fats.

Canadian Wiltshire bacon, I-XI (*Canad. Jour. Res.*, 18 (1940), Sect. D, No. 4, pp. 123-134, figs. 3; pp. 135-148, fig. 1; pp. 149-158, 159-163; 5, pp. 191-201, fig. 1; pp. 202-210, figs. 2; 6, pp. 211-216, 217-224, 225-232; 7, pp. 249-259, figs. 2; pp. 260-265, fig. 1).—Eleven reports on this extensive investigation are noted.

I. Outline of investigation and methods, W. H. Cook, N. E. Gibbons, C. A. Winkler, and W. H. White.—The studies described below involved bacteriological, chemical, and physical measurements on bacon and pickle from 22 packing plants. The methods employed for shipping the samples, sampling, and analyses are described.

II. Chloride, nitrate, and nitrite content of bacon and pickle, W. H. Cook and W. H. White.—Analysis of Wiltshire bacon from the different plants showed a significant variation in the chloride, nitrate, and nitrite content of the sides, although such variations did not necessarily affect the quality. Differences between sides from different plants were the main source of variation in chloride and nitrate, while differences between sides from the same plant were the main source of variation in nitrite content. Composition of the pickles used in different plants differed more than variations within a plant. The number of injections used for pumping was correlated with the chloride and nitrite content, while nitrate content was directly correlated with the level of this ingredient in the pickle. It appeared that most of the observed variation in the bacon was due to other unmeasured factors or to inherent differences between carcasses.

III. pH, Oxidation-reduction potential, and miscellaneous measurements on bacon and pickle, W. H. Cook and A. E. Chadderton.—The pH of bacon, while relatively constant both between and within plants, appeared to be affected by the pH of the pump pickle, to decrease with the time in cure, and to increase with age from curing. A significant difference was observed between the absolute values of the oxidation-reduction potentials of sides from different plants, suggesting that this property may be a function of curing practice. Moisture content of bacon at comparable stages of curing was relatively uniform. A significant loss of moisture occurred during maturation and smoking. A direct relation between protein content and pH of the pickle was noted.

IV. Correlation between constituents and properties of bacon, W. H. Cook and W. H. White.—Significant correlations were found to exist between the following: Nitrate and chloride contents, nitrite and chloride contents, nitrite content and pH, and moisture and chloride contents. The fact that nitrite content tended to increase with pH and moisture content to decrease with increasing chloride content suggests a certain degree of dependence between

these two properties. However, curing practices favoring a high salt content did not result in the removal of more moisture from the sides.

V. *Quantitative bacteriological studies on curing pickles*, N. E. Gibbons.—Determining the bacterial content of pickle solutions through use of a number of different media, significant differences in pickles from different plants were demonstrated. Counts on spent pickles were higher than on cover pickles, while pump pickles tended to contain relatively high numbers of organisms. Definite qualitative differences in the flora of the pickles were demonstrated. Nutrient agar at 20° C. and 10 percent salt agar with brine dilutions proved most suitable for demonstrating such differences.

VI. *Quantitative bacteriological studies on product*, N. E. Gibbons.—Nutrient agar containing 4 percent salt incubated at 20° C. gave the maximum bacterial counts in surface samples of bacon. No correlation was found to exist between numbers of bacteria in the curing pickle and on the product. Samples from the anterior rib section showed higher counts than those from the posterior ribs. Slime production became evident on the average when the logarithm of the number of organisms per square centimeter exceeded 7.2 (range log 6.7 to log 8.0). Bacterial counts showed a significant relationship to age from cure and from packing.

VII. *Specification of colour and colour stability*, C. A. Winkler and J. W. Hopkins.—A method of specifying the color of bacon by measurements of its red, green, and blue spectral components is described (E. S. R., 82, p. 231).

VIII. *Colour of bacon and its correlation with chemical analyses*, C. A. Winkler, J. W. Hopkins, and M. W. Thistle.—Color determinations were made on samples from the several plants (1) on receipt at the laboratory, (2) after 10 days' storage at 1° C., and (3) after smoking for 14 hr. at 40°. Individual sides differed significantly in respect to both total intensity and quality of color. A moderate degree of association appeared to exist between color quality, pH, and nitrite content. No correlation between color and salt, nitrate, or moisture content of the meat was demonstrable.

IX. *Colour stability of bacon and its correlation with chemical analyses*, C. A. Winkler, J. W. Hopkins, and E. A. Rooke.—Statistically significant differences were found between the products of individual plants with respect to stability of total intensity of color and of the component intensities of red, blue, and green on exposure of freshly cut samples for 20 hr. at 10° C. and 95 percent relative humidity. Smoking tended to reduce color stability. Increased nitrite content was accompanied by increased stability of the red component. Salt, nitrate, moisture content, and pH bore no apparent relationship to color stability.

X. *Distribution of chloride*, W. H. White and W. H. Cook.—The chloride was found to be unevenly distributed at different positions across the ham of Wiltshire sides, the portion next to the tank pickle usually containing the most salt. The number of injections used in pumping and the age from cure were the only factors studied which were found to affect chloride distribution. Within the range studied, the chloride content of the pickle and the time in cure were not significant in this respect.

XI. *Effect of heat treatment on nitric content*, W. H. White, W. H. Cook, and C. A. Winkler.—A study of the nitrite content of small cuts of matured Wiltshire bacon at temperatures ranging from 20° to 80° C. indicated that an increase in nitrite content above the normal level occurred at temperatures below 55° and decreased at temperatures above this point. The decreases at higher temperature were attributed to direct loss, oxidation, or reaction with the constituents of the meat. The increases at relatively low temperature were not typical of commercial cuts, suggesting that some factor such as the greater proportionality of exposed surface in the small cuts accelerated this reaction.

Dry, warm storage for cured ham, P. G. BEDENBAUGH (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 10, pp. 1, 7).—A comparison of various storage conditions for cured pork indicated that hams and bacon should not remain in the cooler after curing and smoking but should be removed to conditions of lower moisture and higher temperature. Hams and bacon not wrapped or otherwise treated after smoking were superior to those wrapped without padding or with padding of sawdust or shredded corn shucks, or wrapped and treated with whitewash paste, when all were stored at natural temperatures. Hams were of high quality after 6 months' storage under farm conditions, but bacon showed marked deterioration after 90 days' storage.

A study of some problems involved in measuring performance in the horse, R. W. PHILLIPS, G. W. BRIER, and W. V. LAMBERT (*U. S. Dept. Agr., Bur. Anim. Indus.*, [1940], pp. [2]+34, figs. 5).—Observations were made on 14 Morgan horses to study the variability of measurable characters for walking and trotting speed, length of stride, and respiration and heart rates before and after exercise, with estimated variance in these measures due to variability of the others. This analysis showed that the horses used responded differently in separate tests repeated on the same individual. Evidently there is need for standardizing conditions under which the tests are to be made. The amount of exercise was a factor in increasing both the heart and respiration rates and the rapidity of the return of these rates to normal.

Gross value of protein supplements for poultry, E. I. ROBERTSON, J. S. CARVER, and J. W. COOK (*Washington Sta. Bul.* 388 (1940), pp. 22).—Employing the previously described method for determining the gross value of protein concentrates (E. S. R., 82, p. 377), 47 different samples of protein supplements were evaluated as follows: 6 herring fish meals, average 101; 5 pilchard fish meals, 96; 2 sardine fish meals, 95; 9 salmon fish meals, 86; 7 meat meals, 55; 2 Manchurian soybean oil meals, 78; 4 domestic soybean oil meals, 76; 7 dried Alaska peas, average 61; and 1 dried skim milk, 87; dried buttermilk, 92; liver meal, 59; dehydrated alfalfa, 37; and copra meal, 22. The source of fish meal appeared to have more influence on the gross value than the method of manufacture. Combinations of herring or salmon fish meal with Alaska peas had gross values similar to the fish meal alone, and mixtures of equal parts of the fish meal and peas gave as high as or higher gross values than higher percentages of the fish meal.

Legume silage as a poultry feed, P. W. ALLEN, M. JACOB, N. O. SJOLANDER, and J. A. MCBEE (*Tennessee Sta. Bul.* 172 (1940), pp. 23, figs. 7).—A portion of this report is devoted to a general discussion of the preparation and use of legume silage. Formulas used for making legume silage for poultry involved the addition of preservatives, including molasses, soured skim milk, and powdered buttermilk in appropriate amounts to the material as it was ensiled, and the crop-admixture method, in which suitable amounts of carbohydrate-rich plant material were mixed with the legume for ensiling. The results of a series of experiments, involving growing chicks, growing ducks, and laying hens, in which legume silage was fed as a supplement to the regular rations led to the conclusion that legume silage feeding to poultry is a desirable practice. The advantages of silage feeding include greater zest for eating and higher daily feed consumption, increase in weight over poultry not receiving such silage, and better physical condition as determined by appearance, vitality, weight production, egg production, and post-mortem examinations.

Palm kernel and earthnut meals in the rations for laying pullets, H. TEMPERTON and F. J. DUDLEY (*Harper Adams Util. Poultry Jour.*, 25 (1939-40), No. 11, pp. 285-287).—In a trial with laying hens maintained in individual lay-

ing cages, the use of palm-kernel meal to partially or wholly replace wheat middlings, the use of peanut meal to replace both fish meal and dried skim milk, or the use of a combination of the palm-kernel and peanut meals to replace all of the fish meal and dried skim milk and part of the middlings in a basic laying ration did not significantly influence the rate of egg production, final body weight, or mortality of the hens. Egg production was somewhat lower and feed consumption per unit of egg production considerably higher in the last-named case. It seemed evident that these two feeds could be introduced into the rations of battery layers without risk of injury to the health of the birds or serious effect on production.

Feeding laying hens, R. PENQUITE and R. B. THOMPSON (*Oklahoma Sta. Bul.* [244] (1940), pp. 16, figs. 4).—A practical handbook on feeds and feeding methods for the laying flock.

Physicochemical changes in unfertilized, incubated eggs of *Gallus domesticus*, A. L. ROMANOFF. (Cornell Univ.). (*Food Res.*, 5 (1940), No. 3, pp. 291-306, figs. 5).—This investigation dealt with (1) the loss in weight of whole eggs, including time and rate of loss in weight to complete dehydration and the relative loss in weight under varying conditions, and (2) progressive changes in physicochemical properties of egg content during 21 days of incubation. Eggs were completely dehydrated in 10 mo. at 20° C. and in slightly over 4 mo. at 37.5°. The average daily weight loss of a 60-gm. egg incubated at 38° and 60 percent relative humidity was 0.446 gm. A change in daily loss of 0.01 gm. per egg resulted from any one of the following variations: 0.6 percent relative humidity, 1.9°, 2.6 ft. per second air movement, 3 cc./1 cm.²/1 min. permeability of shell to air, or 6 gm. of egg weight. As incubation progressed the volume of albumen diminished, while that of the yolk first increased and then decreased, attributable to the flow of water from albumen to yolk and back by osmosis. This was accompanied by noticeable changes in specific gravity, refractive index, and pH in both yolk and albumen. The dry matter of the yolk decreased and that of the albumen increased, and at the end of the incubation period the egg contained less total nitrogen and ether extract but proportionately more calcium than the fresh egg. It appeared that 1 day of incubation of unfertilized eggs caused deterioration equivalent to that occurring 5 or 6 weeks in cold storage, suggesting that for each degree of holding temperature above 0° there should be added approximately 1 day for aging.

Capons in Iowa, R. E. PHILLIPS and A. D. ODEBKIRK (*Iowa Sta. Bul.* P16, n. ser. (1940), pp. 469-490, figs. 9).—A practical publication presenting information concerning the various phases of capon production and marketing.

Turkey management, H. M. SCOTT (*Kansas Sta. Cir.* 200 (1940), pp. 20, figs. 18).—A presentation of recommended practices in hatching, brooding, housing, and marketing of turkeys.

Pigeon anemia as a deficiency disease, A. G. HOGAN, L. R. RICHARDSON, P. E. JOHNSON, and R. N. NISBET. (Univ. Mo.). (*Jour. Nutr.*, 20 (1940), No. 3, pp. 203-214, pl. 1, figs. 5).—Pigeons maintained on a basal diet devoid of all members of the vitamin B complex for 4 or 5 weeks, or until they had lost about 30 percent of their initial weight, and then supplied with vitamin B₁ became severely anemic in about 7 weeks. Some of the erythrocytes of the anemic birds were abnormal in shape. Additions of wheat-germ oil, riboflavin, or nicotinic acid to the diet failed to affect the development of the anemia. This development could not be attributed to partial initiation alone, and it is suggested as due to a deficiency of some previously unrecognized vitamin.

DAIRY FARMING—DAIRYING

[Experiments with dairy cattle and dairy products in Idaho], D. L. FOUNT, I. H. LOUGHARY, and H. C. HANSEN (*Idaho Sta. Bul. 236 (1940), pp. 12, 13, 14*).—Progress results are briefly reported on improvement in the milk and butterfat production of Holstein and Jersey herds through the use of proved sires, stud bull associations as a successful means of providing the service of high-quality bulls to the small dairy herd, a quality-improvement program as a means of raising the quality of milk delivered to creameries, and a comparison of production records determined with and without preliminary milkings and by the 1-day monthly test v. the official test.

Rumen digestion in the bovine, with some observations on the digestibility of alfalfa hay, E. B. HALE, C. W. DUNCAN, and C. F. HUFFMAN. (Mich. Expt. Sta.). (*Jour. Dairy Sci., 23 (1940), No. 10, pp. 953-967, fig. 1*).—This report deals with digestion trials with five normal Holstein cows, each fed alfalfa hay as a sole ration at levels of 10, 20, and 30 lb. per head daily, and also trials with one cow with rumen fistula, similarly fed, in which the rumen contents were removed at varying intervals (usually 14 hr.) after feeding and analyzed. Chemical analyses of hay, rumen contents, and feces included moisture, protein, ash, ether extract, true fat, crude fiber, nitrogen-free extract, lignin, cellulose, other carbohydrates, crude fiber by an enzymatic method, a new nitrogen-free extract (by difference), and iron. Iron ratios proved unreliable for determining rumen or total digestion coefficients. As the plane of nutrition increased, the rumen digestion of protein and true fat decreased while that of ether extract, crude fiber, and new crude fiber increased. Total digestion coefficients for nitrogen-free extract, new nitrogen-free extract, and true fat decreased as the level of feeding increased, while other nutrients were either not affected or increased slightly in digestibility. Ninety percent of the digestible dry matter passed from the rumen before 14 hr. after feeding, and digestible nitrogen-free extract, other carbohydrates, and new nitrogen-free extract were completely removed from the ingesta during this period of rumen digestion. Eighty-five percent of the digestible cellulose was digested during this period. Lignin did not appear to be appreciably digested in the rumen, but digestible crude fiber was two-thirds digested. True fat was not digested to any extent in the rumen, and at the highest level of feeding there was an actual increase in true fat, suggesting synthesis through bacterial action.

It is concluded that the separation of the carbohydrate fraction into lignin, cellulose, and other carbohydrates is a better index of biological value of alfalfa hay than the present system of division into crude fiber and nitrogen-free extract. Values obtained by the enzymatic determination of crude fiber gave a much sharper biological distinction between carbohydrate fractions than the standard method. Also, true-fat determination is of much greater biological significance than ether-extract determination.

The feeding value of alfalfa hay compared with mixed hay and grass silage as a ration for dairy cattle, R. E. HODGSON and J. C. KNOTT. (Coop. West. Wash. Expt. Sta. and U. S. D. A.). (*Washington Sta. Bul. 386 (1940), pp. 27*).—Following an earlier investigation (E. S. R., 80, p. 816), two experiments were conducted comparing alfalfa hay v. mixed grass and clover hay and grass silage as sole rations for milking cows during the winter feeding period. The grass silages used included those made from (1) herbage similar to that in the mixed hay, (2) immature oats and peas, and (3) pea vines. Coefficients of digestibility of the various roughages were determined in trials with sheep.

In trials 1 and 2, respectively, the average daily consumption of dry matter per 1,000 lb. live weight for the alfalfa-fed cows was 24.2 and 24 lb. and for the cows fed hay and silage 20.6 and 19.6 lb. The average daily loss in live weight for cows fed alfalfa was 0.13 and 0.38 lb., and for those fed hay and silage 0.86 and 1.2 lb. The average production of 4-percent fat-corrected milk per 1,000 lb. live weight for the alfalfa-fed cows was 17.4 and 17.6 and for those fed hay and silage 17.3 and 17.7 lb. The consumption of total digestible nutrients per 100 lb. of 4-percent fat-corrected milk was for the alfalfa group 72.8 and 73.5 lb. and for the hay and silage group 64.1 and 63.3 lb. It appeared that the digestible crude protein and total digestible nutrients were somewhat better utilized in the mixed hay and grass silage ration. Because of its lower palatability, consumption of dry matter and nutrients was lower on this ration than on the alfalfa ration, but this was reflected in decreases in body weight rather than in lower milk production.

Broomcorn silage for dairy cattle, W. B. NEVENS and K. E. HARSHBARGER. (Ill. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 10, pp. 1023-1029, fig. 1).—Preliminary investigations on ensiling broomcorn stalks, involving two varieties at various stages of maturity, indicated that broomcorn produces a tonnage per acre comparable to hybrid corn or Orange sorgo. Best results were obtained when the plant was ensiled at the normal stage for brush harvest. A poor-quality product of very low acidity resulted when no preservative was added, but good-quality silage resulted when 5 percent of molasses was added to material harvested at the proper stage of maturity. Such silage was high in crude fiber and contained a rather large amount of hard, splintered material which was refused by cows. Otherwise, it was readily consumed by them, and on the basis of dry matter consumed compared favorably with corn silage for milk production.

The effect of phosphoric acid silage on the acid-base balance in dairy cows, O. L. LEPARD, E. PAGÉ, L. A. MAYNARD, R. A. RASMUSSEN, and E. S. SAVAGE. (Cornell Univ.). (*Jour. Dairy Sci.*, 23 (1940), No. 10, pp. 1013-1022).—In experiments involving 12 dairy cows, ranging from heavy-milking animals to dry, nonbreeding individuals, phosphoric acid silage was fed with and without hay or ground limestone. When the silage was supplemented with hay or ground limestone the composition of the blood and urine did not differ significantly from that existing when corn and molasses silage was fed. When phosphoric acid silage was fed alone marked changes in the composition of the urine indicative of acidosis occurred, although the alkaline reserve of the blood was unaffected. Three of the four animals fed the silage alone became unthrifty. This condition was relieved and the urine values were restored to normal by the addition of hay or limestone to the ration. Apparently the inclusion of hay containing an appreciable amount of legume or ground limestone in the ration is necessary to render phosphoric acid silage a satisfactory feed.

Wastage, length of productive life, replacement, and depreciation of dairy cows, G. H. N. PETTIT (*Jour. Agr. Sci. [England]*, 30 (1940), No. 3, pp. 485-497, figs. 3).—Based on a 3-yr. study of dairy herds in the eastern counties of England, it is reported that the annual loss of cows from milking herds averaged 29.3 percent of the number of cows at the beginning of the year, equivalent to an average length of productive herd life of 3.4 yr. Average total productive life in all herds was estimated to be about 5 yr. Death accounted for 10.4 percent of the annual removal of cows from herds, which represents a mortality rate of 3 percent of the number of cows at the beginning of the year. Cows removed from herds had an average net value of less than one-half that of cows or heifers for replacement purposes. Approximately 67 percent

of all replacements were heifers, while of all replacement animals about 49 percent were home-bred and 50 percent purchased. Size of herd had little effect on the rate of turn-over, but herds replaced entirely with heifers showed the lowest rate of removal.

Age, live weight, and milk-energy yield in Illinois cows, W. L. GAINES, C. S. RHODE, and J. G. CASH. (UNIV. ILL.). (*Jour. Dairy Sci.*, 23 (1940), No. 10, pp. 1031-1043, figs. 6).—Following a plan previously described (E. S. R., 78, p. 241), data consisting of the records of 957 Holstein cows and 195 Jersey cows for partial lactations in Illinois Dairy Herd Improvement Associations were statistically analyzed. It is shown that the relationship between the amount of fat-corrected 4-percent milk produced and the live weight of the animal is practically independent of the age of the animal, leading to the conclusion that the use of age-correction factors is justified only in case live weight is unknown and then only insofar as weight is associated with age and correctly portrayed by the factors used. It is further concluded that as between cows of different live weights in either the Holstein or Jersey breed *FCM/W* affords an equitable criterion of dairy merit or development. It appeared that *FCM/W* is independent of the fatness of the cow at time of calving.

Adequate feed to avoid winter fall in yield of milk, J. S. MOORE (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 10, pp. 1, 2).—Practical suggestions concerning the winter feeding of the dairy herd are offered.

Lactation, S. J. FOLLEY (*Biol. Rev. Cambridge Phil. Soc.*, 15 (1940), No. 4, pp. 421-458).—A review, with 250 references to the literature.

The concentration of vitamin D in the blood of dairy cattle as compared with the potency of the milk produced, G. C. WALLIS. (S. Dak. State Col.). (*S. Dak. Acad. Sci. Proc.*, 19 (1939), pp. 55-60).—Assays of blood samples from one Jersey and one Holstein cow, each receiving 7,500 International Units of vitamin D daily from alfalfa hay, revealed no significant difference in the vitamin D potency of the blood plasma. Butterfat samples obtained from these cows contained approximately the same amount of vitamin D per gram. Since the two animals were producing about the same quantity of milk, the higher butterfat test of the Jersey milk accounted for a proportionately higher amount of vitamin D per quart of Jersey milk and a proportionately larger total amount of the ingested vitamin D recovered in the milk.

Changes observed in milk "sham fed" to dairy calves, G. H. WISE, P. G. MILLER, and G. W. ANDERSON. (S. C. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 10, pp. 997-1011, figs. 2).—Three calves having rumen fistulas and one with an esophageal fistula were used in this study. The pasteurized and superheated whole milks and skim milk fed to these experimental subjects were collected from the cardiac end or the medial section of the esophagus. Samples thus obtained were subsequently examined. As compared with normal milk, the sham-fed pasteurized whole milk increased in rate of rennet coagulation, in curd tension, in pH, in lipolytic activity, and in cream volume. Corresponding changes in the superheated whole milk were in the same direction but of less magnitude. The sham-fed skim milk increased slightly in rate of coagulation, decreased very slightly in curd tension, showed little change in pH, but increased markedly in lipolytic activity. Holding the sham-fed samples for 2 hr. at 38° C. brought about further alterations, all initial changes in the whole milks, except for a reduction in curd tension, being further amplified. With skim milk, holding caused a slight increase in rate of coagulation and curd tension. Ingestion of milk through a nipple as compared with open-pail feeding amplified the changes in the whole milks, but produced little difference, except increased lipolysis, in skim milk.

A study of the reducing system of milk, I. A. GOULD. (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 10, pp. 977-984, fig. 1).—Determination of ascorbic acid values and potassium iodate titration values (total reducing power of milk) indicated that milk contains reducing substances other than ascorbic acid. These other substances accounted for from 40 to 70 percent of the total, and were unaffected by sunlight or by the presence of copper in milk, but were slightly affected by treatment of the milk with iodoacetate. Potassium iodate values were lowered by heating milk to 80° C. or above, probably due to destruction or rearrangement of the nonascorbic acid portion of the reducing materials.

The disappearance of added glutathione in milk, I. A. GOULD. (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 10, pp. 985-989, figs. 3).—Glutathione was added at the rate of 50 mg. percent to fresh raw milk, to rennet serum prepared from the same milk, and to portions of the same milk heated momentarily to 70°, 80°, and 90° C. Determinations on the milk after 15 min., 1 hr., and 4 hr. of incubation at 20° indicated that the raw milk or rennet serum caused a rapid disappearance of the added reduced glutathione. A major portion of the glutathione which disappeared was destroyed, since only a relatively small quantity was found in the oxidized form after 2 hr. A slightly larger proportion of this substance was found in the oxidized form after 4 hr. than after 2 hr. Heating milk to 80° or 90° and then cooling prior to adding glutathione resulted in complete stabilization of this substance, while a temperature of 70° was only partially effective in this respect.

Protective influence of glutathione on copper-induced oxidation of ascorbic acid in milk, I. A. GOULD. (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 10, pp. 991-996, figs. 2).—Milk which had been heated momentarily to 80° C., cooled, and treated with 1.5 p. p. m. of copper was completely protected against oxidized flavor development for 48 hr. by the addition of 25 mg. percent of glutathione, and 15 mg. percent of this substance was only slightly less efficient in preventing this off-flavor. While it prevented copper catalysis of the oxidation of ascorbic acid, the glutathione itself slowly disappeared from the system.

The milk fat globule, P. F. SHARP. (Cornell Univ.). (*Jour. Dairy Sci.*, 23 (1940), No. 8, pp. 771-782).—A general discussion, with emphasis on the need for further research on the fat globule.

Growth of certain organisms of importance to the dairy industry on new standard milk agar, V. D. FOLTZ and L. D. BUSHNELL. (Kans. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 10, pp. 973-975).—The growth responses of numerous pure cultures of bacteria on the old and the new standard media were compared. Seven strains of pyogenic streptococci responded exceptionally well to the new medium. Other streptococci and bactobacilli, while not showing the high degree of response as the pyogenes, generally showed definitely improved growth on the new medium, although little difference in response was noted in the case of a few organisms. Milks from cows on a mastitis-control project showed definitely higher plate counts when the new medium was used. The milk from one animal shedding organisms responsible for an outbreak of septic sore throat gave higher counts on the new medium than on blood agar, although the use of the latter medium is deemed essential in detecting such organisms.

Cooling, storage, and transportation of milk and cream, P. A. DOWNS and F. D. YUNG (*Nebraska Sta. Cir.* 65 [1940], pp. 20, figs. 24).—This is a nontechnical discussion of most of the common methods of cooling milk and cream and of maintaining a temperature low enough to prevent spoilage or deterioration during storage and transportation. Emphasis is placed on the proper

cooling and storage of milk and cream for consumption on the farm as well as for marketing.

Vacuum pasteurization of cream for butter, G. H. WILSTER (*Oregon Sta. Bul. 368 (1940), pp. 48, figs. 7*).—The findings reported are based on extensive comparisons of the conventional holder-type method of pasteurization with high-temperature vacuum pasteurization (Vacreator process) of cream for buttermaking. In a series of comparisons with good-quality cream, ranging from sweet to slightly sour, fresh butter from vat-pasteurized cream averaged 91.55 in score, while comparable lots from vacuum-pasteurized cream averaged 92.38, with greatest improvement due to vacuum pasteurization occurring in April, May, and June. Improvements in body and texture as well as in flavor were noted. Butter from vacuum-pasteurized cream declined less in score during 1 month's storage at 40°–50° F. or 4 months' storage at 0°–10° than did that from vat-pasteurized cream. Vacuum pasteurization was more efficient in destroying bacteria than the conventional method at the temperatures used. Strong onion or penycress flavors were largely eliminated from cream by vacreation, whereas vat pasteurization was not effective. After 5 and 8 months' storage the undesirable flavor was absent in butter made from vacreated cream, while it had not decreased noticeably in intensity in butter made from the vat-pasteurized cream. The vacreation method is considered a practical and efficient method of pasteurizing cream for buttermaking under Oregon conditions.

A microscopic and statistical analysis of texture and structure of ice cream as affected by composition, physical properties, and processing methods, W. S. ARBUCKLE (*Missouri Sta. Res. Bul. 320 (1940), pp. 48, figs. 9*).—The size and arrangement of ice crystals and air cells as determined by photomicrographs of thin sections of ice cream have been studied in relation to the texture of the finished ice cream. Fat content improved ice cream texture chiefly through reduction of ice crystal size by mechanical obstruction of crystal formation. Serum solids affected texture by reducing ice crystal and air cell size and by increasing the distribution of air cells and the amount of unfrozen material between crystals. Sugar affected texture by reducing ice crystal size and increasing the amount of unfrozen material between crystals. Fat and serum solids had a greater combined effect in this regard than either alone. The addition of monosaccharide sugar in combination with disaccharides increased crystal size due to the low water-holding capacity of the monosaccharide molecule. The smallest ice crystals were formed when the pH of the mix was near the neutral point as calcium and magnesium acidity neutralizers were used. Increasing the overrun tended to decrease ice crystal and air cell size. All lactose crystals in ice cream were found to be crystallographically the same, variation in crystal forms being attributed to interference with lactose crystal formation by certain substances in the mix.

A taxonomic study of some bacteria found in ice cream, J. M. BRANNON. (*Univ. Ill.*). (*Ill. State Acad. Sci. Trans., 32 (1939), No. 2, pp. 42, 43*).—Based on the bacterial analyses of 500 samples of commercial ice creams, a list of classified organisms, including numerous species of 10 genera, is presented.

VETERINARY MEDICINE

[Contributions on veterinary medicine] (*Jour. Amer. Vet. Med. Assoc., 97 (1940), No. 764, pp. 527–558*).—Among the contributions presented at the annual meeting of the American Veterinary Medical Association held at Washington,

D. C., August 26-30, 1940, abstracts of which are given, are the following: Laboratory Tests of the Potency of Rabies Vaccines, by R. W. G. Wyckoff (pp. 527, 528); Purification and Properties of the Equine Encephalomyelitis and Rabbit-Papilloma Viruses, by J. W. Beard (pp. 528, 529); Canine Rabies Vaccination—An Experimental Study of the Efficacy of the Single Intraperitoneal Injection Method With Phenol-Treated Vaccine, by H. N. Johnson and C. N. Leach (pp. 529, 530); Twenty-five Years' Progress in the Study of Brucellosis, by I. F. Huddleson (p. 530); Vaccine To Control Brucellosis in Cattle, by C. M. Haring and J. Traum (pp. 530, 531); The Need and Significance of Veterinary Preventive Medicine in Present-Day Veterinary Education, by A. F. Schalk (pp. 531, 532); The Role of the Veterinarian in Effective Immunization Against Hog Cholera With Tissue Vaccine, by W. H. Boynton, G. M. Woods, and F. W. Wood (pp. 532, 533); Diseases of Swine Due to Nutritive Deficiencies, by H. C. H. Kernkamp (p. 533); Acetonemia in Dairy Cattle, by W. A. Barnette (pp. 533, 534); The Physiology of Ketone-Body Formation, by C. E. Hayden (p. 534); Gastrointestinal Parasites of Sheep and Their Control, by R. E. Rebrasser (pp. 535, 536); The Effects of Disease on the Calcium, Inorganic Phosphorus, and Serum Proteins of Horse Blood, by A. H. Craige, Jr., and J. D. Gadd (p. 536); Digestive Diseases of Ruminants Resulting From Abnormal Conditions Affecting the Fore Stomachs, by R. A. McIntosh (pp. 536, 537); Further Investigations of Rumen Gases and Bloat in Ruminants, by R. W. Dougherty (pp. 537, 538); Studies on the Relationship of Brucellosis to Periodic Ophthalmia, by E. L. Stubbs and W. G. Love (p. 538); Ophthalmology in Equidae, by B. J. Errington (pp. 538, 539); Studies on Bovine Mastitis—Mastitis in Heifers, by C. C. Palmer, J. C. Kakavas, and J. R. Lee (p. 558); and A Comparative Study of Pullorum Disease in Barred Plymouth Rock and New Hampshire Red Chickens, by E. P. Johnson (p. 558).

[Work in animal pathology by the Idaho Station], E. M. GILDOW, W. M. BEESON, G. C. HOLM, R. L. GRIFFITH, W. V. HALVERSEN, D. L. FOURT, and V. A. CHERRINGTON (*Idaho Sta. Bul.* 236 (1940), pp. 11, 12, 13, 37, 39, 40, fig. 1).—The work of the year reported upon (E. S. R., 81, p. 707) includes swine erysipelas; the cause of bovine mastitis and its control by means of X-ray, diathermy, vaccines, monocalcium phosphate, and acriflavine; and control and eradication of pullorum disease in poultry flocks.

Phenothiazine—a remarkably efficient anthelmintic, E. L. TAYLOR and K. M. SANDERSON (*Vet. Rec.*, 52 (1940), No. 36, pp. 635-647).—The results of experimental administration of phenothiazine to sheep, goats, cattle, and horses are reported in detail in 10 tables. Tests on some 150 horses have shown this drug to be remarkably efficient against strongyloid parasites in the large bowel of these animals, a dose of from 30 to 40 gm. proving to have an absolute efficiency of 100 percent for adult worms. "The ease of administration and the safety of the drug are such that the eradication of red worms from well-managed studs now appears to be a possibility. Phenothiazine is also remarkably efficient against the stomach worms associated with parasitic gastritis in ruminants, as demonstrated by the several observations involving some 300 to 400 sheep, 70 to 80 goats, and a dozen cattle. In the small intestine of these animals it is less efficient but removes about 80 percent of the trichostrongylid parasites there, with the exception of *Nematodirus*, on which it exerts very little action. There is no action against *Fasciola* nor against the anoplocephaline cestodes *Moniezia* and *Anoplocephala*. Ten gm. appears to be an adequate dose in sheep or goats, although doses of 20 to 30 gm. are more likely to produce the maximum effect. Cattle respond well but are much less tolerant of the drug than are sheep or horses. Experiments on pigs and dogs have been few, but it is clear that although the drug acts well on ascarids in the horse its action against these parasites is uncertain in the pig and is absent in the dog. The anthelmintic effect noted on sheep that have been more or less heavily infested with stomach worms has been extraordinarily good and, where comparisons have been made, has generally been superior to that of copper sulfate and nicotine sulfate. The tolerance of sheep and goats is very high, 400 gm. causing no ill effect. Horses withstand up to 17 times the anthelmintic dose. Some evidence of idiosyncrasy has been observed, in that a group of goats showed some sensitivity to the drug on one occasion and on a later occasion proved to be very resistant to toxic action. Repeated small doses are considerably more toxic than are occasional larger doses, the minimum toxic single dose being about 40 times as great as the minimum toxic dose when repeated daily. The tasteless character of phenothiazine is a great advantage, in that horses will take it voluntarily in the food. Pigs and sheep may also be dosed in this way." Fourteen references to the literature are included.

Experiments on the anthelmintic action of phenothiazine, G. LAPAGE (*Vet. Rec.*, 52 (1940), No. 36, pp. 648-657).—An experimental study of the anthelmintic action of phenothiazine in which sheep and lambs, goats, calves, horses, and pigs were used is reported, the details being given in five tables. Comparisons of the effect of phenothiazine, copper sulfate, and copper sulfate and nicotine on nematode infestations of ewes and lambs in the field indicated that small doses (about 0.1 gm. per pound body weight) of phenothiazine lowered the egg counts more effectively than did either of the other two anthelmintics and tended to maintain them more effectively at a lower level.

Antigenic relationships of strains of *Bacterium necrophorum*, P. H. WALKER and G. M. DACK (*Jour. Infect. Diseases*, 65 (1939), No. 3, pp. 285-290).—The results of a serological study of 12 strains of *B. necrophorum*, 9 of human origin and 3 of bovine, are reported. "Rabbits were immunized with 10 different strains of *B. necrophorum*. The immune serum thus produced agglutinated homologous strains in dilutions ranging from 1:160 to 1:1,280. Some heterologous strains were agglutinated to titer or nearly so by certain of these antiserums. Distinct antigenic groups were demonstrated by means of agglutination and agglutinin absorption tests. One comprised 3 strains, another 2, and a third included 3. Four other strains were highly specific and probably represented other serological groups. Virulence of these strains, as evidenced by their pathogenicity for rabbits, was no criterion for differentiating antigenic relationships, since 2 virulent strains were antigenically related to 1 of low virulence. Source of strains was not a differentiating characteristic, for strains from cases of chronic ulcerative colitis were serologically related to those isolated from a metastatic subacromial abscess in 1 case and from the blood stream of another."

Isolation of *Brucella* from lymph nodes, M. A. POSTON and P. B. PARSONS (*Jour. Infect. Diseases*, 66 (1940), No. 1, pp. 86-90, figs. 5).—A detailed description is given of a method used successfully in the isolation of *B. abortus* from lymph nodes. Lymph nodes from 10 of 19 patients with Hodgkin's disease yielded positive cultures of *Brucella*, 7 of which were of the *suis* variety and 3 of the *melitensis* variety. Cultures of lymph nodes from 3 patients with chronic brucellosis without clinical evidence of Hodgkin's disease were positive for *B. melitensis melitensis* in 2 instances and *B. melitensis suis* in 1. In a control series of cultures from 67 lymph nodes which were biopsied for a variety of causes, *B. melitensis suis* was isolated from only 1.

The preparation of *Brucella abortus* plate antigen and some factors affecting the sensitivity of the antigen, M. H. RÖPKE and C. P. FITCH. (Minn. Expt. Sta.). (*Jour. Infect. Diseases*, 66 (1940), No. 1, pp. 17-22).—It has been found that *B. abortus* antigens prepared by washing cultures with small amounts of phenol saline solution and then heating over a free flame to the simmering point for 10 min. yield antigens of varying composition and sensitivity. The results obtained with antigens thus prepared show that if a 0.5-percent phenol solution is used to suspend the bacteria, the major portion of the phenol is absorbed by the medium and thereby results in antigens with much below the desired phenol concentration. The soluble agar concentrations of the antigens varied from 0.28 to 0.54 percent, depending upon the amount of phenol saline solution used to suspend the bacteria and the time of contact with the medium. Marked variations in the relative sensitivities of the antigens were noted. Variations in the sensitivity up to 200 percent were found for suspensions of the same bacterial concentrations. Antigens prepared by washing the cultures with large amounts of saline and then centrifuging to remove the substances absorbed from the medium resulted in antigens with much more uniform sensitivities.

Erysipeloid: Occurrence among veterinary students, C. C. MORRILL. (Kans. State Col.). (*Jour. Infect. Diseases*, 65 (1939), No. 3, pp. 322-324).—Evidence presented indicates that an infectious condition found in students of comparative pathology was caused by an organism of the genus *Erysipelothrix*, and that the sources of infection were horse cadavers used for dissection.

Endocarditis caused by Salmonella suipestifer, C. T. READ (*Jour. Infect. Diseases*, 65 (1939), No. 3, pp. 263-266).

Susceptibility and resistance of certain species of American deer mice, genus Peromyscus, and other rodents to Leptospira icterohaemorrhagiae, A. PACKCHANIAN (*Pub. Health Rpts. [U. S.]*, 55 (1940), No. 31, pp. 1389-1402, pls. 2).—Of the 32 species and subspecies of rodents inoculated with virulent strains of *L. icterohaemorrhagiae*, the cause of infectious jaundice or Weil's disease, 26 species and subspecies were found to be susceptible, with the remaining 6 resistant to the experimental infection.

Studies on Listerella.—I, A Listerella strain isolated from a premature bovine fetus, R. GRAHAM, H. R. HESTER, and N. D. LEVINE. (Univ. Ill.). (*Jour. Infect. Diseases*, 66 (1940), No. 1, pp. 91-96, figs. 3).—The isolation of an organism of the genus *Listerella* (= *Listeria*, see Pirie (E. S. R., 83, p. 541)) from a 7-mo. aborted bovine fetus, as previously noted (E. S. R., 82, p. 388), led to an inquiry into the abortifacient properties of the organism. The inoculation of a strain of this organism isolated from the aborted bovine fetus was followed by the abortion of a pregnant heifer. *Listeria* was recovered from the fetus but not from the placenta, colostrum, or vaginal discharges of the heifer. The heifer recovered. Attempts to induce abortion in pregnant rabbits, guinea pigs, and swine by inoculation of the same strain of *Listeria* failed, but it caused temporary illness when inoculated intravenously into a nonpregnant heifer, and similar inoculation of a 6-week-old pig produced death in 3 days and in rabbits and guinea pigs in a few days. Conjunctivitis was produced in rabbits and guinea pigs by instillation of this *Listeria* into the conjunctival sac. Massive necrosis of the myocardium was produced in chickens by intravenous inoculation.

Studies on Listerella, II-IV. (Univ. Ill. et al.). (*Cornell Vet.*, 30 (1940), Nos. 1, pp. 97-111, figs. 2; 3, pp. 268-298, figs. 2).—A continuation of the study above noted.

II. *Field outbreaks of listerellosis in sheep and cattle*, R. Graham, H. R. Hester, and N. D. Levine (pp. 97-111).—A description is given of 3 flocks of sheep and 3 herds of cattle in Illinois in which outbreaks of *Listeria* (*Listerella*) encephalitis or encephalomyelitis occurred. Clinical and autopsy observations, as well as other aspects of the disease and its epidemiology, are discussed. A list is given of 39 references to the literature.

III. *Experimental listerellosis in domestic animals*, R. Graham, G. L. Dunlap, and N. D. Levine (pp. 268-290).—Experiments were conducted with the view to determining (1) whether or not the disease caused by *Listeria* (*Listerella*) is transmissible to certain domestic animals and (2) the effect of *Listeria* experimentally administered by different channels to healthy animals. The intracerebral inoculation of an ovine strain of the organism resulted in the death of a sheep, a heifer, a horse, and a number of chickens. A purulent encephalomyelitis was induced. A cat similarly exposed became ill but recovered. "Intravenous inoculation of a sheep, a cat, a young pig, and a number of chickens with ovine *Listerella* resulted in death. Conjunctivitis and keratitis were observed in the cat. Similar inoculation of a yearling steer, 2 horses, and another young pig was followed by illness and then recovery. A dog similarly exposed suffered a slight indisposition. Symptoms of cerebral involvement similar to those observed in natural cases were produced by intra-

venous inoculation of an experimental lamb, and the typical perivascular infiltration and meningeal infiltration was predominantly a mononuclear one. Subcutaneous exposure of chickens to ovine *Listerella* elicited no reaction. Conjunctival exposure of a sheep to ovine *Listerella* caused conjunctivitis and keratitis, while similar exposure of a steer and a horse caused a less marked conjunctivitis of short duration. Two pigs similarly exposed died, although no ocular symptoms appeared, but *Listerella* was regained from the brain of only 1 upon culture. A transient conjunctivitis was produced in 3 of 8 chickens inoculated conjunctivally. Similar exposure of a puppy failed to elicit symptoms. Intrastomachal exposure of a sheep and a horse caused temporary illness but produced no noticeable effect in a steer and another horse. *Listerella* was fed to chickens without effect. Two lambs which were confined continuously in the same pen with inoculated lambs that died following exposure remained apparently healthy. From observations made upon naturally or experimentally affected sheep, cattle, and horses it appears that a marked circulating monocytosis is not a characteristic of listerellosis in these animals." Thirty-three references to the literature are cited.

IV. *Unsuccessful attempts at immunization with living and dead Listerella cultures*, R. Graham, C. C. Morrill, and N. D. Levine (pp. 291-298).—An attempt to immunize rabbits against intravenous exposure with *Listeria* (*Listerella*) by repeated subcutaneous inoculations of a formalin-killed broth culture of the organism failed. A similar attempt was made to immunize sheep against intravenous exposure with the organism, eight animals having been vaccinated with two subcutaneous doses of a formalin-killed broth culture. Exposure of these animals and of five unvaccinated animals resulted in the death of all the sheep except one in the control group. An attempt to immunize young chickens against intracerebral exposure to the organism by single or repeated subcutaneous inoculations with heavy killed *Listeria* suspensions or by a single subcutaneous inoculation with a heavy living suspension was unsuccessful, as were also attempts to immunize rabbits and guinea pigs against conjunctival and subcutaneous exposure with bovine serum (with anti-*Listeria* agglutinin titer of 1/50,000), with formalized cultures, and with live cultures.

Plague in the western part of the United States, C. R. ESKEY and V. H. HAAZ (*U. S. Pub. Health Serv., Pub. Health Bul. 254* (1940), pp. 83, pls. 31, figs. 4).—Part 1 of this account (pp. 1-28) relates to the introduction of plague and its spread to the interior of the United States; wild rodents (1) of the western United States and (2) as a reservoir of the plague, including notes on identification; revised designation of ground squirrels; and domestic rats in the West. Part 2 (pp. 29-74) relates to observations on the ecology of fleas and experimental transmission of plague; plague among different species of wild rodents, with reference to the flea vectors, ground squirrels, prairie dogs, marmots, chipmunks, native rats, native mice, and tree squirrels, with an alphabetical list of fleas encountered during plague investigations, 1936-38. Part 3 (pp. 75-82) reports upon the demonstration of plague infection by inoculation of parasites.

Plague in the United States, B. C. HAMPTON (*Pub. Health Rpts. [U. S.]*, 55 (1940), No. 26, pp. 1143-1158, fig. 1).—Included is a list of the wild rodents, 29 in number, and a cottontail rabbit of the Western States which have been found plague-infected or are known to suffer from spontaneous plague.

Two epizootics of plague infection in wild rodents in the western United States in 1938, L. B. BYINGTON (*Pub. Health Rpts. [U. S.]*, 55 (1940), No. 33, pp. 1496-1501, figs. 3).—Report is made of two epizootic outbreaks of plague among rodents (Uinta ground squirrels (*Citellus armatus*), Wyoming ground

squirrels (*C. richardsonii elegans*), and woodchucks (*Marmota flaviventris*) that took place in regions of Wyoming and New Mexico sparsely inhabited by man. No human cases are known to have been associated with the rodent infection.

Psittacosis in importations of psittacine birds from the South American and Australian Continent, K. F. MEYER and B. EDDIE (*Jour. Infect. Diseases*, 65 (1939), No. 3, pp. 234-241).

Rickettsia diaporica: Its persistence in the tissues of Ornithodoros turicata, G. E. DAVIS (*Pub. Health Rpts. [U. S.]*, 55 (1940), No. 41, pp. 1862-1864).—Report is made on the finding that *R. diaporica* may survive in the tissues of *O. turicata* for at least 1,001 days, but is not transmitted during the process of feeding nor through the egg to the next generation. The virulence of the organism is not adversely affected by its long residence in the tick or by prolonged fasting of the tick. The tick excrement is infective.

The streptococci: Their descriptions, classification, and distribution, with special reference to those in milk, W. D. FROST and M. A. ENGELBRECHT (*Madison, Wis.: Willdof Book Co.*, [1940], pp. X+172, figs. 48).—The several parts of this work, following an introduction by J. H. Brown, deal with the biology of the genus *Streptococcus* (pp. 1-10), criteria of classification (pp. 11-19), detailed descriptions of hemolytic streptococci (beta type) (pp. 20-47) and of nonhemolytic streptococci (alpha, gamma, etc., types) (pp. 48-66), technic for the study of streptococci in general (pp. 67-72), the historical development of our knowledge of the streptococci in milk (pp. 73-80), methods used for the isolation and study of the streptococci in milk (pp. 81-88), streptococci found in the cow's udder (pp. 89-99), infections of the bovine udder with hemolytic streptococci and their relation to human disease (pp. 100-115), distribution of streptococci in the udders of individual cows (pp. 116-137), and streptococci in pasteurized milk (pp. 138-142) and in the throats of dairy employees (pp. 143-149). A bibliography of 16 pages and author and subject indexes are included.

Observations on differences within the species Streptococcus agalactiae, J. M. MURPHY. (N. J. Expt. Stas.). (*Cornell Vet.*, 30 (1940), No. 3, pp. 261-267).—Report is made of a cultural and serological study of 85 strains of streptococci found in a like number of aseptically drawn quarter samples of milk from a herd of 144 cows. All strains fermented dextrose and lactose, produced no change in methylene blue milk (1:20,000) at 37° C., hydrolyzed sodium hippurate, failed to split aesculin, did not ferment mannitol, sorbitol, raffinose or inulin, and conform serologically to Lancefield's group B. "Confirming tests on freshly isolated cultures were made at short intervals, and no variation within a strain was found. Repeat tests were not made on cultures after being kept on artificial mediums. It was found that a division of the 85 strains of *S. agalactiae* could be made on the basis of the action of individual strains on trehalose and salicin. The first division corresponds to the usual description of *S. agalactiae* in that they are beta, alpha, or nonhemolytic, are positive on trehalose, and either positive or negative on salicin. The second group includes strains that show either alpha or no hemolysis, do not ferment trehalose, but do ferment salicin." Thirteen references to the literature are included.

Natural infection of Triatoma heidemanni with Trypanosoma cruzi in Texas, A. PACKCHANIAN (*Pub. Health Rpts. [U. S.]*, 55 (1940), No. 29, pp. 1300-1306, pls. 2).

A survey of municipal garbage disposal methods as related to the spread of trichinosis, W. H. WRIGHT (*Pub. Health Rpts. [U. S.]*, 55 (1940), No. 24, pp. 1069-1077).

The transmission of cutaneous papilloma in cattle, L. E. BOLEY. (Univ. Ill.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 763, p. 325, figs. 2).—The inoculation experiment reported confirms earlier reports on the infectious character of warts or cutaneous papilloma of cattle.

Studies on bovine gastro-intestinal parasites.—II, Immunity to hookworm and nodular worm infection in calves, R. L. MAYHEW. (La. Expt. Sta.). (*Jour. Parasitol.*, 26 (1940), No. 5, pp. 345-357, figs. 2).—In continuation of the study previously noted (E. S. R., 82, p. 537), a description is given of the immunity in three calves to a mixed infection of nodular worms and hookworms that was induced by previous infection, also the immunity in one calf to a pure infection of nodular worms. The development of the immune reaction was not associated with age of host (range from 0.5 to 1.25 yr.), length of the infection period, or the degree of infection in the experiments described. Three of the animals were resistant to reinfection as tested by reinoculation over a period of 6 mo., although one was somewhat less so than the others. That the resistance is probably not permanent, however, is indicated by the fact that one individual acquired a much higher infection after 5 mo. under nonexperimental conditions than under the controlled conditions. The resistance of the fourth was not tested. Seventeen references to the literature are listed.

Losses from liver flukes in cattle, W. H. KRULL. (U. S. D. A.). (*Vet. Med.*, 35 (1940), No. 9, p. 507).—Losses due to liver flukes in cattle at an abattoir at Logan, Utah, in an area where infestation by this parasite is enzootic, are noted. Because of liver fluke infestation the livers of 50 percent of 835 cows, 30 percent of 1,241 heifers, 24 percent of 189 steers, and 27 percent of 99 bulls were condemned. This represented a total loss of 37 percent of the livers.

The bacteriology of acute mastitis, J. FERGUSON (*Cornell Vet.*, 30 (1940), No. 3, pp. 299-309).—The bacteriological examination of 54 cases of mastitis diagnosed as acute by a veterinarian is reported upon. Except in 1 case of a mixed infection, the common agent of bovine mastitis, *Streptococcus agalactiae*, was not found. The types of organisms present and the incidence and nature of the acute attacks are considered to suggest wound infections. The 13 of 109 subacute cases examined in which *S. agalactiae* was present are considered to have been flare-ups of chronic infections. The variation in the kinds and frequency of occurrence of bacteria reported in bovine mastitis is dealt with in relation to sample selection.

Hippelates flies as vectors of bovine mastitis (preliminary report), D. A. SANDERS. (Fla. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 763, pp. 306-308, fig. 1).—Having incriminated the housefly as a vector of bovine mastitis (E. S. R., 83, p. 679), an investigation of species of *Hippelates*, or eye gnats, has been conducted. The findings have led to the conclusion that they may act as vectors and that the incrimination of these insects in the transmission of the disease offers a plausible explanation for the occurrence of mastitis organisms in the mammary tissues of cattle in the area. It is pointed out that in addition to acting as vectors the possibility exists that they may also serve as a reservoir of bacterial species capable of inducing mastitis through continuous daily exposure of the teat orifice over long periods of time. This is worthy of consideration, since smears made of gnats taken in localities far removed from dairy herds have shown a bacterial flora resembling that in gnats collected about animals.

Musca domestica and Hippelates flies—vectors of bovine mastitis, D. A. SANDERS. (Fla. Expt. Sta.). (*Science*, 92 (1940), No. 2387, p. 286).—A more detailed account of this work is noted above.

Studies on streptococci of bovine mastitis, L. W. SLANETZ and J. NAGHSKI (*Jour. Infect. Diseases*, 66 (1940), No. 1, pp. 80-85; also *New Hampshire Sta. Sci. Contrib.* 74 [1940], pp. 80-85).—During the course of a study of the efficiency of different tests for the diagnosis of mastitis, as reported (E. S. R., 81, p. 281), cultures of streptococci were isolated from all cows in 10 different herds that gave evidence of streptococcic mastitis infection. The results of the classification of these streptococci, 680 in number, by means of biochemical and serological tests are reported, and the value of the Edwards' medium for the identification of *Streptococcus agalactiae* and the presence of mastitis streptococci in bovine mammary tissue are considered. Of the cultures 573 were identified as *S. agalactiae*, 83 as *S. uberis*, 15 as *S. dysgalactiae*, and 9 as *S. fecalis*. Serological tests indicated that there were two or more serological types within the *S. uberis*, *S. dysgalactiae*, and *S. fecalis* species. Edwards' medium was found highly satisfactory for the differentiation of mastitis streptococci; 98.7 percent of the gray-blue colonies developing on Edwards' medium were identified as *S. agalactiae*. No cultures of *S. agalactiae* could be isolated from the mammary tissue of 5 cows which were known to be mastitis-free for two or more lactation periods on the basis of bacteriological tests.

Bovine mastitis caused by unusual types of streptococci, W. T. MILLER and J. O. HEISHMAN. (U. S. D. A.). (*Cornell Vet.*, 30 (1940), No. 3, pp. 310-318).—Report is made of the recovery of streptococci, not recorded heretofore as occurring in the bovine udder, in cases of mastitis among 44 lactating cows in a small dairy herd in the vicinity of Washington, D. C. Sixty-nine strains of streptococci were isolated in the course of 4 examinations of milk samples from 28 animals. "Of the 68 strains tested biochemically and serologically, 44 were alike. These were designated type 1 and proved to belong to group G of Lancefield by the precipitin test. This type of streptococcus was recovered on as many as 4 occasions from 4 cows over a period of 8 mo. In addition, several fresh cases of infection occurred during this period, 1 being in a first-pregnancy heifer. That these streptococci caused considerable damage in the udder is indicated by the fact that 13 of 19 cows with marked physical cases of mastitis were infected with type 1. Of the other types of streptococci found in this herd only one, type 5, is found commonly in bovine mastitis. This is group III, or *S[treptococcus] uberis*. The other 3 types, numbers 2, 3, and 4, are of relatively little importance in mastitis."

Sulfanilamide in the treatment of streptococcic mastitis, C. S. BRYAN and J. J. ARNOLD. (Mich. Expt. Sta.). (*Vet. Med.*, 35 (1940), No. 9, pp. 508-510).—A study was undertaken to determine what therapeutic effect sulfanilamide may have in acute and chronic cases of streptococcic mastitis. When administered for 12 days at the rate of 0.6 gr. per pound per day to one cow and 1.2 gr. per pound per day to another cow, it was very effective in relieving the system reaction in acute streptococcic mastitis, as indicated by the decrease in body temperature and the return of the cow's appetite. The larger dose was the more effective; for although in the cow so treated the reaction was more severe (as indicated by the temperature of 107° F., compared to 105° for the cow receiving the smaller dose), the symptoms subsided more rapidly and the cow returned to the milking line, producing more milk than did the cow receiving only 0.6 gr. per pound per day. When administered for 12 days to five cows at the rate of 0.3 gr. per pound per day, to four cows at the rate of 0.6 gr. per pound per day, and to four cows at the rate of 1.2 gr. per pound per day, all the cows being affected with chronic streptococcic mastitis, it did not affect the streptococcic infection of the udder. The number of streptococci eliminated in the milk decreased during treatment, but in all cases the numbers subsequently returned to

the levels prior to treatment. The drug appears to be quite toxic for cows when administered in repeated large doses. It is thought that calcium gluconate solution may be a reliable antidote to sulfanilamide poisoning in cattle.

An unusual case of bovine trichomoniasis and a suggestion for chemotherapy of the disease, L. J. POELMA and G. E. DANIEL. (Univ. Md.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 763, pp. 323, 324).—Report is made of one of the few instances of infection with *Trichomonas fetus* which had run a severely chronic course lasting at least 15 mo. The administration of phenothiazine to this 8-year-old cow over a period of 10 days in daily doses varying from 14 to 60 gm., with a total of 234 gm., appeared to have been highly satisfactory.

Phenothiazine as an anthelmintic for intestinal nematode parasitisms in sheep, A. J. SINGER and D. W. BAKER (*Cornell Vet.*, 30 (1940), No. 3, pp. 375-382).—The experimental work reported, the details of which are given in two tables, is considered to confirm the reports of Harwood and his associates (E. S. R., 81, p. 715) and others that phenothiazine is an effective anthelmintic for the intestinal nematode parasites of sheep. The drug seems to be particularly effective for the removal of *Oesophagostomum columbianum*, *Ostertagia ostertagi*, and *Cooperia curticei*, less effective against infections with *Nematodirus filicollis* and *Haemonchus contortus*, and ineffective for infections with *Trichostrongylus* spp., *Strongyloides* spp., and *Trichuris oris*. The data presented indicate that phenothiazine is a more efficient anthelmintic than the copper sulfate-nicotine sulfate mixture and tetrachloroethylene. This is particularly evident in its action against the nodular worm, a parasite which neither of the other drugs affect. The drug does not seem to be toxic and produces none of the untoward effects resulting from the use of tetrachloroethylene and carbon tetrachloride. It is pointed out that in the case of heavy parasitic infections the drug is less efficacious than in light infections, as the average reduction in parasite load as indicated by fecal egg counts was only 66 percent of the total egg count in heavily infected sheep, whereas in light infections the average reduction was approximately 92 percent.

Phenothiazine in parasitic gastritis, W. T. ROWLANDS (*Vet. Rec.*, 52 (1940), No. 36, pp. 658-660).—Phenothiazine has been found to be a very efficient anthelmintic in sheep, providing the dose is 20 gm. or more. It is well tolerated, 60 gm. having been given to a 50-lb. lamb without ill effects. The drug is best administered in liquid form with the aid of a dosing syringe.

Comparative tests on the treatment of lambs with phenothiazine and with copper sulphate and nicotine sulphate, A. D. McEWEN (*Vet. Rec.*, 52 (1940), No. 36, pp. 657, 658).—Comparative tests on five flocks of lambs have indicated that phenothiazine is a more effective anthelmintic than copper sulfate and nicotine sulfate.

The influence of the nutritional condition of lambs on their susceptibility to an artificial infestation with parasitic nematodes, A. H. H. FRASER, W. THOMSON, D. ROBERTSON, and W. GEORGE (*Empire Jour. Expt. Agr.*, 6 (1938), No. 24, pp. 316-322).—Two groups of 20 parasite-free lambs, 1 group of which was well fed and the other ill fed, were artificially infested with an approximately equal number of infective nematode larvae. Following slaughter the contents of the fourth stomachs were examined, and it was found that the average count for the ill-fed group was *Ostertagia* 229, *Haemonchus* 81, and *Trichostrongylus axei* 0, and for the well-fed group *Ostertagia* 11, *Haemonchus* 2, and *T. axei* 0.

Control of worm parasites in market lambs, D. W. BAKER and J. P. WILLMAN. (Cornell Univ. et al.). (*Cornell Vet.*, 30 (1940), No. 3, pp. 401-404).—A progress report.

Prophylaxis in equine encephalomyelitis, R. A. KELSER (*Cornell Vet.*, 30 (1940), No. 3, pp. 350-358).

Report on phenothiazine as an anthelmintic in horses, T. GRAHAME, D. O. MORGAN, and J. E. N. SLOANE (*Vet. Rec.*, 52 (1940), No. 36, pp. 660-663).—The results obtained from egg counts and from the improvement observed in the general condition of animals treated with phenothiazine have shown that it has distinct merits as an anthelmintic for strongyles in horses. The effective minimum dose for horses averaging approximately 1,000 lb. was 30 gm.

Treatment of equine strongylosis by phenothiazine, R. H. KNOWLES and A. V. FRANKLIN (*Vet. Rec.*, 52 (1940), No. 36, pp. 663, 664).

Control of equine strongylosis.—II, **The effect of anthelmintic treatment of mares on the development of strongylosis in foals**, G. W. SALISBURY, D. W. BAKER, and J. W. BRITTON. (*Cornell Univ. et al.*). (*Cornell Vet.*, 30 (1940), No. 3, pp. 367-375).—In continuation of their studies (*E. S. R.*, 82, p. 107) the authors have found the average rate of pick-up of strongyle infection by foals running under excessively dry pasture conditions and following a 39-percent reduction of exposure through treating the brood mares to be 39 percent less than the rate of pick-up in 1938 where the foals were run under natural conditions. The low strongyle egg counts of foals at weaning time would suggest treatment at this time as valueless. Further indications of breed as well as individual resistance are suggested. The time at which the eggs of *Strongyloides westeri*, *Trichostrongylus axei*, *Ascaris equorum*, and the strongyles appear in the feces of the foals is noted as 22, 33, 94, and from 95 to 102 days following foaling, respectively. Evidence of prenatal *Ascaris* infection was noted in one foal. Eleven references to the literature are cited.

The occurrence of paratyphoid infection in horses following treatment for intestinal parasites, W. W. DIMOCK, P. R. EDWARDS, and D. W. BRUNER. (*Ky. Expt. Sta.*). (*Cornell Vet.*, 30 (1940), No. 3, pp. 319, 320).—Report is made of the findings in 2 horses which had succumbed following treatment with an oil of chenopodium mixture, as sometimes occurs. The first, a 3-year-old thoroughbred gelding, was 1 of a group of 32 horses each of which received by stomach tube a mixture consisting of oil of chenopodium 12 cc., spirits of turpentine 60 cc., and equal parts of oil of linseed and mineral oil to make a total volume of 950 cc. All of the horses made an uneventful recovery from treatment, except this animal which apparently recovered from the purgative effect of the treatment within 72 hr. However, on the fourth day following administration of the oil, diarrhea again appeared and the temperature of the animal was 104° F., both the diarrhea and fever continuing until death occurred on the seventh day following treatment. On post-mortem examination gastritis and enteritis were detected, and paratyphoid bacilli were isolated from the heart blood, liver, spleen, and intestinal contents. The second case was a 2-year-old thoroughbred colt, 1 of a group of 8 horses, each of which received the same treatment as those of the first mentioned group. This colt in the afternoon of the day of treatment exhibited constipation and anorexia and had a temperature of 105.8°. A fetid diarrhea developed, and the temperature ranged from 103° to 104° until death occurred on the eighth day. Large numbers of paratyphoid bacilli were found, on the third day following treatment, in a sample of feces brought to the laboratory. On post-mortem examination the colt exhibited pathological changes similar to those found in the first case, and paratyphoid bacilli were isolated from the internal organs and from the intestinal contents. Bacteriological examination of fecal samples from horses at the farm on which the colt was reared resulted in the discovery of 1 mare to be a carrier of paratyphoid bacilli. The bacilli isolated from the fatal cases as well as those isolated

from the mare upon subjection to serological examination proved to be *Salmonella typhimurium* (*S. aertrycke*).

It is concluded that the horses were carriers of *S. typhimurium* and that administration of the anthelmintic drugs caused a sufficient derangement of the intestinal tract to allow the organism to initiate a systemic infection.

Trial of phenothiazine in ascarid infestation in dogs, R. F. MONTGOMERIE (*Vet. Rec.*, 52 (1940), No. 36, p. 665).—The treatment of 10 puppies in 2 litters with phenothiazine in doses varying from 6 to 12 gm. had little or no effect on ascarid infestation.

The treatment of canine piroplasmiasis with sulfanilamide, J. W. LANDSBERG (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 763, pp. 309–311).—The administration of sulfanilamide to seven animals appeared to have had some beneficial action in canine piroplasmiasis infections. Further study, particularly of the dosage, is required before definite conclusions can be drawn.

Measures for the control and prevention of rabies, R. A. KELSER (*Cornell Vet.*, 30 (1940), No. 3, pp. 321–330).

Paratyphoid in chinchilla, G. C. HOLM and P. H. GRAVES. (Idaho Expt. Sta.). (*Vet. Med.*, 35 (1940), No. 9, p. 501).—A brief account is given of an infectious disease of chinchilla which appeared recently and has caused a loss of young adult animals in Idaho. A Gram-negative organism differing from the described forms of *Salmonella* was isolated from the blood, liver, spleen, kidneys, intestine, cecum, and colon. Immune serums with a titer of 1:3,200 were developed after three 1-cc. injections of the antigen, indicating that a good vaccine can be obtained from the organism.

A report of a field and laboratory trial of vaccinating chickens for infectious coryza with avian mixed bacterin, J. R. BEACH and R. A. BANKOWSKI. (Univ. Calif.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 763, pp. 320–322).—In field and laboratory tests of the effectiveness of avian mixed bacterin in the control of outbreaks of infectious coryza, conducted in the fall of 1939, the administration of three doses of the bacterin to a flock of pullets among which the disease had been present for 2 mo. did not have any curative effect on birds already infected and did not give protection to the birds which were not infected at the time of vaccination. Neither did the treatment influence the mortality or the number of birds that were culled because of poor physical condition. Chickens which were given one, two, or three doses of the bacterin were not protected against contact exposure to coryza from 9 to 24 days later.

Some causes for false reactions with whole blood pullorum disease testing, G. C. HOLM, J. K. WILLIAMS, B. F. CALLAHAN, and W. V. HALVERSEN. (Idaho Expt. Sta.). (*Vet. Med.*, 35 (1940), No. 9, pp. 511–513, fig. 1).

The initiation of avian coccidial infection with merozoites, P. P. LEVINE (*Jour. Parasitol.*, 26 (1940), No. 5, pp. 337–343).—The difficulty of separating *Eimeria necatrix* from *E. tenella* when the oocysts of both species are present in the ceca led the author to investigate the possibility of infecting chickens with merozoites. Infection was initiated by introducing merozoites of *E. maxima*, *E. hagani*, *E. praecox*, and *E. necatrix* into the intestine of parasite-free chickens. Merozoites of *E. tenella*, when introduced into the intestine or into the ceca by cloacal injection, also caused infection, but failed to do so when placed in the crop. The separation, by the use of the merozoite infection technic, of *E. necatrix* from *E. tenella*, when both species are present in the same culture, is described.

The effect of sulfapyridine on experimental avian coccidiosis, P. P. LEVINE (*Jour. Parasitol.*, 26 (1940), No. 3, pp. 233–235).—The data presented in this report, the details of which are given in table form, indicate that sulfapyridine, like sulfanilamide, is an effective chemotherapeutic agent against

several species of coccidia affecting chickens and has the advantage that it is nontoxic to the bird in effective concentrations. Neither of these substances is effective against the most destructive species, i. e., *Eimeria tenella* and *E. necatrix*, and both are too expensive for practical use. The experience indicates, however, that the search for a chemotherapeutic agent for coccidiosis is not a futile one.

Endoparasitism in ruffed grouse near Hanover, New Hampshire, F. H. CONNELL and H. M. DOREMUS (*Auk*, 54 (1937), No. 3, pp. 321-323).—Twenty-six percent of 58 birds shot in the vicinity of Hanover during the hunting seasons of 1935 and 1936 and examined for intestinal protozoans were found infested with *Trichomonas bonasae*. Thirty-one percent of 70 birds examined for worms were infested with *Ascaridia lineata*. No other parasites were noted.

A new intestinal roundworm from the ruffed grouse (*Bonasa umbellus*) in the United States, E. E. WEHR. (U. S. D. A.). (*Jour. Parasitol.*, 26 (1940), No. 5, pp. 373-376, figs. 6) —Under the name *Ascaridia bonasae*, the ascarid usually encountered in the ruffed grouse of the Eastern and Middle Western States is described as new. This form had previously been assumed to be *A. lineata*, the large intestinal roundworm of the domestic fowl.

The occurrence of tuberculosis in the starling (*Sturnus v. vulgaris* L.), S. L. HIGNETT and D. A. MCKENZIE (*Vet. Rec.*, 52 (1940), No. 33, pp. 585-587).—An outbreak of avian tuberculosis among the stock in a well-managed poultry establishment led to an investigation of the occurrence of the disease among the wildlife in the neighborhood. Starlings alone gave positive results in three cases and were investigated, with the result that avian tuberculosis was found present in from 1.3 to 4.8 percent. Tuberculosis organisms were also found in the rectal contents and probably in the excreta on trees in the roost. The importance of the starling as a vehicle of infection is emphasized.

Excystment and sterilization of metacercariae of the avian strigeid trematode, *Posthodiplostomum minimum*, and their development into adult worms in sterile cultures, M. S. FERGUSON (*Jour. Parasitol.*, 26 (1940), No. 5, pp. 359-372, figs. 8).—Report is made of observations on the morphology and natural development of stages in the life cycle of the trematode parasite *P. minimum*. Twenty-eight references to the literature cited are listed.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Idaho Station]. (Partly coop. U. S. D. A.). (*Idaho Sta. Bul.* 236 (1940), pp. 27-33, figs. 2).—Irrigation pumping and use and the effect of altitude on precipitation were studied by H. Beresford, J. P. Bonner, M. R. Kulp, J. C. Marr, J. L. Toevs, and W. Watson; vegetable-seed threshing by Beresford, C. F. Dietz, E. N. Humphrey, and G. W. Woodbury; beet harvesting machinery by Beresford and Humphrey; mechanized dusting for pea weevil by Humphrey; and rural electrification by Beresford and J. B. Rodgers as to electric brooder design, a feed mixer and grinder for poultry feed, the use of compressed air in washing dairy equipment, and the use of electric soil heating cable for warming milk and melting ice in roof gutters and downspouts.

The groundwater supply of the Eloy district in Pinal County, Arizona, G. E. P. SMITH (*Arizona Sta. Tech. Bul.* 87 (1940), pp. 42, pls. 3, figs. 7).—The Eloy district is a partially closed basin about 25 miles long by 17 miles wide, in which development of pumping began in 1914, was slow until 1936, and has since proceeded rapidly. The principal crop is cotton, next winter

grain. There is a considerable acreage of winter vegetables, to which the district is well adapted by reason of its climate and soil.

Because of low rainfall and absence of great floods during the 3 yr. 1936-38, the period was favorable for the study of ground water. The large summer floods of 1939 presented a new factor for study. The quantity of water pumped was determined by indirect methods. The maximum was 63,600 acre-ft. in 1937. The water table near each well was depressed during each pumping season but recovered partially during the fall and winter as the water table of the district became leveled again.

The ground-water supply is developed adequately where the intervals between wells is 1 mile. Closer spacing is not justified. The water pumped in any year was derived partly from the slow-moving underground inflow, and the balance was drawn from the stored supply.

For the 3 yr. 1936-38 the quantity of water which could be pumped without a residual loss to the stored supply was of the order of 20,000 acre-ft. per year. The excess over that quantity was drawn from storage. The heavy summer floods of 1939 were expected to contribute an important additional recharge by downward percolation to the water table. The evidence deduced from the field observations indicated very little effect, however, implying that the surface waters penetrated only to shallow depths and were lost subsequently by evaporation.

The pumping operations in 1936 were nearly twice as great as they should be if a permanent agriculture in the valley is contemplated. Operations in 1937 and 1939 were at a rate three times as great as desirable from the standpoint of permanence. There is no legal restriction applicable to the district which can reduce the pumping draft or prevent still further expansion of agriculture.

The possibilities of increasing the water supply by surface storage or some form of conservation, such as water spreading, should be thoroughly explored. Detention reservoir projects, even though costly, might be found feasible. The total surface discharge reaching Sasco in the last 18 yr. has averaged only from about 12,000 to 16,000 acre-ft., however, and, if all of it were stored solely for the Eloy district, it would provide a supply for only about 5,000 acres. A diversion canal from the Sasco flats with lateral distributaries both north and south of the Greene Canal to the most porous lands might be helpful, and an area on the east side of the valley could be utilized also for water spreading if the soil can be made to take water. Other water conservation measures are also discussed.

Salinity condition in the Big Horn River during the years 1938 and 1939, T. J. DUNNEWALD. (Coop. U. S. D. A. et al.). (*Wyoming Sta. Bul.* 240 (1940), pp. 28, fig. 1).—This bulletin reports the work carried out from October 1, 1937, to October 1, 1939.

The river discharged, in 1938, approximately 550,000 acre-ft. of water at Riverton, the upper station. This was increased to 928,000 acre-ft. at Thermopolis, to 1,496,000 acre-ft. at Kane, and to 2,416,000 acre-ft. at St. Xavier (Mont.). The respective salt burdens were 163,000, 516,000, 1,166,000, and an estimated 2,600,000 tons of total dissolved solids. The weighted mean concentrations of total dissolved solids, computed as tons per acre-foot, ranged from 0.396 at Riverton, 0.697 at Thermopolis, and 0.968 at Kane, to an estimated 1.09 at St. Xavier. The data for the 7-mo. winter period show higher concentrations for that period of low discharge than for the full year, because of the diluting effect of the summer floodwaters. Similar data concerning the 1939 observations are given, the river showing a much lower discharge and a

higher concentration of total dissolved solids, 77 percent of the 1938 discharge carrying a salt burden amounting to 88 percent of that of 1938. The river was found to furnish good irrigation water at the upper gaging station, but in passing down stream the composition of the dissolved matter changes from chiefly calcium and magnesium to a higher proportion of the alkalis. Sulfates increase and carbonate and chloride decrease. Nitrate is greatest near the head.

"The farmer can reduce the bad effects on the soil by using the most water when the salt content is lowest [May, June, and July], by reducing evaporation from the soil surface, and by frequent small irrigations designed to keep the major movement of water downward. High water tables in the subsoil favor the concentration of salt at the surface and can be lowered by drainage, by avoiding the continuous flow method of irrigation, by sealing up ditch and canal bottoms."

Improved fertilizer distributor, R. H. MEANS (*Miss. Farm Res. [Mississippi Sta.], 3 (1940), No. 9, p. 7, fig. 1.*)—The design of this machine was adapted from that of a smaller distributor of the wheelbarrow form. Old cultivator wheels were attached to a 1½-in. solid shaft passing through the length (not specified) of the fertilizer box, or width of the machine, and provided with agitators. The rate of distribution was controlled by a strap-iron strip, 2 by ¼ in., carrying holes ranging from ⅜ to ⅝ in. in diameter. The machine was found adjustable to a minimum rate of distribution of 150 lb. of superphosphate per acre and up to a maximum of 400 lb. per acre. The capacity of the fertilizer box was about 400 lb. of superphosphate. The cost of construction was about \$5.

AGRICULTURAL ECONOMICS

Annual Agricultural Conference for Southwestern States (*Ann. Agr. Conf. Southwest. States, Texarkana, 1939, Proc., pp. [4]+100, pls. 3.*)—Included are the following papers with discussions presented at the meeting held at Texarkana, December 8 and 9, 1939: Changes in Methods of Producing Farm Products Affecting Labor Organization, by C. A. Bonnen (pp. 1-6) (Tex. Expt. Sta.); Trends in the Social and Economic Conditions of Renters, Share Croppers, and Day Hands, by J. G. McNeely (pp. 9-12) (U. S. D. A.); Practical Policies for Raising the Status of Tenants, Croppers, and Day Laborers, by W. H. Metzler (pp. 13, 14) (Univ. Ark.); Legal Barriers That Hinder Improved Tenancy Relations, by M. Harris (pp. 16-25), and "Helping the Farmer Up," by A. M. Rogers (pp. 26-31) (both U. S. D. A.); Educational Programs for Improving Tenure Conditions, by J. P. Montgomery (p. 32) (La. Sta.); Programs for Improving Tenure Conditions Through County Agricultural Planning Committees, by G. E. Adams (p. 33) (Tex. A. and M. Col.); What the County Land Use Planning Committees Can Do To Improve Tenure Conditions, by R. Mauney (p. 34) (Univ. Ark.); County Agricultural Planning Committees—Improving Tenure Conditions, by E. D. Hunter (p. 35) (Okla. A. and M. Col.); The Anticipated Goals of Tenure Improvement in the South, by C. O. Brannen (p. 36) (Univ. Ark.); Needed Types of Research on Tenure Problems, by P. Nelson (pp. 49-54) (Okla. A. and M. Col.); Immediate Backgrounds of Present Agricultural Policies and Programs, by H. C. Taylor (pp. 56-67); Present Status of Cooperative Supply Business in the Southwest, by W. E. Paulson (pp. 68-71) (Tex. Sta.); Types and Evaluation of Service Rendered by Cooperative Selling and Service Associations in the Southwest, by A. W. Jacob (pp. 72-81) (Okla. A. and M. Col.); Types of Cooperatives Financed in Region VI Through the Farm Security Administration, by C. Woolsey (pp. 82-86) (U. S. D. A.);

Responsibilities of Land Grant Colleges to the Cooperative Movement, With Respect to Research and Teaching, by R. A. Ballinger (pp. 87-91) (La. State Univ.); and Responsibility of the Extension Service to the Cooperative Movement, by H. E. Thompson (pp. 92-95) (Univ. Ark.).

[Investigations in agricultural economics by the Idaho Station, 1939] (*Idaho Sta. Bul.* 236 (1940), pp. 33-37, fig. 1).—Brief general findings are reported in studies of farm and community reorganization in two communities in Washington County, by A. Eriksen; a study of the relation of tenancy and ownership to farm crop enterprises, by P. A. Eke; and an economic and sociological study of recent settlement on cut-over land in the northern part of the State, by C. O. Youngstrom. A map by N. Nybroten shows the location of farmers' cooperative associations in the State.

Current Farm Economics, [October 1940] (*Oklahoma Sta., Cur. Farm Econ.*, 13 (1940), No. 5, pp. 107-138, figs. 5).—In addition to the usual discussion of the agricultural situation and the tables of indexes of prices, purchasing power of Oklahoma farm products, etc., the following articles are included: Cotton Loans to Farmers, by K. C. Davis (pp. 113-116), discussing the 1940-41 Commodity Credit Corporation rates; The Proposed Graduated Land Tax Law in Operation, by R. T. Klemme (pp. 117-130), describing the probable effects of some of the exemptions in the proposed law; and Does a Program of Conservation Interfere with Farm Operations? by E. A. Tucker and P. Nelson (pp. 130-135), including tables showing for farms studied in Payne and Muskogee Counties, in connection with the Soil Conservation Service program, the size, selected organization data and farm income, and the effects of erosion on crop yields.

Technology on the farm (*U. S. Dept. Agr.*, 1940, pp. XIII+224, figs. 37).—This is a special report of the Interbureau Committee on Technology of the United States Department of Agriculture. Part 1, Meanings (pp. 1-98), includes chapters on the problems of change; our dynamic agriculture; changes in machines, animals, plants, and uses of land; improvements in processes and uses; a summary of primary changes; the effects on volume of production, regional specialization, prices, costs, and returns, employment and people, and on the national economy; technology and the farm problem; and suggestions for measures to provide employment and security for displaced and underprivileged persons, to stabilize agricultural economic conditions, and to create a wider appreciation for the values and benefits of rural life. Part 2, Surveys (pp. 99-221), discusses in greater detail the changes and improvements in agricultural practices in chapters on machines; rural electrification; farm transportation; animal feeding and diseases; breeding of animals; plants; control of plant pests; vegetable oils and starch crops; preservation of foods; commercial fertilizers; minor soil elements, manures, and lime; conservation practices; farm forestry; technology in the farm home; and things to come—1940. A list of the literature cited is included.

North America: Its people and the resources, development, and prospects of the continent as the home of man, J. R. SMITH and M. O. PHILLIPS (*New York: Harcourt, Brace & Co.*, [1940], [2. ed.], pp. XIII+1008, [pl. 1], figs. [564], map 1).—The population, climate, resources, industries, present and possible future developments, etc., are discussed by regions.

The economic almanac for 1940 (*New York: Natl. Indus. Conf. Bd.*, [1940], pp. X+384).—This is a handbook of facts regarding business, labor, and government in the United States and other countries grouped under the headings of chronologies and calendars, legislation affecting national economic life, general business conditions, and recent economic developments.

Types of farming in Maryland, A. B. HAMILTON and T. D. JOHNSON. (Coop. U. S. D. A.). (*Maryland Sta. Bul.* 432 (1940), pp. 217-271, figs. 34, maps 2).—“The purpose of this bulletin is to portray the agriculture in Maryland by showing the kind, proportion, and distribution of crops and livestock produced; to analyze the factors affecting agricultural development; to delineate areas within which certain combinations of crops and kinds of livestock predominate; and to show how the type of farm organization is related to the physical and economic conditions existing in the area.” The physical and economic factors that determine a type area and the general, tobacco, truck crop, and strawberry rotation systems of the State are described, with maps showing the natural regions of the State, slope classification of lands, extent of soil erosion, precipitation, length of growing season, principal soil series, and relative productivity of soils. Other maps included and discussed show the acreages of the principal crops, numbers of different kinds of livestock and chickens, amounts of milk, and number of eggs produced as shown by the 1935 census. On the basis of these data, the State is divided into 12 types-of-farm areas and each briefly described.

The place of dairying in Mississippi agriculture, J. S. MOORE and W. C. COWSERT (*Mississippi Sta. Bul.* 343 (1940), pp. 19, figs. 3).—The results are summarized of a 10-yr. experiment on a 14.25-acre combination cotton and dairy farm having the following organization: An average of 4.8 cows, 6 acres in pasture, 2 acres in cotton, and 6.25 acres in feed crops. Some of the findings were yield of cotton increased 32.7 percent and that of corn 65.49 percent from the first to the second 5-yr. period. During the 10 yr. it was possible to increase the number of cows from 4 to 6. Average returns per year per acre less cost of labor and seed were cotton \$20.21, corn \$12.61, sagrain \$20.75, silage \$41.37, hay \$23.66, and pasture \$30.88. The value of products per cow less cost of labor and feed was \$47.39. The total returns for the 10 yr. were crops \$1,280.49 and dairy products \$2,274.85.

An economic study of dairy farms in the Kentwood area of southeastern Louisiana, 1937-38, J. N. EFFERSON and F. MERRICK (*Louisiana Sta. Bul.* 325 (1940), pp. 28).—This bulletin makes fuller analysis of the data in the study previously noted (E. S. R., 84, p. 116).

The average labor earnings per farm (labor income plus value of farm privileges) were \$755. The labor income averaged \$370, being —\$570 for 5 farms with the lowest and \$1,933 for 5 with the highest income. Net returns per farm and per 100 lb. of milk produced and returns per hour of labor were \$117 and 31 and 17 ct. on the farms with less than 15 cows, \$204 and 32 and 19 ct. on farms with from 15 to 22 cows, and \$553 and 30 and 17 ct. on those with 23 or more cows; —\$28 and —7 and 9 ct. on farms with an average production of less than 2,900 lb. of milk per cow, \$216 and 26 and 16 ct. where the production was from 2,900 to 3,800 lb., and \$453 and 50 and 24 ct. where the production was 3,800 lb. or more; —\$20 and —3 and 10 ct. where the price received for milk was less than \$2.03 per 100 lb., \$325 and 39 and 19 ct. where the price was \$2.03 to \$2.29, and \$344 and 49 and 20 ct. where the price was \$2.30 or over; and —\$77 and —13 and 8 ct. where less than 58 percent of the total receipts were from dairying, \$294 and 37 and 19 ct. where from 58 to 72 percent were from dairying, and \$596 and 50 and 23 ct. where it was 73 percent or more. “On the farms studied for the 1937-38 fiscal year, the most successful ones were those having a fairly large productive herd of dairy cattle, but also having a diversity of business sufficient that 30 to 40 percent of the receipts were from sources other than the dairy enterprise.”

Dairy and hog farming in northeastern Iowa, R. K. BUCK, J. A. HOPKINS, and C. C. MALONE (*Iowa Sta. Res. Bul. 275 (1940), pp. 673-718, figs. 8*).—This study made in 1935 and 1936 includes 61 farms in 6 counties in the area studied in 1923-24 (E. S. R., 58, p. 488). In the study of the relationships between cropping and livestock systems, the farms were divided into 3 groups—dairy-hog farms (27) with over 25 percent of the gross income from dairy products, dairy-hog farms (28) with under 25 percent of the gross income from dairy products, and beef-dairy-hog farms (6). Detailed labor records were kept on 10 farms. Analysis is made for each type of farm of the cropping system, disposition of total grain, and feed unit production and disposition. The changes in livestock production; the dairy, beef-dairy, hog, and poultry enterprises; the sources and monthly distribution of labor; the combination of enterprises; the financial returns; and the factors affecting farm profits are discussed.

On dairy and hog farms the highest returns were obtained where the number of milk cows equaled the number of litters of pigs per year, which meant about 6 lb. of hogs produced to each pound of butterfat. Strictly dairy herds were more profitable than the dual-purpose herds, although butterfat prices were unfavorable in comparison with beef prices. The average hog enterprise consisted of 10 spring and 3 fall litters, averaging 1,420 lb. per litter. The milk cows furnished the hog enterprise an average of 5,370 gal. of skim milk per farm, or 30 gal. per 100 lb. of hogs produced. Home-produced protein comprised about two-thirds of the protein supplement of the hog enterprise and was valued at about \$81 per farm. Two-thirds of the farmers produced 100 lb. of hogs, with from 385 to 531 lb. of concentrates. Under the 1935-36 price relationships, poultry generally paid higher returns for feed fed than any other livestock. The yearly labor requirements on the 10 farms on which detailed labor records were kept were 143 hr. per cow for the dairy enterprises, 31 hr. per litter of pigs for the hog enterprises, and 2.1 hr. per hen for the poultry enterprises. Of the total feed units produced, corn comprised about 40 percent, small grains 13 percent, and hay and pasture 47 percent. On the dairy and hog farms about 55 percent of the feed units produced were consumed by dairy cattle, 29 percent by hogs, 11 percent by horses, and 5 percent by poultry and sheep. "A comparison of the high and low profit dairy-hog farms shows that the high profit group had one-third larger farms, 4 percent more land in crops, a faster turnover of capital invested, higher crop yields, more efficiency in both the dairy and hog enterprises, and greater efficiency in the use of labor and machinery."

Importance of different farm management factors under varying price conditions in northwestern Indiana (Type-of-farming area No. 1), L. ROBERTSON (*Indiana Sta. Bul. 452 (1940), pp. 16, figs. 12*).—This study was based on financial accounts kept by approximately 50 farmers each year from 1929 to 1938. Most of the farms were general or dairy farms and averaged 198 acres in size, with 138 acres in crops, 15 dairy cows, 5 sows, and 148 hens. The farmers were above average in farming ability and success. The accounts were continuous during the period for 22 of the farms. An analysis is made of the relation between prices of farm products in Indiana and of the effects on labor income of the 6 factors—livestock efficiency, crop yields, size of farm, labor efficiency, amount of livestock, and intensity of crops, the farms being grouped into the high, medium, and low third for each factor. Charts show by years the relationship of the indexes of prices of farm products in Indiana to (1) the average labor income, and (2) the average income for each of the 3 groups of farms for each of the factors studied.

The average annual labor income varied from —\$649 in 1932 to \$1,811 in 1936, averaging \$604 for the 10-yr. period. The average labor incomes for the highest and lowest thirds under each factor were livestock efficiency \$1,071 and \$97, crop yields \$1,192 and \$276, labor efficiency \$844 and \$395, intensity of crops \$830 and \$424, acres per farm \$812 and \$477, and livestock investment per tillable acre \$762 and \$505. The average labor incomes where different numbers of the 6 factors were equal to or above the average were as follows: None or one —\$67, two \$310, three \$692, four \$1,386, and five or six \$1,624.

[Mississippi cash farm income, 1936-39], M. GUIN and D. W. PARVIN (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 9, p. 8).—A table shows the cash income by years from different crops, different kinds of livestock, and Government payments.

17-year-average costs give basis from which to estimate feeding possibilities, R. T. BURDICK (*Colo. Farm Bul. [Colorado Sta.]*, 2 (1940), No. 4, pp. 8, 9).—A table is included and discussed showing the 17-yr. average 1922-38 and the 1939-40 data for items of cost in feeding, purchase and sale weights and prices, gains per day, etc., in lamb feeding in northern Colorado.

Records point way to profits, P. L. PUTNAM. (Univ. Conn.). (*U. S. Egg and Poultry Mag.*, 46 (1940), No. 10, pp. 586-588, 637, 638).—Analysis is made of the records kept during 1933-39 by Connecticut poultrymen in cooperation with the University of Connecticut to show the labor income by years and the effects on labor income in 1939 on 121 farms of egg production per bird, fall egg production, mortality, labor costs, investment, and gross sales. Labor income in 1939 averaged \$1,081 and increased from —\$8 for the farms with none of the six factors above the average to \$2,438 for those with all factors above the average.

Studies in economics of apple orcharding.—III, A study of orchard problems by the budget method of analysis, H. C. WOODWORTH and G. F. POTTER (*New Hampshire Sta. Bul.* 323 (1940), pp. 23, figs. 20).—This third bulletin in the series (*E. S. R.*, 71, p. 547) includes curves with explanations showing per 1,000 trees by years for 60 yr. the hours of labor for various operations; cost of materials and labor with permanent, permanent and semipermanent, and permanent, semipermanent, and filler trees, and with normal, delayed, high, and low yields; expected yields with each of the three different plans of planting; annual net returns for each plan of planting, and for high and low cost methods with late and early bearing and with good and poor soils; and inventory value per tree.

State rural land use legislation in 1939, K. WERNIMONT. (U. S. D. A.) (*Jour. Land and Pub. Util. Econ.*, 16 (1940), No. 1, pp. 110-116).—The legislation is summarized under the headings interstate compacts, Federal-State relations, local government reorganization, planning and zoning, forestry, grazing, soil conservation districts, land tenure, public lands, taxation, and water utilization. The tendency was to extend or clarify existing laws, no widespread innovations, such as conservation districts or rural zoning acts, being enacted.

Economic utilization of rural land resources in Beauregard Parish, Louisiana, B. M. GILE (*Louisiana Sta. Bul.* 322 (1940), pp. 35, figs. 6).—This study was made to ascertain the possibilities of earning sufficient income for satisfactory support of families dependent on farming through commercial crop and livestock production, the necessary assets of a prospective settler, acreage necessary for a family-sized farm, the value of unimproved lands for grazing and crop production, and whether it would be to the public welfare to develop the entire parish into residential farms. The area, tax delinquency, recent pop-

ulation changes, classes of land, crop yields, ownership of lands, factors affecting the agriculture, the relation of acres of land used to income, and the possibilities and advisability of land zoning are discussed.

Farm adjustments in Montana: Graphic supplement, N. W. JOHNSON. (Coop. Mont. Expt. Sta. et al.). (*U. S. Dept. Agr., Bur. Agr. Econ., 1940, F. M. 8, pp. [5]+55, pls. 48, fig. 1*).—Included are maps and charts for type-of-farming areas in Montana except II, VIII, and IX, supplementing the data in Montana Experiment Station Bulletins 328 (E. S. R., 76, p. 708), 367 (E. S. R., 81, p. 586), and 377 (E. S. R., 83, p. 258), and similar studies of areas I, III, V, and VI now under way.

Probable effects of the agricultural conservation program on livestock production in the Midwest dairy region, I-V, S. E. JOHNSON, R. L. MIGHELL, and F. T. HADY. (Coop. Iowa, Minn., Wis., and Mich. Expt. Stas.). (*U. S. Dept. Agr., Bur. Agr. Econ., 1940, pts 1, pp. [2]+24, figs. 3; 2, pp. [3]+53, figs. 3; 3, pp. [4]+123, figs. 9; 4, pp. [3]+75, figs. 10; 5, pp. [3]+116, figs. 4*).—This report consists of five parts, which were originally submitted to the A. A. A. in June 1937 in response to a request for a study of the subject. The reports are based on studies carried on during 1936 and 1937 in selected areas in Iowa, Minnesota, Wisconsin, and Michigan. "No changes have been made from the text as completed in 1937 except for the insertion of a few comments and footnotes calling attention to important occurrences since then." Part 1 is a general summary for all the areas studied in the four States. Parts 2 to 5 deal, respectively, with Northeastern Iowa—A Corn Belt Transition Area; Southeastern Minnesota—A Corn Belt Transition Area, and East Central Minnesota—An Area With No Close Alternatives to Dairying; Four Wisconsin Areas—Areas With No Close Alternatives to Dairying; and Southeastern Michigan—A Corn Belt Transition Area, and West-Central Michigan—An Area With No Close Alternatives to Dairying.

Farm tenure improvement: Landlord-tenant cooperation and leasing procedure (*U. S. Dept. Agr., 1940, pp. [1]+64*).—The tenancy situation is described briefly, and the advantages to tenants, landlords, and society of improvements in landlord-tenant cooperation and leasing are discussed. Some suggestions and instructions are given for executing the lease forms included.

Legal aspects of landlord-tenant relationships in Oklahoma, W. J. COLEMAN and H. A. HOCKLEY. (Coop. U. S. D. A.). (*Oklahoma Sta. Bul. 241 (1940), pp. 47, figs. 2*).—The legal aspects of the problems in the State and the various adjustments that need consideration are discussed. The discussions are based on a study of the laws and decisions in the State and other States, and interviews with approximately 200 landlords, tenants, agricultural economists, agricultural bank and State school land officials, representatives of credit agencies, Indian agents, legislators, court officials, and others. Appendixes include a table of Oklahoma statutes and court decisions regarding landlords and tenants, a table showing the attitude of landlords, owner-operators, and tenants regarding different improvements in the relationships of landlords and tenants, the recommendations of the President's committee on farm tenancy, the provisions of the Alabama statute providing that all farm renters shall be tenants, and a bibliography.

Landlord-tenant relations in Roane County, Tennessee, C. E. ALLRED, B. H. LUEBKE, and L. D. MALPHRUS (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 117 (1940), pp. [1]+IV+32, figs. 21*).—Information as to 35 share-renters and 27 sharecroppers was obtained from schedules taken from 31 landlords and 31 tenants. Eighteen community schedules were also obtained from representative farmers familiar with leasing practices in their

communities. The chapters deal with length, renewal, and termination of leases; compensation for disturbance, improvements, and deterioration; methods of settlement of disputes and limitation of liens; methods of paying rent; and farm ownership for tenants.

The graduated farm land transfer stamp tax, J. A. BAKER. (U. S. D. A.). (*Jour. Land and Pub. Util. Econ.*, 16 (1940), No. 1, pp. 21-29).—The need for control of speculation of farm real estate, a plan for a graduated transfer stamp tax, and the advantages, economic effects, and constitutionality of such a tax are discussed.

Determining value of buildings to a farm, J. C. WOOLEY. (Univ. Mo.). (*Agr. Engin.*, 21 (1940), No. 5, pp. 171, 172, figs. 2).—A method of determining building requirements of a farm based on size, acres in pasture and in cultivated crops, soil productivity, and pasture and feed units per animal is outlined, and its use illustrated.

Marketing farm products through community auctions, P. R. POFFENBERGER and S. H. DEVAULT (*Maryland Sta. Bul.* 434 (1940), pp. 317-349, figs. 12).—Data are presented as to the number and types of auctions in the State; volume of business and its value of livestock, produce, poultry and eggs, and tobacco auctions; operation practices; areas served; prices received; types of buyers and producers patronizing each type of auction; and other information on which recommendations could be made for improving the marketing of farm products. The data were gathered from auction managers by questionnaires and interviews and, in the case of all types except livestock auctions, were secured from auction records.

Some facts concerning country fruit and vegetable auctions in eastern seaboard States, E. W. CAKE (*[New York] Cornell Sta. Bul.* 737 (1940), pp. 51, figs. 11).—This study was made to obtain data that would be of assistance to growers, cooperative associations, and others in appraising the importance and effectiveness of country fruit and vegetable auctions. Data were obtained from 64 auctions operating in 1936 in 10 eastern seaboard States and from 9 that had operated previously. Eighty-five percent of the auctions were located in Virginia, North Carolina, Maryland, New Jersey, and Delaware. Twenty-seven of the auctions were cooperative and 37 private or municipal auctions. Data were obtained from 431 growers and 114 buyers. The development, facilities, operating methods, factors affecting volume of sales, sources of income, expenses and factors affecting expenses, use made of auctions by growers and buyers, etc., are analyzed and discussed.

The number of growers patronizing each auction daily ranged from 15 to 400, average 160, and the number of buyers from 2 to 75, average 16. Average gross value of sales averaged approximately \$142,000, ranging from less than \$2,500 to over \$600,000. About two-thirds of the income was from fees charged growers, one-fourth from fees paid by outside buyers, and 8 percent from fees paid by buyers. Fees charged to growers (60 auctions) ranged from 0.14 to 5.13 ct., average 2 ct., per \$1 of sales. Total expenses varied from 0.1 to 5.15 ct., average approximately 1.2 ct. Volume of sales, number of commodities handled, length of operating season, efficiency in use of labor, and type of ownership were the most important factors affecting expenses. Growers' patronage was influenced by distance, size of business, and attitude toward auctions. Approximately 58 percent of 375 growers gave higher net returns as the major reason for patronizing the auctions. Buyers' use of auctions was influenced by type of buyer, number of years in business, whether the buyer had ownership in the market, attitude toward auctions, and size of business. Of the total purchases of the buyer about 58

percent were at country auctions, 33 percent at small local markets, 9 percent at the farm, and 1 percent at city markets. Of the total sales by all auctions approximately 40 percent were to local country dealers, 13 percent to country dealers from other shipping points, 29 percent to merchant truckers, 14 percent to city wholesalers and jobbers, 3 percent to canneries, juice plants, and wine factories, and 1 percent to other buyers. The chances of success of country auctions were greatest where a large volume of perishable fruits and vegetables was obtained, where there was no competing auction closer than 15 miles, where the period of operation could be restricted to a season when large volumes can be handled daily, where there were minimum investments in physical equipment, and where maximum use could be made of the hired personnel.

Knoxville wholesale fruit and vegetable market.—II, Taxes and regulations, C. E. ALLRED, B. H. LUEBKE, and W. S. CRAWFORD (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 118 (1940), pp. [I]+II+22*).—This second bulletin of the series (E. S. R., 84, p. 264) describes and comments on the property taxes, licenses, health regulations, and rules of the market.

Some facts concerning retail demand for apples and other fruits, M. P. RASMUSSEN. (Cornell Univ. et al.). (*Ill. State Hort. Soc. Trans., 73 (1939), pp. 117-143*).—Some of the findings in studies by Cornell University and the U. S. D. A. Farm Credit Administration of fruit marketing in New York City are discussed.

The use of motor trucks in the marketing of Illinois peaches, V. A. EKSTROM. (Univ. Ill.). (*Ill. State Hort. Soc. Trans., 73 (1939), pp. 145-152*).—Data for 1939 are included showing the percentages of peaches from southern Illinois transported by truck and rail and the proportions of 364 truckloads hauled by different types of truckers and distributed to different outlets.

Cooperation in grain marketing in Iowa, F. ROBOTKA and R. C. BENTLEY (*Iowa Sta. Res. Bul. 276 (1940), pp. 721-756, figs. 8*).—This study was made to bring the history of the cooperative movement in grain marketing in the State up to date (E. S. R., 49, p. 293), to present a brief cross-section view of the present status of farmers' elevators in the State, and to reappraise the movement. Analysis is made as of 1937 of the volume of business, number and location of elevators, members and patrons, capital, overhead organizations, cooperative features of the organizations, and the reorganization and accomplishments of the elevators. The future of the movement is discussed in sections on costs of operation, quality of service, management, cooperation v. competition, and merchandising federations.

Wheat futures (*U. S. Dept. Agr. Statist. Bul. 72 (1940), pp. 131, figs. 4*).—This is a continuation of the series (E. S. R., 77, p. 121). Data are presented on the volume of trading and open contracts from January 2, 1936, to December 31, 1938, as compiled from reports furnished the Commodity Exchange Administration by the clearing members and clearing associations of the exchanges. The price data for the period were compiled from the official quotations of the Chicago Board of Trade for transactions in "round lots" (5,000 bu. or multiples thereof), supplemented by a few quotations secured from brokerage houses.

Seasonal movements in prices and sales of Burley tobacco, D. G. CARD and C. M. CLARK (*Kentucky Sta. Bul. 409 (1940), pp. 401-485, figs. 21*).—The sources of data used for this bulletin were reports of monthly sales in Kentucky warehouses from 1916 to 1938 made to the State Department of Agriculture, Labor and Statistics; sales and prices on the Lexington market, by weeks from 1909 to date, compiled from reports of the market supervisor of sales and from newspapers; similar data from the Carrollton, Ky., market for

several years and from most of the Burley markets for the 1935-36 marketing season; and information on sales and prices gathered by the Federal Tobacco Market News Service since 1931. The historical developments in the seasonal movement of sales and prices, the long- and short-time factors associated with the movements, the movement of sales and prices by grades, and the effect of size of market and geographical location for markets other than Lexington are discussed.

The length of marketing season for Burley tobacco has shortened about 60 percent during the past 30 yr., opening about 3 or 4 weeks later and closing 8 to 10 weeks earlier. Nearly 40 percent of the tobacco is now sold in the first quarter of the season. Long-time trends in the seasonal changes in sales and prices were associated with improvement in transportation facilities, increase in market capacity, increased competition, cumulative effect of high prices early in the season, and changes in type of tobacco. The short-time factors associated with the changes were weather, annual production, market information available, quality, relation between prices by grades, and control programs. High-quality and light-colored tobacco moved to market somewhat earlier than the low-quality, dark-colored tobacco. Grades of fine and medium qualities and tan color were relatively more important in the early weeks and less important in the later weeks. Color was closely associated with quality in the distribution of sales. Prices of the better grades were usually more stable than those of the poorer grades. Variations in the prices of the medium- and low-quality grades were most important in influencing total receipts of the average Burley grower due to the large volume in these grades. A large part of the decline in prices toward the end of the season has been due to poor quality. Movement of prices of individual grades differs considerably from that of the market as a whole.

Prices and production of Louisiana farm products, 1910-1939, J. N. EFFERSON (*Louisiana Sta. Bul. 324 (1940), pp. 44, figs. 5*).—Tables and charts are included and discussed showing (1) the production, prices, and value by crop years, 1909-10 to 1938-39, for crops and the number, prices, and value of livestock from January 1, 1910-39, 19 of the most important farm products being included, and (2) indexes of prices (August 1924 to July 1929=100) of the different products, the composite index for all the products, and the indexes by groups of products—cotton, feed crops, livestock products, meat animals, rice, sugarcane, and truck crops.

A study of farm woodland cooperatives in the United States, L. SOLIN (*N. Y. State Col. Forestry, Syracuse Univ., Bul., 13 (1940), No. 2, pp. 118, figs. 9*).—The fundamentals of cooperation, the place of cooperation in farm woodland management, experience in cooperative marketing of forest products in Europe and the United States, and recent developments and trends in cooperative woodland management and marketing of forest products are discussed. The purposes, organization, operation, advantages and disadvantages, etc., of the Otsego Forest Products Cooperative Association, Inc., Cooperstown, N. Y., Forest Products Association, Inc., Groveton, N. H., West Virginia Forest Products Association, Terra Alta, W. Va., and Tioga County Woodland Owners Cooperative Association, Inc., Owego, N. Y., are described and discussed in some detail.

The transportation of New Hampshire milk.—II, Reorganization of truck routes, A. MACLEOD (*New Hampshire Sta. Bul. 325 (1940), pp. 23, figs. 4*).—This phase of the study (*E. S. R.*, 80, p. 263) was made to discover whether equipment and personnel were being used efficiently and the extent of duplication, overcapacity, and useless effort in milk transportation in the State. June 1937 was used as the basis. Three schemes of reorganization of truck

routes are outlined: The first assumes that producer-dealer relationships will be undisturbed and that only producers whose milk is hauled on commercial routes will participate; the second would require all milk sold by producers to be hauled on commercial truck routes; and the third would include relocation of milkshed boundaries. Maps show the routes in June 1937 and the suggested routes under the reorganization plans.

The number of commercial truck routes and self-haulers are before reorganization 265, plan I 246, plan II 60, and plan III 57; the mileages 5,042, 4,485, 2,357, and 2,161 miles, respectively; and the relative costs of hauling 100, 88.5, 76.2, and 73.3 percent, respectively. By plan III the daily cost of assembling will be reduced \$97, or 27 percent from that in June 1937. The reduction would amount to from \$30,000 to \$35,000 for the State; from \$39 to \$45 per farm, and about 7 ct. per 100 lb. of milk.

The Ohio farmer and his milk market, C. G. McBRIDE (*Ohio Sta. Bul.* 614 (1940), pp. [1]+50, figs. 7).—“This bulletin deals with some of the problems arising in the day-to-day contacts of the producer with the market and the various agencies involved. The emphasis is upon the interests of the individual producer rather than upon the peculiar problems involved in marketing milk through a cooperative association.” It is based on studies of the experience of approximately 400 farmers in 5 different areas of the State who were selling whole milk for fresh consumption or manufacturing. It discusses the finding and holding of a market; the dealer's milk statement; weighing, sampling, and testing; transportation of milk; board of health requirements; how the marketing plan affects the producer; how the farmer can fit himself into the marketing plan; the producer's contact with the dealer; and the division of responsibilities among producers, organization leaders, and dealers in solving the problems. The factors affecting average yearly returns of 67 farmers in Medina County and the effect of marketing plan upon producers' returns, 1935-37, as shown by a study of the experience of 100 producers in Stark County, are discussed in some detail.

Modern trends in the retail ice cream store, R. J. COOLEY and W. H. E. REID (*Missouri Sta. Bul.* 420 (1940), pp. 23, figs. 37).—Included are charts with brief discussions compiled from data obtained from the questionnaires distributed to representatives of the National Association of Retail Ice Cream Manufacturers at its annual meeting in October 1939. The charts present findings as to the past, present, and future type of retail store, supplementary merchandise, investments, leases, rents, inventories, parking facilities, reputation of store, seasonal influence on sales, store managers, operation, advertising, causes of dissatisfied customers, etc.

Foreign Agriculture, [October 1940] (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr.*, 4 (1940), No. 10, pp. 573-623, figs. 16).—Included are articles on Sweden's Agriculture and the War, by P. G. Minneman (pp. 577-616), which discusses the climate, natural resources, forests, agricultural production, agricultural relief measures during the depression, effects of the World War and the present war on Swedish agriculture, trade with the United States, etc.; and on The Production of Oiticica Oil in Brazil, by P. L. Green (pp. 617-623), which discusses the oiticica tree and its cultivation, the harvesting of the nuts and the extraction of the oil, the research being done, and the assistance being given the research by the Brazilian Government.

A history of Worcestershire agriculture and rural evolution, R. C. GAUT (*Worcester: Littlebury & Co., 1939, pp. XVI+490*).—“The object of this work is to present a historical survey of the agriculture of Worcestershire [England] from remote times to the present day.”

Food production in western Europe: An economic survey of agriculture in six countries, P. L. YATES (*London and New York: Longmans, Green & Co., 1940, pp. XV+572, pls. 16, figs. [59]*).—This economic survey of agriculture in Denmark, the Netherlands, Belgium, France, Switzerland, and Germany discusses the farming systems, production, land tenure, indebtedness, social and economic conditions, marketing, methods, State policies, assistance and control, standards of living, etc. The final part draws conclusions under the headings of agriculture and prosperity and the planning of agriculture.

Tobacco production and consumption in Manchuria, J. B. GIBBS (*U. S. Dept. Agr., Off. Foreign Agr. Relat., F. S. 83 (1940), pp. [2]+23, fig. 1*).—The general economic, soil, and climate factors of the area, and the production, grading and marketing, exports and imports, manufacture and consumption of, and the outlook for tobacco are described and discussed.

Maté, A. M. HANNAY (*U. S. Dept. Agr., Bur. Agr. Econ., Econ. Libr. List 16 (1940), pp. 9*).—A list of 61 annotated references.

RURAL SOCIOLOGY

A study of rural society: Its organization and changes, J. H. KOLB and E. DES. BRUNNER, edited by W. F. OGBURN (*Boston: Houghton Mifflin Co., [1940, 2. ed.], rev. and enl., pp. XVII+694, figs. 45*).—This is a revision of the original treatise (*E. S. R., 74, p. 562*).

Possibilities of rural zoning in South Dakota: A study in Corson County, R. J. PENN, W. F. MUSBACH, and W. C. CLARK. (*Coop. U. S. D. A.*) (*South Dakota Sta. Bul. 345 (1940), pp. 23, figs. 2*).—The possibilities of rural zoning as a means of restricting cash-crop farming and controlling settlement in Corson County were studied with a view to ascertaining the feasibility of zoning in the Northern Great Plains region. The nature and status of rural zoning in the United States and the characteristics of Corson County are described. The reasons for restricting cash-crop farming and controlling settlement in the county and area, the possible methods of zoning, and the probable results of zoning are discussed.

Content of Washington weekly newspapers, C. F. REUSS (*Washington Sta. Bul. 387 (1940), pp. 48, figs. 6*).—Ranked in the order of the proportionate importance of their corresponding types of material in the total content of 541 issues of 22 representative Washington weekly newspapers, the functions of the newspaper are (1) providing an advertising medium whereby buyer and seller may be made acquainted; (2) gathering, preparing, and circulating the news; (3) entertaining or informing its readers through nontimely magazine material; and (4) serving as a vehicle for opinion and comment on timely topics. "By stimulating trade, advertising in the weekly paper has the important effect of increasing social contacts among town and country residents; by featuring identical products available equally in the hamlet and the metropolis, it performs the significant task of helping to level town-country, rural-urban, and sectional differences. News, dealing with the new, is an evidence of social change. At the same time, by presenting information on the new in order that individuals may make necessary adjustments, news calls attention to the new and changed. Eventually change comes to be regarded as normal, social inertia against the new is decreased, and change is stimulated, leading to the incidence of more news. The chief social value of magazine material in the small-town weekly paper lies in the influence it may have in reducing the spread between urban and rural standards in attire, fashions, home decorations, cooking, and the like. Opinion material which arouses intelligent discussion over controversial

issues performs a social service, but the newspaper serves as a true forum if it gives equal opportunity for the expression of various shades of opinion. . . .

"The future of the weekly newspaper appears closely bound up with the fortunes of its town as a trade center. The town serving in a vital way as a trade center for a large territory needs some medium of indirect communication such as the newspaper to carry both its business and social messages to its supporting population. Conversely, however, only a vitally functioning trade center can afford to support a newspaper with advertising and thereby insure its continued operation. As realignments occur in the trade and social relationships of the small town and open country, the weekly newspapers serving these local areas will adapt themselves to the changed social conditions, those in centers of declining importance disappearing, in centers of increasing trade and social influence expanding their coverage to meet the needs of the enlarged territory."

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Conserving farm lands: Planning for soil-erosion control, water conservation, and efficient land use, T. DALE and W. A. ROSS. (Coop. U. S. D. A.) (*U. S. Dept. Int., Off. Ed., Vocat. Div. Bul. 201 (1939), pp. VIII+104, pls. 6, figs. 29*).—Organized teaching material is included, designed to assist teachers of vocational agriculture in planning a soil conservation program for soil-erosion control, water conservation, and efficient land use. Training content, interpretive science, and related information are outlined for 10 jobs involved in planning a soil conservation program for a farm.

FOODS—HUMAN NUTRITION

Nutrition [studies by the Idaho Station] (*Idaho Sta. Bul. 236 (1940), pp. 53, 54*).—Progress is reported on studies of the ascorbic acid metabolism of college men, by E. Woods and F. Claypool; and the water-soluble fraction in potatoes, by Woods.

Chemical analysis and vitamin assays of opihi, the Hawaiian limpet, C. D. MILLER and R. C. ROBBINS. (Hawaii Expt. Sta.). (*Philippine Jour. Sci., 71 (1940), No. 2, pp. 141-163, pl. 1, fig. 1*).—Proximate and mineral constituents and vitamin content were determined in the opihi or Hawaiian limpet (*Helcioniscus exaratus* and *H. argentatus*). The edible portion constituted approximately 35 percent of the mollusk, and of this the solid portion (foot and mantle) constituted 72.2 percent on an average and the viscera 27.5 percent. Separate analyses were made of the solid portion and of the viscera from which the composition of the whole was calculated. Values (in percent) for the two parts and the whole, respectively, are reported as follows: Moisture 77.8, 73.3, and 76.6; protein (N×6.25) 18.8, 13.3, and 17.3; ether extract 0.3, 5.5, and 1.7; ash 1.52, 4.05, and 2.21; calcium 0.052, 0.698, and 0.230; phosphorus 0.122, 0.211, and 0.146; iron 0.00204, 0.04536, and 0.01395; copper 0.00011, 0.00008, and 0.00010; and silicon 0.04, 0.28, and 0.11. Glycogen, determined satisfactorily by the A. O. A. C. method, was found to be about the same for market samples as for those collected from the sea, values of 1.23 and 0.47 percent for foot and mantle and for viscera, respectively, being reported for the species collected from the sea.

Ovaries and testes were analyzed separately, the following values, respectively, being reported: Moisture 62.6 and 76.00, protein 23.9 and 20.0 percent, ether extract 8.7 and 2.2, and ash 1.74 and 2.45 percent. The results indicate that opihi are

a good dietary source of protein, calcium, and iron. "Experiments with anemic rats showed that the feeding of opihi, which are low in copper, did not result in any marked regeneration of hemoglobin until this mineral was added. Whole fresh opihi contain, per 100 gm., approximate quantities of the vitamins as follows: 4,000 International Units of vitamin A, 130 Sherman-Bourquin units of vitamin B₂ (G) (300 γ flavin), and 30 I. U. of vitamin D. They contain little or no vitamin B₁ and are devoid of vitamin C."

A study credited to M. C. Neal, botanist of the Bernice P. Bishop Museum, Honolulu, was made of the contents of the digestive tracts of the opihi. It was found that "their food consists largely of blue-green and other algae, and that diatoms, although present, are probably a relatively unimportant food source."

The physical and chemical characteristics of lards and other fats in relation to their culinary value.—III, For frying purposes, B. LOWE, P. M. NELSON, and J. H. BUCHANAN (*Iowa Sta. Res. Bul.* 279 (1940), pp. 877-926).—The lards and other fats used were the same as those noted in the previous report of the series (*E. S. R.*, 81, p. 861). In the present study these were compared as to their frying life when used under household conditions for frying doughnuts and in a few instances potato chips. The doughnuts were made throughout the study by a uniform formula and procedure except that the frying trials were made at a number of temperatures. The potato chips were fried by a standard procedure. The total time for use of each fat was 10 hr. 14 min.

The doughnuts absorbed more fat when the dough temperature was near 24° C. than when it was near 26°. The longer the dough was handled and rerolled the less fat it absorbed. There were no significant differences in fat absorption for doughnuts cooked at 170°, 185°, and 200°, and the fat absorption was greater in doughnuts cooked in fats with the lower smoking points. The lowest cooking temperature (170°) produced the most palatable doughnuts and, except for lards with a strong initial odor, the first doughnuts cooked in a fat were more palatable than those cooked after the fat had been used for some time. In general, doughnuts fried in lard did not score as high as those fried in hydrogenated fats and corn oils.

As for the chemical and physical changes in the fats during use, it was observed that gum formed at the edge of the container and the fat line, the quantity being greater with oils than with fats; that all fats darkened in use, the darkening being greater the higher the temperature; that some lards with disagreeable original odors became milder as heating continued; that iodine value and smoking point were lowered, while free fatty acid content and peroxide value were increased during use, these changes being more pronounced the higher the temperature of use; and that refractive index increased during the period of use. There was a highly significant correlation between refractive index and iodine value and a highly significant negative correlation between smoking point and the free fatty acid content.

The comparative nutritive value of butter fat and certain vegetable oils, E. J. SCHANTZ, C. A. ELVEHJEM, and E. B. HART. (*Wis. Expt. Sta.*). (*Jour. Dairy Sci.*, 23 (1940), No. 2, pp. 181-189, figs. 5).—In this comparison young rats were kept for 6 weeks on mineralized skim milk in which 4 percent of butterfat, corn oil, cottonseed oil, or soybean oil had been homogenized. Crystalline carotene was added to butterfat in amounts of 10 γ per gram and to the other fats in amounts of 20 γ per gram. All animals were irradiated for 10 min. each day and were weighed weekly. The rats on the butterfat made significantly greater gains during the first 2 or 3 weeks than those on the

vegetable oils and on the whole appeared to utilize the butterfat ration more economically. After the third or fourth week the growth difference became less, but the animals on the butterfat had a better general appearance and finer coat of hair than the others. The superior growth-stimulating potency of the butterfat appeared to be located in the saponifiable fraction of the fat.

The animals on the butterfat, corn oil, and coconut oil rations were carried to maturity and the females mated with a male from the same group. Oestrus cycles were normal in all cases, but only on the butterfat ration was reproduction normal. Small litters were produced but not raised on the corn oil and none on the coconut oil. The administration of 2-3 mg. of pure natural α -tocopherol to corn oil-fed rats relieved the reproduction difficulties, but the litters were in poor condition.

The relation of the calcium ion to the sloughing of potatoes, W. E. PYKE and G. JOHNSON. (Colo. Expt. Sta.). (*Amer. Potato Jour.*, 17 (1940), No. 1, pp. 1-9, figs. 2).—Essentially noted from another source (E. S. R., 82, p. 847).

Relation of mixing methods and a balanced formula to quality and economy in high-sugar-ratio cakes, W. E. PYKE and G. JOHNSON. (Colo. Expt. Sta.). (*Food Res.*, 5 (1940), No. 4, pp. 335-359, figs. 12).—Curdled batter, a difficulty arising from the use of ordinary commercial hydrogenated shortening in the single-stage method of mixing with high-sugar-ratio, whole-egg, butter-type cakes, was overcome by holding back a portion of the liquid until a smooth batter had been formed, slowly adding the remaining liquid, and then the baking powder or the acid ingredient if sodium bicarbonate and acid were used. Batters thus prepared with ordinary hydrogenated shortening and the cakes baked from them had greater volumes than batters and cakes produced through the use of shortenings containing emulsifiers. Heavy batters, such as those produced with emulsifiers, tended to give cakes of coarse structure and texture when an attempt was made to increase their volume by an increase in the leavening.

A basic whole-egg cake formula, lean in sugar, eggs, and liquid, was rebalanced stepwise, for use at 5,000 ft., with increments of sugar, egg solids, shortening, and liquid. Thus balanced, finished batters of desirable specific gravity and cakes of high quality were maintained. It was necessary when any ingredient was increased to make comparable increases in the other ingredients in order to obtain cakes of comparable volume, texture, and quality. It was shown also that the type of mixing equipment and the method of mixing are as important as the use of a properly balanced formula.

The principles involved in rebalancing whole-egg cake formulas of varying sugar content were extended and modified for use at altitudes from 0 to 10,000 ft., the modified single-stage method of mixing being recommended for all but the 92-percent sugar formula. Equations for baking powder corrections and water requirement variations are given. A nomograph is presented which permits the formulation of an indefinite number of whole-egg, butter-type cake formulas for any selected altitude up to 10,000 ft.

Effect of storage temperatures upon the viability and baking properties of compressed yeast, L. H. BAILEY, M. T. BARTRAM, and S. C. ROWE. (U. S. D. A.). (*Cereal Chem.*, 17 (1940), No. 1, pp. 55-66, figs. 5).—Two samples of compressed yeast, one packed with dry ice for 2 days and another a fresh sample, were divided into subsamples which were stored at 0°, 20°, 30°, and 45° F., respectively; portions of each lot thus stored were withdrawn at the end of 1, 2, and 3 months' storage. Plate counts (million cells per gram), percentage of dead cells, and pH of the yeast were determined, and baking tests with observations as to loaf volume and character were made at the beginning of

the study and at the end of each storage period. The data are presented, together with photographs showing the character of the loaves.

The frozen yeast made very good bread when first received but deteriorated rapidly; there was some deterioration at the end of the first month's storage, particularly with the storage temperatures of 0° and 45°; by the end of the second month the deterioration was still more pronounced, none of the loaves being satisfactory; and at the end of the third month of storage the loaves from the yeast that had been frozen through packing with dry ice were quite unsatisfactory. The fresh yeast, on the other hand, did not deteriorate rapidly and still made quite good loaves of bread when stored for 2 mo. at any of the different temperatures; at the end of the third month, however, none of the loaves was entirely satisfactory.

The yeasts stored at 0° did not make quite as good loaves as those stored at 20° or 30°; at 45° the yeast darkened in color and did not keep as well as at 20° and 30°, but when not previously frozen gave satisfactory results up to the end of 2 months' storage. The frozen yeast became mushy after thawing, due to rupture of the granules of the incorporated starch. The temperature of evaporating dry ice (−109°) injured the yeast in 24 hr., and storage of any of the yeasts at 0° tended to injure them. At 30° the yeast did not freeze, however, and the resulting breads were satisfactory. It is concluded, therefore, that approximately 30° is the most suitable temperature for the storage of compressed yeast.

How to prepare fruits and vegetables for freezer storage and how to use them, H. KLAAS and S. WOODRUFF (*Ill. Agr. Col. Ext. Cir. 510 (1940)*, pp. 20, figs. 4).—This circular, which is based on tests of various procedures conducted by the department of home economics and of specific varieties of fruits and vegetables by the departments of horticulture and home economics of the Illinois Experiment Station, contains practical information of general application on rules of success in packing fruits and vegetables for locker storage with reference to reduction of enzyme action and prevention of bacterial contamination, selection of kinds and varieties of fruits and vegetables, choice of containers, methods of packing different fruits and vegetables, and methods of using the frozen products. Information for Illinois housewives is given on ratings with respect to the suitability for freezing of certain varieties of Illinois-grown blackberries, dewberries, gooseberries, peaches, raspberries, strawberries, sweet cherries, asparagus, sweet corn, lima beans, peas, snap beans, soybeans, and spinach. In the general directions special attention is given to types of containers on the market, with their advantages and disadvantages, and to the blanching of vegetables with reference to appropriate quantities of vegetables and corresponding volumes of boiling water to blanch at one time in order to insure good keeping. A list compiled by H. G. Russell of freezer storage plants in Illinois classified by county and cities within the county, with estimated number of lockers in each, is appended.

The diameter of red blood cells in healthy young women, E. G. DONELSON, J. M. LEICHSENRING, and L. M. WALL. (*Minn. Expt. Sta.*). (*Amer. Jour. Physiol.*, 128 (1940), No. 2, pp. 382–389, fig. 1).—This is paper No. 3 of the Regional Project of the North Central States relating to the nutritional status of college women (*E. S. R.*, 82, p. 300). The subjects were 80 healthy college women ranging in age from 17 to 24 yr., with 84 percent falling between 18 and 20 yr. and 1 middle-aged woman. Fingertip blood samples totaling 250 for the younger subjects and 27 over a period of 32 days for the older subject were taken with the subjects in a basal condition and at the same time of day. The method consisted of diluting the samples with Hayem's solution, charging the

counter chamber, and measuring one diameter of each of 200 round cells immediately. The measurements were made by one investigator, using the Bausch and Lomb ocular micrometer.

For the larger series the mean diameter of round cells was 7.35μ , the range of means from 6.53μ to 7.76μ , and the mean difference between the smallest and largest cells 3.56μ . A frequency distribution, based on a measurement of 20,000 cells, showed a maximum spread of 3.96μ – 10.80μ with a mean and standard deviation of 7.31μ and 0.62μ , respectively. There was no essential difference between the dispersion in the red cell population in samples with a high and in those with a low mean cell diameter. The means of the values for the smallest and largest cells in each of the determinations were 5.52μ and 9.08μ . Samples taken 1 yr. apart on 28 individuals showed a statistically significant increase in cell diameter of 0.2μ . The repeated observations on the older subject gave values ranging from 6.91μ to 7.25μ , with a mean value of 7.06μ . A tabulated summary is given of all available red cell diameter data from recent literature for comparison with the data of the present study.

Basal metabolism of Indians: A study based on the examination of sixty normal Indian men, S. S. SOKHEY and M. A. MALANDKAR (*Indian Jour. Med. Res.*, 27 (1939), No. 2, pp. 501–529, figs. 4).—Sixty normal Indian men with ages ranging from 20 to 49 yr. served as subjects in the measurement of heat production under precise standard conditions employing the open-circuit method with Tissot-type gasometer to measure the gas exchange and using the first satisfactory determinations to establish the rate. The findings, presented in some detail, indicated a mean metabolic rate of –8 percent by the Aub-Du Bois standard. It is suggested that this low basal metabolic rate of normal Indian subjects is due not to racial or climatic factors as such, but to the very low protein content of the usual Indian diet.

Studies in human metabolism.—II, Calcium and phosphorus metabolism in Indians on rice and on wheat diets, K. P. BASU, N. M. BASAK, and B. C. RAI SIRCAR (*Indian Jour. Med. Res.*, 27 (1939), No. 2, pp. 471–499).—Continuing the series (*E. S. R.*, 82, p. 418), balance experiments, the results of which are reported in detail, were conducted on three healthy adult men. The maintenance calcium requirement based on 24 experiments in which equilibrium was nearly maintained was found to be 0.388 gm. per 70 kg. body weight per day; for phosphorus (average 13 experiments) the maintenance requirement was calculated to be 1.001 gm. per day. Typical vegetarian rice diets failed to maintain adults in calcium balance; wheat diets containing somewhat more calcium (although still a 1 : 6 calcium : phosphorus ratio) gave somewhat better results than the rice diets. Both the rice and the wheat kept the subjects in positive phosphate balance. Milk (466 gm. daily) added to a rice-fish diet increased the daily calcium content to 0.86 gm., brought the calcium : phosphorus ratio to 1 : 2.2, and resulted in a favorable calcium balance. From 9 to 40 percent of the total calcium excretion and 35 to 60 percent of the total phosphorus excretion occurred through the kidney.

Composition of bone in extreme osteoporosis associated with hepatoma, A. E. HANSEN, L. S. PALMER, and J. W. NELSON. (Univ. Minn.). (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 1, pp. 206, 207).—The results of analyses of a rib bone from a 10-year-old boy who succumbed to an extensive carcinomatous involvement of the liver are reported on the basis of green, dry, and dry extracted bone; ash, Ca, P, Mg, and CO_2 were determined. The data, compared with similar analyses from an apparently normal control, indicated that 27.8 percent of the bone minerals had been replaced by lipide and water, more than 80 percent of the replacement being by lipide. The data also showed that the

dry lipide-free bone of the hepatoma patient had 31.4 percent less Ca, 33.8 less P, 39.0 less Mg, and 37.9 percent less CO_2 than the control. On the basis of the system of calculation employed, it appeared from these results that there was withdrawal from the bone of relatively more CaCO_3 and $\text{Mg}_3(\text{PO}_4)_2$ than $\text{Ca}_3(\text{PO}_4)_2$. The high $\text{Ca}_3(\text{PO}_4)_2 : \text{CaCO}_3$ ratio indicated that the abnormality was associated with a calcium deficiency rather than a phosphorus deficiency or rickets.

Chronic selenium poisoning of rats as influenced by dietary protein, R. A. GORTNER, JR. (*Jour. Nutr.*, 19 (1940), No. 2, pp. 105-112, figs. 2).—Earlier observations (unpublished) that casein at high levels exerted a protective action against selenium poisoning in rats are noted as confirmed by the present study. When as much as 35 p. p. m. of selenium was incorporated, good growth results were obtained with diets containing 30 percent casein. When lactalbumin, gelatin, and edestin were superimposed at a 30 percent level upon diets containing casein at a basal level of 6 percent, the lactalbumin, though not as consistently effective as casein, tended to counteract the effects of the dietary selenium but the edestin and gelatin did not.

The edestin was selected as a complete protein, and the gelatin ration was supplemented with 0.68 percent of cystine, so that it is considered doubtful whether the results can be explained on the basis of an amino acid deficiency. It is suggested that the discrepancies between proteins in the matter of their protective action may lie in the ease with which the various proteins are digested and absorbed from the intestinal tract.

Adequacy of a milk diet for the rat, L. R. RICHARDSON and A. G. HOGAN. (Mo. Expt. Sta.). (*Jour. Nutr.*, 19 (1940), No. 1, pp. 13-19, figs. 3).—Four generations of female rats which received equal parts by weight of fresh unpasteurized milk and whole milk powder supplemented by a mineral mixture furnishing iron, copper, manganese, and iodine in amounts averaging 2.5, 0.254, 0.167, and 0.076 mg., respectively, per rat per day produced and weaned almost as many young per litter as did controls on the Steenbock stock diet (E. S. R., 50, p. 765). However, the experimental animals produced only about half as many litters per female as did the controls. Further supplementing of the milk ration with yeast, cod-liver oil, and wheat-germ oil did not improve the reproductive performance. The authors conclude that "apparently milk is deficient in some nutriment other than iron, copper, manganese, or iodine which is essential for normal reproduction."

Effect of exercise on growth and cataract development of rats fed galactose, H. S. MITCHELL and G. M. COOK. (Mass. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 1, pp. 85, 86).—This preliminary report summarizes the results of a comparison of the growth, content of blood sugar, and development of cataract in exercised and nonexercised rats on diets containing 25 percent of glucose and galactose, respectively, the investigation being undertaken because of the high blood galactose and galactemia previously demonstrated in rats on rations containing as much as 25 percent galactose (E. S. R., 78, p. 571). Growth was remarkably constant and similar for all groups. The calculated extra calories over the amount required for basal expenditures were similar for the two carbohydrates and not consistently greater for exercised than nonexercised animals. The rats were equally active on galactose and glucose. The same degree of galactemia (202-255 mg. per 100 cc.) was found in both galactose groups and normal blood sugar (106-134 mg. per 100 cc.) in both glucose groups. All of the galactose rats developed cataract, but the onset was much earlier (average 20.6 days) for the nonexercised than for the

exercised animals (28 days), "a difference which cannot be ignored in view of the consistency of the figures making up each average."

Vitamin values of garden-type peas preserved by frozen-pack method, II, III (*Food Res.*, 4 (1939), No. 6, pp. 587-592, 605-611).—These papers continue the studies cooperative between the Oregon and Washington Experiment Stations on material furnished by the U. S. D. A. Bureau of Chemistry and Soils.

II. *Vitamin A*, E. N. Tedhunter. (Wash. Expt. Sta.).—Data obtained by the U. S. P. XI biological method are reported on the effect of various factors on the vitamin A content of frozen-pack garden peas. In three of the five series, the peas (Telephone variety) were the same as those used in the vitamin C tests reported in paper I (E. S. R., 81, p. 313). In series IV the Dwarf Aldermann, grown in 1937, and in series V the Tall Alderman, grown in 1938, were used. The latter had been frozen in the dry state, as had all the previous samples, and also in $7\frac{1}{2}^{\circ}$ salometer brine.

Calculated from data within the series, Telephone peas were consistently lower in their vitamin A content (10 International Units per gram) than Tall Alderman (less than 13) and these in turn than Dwarf Alderman (14 I. U. per gram). Calculated from a reference curve obtained as described by Coward (E. S. R., 79, p. 710), the corresponding values were from 6 to 9, 10, and from 13 to 16 I. U., respectively. Scalding in steam or in water at 99° C. for 1 or 2 min., or in water at 88° for from 2 to 6 min., or holding from 4 to 8 hr. before scalding, or cooking the frozen peas did not alter the content of vitamin A. There was no difference between the vitamin A content of the skins and cotyledons of the samples of Telephone peas tested and no difference between peas frozen packed by the dry and by the brine process.

III. *Thiamin (vitamin B₁)*, M. L. Fincke. (Oreg. State Col.).—In this investigation, in which the author had the technical assistance of H. Hayden and H. Feikert, the effect of time and temperature of blanching prior to freezing on the content of thiamin in peas was determined on Telephone peas representing duplicate lots of those studied by Todhunter as noted above. The peas prior to freezing had been blanched in hot water at 99° C. for 1, 2, or 3 min., at 88° for 2, 4, or 6 min., and at 71° for 2, 4, or 6 min.; and in steam at 99° for 1 min. Two lots were held at room temperature for 4 and 8 hr., respectively, before being scalded for 1 min. in water at 99° . The thiamin values were determined by the Chase and Sherman rat-growth method, from 6 to 10 animals being used for each of two levels of feeding. The gains in weight during a 4-week period were compared with reference curves of the response to graded doses of thiamin obtained with rats from the same colony. For the most part the peas were fed at levels of 0.8 and 1.2 gm. daily. The animals receiving 1.2 gm. or more daily grew at a rate too great to convert their gains in weight into thiamin values in the reference curve, and consequently only the gains on the smaller dosage were used in the calculations. The highest thiamin value, 4γ per gram, was obtained for the sample blanched at 71° for 2 min. and the lowest, 2.6γ per gram, for those blanched for 2 and 3 min. at 99° . The trend was toward lower values with either increased temperature or time of blanching, but the differences were significant only when the two factors were combined. There was no significant difference between the effect of steam and hot-water blanching, and little effect from holding at room temperature before freezing.

A variety comparison was also made, using 10 varieties of peas grown under identical conditions and frozen after blanching at 88° - 93° for 1 min. Asgrow 40, World Record, Alderman, and Rogers 95 ranged from 7.4γ to 6.5γ per gram; Stratagem, Extra Early Gradus, and Confidence from 5.2γ to 4.3γ ; and Glacier Park, Telephone, and Laxton Progress from 3.6γ to 2γ per gram.

Vitamin considerations in wheat products, J. S. HUGHES and W. J. PETERSON. (Kans. State Col.). (*Southwest. Miller*, 19 (1940), No. 9, pp. 19, 20, 27).—This survey, concerned with the vitamin contribution made to the diet by wheat and wheat products, deals chiefly with thiamin. The role of thiamin in nutrition and the daily human requirement for this vitamin are discussed briefly as a basis for indicating the significance of the milling process as it affects the vitamin B₁ content of wheat products. Vitamin losses in milling, the return of germ to the flour, the vitamin value of white and whole-grain breads, and the rancidity problem are considered.

The vitamin A status of families in widely different economic levels, P. B. MACK and A. P. SANDERS. (Pa. Expt. Sta.). (*Amer. Jour. Med. Sci.*, 199 (1940), No. 5, pp. 686-697, figs. 4).—As a part of the study previously referred to (E. S. R., 81, p. 141) biophotometer measurements were made on all the 327 persons 6 yr. of age or older in the various families. The method of Jeans and Zentmire (E. S. R., 71, p. 566), using an electrically illuminated Birch-Hirschfeld photometer, was applied in the study of the members of 81 families; in the study of the other 19 families (distributed throughout the various cash income groups) the biophotometer described by Jeans, Blanchard, and Zentmire (E. S. R., 77, p. 886) was used.

Statistical study of the results indicated that there were definite relationships between the average vitamin A intake in the diet per unit person and the response to photometer tests. Cash incomes, money spent for food, and the education of adult members of the family were shown to be related to the vitamin A consumption of the family. The study showed that many families, particularly in the lower economic groups, were not selecting foods with a satisfactorily high vitamin A content. It showed further that poor darkness adaptation is apparently possible with high vitamin A intake (12,000 International Units or more of vitamin A per unit person daily), but that good response is not possible with an intake less than 8,000 I. U. per person daily.

Vitamin A and nightblindness: Some studies on college students (an abstract), H. C. CAMERON. (W. Va. Expt. Sta.). (*W. Va. Univ. Bul.*, 40, ser., No. 10-I (1940), p. 28).—Biophotometer tests on small groups of college women are noted in abstract. Among a group of 28 home economics students, 17 showed normal reserves of vitamin A, as judged by the biophotometer readings, 5 borderline, and 6 sufficiently low reserves to indicate night blindness and a potential hazard in night driving. One of these 6 brought her reading up to normal by changing her boarding house to one serving more green and yellow vegetables and more milk. Two improved their readings by increasing their milk consumption to 1 qt. daily, and the other 3 showed rapid improvement following 6 weeks' use of cod-liver oil or halibut-liver oil. Of a group of 14 students in the physical education department, 64 percent gave borderline or low readings as compared with 39 percent in the home economics group. "While the numbers are small, it appears that education in food values is a help in avoiding deficiencies and that it needs to be extended."

Graying of fur and other disturbances in several species due to a vitamin deficiency, A. F. MORGAN and H. D. SIMMS. (Univ. Calif.). (*Jour. Nutr.*, 19 (1940), No. 3, pp. 233-250, figs. 3).—This paper brings together the results of a miscellaneous series of experiments, particularly with reference to the phenomena of senescence, in extension of the earlier work in the senior author's laboratory (E. S. R., 79, p. 566) which first demonstrated that the active substance which prevents and cures the graying of fur of rats on diets deficient in certain of the B vitamins is present in the filtrate fraction of the vitamin B₂ complex. In addition to findings already noted from a preliminary report (E. S. R., 81, p. 743), two types of dermatitis, one unlike and the other similar

in some respects to that of vitamin B₆ deficiency, are described; the relation of growth to graying is discussed, with data showing that the curative and growth-promoting properties of filtrates from different vitamin B₂ complex extracts do not run parallel; accompanying damage to the thyroids as well as the adrenals is noted; and almost complete failure in lactation of all rats placed on the filtrate factor-deficient diet on either the day of mating or littering is demonstrated. The production of graying in one guinea pig, eight young dogs, and two young silver foxes is reported, with details on the basal diets used. Survival of thymus tissue was noted in all of the foxes on the deficient diet as compared with the controls in which no thymuses were evident. Survival of thymus tissue was also detected in some but not all of the rats on the deficient diet.

"The occurrence of unmistakable depigmentation in these young dogs and in one guinea pig as well as in several hundred rats and in two young silver foxes as a result of filtrate factor deficiency justifies the assumption that the graying phenomenon is truly a deficiency symptom. The concurrent skin and gland changes seen in the rats may well be suspected as being products of the same mechanism. These changes are typical of senescence, a process of obscure etiology. Perhaps the aging process is conditioned by an increasing need for this sparsely distributed factor. In any case further study of the interrelation of the adrenal cortical and other hormones, the B vitamins, and the phenomena of aging appears justified."

[**Dietary requirements for fertility and lactation, XXVI, XXVII**], B. SURE. (Univ. Ark.). (*Jour. Nutr.*, 19 (1940), No. 1, pp. 57-69, figs. 6; pp. 71-76, figs. 3).—In continuation of the series noted previously (E. S. R., 69, p. 618), two papers are presented.

[XXVI]. *Quantitative requirements of the components of the vitamin B complex for lactation and growth of nursing young of the albino rat.*—Using the same general technic as in the preceding studies, the author, with the technical assistance of A. Beach, attempted to determine the quantities of the various known components of the B complex required for successful lactation of the rat. Vitamin B₁, riboflavin, and vitamin B₆ were used in the crystalline form. Nicotinic acid was also incorporated in the vitamin B mixture, but no attempt was made to furnish the chick antidermatitis factor. Other factors in the B complex were furnished by a concentrate of the W factor of Elvehjem, Koehn, and Oleson (E. S. R., 78, p. 285). Choline was given as choline chloride, 15 mg. daily. The proportion of casein in the ration was increased from the 20 percent used in the earlier work to 25 percent and was supplemented by 0.2 or 0.5 percent of cystine. Vitamins A and D were furnished by 10 drops daily of cod-liver oil. The relative efficiencies of the diets containing different proportions of the various B vitamins were determined by calculations of the lactation index (E. S. R., 61, p. 696).

It was found that following depletion of the vitamin B reserves, rearing of the young proceeded at a rate comparable with that secured on an optimum stock diet when the mother was given daily 120 μ g. of thiamin, 120 μ g. of riboflavin, 50 μ g. of vitamin B₆, 15 mg. of choline chloride, 1 cc. of a solution of the W factor equivalent to 1 gm. of liver extract, and 6 mg. of nicotinic acid. The need for nicotinic acid was, however, not established. Attention is called to two problems that still await solution. One is the reason for the extremely high requirements for certain of the B vitamins for rearing of the young as compared with the requirements for growth. The other is the difficulty shown by many mother rats in transferring to the milk the pure thiamin, riboflavin, B₆, and choline chloride. It is noted that the addition of a daily dose of 2 mg. of manganous chloride overcame the difficulty with vitamin B₁.

[XXVII]. *The essential nature of choline for lactation and growth of the albino rat.*—This paper summarizes evidence, obtained by the author with the technical assistance of A. Beach, which led to the inclusion of choline chloride in the diets used in the study noted above. The evidence includes both lactation and growth records.

The relation of vitamin B₆ and pantothenic acid to factor W studies, S. BLACK, D. V. FROST, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 132 (1940), No. 1, pp. 65-75, fig. 1).—Factor W as part of the B complex was previously defined (E. S. R., 81, p. 879) as the fraction of liver extract which must be supplied in addition to thiamin, riboflavin, and vitamin B₆ to produce optimum growth in the rat. The present paper describes a procedure for the preparation of highly purified factor W concentrates. Various fractions of the liver extract prepared in the course of this concentration were tested for the rat growth response elicited. In some of these tests vitamin B₆ was added to the basal ration, evidence having been obtained that this basal ration, as previously used for factor W assays, was deficient in vitamin B₆. Significant growth responses were obtained when synthetic vitamin B₆ was added to the basal ration plus factor W concentrates. Some of the fractions tested were assayed for pantothenic acid, and significant amounts of this acid were found in those factor W preparations which promoted normal growth.

The filtrate obtained by treating the liver extract with hexane and butanol was subjected to extraction with acid ether. The extract, which contained pantothenic acid, promoted some growth in rats, whereas the residue, containing no pantothenic acid, effected little or none; the two together, however, gave pronounced growth. Since the effect of the extract is probably due to pantothenic acid, it is thought that the term factor W should be reserved for the factor in the residue. The greater growth response given by liver extract over the hexane-butanol filtrate, which contained both pantothenic acid and factor W, is considered to suggest that still another factor may be essential to the nutrition of the rat.

Spectacled eye condition in rats, J. J. OLESON, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 1, pp. 161-164).—Further studies are reported on conditions described in an earlier paper as "spectacled eye condition" (E. S. R., 81, p. 450). A dehydrated cereal grass and a liver fraction were tested at several levels as supplements to the previous basal diet on which many rats had failed to survive long enough to develop the specific symptoms. Growth, with development of all of the specific symptoms, occurred on the diet containing 1 percent of the liver extract, and the extract in this proportion was added to the diet for all of the tests reported. Crystalline vitamin B₆ in amounts of 10 γ daily cured the acrodynia in about 3 weeks but had no effect on the eye lesions. Corn oil, 2 or 3 drops daily, healed the severe eye erosions in 3 weeks, but α -tocopherol was completely inactive in doses of 50 γ per week. The fuller's earth filtrate of liver extract, prepared by the method described in the earlier paper and fed in amounts equivalent to 250 mg. of liver extract daily, brought about healing in 4-6 weeks. A purified extract of pantothenic acid fed at a level of 100 γ of pantothenic acid daily and the same concentrate in which the pantothenic acid had been inactivated both induced healing in about 8 weeks. The equal potency of the two extracts is considered to prove the nonidentity of pantothenic acid and the spectacled eye factor. Factor W and the antigreying factor, which corn oil does not supply, are also definitely eliminated. Because of the curative action of corn oil, a possible relationship is suggested between the factor and the "accessory factor" in the filtrate required in addition to vitamin B₆ for the complete healing of acrodynia. A relationship between the spectacled eye

condition and type III dermatitis of György and Eckhardt is discounted because the scaly tail condition has been produced on diets containing enough liver extract to supply ample amounts of the spectacled eye factor.

Riboflavin content of some common vegetables and fruits, A. Z. HODSON. (Cornell Univ.). (*Food Res.*, 5 (1940), No. 4, pp. 395-398).—Data on the percentage of dry matter and the riboflavin content, expressed as micrograms per gram on both the dry matter and the fresh wet basis, are reported for 7 fruits and 40 samples of vegetables (2 or more samples of some kinds) obtained on the local market. Analyses were made of the edible portions (skins being retained except in potatoes, sweetpotatoes, and turnips) by the fluorometric method of Hodson and Norris (*E. S. R.*, 83, p. 151). The study, considered as a preliminary investigation, indicates considerable variation from sample to sample, even for a given kind of vegetable. Values reported range from 0.21 to 2.26 μg . per gram on the fresh basis.

Essential fatty acids, vitamin B₆, and other factors in the cure of rat acrodynia, H. SCHNEIDER, H. STEENBOCK, and B. R. PLATZ. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 132 (1940), No. 2, pp. 539-551, figs. 2).—Acrodynia produced in young rats on a fat-free vitamin B₆-deficient diet was cured within a 3-week period by corn oil or cottonseed oil at levels of 5-10 mg. per day. That this was not due to any vitamin B₆ contained in the oils was demonstrated in that methyl esters of fatty acids of corn and cottonseed oils (as well as the ester of linoleic acid), prepared by the action of diazomethane on the free acids, were all curative within 3 weeks at a level of 20 mg. daily. The methyl ester of vitamin B₆ formed by this method was known to be biologically inactive. Moreover, vitamin B₆ does not form an insoluble barium salt, yet three successive precipitations of the fatty acids from corn oil by Ba(OH)₂ gave a product which, when converted to the ethyl ester, possessed anti-acrodynic potency when administered in daily curative doses of 20 mg. Crude phenols and crude lactones of corn oil, prepared by methods outlined, were ineffective in curing the acrodynia. These several experiments demonstrated that the anti-acrodynic activity of certain vegetable oils was resident in the fatty acid fraction as a fatty acid.

Further experiments demonstrated that the acrodynia as produced under the dietary regime employed could be cured by another type of substance, namely, the completely water-soluble rice bran concentrate Vitab. This product as such, or after ether extraction, was curative when fed daily at the 100-gm. level. Upon treatment of the rice bran concentrate with fuller's earth, the filtrate was found inactive in the cure of acrodynia, whereas the eluate (vitamin B₆) gave temporary improvement but permitted a relapse; the combined filtrate and eluate, however, were curative. Likewise, vitamin B₆ in crystalline form fed in amounts of 10 γ -50 γ per day gave only temporary improvement when fed alone but complete cure when fed with the filtrate factor. These experiments demonstrate that acrodynia can be cured by rice bran concentrate, and that this action is independent of fatty acids but is dependent upon vitamin B₆ plus an accessory factor included in the filtrate from the fuller's earth treatment of the concentrate.

In the course of these experiments it was shown that the severe symptoms of acrodynia could be modified by feeding increasing amounts of yeast, the mild symptoms of the Burr and Burr syndrome thus being produced. This syndrome, like the acrodynia, was cured by the "essential fatty acids" or by the rice bran concentrate.

Ascorbic acid content of cabbage as influenced by variety, season, and soil fertility, R. C. BURRELL, H. D. BROWN, and V. R. EBRIGHT. (Ohio State Univ.). (*Food Res.*, 5 (1940), No. 3, pp. 247-252).—Thirty varieties and strains of cabbage grown under similar conditions in the university gardens at Colum-

bus, Ohio, with sufficient moisture available at all times during growth, were tested for ascorbic acid content by indophenol titration immediately after harvesting or not later than overnight storage in a refrigerator at 4° C. (39.2° F.). The ascorbic acid values, representing analyses of duplicates from two separate samples taken from each of two heads of the same variety, ranged from an average of 48 mg. per 100 gm. fresh weight for Allhead Select to 180.9 mg. per 100 gm. for Midseason Market. The average value for the entire number of varieties and strains was 100.2, for the 10 varieties highest in ascorbic acid 152.9, and for the 10 lowest in ascorbic acid 59.2 mg. per 100 gm. "The same variety did not have numerically the same ascorbic acid content at different seasons or in different years, although, in general, varieties that are high in ascorbic acid as compared with other varieties tend to remain so, and those that are low remain low. Preliminary tests in fertilizer experiments indicate that high nitrogen or a complete fertilizer gives rise to a higher ascorbic acid content in cabbage than do six other treatments."

Ascorbic acid content of parsnips, H. L. MAYFIELD and J. E. RICHARDSON. (Mont. Expt. Sta.). (*Food Res.*, 5 (1940), No. 4, pp. 361-368).—Several lots of Hollow Crown parsnips, purchased on a local market in the fall and in the spring soon after being dug, were analyzed in the raw state and when cooked in various ways for ascorbic acid content, as determined by the method of Bessey and King (E. S. R., 71, p. 137), with a modification in the extracting solution as suggested by Bessey (E. S. R., 80, p. 711). The data reported show that the ascorbic acid content of individual raw parsnips varies considerably, and that overwinter storage in the ground results in considerable losses. In the fall values ranged from 12.8 to 39.9 mg. of ascorbic acid per 100 gm. of edible portion, and in the spring from 5.5 to 12.7 mg. Parsnips boiled whole with the skin on averaged 27.9 and 8.5 mg. per 100 gm. for fall and spring lots, respectively; when boiled after peeling and slicing the fall and spring lots averaged 14.3 and 6.7 mg. Frying the boiled parsnips seemed to effect a regain in the ascorbic acid content which could not be accounted for through moisture losses in frying.

Changes in vitamin C content during boiling of turnip greens in various waters in covered and uncovered containers, W. W. FLOYD and G. S. FRAPS. (Tex. A. and M. Col. et al.). (*Food Res.*, 5 (1940), No. 1, pp. 33-41).—To study the effect of various cooking processes on the vitamin C content of turnip greens, samples for analysis in the raw state were taken from one side of the midrib of fresh mature leaves with perfect bilateral symmetry and for cooking from the other side. The ascorbic acid content of 141 samples of the raw greens ranged from 67 to 422 mg. per 100 gm. Under conditions considered similar to practical cooking, using 50 gm. of the greens in from 75 to 200 cc. of water, an average of 88 mg. of ascorbic acid per 100 gm. of greens was found in solution and 53 mg. per 100 gm. in the greens. "Losses of total vitamin C under conditions similar to practical cooking ranged from 15.5 to 26.7 percent on rapid cooking and from 23.8 to 36.5 percent on slow cooking. There were lower losses in uncovered enamel, Pyrex, or stainless steel vessels when the greens were cooked rapidly than when they were cooked slowly. The losses were the same (25.3 to 26.9 percent) when aluminum was used, covered or uncovered. An increase in titratable vitamin C occurred when 2.5 gm. of greens were cooked in 50 cc. of water in covered aluminum vessels, but this increase was probably due to reduction of reversibly oxidized ascorbic acid, which is biologically active."

Varietal differences in ascorbic acid (vitamin C) content of strawberries, G. H. SATTERFIELD and M. YARBROUGH. (Univ. N. C. et al.) (*Food Res.*, 5 (1940), No. 3, pp. 241-245).—Seven varieties of strawberries grown in North Carolina in 1938 under identical conditions of soil, fertilizer, and climate were

analyzed in the firm ripe stage for ascorbic acid by the indophenol titration method after partial removal of pigment as suggested by McHenry and Graham (E. S. R., 75, p. 572). The varieties tested with average values for 8 or 10 samples of each variety were Fairmore 64.8 mg. per 100 gm., Fairfax 55, Southland 49.1, Dorsett 45.3, Blakemore 42.6, Klondike 38.8, and Missionary 36.2 mg. per 100 gm. The lowest single value of Fairmore, 59.3 mg. per 100 gm., was higher than the highest values for any of the other varieties except Fairfax, 1 sample of which had a value of 64.5 mg. per 100 gm. The 2 varieties with the lowest ascorbic acid, Klondike and Missionary, are standard commercial varieties widely planted, while Fairmore is a new berry originated as a cross between Fairfax, which ranked second, and Blakemore, which ranked fifth, and was introduced by Darrow and Morrow (E. S. R., 80, p. 771). "The Fairmore is vigorous, is noted for its firmness and shipping quality, is uniform in shape, is deep red in color, and possesses high dessert quality."

Indian gooseberries (*Phyllanthus emblica* Linn.) as a source of vitamin C. K. V. GIRI (*Indian Jour. Med. Res.*, 27 (1939), No. 2, pp. 429-439, figs. 2).—Values of 473, 611, and 680 mg. of ascorbic acid per 100 gm. of fresh gooseberry pulp or 2,428, 3,090, and 3,470 mg. for the fresh fruits on a water-free basis, were obtained for three samples. Bio-assays confirmed the fact that the reducing substance in the fruits, as determined by the dye method, was equivalent to vitamin C in antiscorbutic properties. Drying, particularly under the influence of the sun, exerted some destructive action, as the powder obtained by drying the samples of fruit pulp in the shade at room temperature contained 1,780, 2,280, and 2,660 mg. of ascorbic acid per 100 gm., while values of 1,550 and 1,840 mg. were obtained for portions of the first two samples dried in the sun. Juice extracted from the fruit and containing 9.4 mg. of ascorbic acid per cubic centimeter of juice, when freshly extracted, retained much of the vitamin upon storage at 0° C., since values of 9.0 and 8.5 mg. per cubic centimeter were found after 12 and 26 days of storage, respectively. Preservation of the fruits in concentrated salt solution permitted a retention of only about 50 percent of the vitamin as determined after 2 months' storage.

The ascorbic acid (vitamin C) metabolism of college students: A comparative study. M. L. FINCKE. (Oreg. State Col.). (*Jour. Amer. Dietet. Assoc.*, 16 (1940), No. 4, pp. 325-328).—A brief description is given of the organization and progress of the cooperative project on ascorbic acid metabolism of college students participated in by representatives of five of the experiment stations in the Northwest. Reports from the Montana and Washington Stations on certain phases of this project are noted below.

The amount of ascorbic acid excreted at each urination during twenty-four-hour periods. J. E. RICHARDSON and H. L. MAYFIELD. (Mont. Expt. Sta.). (*Amer. Jour. Physiol.*, 128 (1940), No. 3, pp. 583-587).—This study was undertaken because of lack of agreement as to the number of hours which should be included in the collection of urine for determination of ascorbic acid excretion and the time of day during which the collection should be made. During a 10-day period, two subjects engaged in similar occupations collected separately each voiding of urine during 24 hr., noted its volume, and determined the ascorbic acid content of an aliquot. Careful records were kept of all food and liquid consumed, and estimates were made of the ascorbic acid intake.

Both the volume of urine and the amount of ascorbic acid excreted at each voiding varied widely during the 24-hr. period, with no correlation between the two for each subject. The percentages excreted during the first 6-hr. period also varied widely. Average daily values for the two subjects during the 10-day period were estimated intake of ascorbic acid 215 and 153 mg., liquid intake 2,062 and 908 cc., volume of urine in 24 hr. 2,174 and 918 cc., ascorbic acid

excreted 179.8 and 95.2 mg., and percentage of calculated intake excreted 83.6 and 62.2 percent, respectively. The utilization indexes for the two subjects according to the Sendroy formula were 3.6 and 5.2, indicating that the subjects were in a good state of vitamin C nutrition.

A comparison of the utilization by college women of equivalent amounts of ascorbic acid (vitamin C) in red raspberries and in crystalline form, E. N. TODHUNTER, and A. S. FATZER. (Wash. Expt. Sta.). (*Jour. Nutr.*, 19 (1940), No. 2, pp. 121-130).—The criteria used in this comparison were urinary excretion and blood plasma levels of ascorbic acid following the ingestion of 40 mg. of ascorbic acid in the crystalline form and in frozen red raspberries by seven adult women subjects previously saturated with vitamin C by the ingestion of large quantities of orange juice. The basal diet during the experiment furnished about 20 mg. of ascorbic acid daily. For each subject the raspberry supplement period preceded that on ascorbic acid, but as a check on the possibility of some cumulative effect the experiment was repeated with one of the subjects, using the ascorbic acid before the raspberries. In view of fluctuations in the urinary levels of ascorbic acid in each individual, even on the uniform daily intake, the utilization index was calculated for each from the formula of Sendroy and Schultz which takes into consideration the body weight and age.

For five of the subjects, the urinary excretion, as expressed by the utilization index, and the blood plasma levels were similar for the same subject when receiving the vitamin C from the raspberries and from the crystalline ascorbic acid. Two of the subjects had a much lower utilization index, indicating greater utilization, on the raspberries. No difference was noted when the order of intake of raspberries and ascorbic acid was reversed.

Separate analyses were made of the urine collected during the first 6 and the remaining 18 hr. to determine whether or not a shorter period than 24 hr. might safely be used. Calculations of the percentage excretion during the first 6 hr. showed variations from subject to subject and for the same subject in different periods. The lowest value was 6 percent for a subject who, on another day, excreted 61 percent of the total in the first 6 hr. "With such variations it is to be questioned whether the 6-hr. urine specimen can give reliable information regarding the total daily excretion of ascorbic acid."

Observations on the amount of ascorbic acid required to maintain tissue saturation in normal adults, E. N. TODHUNTER and R. C. ROBBINS. (Wash. Expt. Sta.). (*Jour. Nutr.*, 19 (1940), No. 3, pp. 263-270).—Three college women served as subjects in determinations of saturation requirements for ascorbic acid by the procedure described by Belser, Hauck, and Storvick (*E. S. R.*, 82, p. 428). In addition the ascorbic acid content of the blood plasma was determined by the Farmer and Abt micromethod on samples taken in the morning before breakfast throughout most of the experiment. The lowest levels of ascorbic acid excreted in response to a 400-mg. test dose after saturation with 200 mg. ascorbic acid daily for 4 days were 170, 229, and 227 mg., respectively, and these values were taken as criteria for complete saturation. Although there was some variation in the daily excretions of the same subjects, it was concluded that as a supplement to 20 mg. of ascorbic acid daily furnished by the basal diet, the three subjects required approximately 70, 60, and more than 90 mg. of ascorbic acid daily to maintain tissue saturation. When the intake of ascorbic acid from the regular diet was added to these figures and the requirements were calculated in terms of body weight, the values became 1.7, 1.6, and more than 1.6 mg. per kilogram of body weight, respectively, as compared with from 1 to 1.6 mg. per kilogram in the study by Belser et al.

Blood samples taken on the morning that the 400-mg. test dose was given in the preliminary saturation test and at the end of the 24-hr. urine collection period for the test dose showed practically no difference in ascorbic acid content. Plasma levels for the three saturation periods ranged from 1.33 to 1.70, from 1.29 to 1.84, and from 1.31 to 1.69 mg. per 100 cc., respectively. It is noted that these values are in agreement with reports of various investigators that the renal threshold for ascorbic acid is approximately 1.4 mg. per 100 cc. of plasma. In the second part of the investigation blood plasma values were taken daily except for one subject when on a 40-mg. ascorbic acid intake. At the beginning of each test period after the preliminary saturation, the values ranged from 1.36 to 1.68 mg. for the three subjects. During the 6-day period on the smaller daily intakes, the blood levels fell but rose to 1.4 mg. or above following the 400-mg. dose. More than 120 mg. of ascorbic acid daily was required for each subject to maintain this level. The question is raised as to whether the blood should be maintained at this high level for optimum health, and it is pointed out that from the data of the present study the daily requirement of ascorbic acid would be 60 mg. if the criterion of tissue saturation is a blood plasma level of 0.7 mg. per 100 cc. with an increase to 1.4 mg. 24 hr. after taking a 400-mg. test dose, and would be more than 120 mg. if the criterion is a plasma level maintained at approximately 1.4 mg. per 100 cc.

A method for the study of the availability for human nutrition of the vitamin C in foods, with an application to the study of the potato, M. M. CLAYTON and M. T. FOLSOM. (Maine Expt. Sta.). (*Jour. Home Econ.*, 32 (1940), No. 6, pp. 390-395, fig. 1).—The method developed by the authors for determining the availability of the vitamin C in any food serving as a source of this vitamin in the diet involves the use of a potentially neutral basal diet low in vitamin C to which the vitamin is added successively as pure ascorbic acid and as the test food alone or in combination with ascorbic acid. The experiment is divided into four consecutive periods, the first two of which are 4 days in length and the last two 7 days. Twenty-four hr. urine collections are made throughout, all for ascorbic acid determinations except the final days of periods 3 and 4, which are for pH determinations. Blood samples are taken before breakfast at the beginning of periods 3 and 4 and the end of period 4 for ascorbic acid determinations as a test of saturation in the preceding periods. In period 1 of the present study the subjects received their customary diet plus 150 mg. of ascorbic acid daily, period 2 the basal diet plus 200 mg. of ascorbic acid daily, period 3 the basal diet plus 75 mg. of ascorbic acid daily, and period 4 the basal diet plus 25 mg. of ascorbic acid and enough baked potato to furnish 50 mg. of ascorbic acid, the potato being substituted for isocaloric amounts of bread or cereal in the basal diet. Periods 1 and 2 were for the purpose of saturating the body with ascorbic acid, period 3 to determine if 75 mg. of ascorbic acid daily sufficed to maintain saturation, and period 4 to determine the utilization of the vitamin C of potatoes. Ascorbic acid values were determined by indophenol titration. The technic for the preparation of the indicator and for the determination of reduced and dehydroascorbic acid in the baked potato is described in full.

Four college students, three male and one female, served as subjects. Only one of the subjects showed a maximum excretion of ascorbic acid on the first day of period 2, two showed it on the second day, and the remaining subject on the fourth day. At the end of period 3, the three boys were excreting approximately 20 mg. and the girl 40 mg. of ascorbic acid daily. At the end of period 4, in which potatoes furnished two-thirds of the vitamin C, all of the subjects had a somewhat lower excretion than in period 3, with the girl still excreting somewhat more than the boys.

The blood values at the end of period 2 ranged from 1.05 to 1.38 mg. per 100 cc., indicating saturation on the basis that values above 1 mg. per 100 cc. denote saturation. In period 3 the values for the two smaller subjects weighing 145 (female) and 163 lb. were still above 1 (1.01 and 1.17 mg. per 100 cc., respectively), but for the two larger subjects, weighing 195 and 200 lb., were below 1 (0.93 and 0.82 mg. per 100 cc.). At the end of the fourth or potato period, the values for the first two subjects were slightly lower than in the third period and the others slightly higher, but these differences are considered insignificant, indicating that the total ascorbic acid consumed, 75 mg. in tablets and 10.4 mg. in the basal diet, was not quite enough to keep the two larger subjects in a state of saturation.

A slight increase in potential alkalinity of the diet was produced by the potatoes, but there was no indication from the above data that this had any favorable effect on the retention of vitamin C.

As a practical conclusion to be drawn from this study, the authors state that "by the use of this method it has been demonstrated that in November three medium-sized baked potatoes of the Green Mountain variety can supply two-thirds of the optimum daily requirement for vitamin C of a normal adult."

The effect of drugs on vitamin C excretion, L. T. SAMUELS, N. D. RITZ, and E. B. POYET. (Univ. Minn. et al.). (*Jour. Pharmacol. and Expt. Ther.*, 68 (1940), No. 4, pp. 465-475, figs. 3).—Conflicting evidence as to the effect of acetylsalicylic acid on ascorbic acid excretion led to this study of the effect of this and other drugs on the excretion of ascorbic acid in rats and guinea pigs. Increased excretion was shown in both species by determination of the ascorbic acid content of the urine by titration and the use of the Evelyn photometric colorimeter and by isolation of 2,4-dinitrophenylosazone. There was almost invariably a sharp rise in the excretion of ascorbic acid, followed by a drop to a slightly subnormal level during the second to the fourth subsequent days. The effect is thought to be connected with some direct action of the salicylate bringing about a depletion of body supplies of ascorbic acid. Caffeine, salyrgan, and sodium bicarbonate had no effect and cinchophen an effect similar to that of the salicylate but to a lesser degree. On continued dosage in rats, a level of excretion of ascorbic acid was reached which appeared to represent an approach to equilibrium between increased formation and increased excretion.

It is thought highly probable that salicylates increase vitamin C excretion in human beings, and that the failure of some investigators to demonstrate this has been due to lack of control of such factors as variations in the diet, degree of saturation of the subject, and dosage.

Studies in nutritional anemia, O. SHEETS and M. V. WARD (*Mississippi Sta. Tech. Bul.* 26 (1940), pp. 35, figs. 2).—The antianemic potency of leafy vegetables, legumes, sorgo and sugarcane sirups, and blackstrap molasses was determined by observing in each case the hemoglobin regeneration effected in young anemic rats by the feeding of these foods as supplements to the anemia-producing diet. Each food was fed at a level furnishing 0.25 mg. of iron per rat per day. To determine whether all of the iron in the vegetable was utilized, experiments were conducted in which the ash of the vegetable (usually dissolved in HCl and in a quantity equivalent to the unashed supplement) was fed instead of the vegetable itself.

Upon feeding the leafy vegetables as air-dry material, average hemoglobin gains in male rats over an 8-week period varied from 2.1 to 9.3 gm. per 100 cc. for the nine samples (including two of turnip tops, two of mustard, two of lettuce, and one each of spinach, collards, and tendergreens). Feeding of the ash in five cases resulted in definitely larger gains than were obtained with the air-dry vegetable. Eight samples of the various legumes (including cowpeas, soybeans,

lima, and pinto beans) produced in male animals over the 8-week period hemoglobin gains varying from 7.3 to 11.7 gm. per 100 cc.; when the ash was fed rather than the dry legume, comparable gains (6.5–12.5 gm. per 100 cc.) were obtained. These results indicate that legumes are more effective than leafy vegetables in hemoglobin regeneration, and suggest that the difference is due to greater availability of the iron in the legumes; apparently this is not due to their higher copper content, since the legumes were more effective than the leafy vegetables even when copper intakes in the feeding trials were equalized.

That the iron of legumes is more available than that of leafy vegetables was borne out by further tests comparing the response of various groups of animals fed the several supplements with those fed the same level of iron administered as ferric chloride. In these trials the legume supplements produced hemoglobin gains nearly as great as those obtained with the inorganic iron, while the gains with the leafy vegetables were of a lower order. These biological tests, confirmed by determinations of available iron by the α, α' -dipyridyl method, indicated that 90–93 percent of the iron in legumes and 60–65 percent of the iron in leafy vegetables was available. Similar studies with the sirups and molasses showed an availability for the iron of 84–93 percent.

TEXTILES AND CLOTHING

The effect of climatic exposure on textile fibres and fabrics, A. C. THAYSEN, H. J. BUNKER, K. R. BUTLIN, and L. H. WILLIAMS (*Ann. Appl. Biol.*, 26 (1939), No. 4, pp. 750–781, pl. 1, figs. 3).—Various fabrics, including cotton, linen, hemp, wool, silk, rayon, and jute, were exposed at one or more places representing a wide range of climatic conditions. One series was buried vertically in an open nongrassy soil, another was hung in a place protected from direct rays of the sun but not sheltered from rain, and a third was hung in direct sunlight. In one of the stations samples of one series were suspended in sea water. The samples, examined periodically, were removed from the exposure frames when deterioration was observed, sealed in glass tubes, and held in a cool place until comparison could be made with the original nonexposed fabrics previously analyzed and until bacteriological examination could be made to determine the part played by micro-organisms in the deterioration. In the bacteriological analyses both aerobic and anaerobic, and mesophilic and thermophilic organisms were searched for. Samples of the various soils were also examined to determine the microflora present.

Fabrics exposed to waterlogged conditions deteriorated rapidly, the destruction being due solely to bacteria and not to fungi or actinomycetes in the case of cellulose fabrics; in the case of wool the evidence of microbiological action was not conclusive. In soils microbiological action caused disintegration of cellulose, wool, silk, and cellulose rayon, the rate being governed by the moisture content of the soil and, to a lesser extent, by the temperature. Cellulose acetate rayon was completely resistant. Cellulose and wool fabrics exposed in the shade to very humid tropical conditions showed extensive mildewing, but were damaged much less rapidly than in the soil. Fabrics exposed for a year in the shade in subtropical or temperate climates with moderate rainfall suffered microbiological damage, which was insufficient, however, to affect the strength of the fabric; in these cases there was much mildewing. No microbiological damage or mildewing was observed in shade-exposed fabrics in arid climates. Fabrics exposed to the action of sun as well as rain showed microbiological damage when the moisture conditions were suitable for the growth of micro-organisms, but damage was always less than that observed in fabrics exposed in the shade at the same station. Inert substances such as glass, metals, and

rubber, when used as a covering for cellulosic fabrics, were found to retard microbiological decay in soil and sea exposures. Although flax, hemp, and jute fibers possess parenchymatous and epidermal tissues surrounding the bundles, these apparently exert no shielding effect, since the fabrics decayed at approximately the same rate as cotton, which contains no protective tissue. A provisional technic is described for evaluating the relative merits of mildew protective treatments. The only treatment found to give permanent protection in the case of cellulose fabrics was partial acetylation.

Women's dresses and slips: A buying guide, C. L. SCOTT (*U. S. Dept. Agr., Farmers' Bul. 1851 (1940), pp. [2]+22, figs. 13*).—The use for which intended, the service expected, satisfactory cleaning without undue expense, becomingness, and fit are main factors to be considered in dresses in choosing the best buy for a given outlay. How well these requirements will be met will depend upon the fabric (whether cotton, linen, silk, or wool), the size and fit, the cut, and the construction as seen in seams and stitching, hems and finishes, fastenings, and trim. In the present publication, superseding Leaflet 105 (E. S. R., 72, p. 285), these matters are discussed from the standpoint of what to look for in buying a dress. Materials, style and fit, and workmanship in costume slips are similarly treated.

HOME MANAGEMENT AND EQUIPMENT

Family income and expenditures: Southeast region.—I, Family income, D. BRADY, D. MONROE, G. S. WEISS, and T. DREIS (*U. S. Dept. Agr., Misc. Pub. 375 (1940), pp. V+389, figs. 5*).—This report, the fifth in the series on family income and expenditures, is the fourth in the urban and village series. It is based on a survey of small city and village families in selected communities in the Southeast region, and presents information similar to that previously reported (E. S. R., 83, p. 861).

Price variations among retail grocery stores of Burlington, Vermont, D. D. NUTZMAN and M. MUSE (*Vermont Sta. Bul. 466 (1940), pp. 40, fig. 1*).—Regular and sale prices were obtained for 23 common grocery store commodities as sold in 42 retail grocery stores in Burlington. The items priced were mostly nationally advertised brands of staple commodities. "Prices from all stores were averaged for each commodity, the aggregate of the average prices on the 23 items represented the base (100), and the aggregate of each store's price was related to this base in establishing its index number."

Index numbers of prices averaged 97.3 for downtown, 99.4 for secondary, and 102.5 for outlying stores. Prices quoted by chains averaged 12 percent and by voluntary chains 1 percent below those of independents. It was found that most sale offers were unit ones, with less than half multiple unit, and only a few combination offers. Two-thirds of all sale prices were reduced from regular ones, average savings amounting to 10 percent of the regular prices on all sale offers and to 14 percent on those which were actual reductions. "Percentages of saving averaged 4.9 for chains, 10.9 for voluntary chains, 14.2 for independents on all sale offers; and 12.2, 13.8, and 15.4, respectively, on those actually reduced in price. The amount of saving per offer usually increased as the price of the sale offer rose, while the percentage saved per offer decreased as the price of the sale offer rose."

Home economists study leisure use by farm families, D. DICKINS (*Miss. Farm Res. [Mississippi Sta.], 3 (1940), No. 9, pp. 7, 8*).—This article, stressing the importance of good use of leisure, indicates that reading, resting, and visiting were the leisure activities most often noted in white farm homes, while resting, hunting, and fishing (among the men), visiting, and quilting

(among the women) were the favored recreations in Negro farm homes in Mississippi.

Floor finishes: Attractive, easy to clean, durable, C. H. JEFFERSON (*Michigan Sta. Cir. 172 (1940), pp. 22, figs. 11*).—The author briefly discusses oil, varnish, and paint or enamel floor surfaces, pointing out the time-consuming nature of the oil treatment when done thoroughly enough to produce a lasting surface, and the impossibility of avoiding "traffic lanes" of wear and discoloration in the use of varnish, shellac, or lacquer surfaces, a disadvantage due to lack of penetration and giving rise to wear of a nature such that refinishing the worn areas to match the rest of the floor is usually impossible except by resanding with concomitant excessive wearing down of the wood itself. The penetrating floor seals, so made as to penetrate only a short distance into the pores of the wood and to harden at the surface, are considered adequate to seal the surface of the wood against moisture, dirt, and substances causing stains, while at the same time they have the advantage over the hot-oil treatment that the floor may be used 24 hr. after the application of the seal. Such finishes can usually be renewed in worn areas without need for refinishing the entire floor. The application of such finishes to new floors and their use in refinishing old floors are discussed in detail, and their use on inlaid linoleum and on concrete floors is also taken up. The use of waxes of various types is dealt with.

MISCELLANEOUS

Recent results with the ultramicroscope [trans. title], H. RUSKA (*Chron. Bot., 6 (1940), No. 4, pp. 84, 85*).—Reviews of recent electronmicroscope findings on blood, bacteria, viruses, and dust, with over 25 references.

Report of progress in solving Idaho's farm problems: Forty-seventh Annual Report [of Idaho Station] for the year ending December 31, 1939, C. W. HUNGERFORD ET AL. (*Idaho Sta. Bul. 236 (1940), pp. 75, figs. 17*).—The experimental work not previously reported is for the most part noted elsewhere in this issue.

Mississippi Farm Research, [September–October 1940] (*Miss. Farm Res. [Mississippi Sta.], 3 (1940), Nos. 9, pp. 8, figs. 8; 10, pp. 8, figs. 13*).—In addition to articles noted elsewhere in this issue, these numbers include the following: Nos. 9, Progress in Physical Plant, Research Work, by Mississippi Station, by C. Dorman (pp. 1, 8); and 10, Fewer Horses, More Mules, Fewer Sheep, More Chickens, More Cattle—Shown in 30-Year Livestock Trend on State Farms, by M. Guin, D. W. Parvin, and J. Huff (p. 7).

Publications available from the [Kansas] Agricultural Experiment Station (*Kansas Sta. Cir. 202 (1940), pp. [4]*).—The available bulletins and circulars, classified under agricultural economics, agricultural production, and home economics, are listed.

NOTES

California University and Station.—Charles W. Woodworth, associated with the entomological work of the institution from 1891 to his retirement in 1930, died November 19, 1940, at the age of 75 years. A native of Illinois, he received the B. S. degree from the University of Illinois in 1885 and the M. S. degree in 1886 and for the 2 years following was connected with the Illinois State Laboratory of Natural History. In 1888 he was appointed entomologist and botanist of the newly established Arkansas Station, serving there until 1891. In 1918 and again from 1921 to 1924, he was engaged in entomological work in China, organizing an experiment station from the College of Agriculture and Forestry of the University of Nanking and the Kiangsu Provincial Bureau of Entomology.

Prof. Woodworth was a man of broad interests and varied activities. Concerning his long service in California, a recent tribute in *Science* by his colleague E. O. Essig speaks in part as follows: "Woodworth came to California at the time when there were many new and pressing problems in entomology and a great need for teaching, research, and practical demonstrations in control. Single-handed he set out to do what a hundred or more entomologists are trying to accomplish at the present time. . . . He had much to do with the early development of the manufacture and uses of London purple, paris green, calcium arsenate, acid and basic lead arsenate, calcium arsenite, zinc arsenite, lime-sulfur, petroleum oil emulsions, and sodium and potassium cyanide fumigation. To protect the farmers against losses due to adulteration of paris green he proposed and drafted the first California insecticide law in 1906, was largely instrumental in securing its passage in 1911, and administered the law until July 1, 1923. Entomological campaigns which he conducted in California concerned the codling moth, the peach twig borer, citrus insects, grasshoppers, citrus white fly eradication, and the proper allowances for tent leakage in HCN fumigation of citrus trees."

Florida Station.—Dr. Michael Peech, soil chemist at the Citrus Substation, has been appointed assistant professor of agronomy in Cornell University.

Georgia Station.—The department of agronomy has developed a new variety of wheat which is resistant to leaf rust and especially adapted to Georgia conditions. This wheat, named Sanford for the chancellor of the University System of Georgia, has yielded in 4-year trials 6.8 bu. more per acre than Gasta, a high-yielding bluestem selection, which is a variety the station had previously developed and recommended for the State.

Director H. P. Stuckey has been named by the *Progressive Farmer* "man of the year" for Georgia, an honor awarded each year for the most outstanding service to the agricultural program in national planning, teaching, research, or organization. In announcing this award to Dr. Stuckey as the leader in research, it is stated that "as a result of his own special work in the 32 years at the Georgia Experiment Station we can list 12 superior varieties of muscadine grapes, the cabbage-collard, the now common practice of planting pollinizers in pecan groves, proof that blossom-end rot of tomatoes is due to irregular water supply. Under his supervision and friendly encouragement as director there have been developed

the high-yielding Gasta and Sanford wheats, Terruf oats, Doxi soybeans, and Cherokee sweet corn. An intensive peanut production research program now producing definite results has been under way since 1931. Dr. Stuckey has played a leading part in the development of the pimiento pepper, in recent years one of the leading cash crops of middle Georgia."

H. S. Mills, of the U. S. D. A. Bureau of Plant Industry, has been detailed to the station for work in cooperation with the department of botany in peanut breeding and variety tests.

Purdue University and Indiana Station.—C. B. Richey, instructor in agricultural engineering, resigned February 1 to accept a position as assistant professor of farm machinery in the Ohio State University and Station. Dr. Max R. Zelle has been appointed assistant professor of genetics in the School of Agriculture and assistant in the station.

Iowa College and Station.—Following a gift of a farm and \$10,000 from Rollins E. Hinds of Ottumwa, the Hinds Fund for Agricultural Research has been established. This fund will be used in cooperation with the U. S. D. A. Soil Conservation Service for the study of soil erosion.

Rutgers University and New Jersey Stations.—Dr. Gerald M. Ridenour, associate in water and sewage research and assistant professor in the department of water supplies and sewage disposal in the university, has been appointed associate professor in sanitary engineering in the Pennsylvania College.

Pennsylvania College and Station.—The Ellen H. Richards Institute has been established as a consolidated working unit for studies in human nutrition; textiles, textile chemistry, and detergency; and housing materials and equipment. Among the projects to be developed under these auspices are the college participation in the cooperative textile project involving six northeastern experiment stations and the Pennsylvania mass studies in human nutrition. Numerous fellowships in textiles and detergency will be available, and opportunity will be given graduate students to work on various aspects of the program while taking advanced degrees in the department of home economics or other subject matter departments of the college.

The new forestry building has been occupied. This is a substantial two-story and brick structure replacing a small wooden building in use for many years.

Recent appointments include Dr. Wilford R. Mills, assistant professor of plant pathology in the university and station, to a corresponding position; Dr. George E. Brandow as assistant professor of agricultural economics; and J. J. Werner as assistant in bacteriology.

South Dakota College and Station.—Dr. S. P. Swenson, associate professor and associate agronomist in charge of cereal breeding, has resigned to become associate professor of farm crops and associate geneticist in the Washington College and Station. Dr. Lyman E. Jackson, junior dean of the College of Agriculture of the Ohio State University, entered upon his duties as president on January 1.

Utah College and Station.—Dr. R. H. Walker, who has been directing the work of the U. S. D. A. Regional Salinity Laboratory at Riverside, Calif., resumed his duties as dean of the School of Agriculture and director of the station on January 1.

EXPERIMENT STATION RECORD

VOL. 84

APRIL 1941

No. 4

THE SCOPE AND USE OF EXPERIMENT STATION RECORD

Although the *Record* is now well along in its second half century and its major policies and procedures have been standardized for many years, inquiries are frequently received which indicate a need for a brief discussion as to the scope of this publication and how to use it. The following statement has been prepared mainly to meet these specific objectives.

As its name implies, *Experiment Station Record* is first of all a record of experiment station accomplishments. This record is derived from the stations' published material, including not only what is issued by the stations themselves but all identifiable research contributions by members of their staffs to scientific journals and other mediums of publication. Special efforts are made to obtain and abstract the station series as promptly and regularly as possible.

Under ordinary circumstances about half of the approximately 138 pages available in each issue of the *Record* are required for the station material. Another substantial portion is occupied by the research contributions from the Federal Department of Agriculture, which in general receive the same priority and are handled in the same way as those of the stations. The most important distinction is that resulting from the fact that the Department is more than a research agency. In consequence much material which it issues is along lines outside the scope of the *Record* and is therefore not included in its review.

Such space as still remains is available for abstracts of selected article from nonstation and non-Department sources. Thirty years ago a reasonably complete coverage was possible for all articles of interest to agricultural research. In 1911, however, the year in which the present space limits were established, the State experiment stations had a total aggregate income of \$3,662,425 and technical staffs aggregating 1,564 employees. In the fiscal year 1940, the comparable figures were \$21,216,749 and 4,593 technical employees. This change alone illustrates some of the difficulties in maintaining a coverage as comprehensive as formerly.

In order to conserve space, numerous alterations and procedures have been introduced from time to time. One radical departure of the past decade has been in the method of handling the station annual reports. Here the assumption has been made that such publications are essentially progress reports and that consequently detailed abstracting may be deferred until the results are presented more formally elsewhere. However, an enumeration is attempted of all findings which are reported, thereby securing an index reference both by subject and author for the use of those interested in following the progress of a specific project. More recently, increasing use of title references, with or without annotations, and of descriptive abstracts has been resorted to when deemed practicable and especially in connection with association proceedings. Largely because of these changes and the assignment of less space to editorials and news notes, over 500 more abstracts were published in 1940 than in 1911.

At the present time, it is believed that the major research developments in agriculture and home economics are being placed on record, though in some cases in insufficient detail, for the United States and Canada, and for other parts of the British Empire to the extent that this research is widely applicable to conditions in this country. Special attention is also being given to contributions from Central and South America. For the remainder of the globe it is doubtful if adequate coverage can be achieved under existing conditions, although the attempt is made to locate and make available the more outstanding additions to knowledge.

Aside from the station and Department publications and a considerable number of direct exchanges, by far the principal channel through which material becomes available for abstracting is the Department Library, which has been traditionally most cooperative in facilitating the *Record* work. Since the entire Library resources are available and selection is made by a process of sifting of individual issues, no separate list is maintained of periodicals abstracted in the *Record*, but a guide to the Library receipts is issued from time to time by the Department Library under the title List of Periodicals Currently Received in the Library of the United States Department of Agriculture. The latest issue of this list bears the date of June 1, 1936, contains 3,871 titles of periodicals with addresses of publishers, and is still available as Miscellaneous Publication 245 of the Department. A supplement is now in press.

Another Department publication of direct value to users of the *Record* is Miscellaneous Publication 337, Abbreviations Used in the Department of Agriculture for Titles of Publications. This publication, issued in 1939, has superseded Department Bulletin 1330, Abbreviations Employed in Experiment Station Record for Titles

of Periodicals. This also is an address list, and includes a key for single words which is especially helpful in identifying publications too recent to be specifically included. Although the Office of Experiment Stations is always glad to be of service along bibliographical lines, it is thought that the acquisition and use of these two Department publications would obviate many inquiries as to what publications may be abstracted in the *Record*, the full titles of these publications, and where the publications may be obtained.

Probably the most difficult of fulfillment are the requests received by the Office which ask for copies of the original publications from which abstracts are made. The foregoing discussion indicates the virtual impossibility of complying with most requests of this type. Seldom does the Office have available for distribution copies of any publications which are abstracted aside from the relatively few which it itself issues, notably the annual report on the agricultural experiment stations and the annual report of the Chief of the Office.

In general, requests for other publications of the Department should be made to the Office of Information. The publications of the State experiment stations are distributed only by the individual institutions, an address list of which appears as page 3 of the cover of each issue of the *Record*. Books and periodicals must usually be purchased from the publishers or their agents, although separates of articles are sometimes obtainable from authors or their institutions. Many publications are of course available for consultation in libraries, and it is not always realized that the Union List of Serials in Libraries of the United States and Canada and its supplements may be of much help in locating libraries where specific publications may be found.

Probably the most striking development in documentation aids in recent years has been the application of photography to the making of copies. Through the operation of Bibliofilm Service by the American Documentation Institute in cooperation with the Department Library, photographic reproductions may now be obtained for purposes of research for virtually any article abstracted in the *Record*. These reproductions are available in two forms, photo-prints, which can be read without magnification, and microfilm furnished at much lower cost but requiring a magnifier or projecting apparatus. Order blanks and details for this service can be obtained from the Bibliofilm Service, care of the Library, U. S. Department of Agriculture, Washington, D. C. It is believed that for certain types of articles, such as short papers appearing in voluminous or relatively inaccessible proceedings, this service has many advantages.

The classification of abstracts in the *Record* follows a plan of many years' standing, and it is the endeavor to maintain consistency of

reference and uniformity of treatment. It cannot be emphasized too frequently, however, that many abstracts are of interest to users of other sections than those in which they appear. So complex are modern research interrelations that not even cross references can be expected to encompass complete knowledge within a single section, and it is largely to avoid the creation of a false sense of security that cross references are not employed in the *Record*. To obtain a complete picture, the poultry husbandman should extend his reading beyond the section of Animal Production at least to that of Veterinary Medicine, Genetics, and Agricultural Economics. The soil conservationist cannot hope to find all material of interest in the section on Soils, but should browse currently into the sections of Agricultural Meteorology, Agricultural Botany, Field Crops, Forestry, Agricultural Engineering, Agricultural Economics, and even Rural Sociology. Ultimately, of course, the subject indexes are available regardless of sectional lines, but in the use of these indexes the precaution should still be taken to avoid too narrow a conception of the terminology.

For those who are endeavoring to use the *Record* as a guide to research accomplishments of the past half century, the most rapid method of approach is usually through the combined subject indexes. There are now six of these indexes, and it is the policy to add others at approximately 5-year intervals. Unfortunately the second of the group, covering volumes 13-25, is no longer available, but the remainder, covering volumes 1-12, 26-40, 41-50, 51-60, and 61-70, can still be obtained free of charge by libraries and for institutional use, as well as through purchase from the Superintendent of Documents. The Office of Experiment Stations is always glad to cooperate to the extent of its facilities in the completion of files for both the general indexes and the individual volumes.

In conclusion, suggestions as to ways to improve the *Record* and extend its usefulness are appreciated. Continuity and consistency of policy is so important in an abstract journal of this kind that changes are not always practicable. The attainment of maximum service, however, is the ideal underlying its operation, and constructive criticism to bring this about will not only be welcome but will receive full and sympathetic consideration.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations by the New Haven Station] (*Connecticut [New Haven] Sta. Bul.* 438 (1940), pp. 497-499).—Notes are given on amide synthesis in the tobacco leaf and rhubarb leaf, and on the effect on plants of isotopic nitrogen.

Biochemical studies of some varieties of apples, plums, and grapes grown in Minnesota, E. O. BARNES (*Minnesota Sta. Tech. Bul.* 143 (1940), pp. 35, figs. 8).—The author determined the titratable acidity, pH values, titration curves, and buffer-system characteristics of the juices of various apples, plums, and grapes as grown under Minnesota conditions. The crude pectin content (as indicated by alcohol precipitation) of the apple juices was determined, together with total astringents, astringent nontannins, and tannins in the juices of the plums and grapes and their relative proportions of acid, sugar, and astringent substances.

The indications of these data suggest the desirability of carrying out similar studies over several crop seasons. "Such studies should (1) assist in separating environmental and seasonal factors from genetic behavior, (2) indicate those varieties which exhibit a relatively stable constitution insofar as fruit composition is concerned, and (3) perhaps indicate genetic combinations which will assist the fruit breeder in developing varieties of fruits suitable for specific purposes. . . . If [for example] a desirable grape with a sugar content stabilized at approximately 17 percent can be grown in Minnesota, it might well provide raw material for a local wine industry."

Inversion of sucrose in the different parts of the sugarcane stalk, J. I. LAURITZEN and R. T. BALCH (*Jour. Agr. Res. [U. S.]*, 61 (1940), No. 1, pp. 1-16, figs. 3).—There was less inversion of sucrose in all samples stored at high relative humidities than in corresponding samples stored at low r. h. In general, the rate of inversion of sucrose was correlated with the rate of loss of moisture. In most instances there was more total loss of moisture and inversion of sucrose from the three sections made of samples when sectioned before storage than when sectioned after storage. The exception seemed to be due to the lack of uniform exposure of samples to evaporation. In cane stored as whole stalks there tended to be a gradient in the percentage of loss of moisture, percentage of increase in Brix, drop in purity, and percentage of loss of sucrose. These changes were greatest in the top, next greatest in the middle, and least in the bottom section. In cane sectioned before storage these changes tended to be greater in the top and bottom sections than in the middle section. In the variety P. O. J. 36-M there was greater inversion in the unsevered top third of the stalks than in the severed top third. During the early periods of storage, however, there was greater inversion in the severed bottom third than in the unsevered bottom third, the difference decreasing and sometimes disappearing with lapse of time. The behavior of the variety Co. 290 was similar to that of P. O. J. 36-M except that the differences were not so marked, and after the

first period of storage there was a decrease in the difference in the top sections instead of in the bottom sections.

Density of dry milk solids, O. E. STAMBERG and C. H. BAILEY. (Minn. Expt. Sta.). (*Food Res.*, 5 (1940), No. 3, pp. 275-280, fig. 1).—The method developed for determining density of dry milk solids consisted in weighing 7 gm. of dry milk solids into a 50-cc. sedimentation tube, adding a mixture of naphtha and carbon tetrachloride having a density of 1.250 at 25° C. to the 50-cc. mark, shaking, and allowing to stand for 45 min. A precipitate having a density above 1.250 was then read to the nearest tenth of a cubic centimeter. The value thus obtained times 10 is considered the density index. Data are presented on the density of 30 samples of spray-process dry milk solids. The density index of these samples ranged from 125 to 24, the variation being due apparently to occluded air cells. Practically no air cells were observed in the particles dried by the roller process.

Estimation of submicroquantities of calcium, A. E. SOBEL and I. A. KAYE (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 2, pp. 118-120).—By the method described, submicroquantities (0.004-0.040 mg.) of calcium are determined titrimetrically with the use of an ordinary 5- to 10-cc. microburette. The calcium, precipitated as the oxalate in a specially designed centrifuge tube, is converted to the carbonate by heating at 475°-525° C. The carbonate is dissolved in an excess of 0.01 N hydrochloric acid by heating, the excess HCl then being determined iodometrically by the addition of an excess of potassium iodate and potassium iodide, this resulting in the release of iodine equivalent to the excess acid. The iodine is determined by titration with approximately 0.0007 N sodium thiosulfate, using starch as an indicator. "This procedure retains the theoretical and practical advantages of the methods where calcium oxalate is converted to calcium carbonate and combines with it the sensitivity of iodometric titrations. All solutions are standardized against the relatively stable 0.01 N hydrochloric acid used."

A method for rapid determination of magnesium in body fluids and some preliminary results on clinical material, B. CASSEN (*Jour. Lab. and Clin. Med.*, 25 (1940), No. 4, pp. 411-413, figs. 2).—The rapid spectrographic method described involved the use of 1 or 1.5 cc. of the body fluid diluted with distilled water to 15 cc., this whole amount then being sprayed directly into and on the surface of the electrodes of a carbon spark. While the solution was being sprayed through the spark (pressure regulator on the oxygen tank and atomizer jets adjusted so that 2 min. was required), an exposure was made on an Eastman O-III ultraviolet plate in a small quartz spectrograph. Calibrating exposures were made on each plate with solutions of magnesium chloride containing 1 mg., 0.5, and 0.25 mg. per 100 cc., respectively. The density of the magnesium 2,795.5 line (having the correct range of density for usual concentrations of magnesium in whole blood, blood plasma, cerebrospinal fluid, bile, etc.) was determined with a Hartmann comparator. In about 50 determinations on human blood values of 3-4 mg. per 100 cc. of blood plasma or 6-7 mg. per 100 cc. of whole blood were obtained. Cerebrospinal fluids averaged about 3 mg. per 100 cc.

Crystalline vitamin A palmitate and vitamin A alcohol, J. G. BAXTER and C. D. ROBESON (*Science*, 92 (1940), No. 2383, pp. 203, 204).—The preparation of vitamin A alcohol from rich fish-liver oils is reported. The oils were distilled in a cyclic molecular still, and fractions with extinction coefficients at 328 m μ of 400 or greater were combined and saponified. The vitamin A alcohol concentrate thus obtained was crystallized from ethyl formate (or propylene oxide) at -35° C. and dried in vacuum at low temperature. The solvent-free, pale yellow prismatic

crystals of the vitamin A alcohol melted at 63°-64° and had an average extinction coefficient at 328 m μ of 1,725. An average value of 4,700 for E_{10m}^{1%} (622 m μ) was obtained for the extinction coefficient of the vitamin A alcohol blue color with antimony trichloride. Preliminary biological assay of the vitamin A alcohol indicated a potency greater than 2,700,000 U. S. P. units per gram. Vitamin A palmitate was prepared by esterifying crystalline vitamin A alcohol with palmityl chloride and quinoline in chloroform solution at -15°. The crude ester crystallized from a 2 percent solution in propylene oxide at -30°, and gave pale yellow plates melting at 26°-28° and having an average extinction coefficient of 940. The extinction coefficient of the antimony trichloride blue color with crystalline vitamin A palmitate was found to be 2,490 at 620 m μ . The vitamin A alcohol, its crystalline palmitate, distilled esters from a fish-liver oil, vitamin A 2-naphthoate, and β -carotene were found to be equally stable when stored in refined cottonseed oil (at comparable concentrations) exposed to air in the dark.

Assay of a variety of vitamin B₁ preparations by the fluoro-photometric method, J. W. COLE, W. S. JONES, and W. G. CHRISTIANSEN (*Jour. Amer. Pharm. Assoc.*, 29 (1940), No. 10, pp. 434-436).—This paper reports the successful application of the method of Hennessy and Cerecedo (*E. S. R.*, 82, p. 588) to a wide variety of raw materials, mixtures, and finished products, the latter including complex multivitamin preparations such as the various pastes in capsules. The data reported indicate good agreement between results obtained by the chemical method and those obtained by direct bio-assay of the product, or calculated from the potencies of the components as determined by bio-assay. The preparation of the samples, the most important and often the most difficult part of the procedure, varies from preparation to preparation, and is not reported. It is pointed out, however, that this was successfully accomplished as indicated by the assay results.

The quantitative determination of vitamin C in the urine [trans. title], T. NAGAYAMA, T. TOMOI, and T. SAGARA (*Biochem. Ztschr.*, 303 (1940), No. 5-6, pp. 354-363).—In the method described phosphotungstic acid is used to precipitate nonspecific reducing substances other than glutathione, cysteine, and thiosulfate, which are considered to be present in normal urines in too small amounts to introduce errors in the indophenol reaction. After removal of the precipitate the resulting water-clear solution gives a sharp end point in the titration. In practice 20 cc. of urine is first treated with 2 cc. of 20 percent metaphosphoric acid, 3 cc. of a 10 percent phosphotungstic acid solution (10 gm. of phosphotungstic acid + 25 cc. of H₂SO₄, sp. gr. 1.105, made up to 100 cc. with water) is added, and the mixture is centrifuged for 5 min. The supernatant liquid is then titrated against 4 cc. of 2 mg. percent 2,6-dichlorophenolindophenol. Data are given showing quantitative recovery of added ascorbic acid by this method with undiluted and diluted urines, and satisfactory agreement in results obtained by this method and the fermentation method. It is also noted that urine treated with 5 percent metaphosphoric acid and phosphotungstic acid solution and placed in the ice box retains 95 percent of its ascorbic acid activity after 24 hr.

The synthesis of vitamin K₁, L. F. FIESER (*Science*, 91 (1940), No. 2350, pp. 31-36).—An address summarizing the discovery, isolation, identification, and synthesis of vitamin K.

The oxidation-reduction potential of vitamin K₁, B. RIEGEL, P. G. SMITH, and C. E. SCHWEITZER (*Jour. Amer. Chem. Soc.*, 62 (1940), No. 4, p. 992).—The oxidation-reduction potentials of the vitamin in potent alfalfa concentrates prepared according to the method of Riegel et al. (*E. S. R.*, 83, p. 445) and of the synthetic vitamin prepared according to the method of Fieser (*E. S. R.*, 83, p. 735) were determined; values of 358 and 363 mv., respectively, were obtained

for E_0 against the hydrogen electrode at 20° C. In the solvent used, 95 percent ethanol, 0.2 N in hydrochloric acid, and 0.2 N in lithium chloride, the solubility of the vitamin was found to be about 5 mg. per cubic centimeter at room temperature.

Further compounds having antihemorrhagic activity, L. F. FIESER, M. TISHLER, and W. L. SAMPSON (*Jour. Amer. Chem. Soc.*, 62 (1940), No. 4, p. 996).—By using 1,4-naphthohydroquinone as one component, 2-geranyl-, 2-farnesyl-, and 2-phytyl-1,4-naphthoquinone were synthesized in good yield by the method of Fieser et al. (*E. S. R.*, 83, pp. 586, 735). The phytyl compound, the most active of the three, gave full response in the chick assay at 50 γ ; similarly the 3-farnesyl derivative of 2-methyl-1,4-naphthoquinone was more potent than the 2-geranyl derivative but somewhat less active than vitamin K. Other compounds synthesized and their respective activities as determined are as follows: 2,3,5-trimethyl-6-phytyl-1,4-benzoquinone, no vitamin K activity; 2-methyl-3-phytyl-5,8-dihydro-1,4-naphthoquinone, active at a level of 5 γ –6 γ ; the β,γ -dihydride of the synthetic vitamin K₁, active at 6 γ as the hydroquinone diacetate; the $\beta,\gamma,5,6,7,8$ -hexahydride of the vitamin, slight activity as the diacetate derivative; butadiene-toluquinone, marked activity; 2-methyl-5,8-dihydro-1,4-naphthohydroquinone, marked activity in dosages as low as 8 γ ; and 2,4-dinitrophenylhydrazone, moderate activity.

Soybean oil and soybean protein, H. L. WALSTER (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 2, pp. 5–7).—This short article comprises a brief partial summary of the industrial uses of soybean meal, oil, and proteins, and some discussion of varieties suitable for North Dakota agricultural conditions, including analyses.

Investigations in the sulfuring of fruits for drying, J. D. LONG, E. M. MRAK, and C. D. FISHER (*California Sta. Bul.* 636 (1940), pp. 56, figs. 18).—Satisfactory sulfuring was found to require (1) absorption by the freshly cut fruit of sulfur dioxide sufficient to allow for retention of enough of the preservative to maintain high quality in the fruit after normal drying and storage losses, (2) rapid drying with low sulfur dioxide loss, and (3) storage at temperatures and humidities low enough to permit retention of the sulfur dioxide. The survey and experimental work here reported are concerned with the first two of these requirements.

It was found that in a sulfur house of construction sufficiently tight to prevent drafts, vents to provide air for burning the sulfur are necessary. For the type of vents recommended, a fixed ratio must be maintained between the vent area and the surface area of the sulfur burner. Doors hinged at the side and secured with refrigerator-type latches are preferable to vertical sliding doors or those hinged at the top when the door opening does not exceed 4 ft. For wider openings a door hinged at the top and secured against the jambs with refrigerator-type latches is preferable. The interior surfaces of sulfuring compartments should be painted with acid-resistant paints, regardless of the construction material, for durability and to tighten the structure against air leakage.

Sulfur should be burned in a clean metal pan of 10-in. diameter or in clean concrete hearths of equivalent area. Unlined earthen pits are unsatisfactory. Insulated, regenerative, or forced-draft burners may be desirable for burning the poorer grades of sulfur, or those carrying contaminants. The black film or scum from some low-quality sulfurs consists chiefly of carbon or carbonaceous matter. Of the various kinds of organic materials added to test samples of a high-quality sulfur, petroleum oils were found to cause the formation of a black surface film most rapidly. This decreased the percentage of sulfur

burned. By increasing the temperature of poor-burning sulfurs to cause more rapid volatilization, poor-quality sulfur could be burned completely. A good grade of refined sulfur is recommended as being more economical and less troublesome than cheaper grades. The sulfur should burn completely, leaving not more than 1 or 2 oz. of residue from the standard 4- or 5-lb. charge.

The temperatures at various points in the sulfur house commonly showed a difference of 20° F. between ceiling and floor. Sulfuring fruit at the relatively high temperatures of 100°–120° tends to decrease absorption but increases retention of sulfur dioxide. Fruits sulfured at high temperatures, however, bleed more readily than when sulfured at lower temperatures.

The freshly sulfured fruit should be dried as rapidly as possible. Every possible advantage should be taken in the location of the drying yard, and in placing the fruit on the drying field, to maintain conditions favorable to rapid moisture evaporation. Dehydration offers definite advantages in coastal areas where climatic conditions during the drying season are unfavorable to the production of a high-quality product.

AGRICULTURAL METEOROLOGY

Weather analysis and forecasting: A textbook on synoptic meteorology, S. PETERSEN (*New York and London: McGraw-Hill Book Co., 1940, pp. XVI+505, figs. 249*).—The author has endeavored to meet a widespread demand by presenting in comprehensive form the results of recent researches, scattered in many papers and journals (91 references), setting forth the principles and theories underlying the modern methods of weather analysis and forecasting and in such a manner that their application to actual forecasting may be facilitated. The 11 chapters deal, respectively, with air-mass characteristics; stability and instability in relation to weather phenomena; production and transformation of air masses; kinematic analysis—wind and pressure; kinematic analysis—frontogenesis; frontal characteristics; waves and cyclones; isentropic analysis; forecasting of displacement of pressure systems, fronts, and air masses; deepening and filling; and the technic of analysis and forecasting. A list of the meteorological stations of the world and author and subject indexes are included.

The geographic-complex method for the study of climate, I. K. ТИХОМИРОВ (*U. S. Mo. Weather Rev., 68 (1940), No. 8, pp. 214–216*).—This paper aims to present the general ideas of the proposed method and to show in broad outline a practical way of developing it. The complexity of the relation between climate and landscape is fully appreciated, but the multitude and variety of the objects in nature that reflect climate provide a wide and promising field for search after the indicators of climate in the landscape. It is believed that such a search, properly organized and employed on a large scale, will reveal means for simplifying the entire problem and will also yield considerable accessory information toward the practical realization of the proposed method of climatological investigation.

Reliability of station-year rainfall-frequency determinations, K. CLARKE-HAFSTAD. (*U. S. D. A.*). (*Amer. Soc. Civ. Engin. Proc., 66 (1940), No. 9, pp. 1603–1622, figs. 2*).—The author discusses the factors affecting the accuracy of rainfall frequency determinations and suggests a method involving a statistical test for persistence in estimating the reliability of frequencies calculated by the station-year method. It is emphasized that the accuracy of rainfall frequency values should be considered carefully in designing flood and erosion control structures.

Water planning and rainfall: The story behind Minnesota's water supply, W. S. OLSON (*Conserv. Volunteer*, 1 (1940), No. 1, pp. 10-12).—A semipopular summary of meteorological data for the State over a period of years.

The analysis of hydrologic data for small watersheds, W. W. HORNER (*U. S. Dept. Agr., Soil Conserv. Serv., 1940, SCS-TP-30*, pp. [5]+103, figs. 14).

Hydrologic studies: Compilation of rainfall and run-off from the watersheds of the Missouri Valley Loess Region Conservation Experiment Station, Clarinda, Iowa, 1939, L. H. SCHOENLEBER (*U. S. Dept. Agr., Soil Conserv. Serv., 1940, [SCS-TP-31, Sup.]*, pp. [33], figs. 24).—This supplements the data for 1934-38 (E. S. R., 83, p. 590).

Hydrologic studies: Compilation of rainfall and run-off from the watersheds and terraced areas of the Fort Hays Conservation Experiment Station, Hays, Kansas, 1930-38, R. R. DRAKE, S. A. MICHAEL, and R. O. BAUM (*U. S. Dept. Agr., Soil Conserv. Serv., 1940, SCS-TP-37*, pp. [202], figs. 137).

Monthly Weather Review [July-August 1940] (*U. S. Mo. Weather Rev.*, 68 (1940), Nos. 7, pp. 181-209, pls. 12, figs. 4; 8, pp. 211-239, pls. 12, figs. 6).—In addition to the usual detailed summaries of meteorological and climatological data, including observations on aerology, weather on the Atlantic and Pacific Oceans, and rivers and floods; solar radiation and sunspot data; and other information, these numbers contain an article noted on page 441 and the following contributions:

No. 7.—Night Radiation and Unusual Minimum Temperatures Near New Orleans, La., by W. F. McDonald (pp. 181-185); and Radiative Cooling in the Lower Atmosphere, by W. M. Elsasser (pp. 185-188).

No. 8.—Wind Force and Exceptional Visibility at Sea, by I. R. Tannehill (pp. 211-213); and Tropical Disturbances of August 1940, by J. H. Gallenne (pp. 217, 218).

SOILS—FERTILIZERS

[Soil investigations by the New Haven Station] (*Connecticut [New Haven] Sta. Bul.* 438 (1940), pp. 520-524, 525, 526).—These have included a study of 12 humus materials with reference to the development of Connecticut muck and peat resources to replace imports no longer available, soil leaching studies, fertilizers for vegetable crops, boron deficiency in soils, apple-root and soil-moisture studies, fertilizer ratios, response of ash trees to soil fertility in station frames, chemical fertility of pasture and vegetable field soils, soil fertility studies in the forest nursery, and forest lysimeter studies.

[Soil investigations by the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 399 (1940), pp. 18-21).—Yield increases of corn, oats, wheat, and hay from phosphate applications are reported by C. F. Noll, and correlation of soil nitrogen with yields, nitrogen fixation by micro-organisms, and plant growth as an index of soil fertility, all by J. W. White. Mineral differences among soils are noted by C. D. Jeffries.

[Illinois soil reports] (*Illinois Sta. Soil Rpts.* 67 (1940), pp. 28, figs. 12, maps 2; 68, pp. 27, figs. 12, map 1; 69, pp. 39, figs. 14, map 1).—These reports add three further counties to those covered by State soil survey reports previously noted (E. S. R., 82, p. 154): Nos. 67, De Witt County, by G. D. and L. H. Smith; and 68, Jasper County, and 69, Cumberland County, both by R. S. and L. H. Smith.

Soil survey of Steuben County, Indiana, L. R. SMITH ET AL. (Coop. Ind. Expt. Sta.). (*U. S. Dept. Agr., Bur. Plant Indus. [Soil Survey Rpt.]*, Ser. 1933, No. 35, pp. 63, figs. 2, map 1).

Rain simulator studies of the effect of slope on erosion and run-off, 1938.—A preliminary report, H. L. BORST and R. WOODBURN (*U. S. Dept. Agr.*,

Soil Conserv. Serv., 1940, SCS-TP-36, pp. [54], pls. 10, figs. 12).—By means of an artificial rainfall apparatus developed by the Soil Conservation Service at the Hydraulic Laboratory of the National Bureau of Standards, the amount and intensity of rainfall could be held constant, the length of slope constant, and the land use constant by using fallow plats. Detailed descriptions and photographs of the equipment are given. Obviously soil type could not be held constant. With conditions thus regulated, studies from the Northwest Appalachian Soil and Water Conservation Experiment Station at Zanesville, Ohio, are reported on the effect of degree of slope on erosion and run-off. Plats one-hundredth acre in area (72.6 by 6 ft.) were used. The slope varied from 2.9 to 22.5 percent. The steeper slopes are classified as Muskingum silt loam soil, whereas the more gentle sloping ridge tops are classified as Welston silt loam.

Percentage and rate of run-off and infiltration determinations were made under dry and wet soil conditions. No relationship was found between slope and infiltration or between slope and run-off percentage. Run-off percentages under dry soil were quite variable, while with wet soil the run-off percentage was very nearly the same for all slopes. It is also reported that there was no consistent relationship between percentage of run-off and the soil moisture content. The rate of run-off after equilibrium flow was reached was essentially the same for all slopes. The run-off rate during equilibrium flow was rate of rainfall less rate of infiltration.

Soil loss with dry soil from lower slopes assumed a fairly constant rate soon after run-off started. The rate of soil loss followed the rate of water loss rather closely. With slopes of over 9 percent the soil loss varied greatly. Soil losses were considerably lower from the dry soil than under wet soil conditions. The workers explained this difference by a difference in the amount of run-off. Density of run-off did not differ greatly from wet or from dry soil. Soil losses, in general, increased progressively with increased slope under both wet and dry soil conditions. Results on the velocity of run-off as related to slope are to be investigated further. Soil losses exhibited an exponential relationship to velocity of flow.

Soil management for intensive vegetable production on sandy Connecticut Valley land, M. F. MORGAN and H. G. M. JACOBSON (*Connecticut [New Haven] Sta. Bul. 439 (1940), pp. 553-592, figs. 6*).—Ten years' results of intensive soil management in connection with vegetable production in the Connecticut Valley tobacco area on Merrimac sandy loam (deep phase) are presented. The first 3 yr. of the study involved comparisons of concentrated fertilizer materials prepared to contain magnesium and manganese, but no measurable response was obtained from them, as lime applications were necessary before most vegetables could be grown.

Fertilizer, manure, and lime experiments indicated that high yields of miscellaneous vegetable crops can be produced without depleting the soil by a combination of moderate manuring and the application of a medium rate of a complete fertilizer. The presentation of a summary of climatic conditions in relation to yield and fertilizer response for each year is helpful in analyzing the results. In the wetter seasons half-rate fertilizer applications are usually insufficient, and additional fertilizer is relatively more effective than manure for radishes, spinach, and the later planting of lettuce and beets. Manure alone, even at high rate, gives poor results during wet seasons, except for crops that extend their growing season into the warm months. Also, during the periods of heavier rainfall fertilizer of concentrated grade is less effective than normal-strength grade, and high nitrogen treatment (135 lb. of nitrogen per acre) is decidedly superior to the standard rate of 90 lb. per acre except for the later planting of lettuce, for carrots, and for peppers.

For drier seasons, when much less fertilizer is lost by leaching, the following observations were made: (1) Half-rate fertilizer treatment, while less effective than the full-rate, gave proportionately larger yields than in the wetter seasons. (2) The addition of manure to the half-rate treatment is relatively more effective than applying the full-rate fertilizer treatment without manure. (3) Manure alone gave better results than in the wetter years. (4) Fertilizer of concentrated grade gave equally good or better results than the normal-strength grade, except for beets. (5) The high nitrogen treatment was less effective.

Manure applied at the rate of 40 tons per acre, not excessive for vegetable production in Connecticut, caused a considerable increase in the organic-matter content of the soil, while a 20-ton application also tended to increase it. The application of nitrogen to the preceding rye cover crop was quite effective, and there is an indication that this plan tends to give a better distribution of nitrogen availability through the season. Liming acid soils to keep the reaction at from pH 6.2 to 6.6 is deemed necessary in connection with the production of good crops of spinach, lettuce, radishes, beets, carrots, peppers, and lima beans.

Fertilizers supplying from 90 to 135 lb. of nitrogen, from 90 to 135 lb. of phosphoric acid, and from 120 to 180 lb. of potash per acre are deemed desirable for intensive vegetable production on unmanured land. A potato fertilizer experiment on old tobacco land indicated the need of a fertilizer supplying from 80 to 100 lb. of nitrogen, from 40 to 80 lb. of phosphoric acid, and from 120 to 160 lb. of potash per acre. For sweetpotatoes in continuous culture on very sandy soils, a fertilizer is suggested which supplies from 30 to 40 lb. of nitrogen, from 80 to 120 lb. of phosphoric acid, and from 120 to 160 lb. of potash per acre. This fertilizer is most effective as a side dressing. It was found that the organic-matter content of the soil is reduced under intensive vegetable production unless manure or other organic soil amendment is applied to the soil at frequent intervals. A combination of green manuring, winter cover crops, and liberal rates of application of a well-balanced fertilizer is satisfactory for maintaining favorable yields of most vegetable crops.

Salt balance in irrigated areas, C. S. SCOFIELD. (U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 61 (1940), No. 1, pp. 17-39, fig. 1).—The relationship of salt input to salt output of an area is designated as the salt balance. If the input exceeds the output the salt balance is regarded as adverse. Results from three related irrigated areas are reported; two are irrigated from the Rio Grande in the vicinity of El Paso, Tex., and the third from the Colorado River in the vicinity of Yuma, Ariz. These areas were studied because of the relatively high concentration of salt in the irrigation waters, averaging approximately 1 ton of dissolved salts to an acre-foot of water, and because of the fact that it was possible to measure the input and output at gaging stations where the water entered and left the areas. As to evaporation losses, consideration must also be given to water entering as rainfall, and the total salt output includes not only the dissolved salts carried away by the drainage and unused irrigation water but also the salts removed by the crops, the quantity that has been removed from solution in the soil, and the quantity that may have decomposed in the soil. The difficulty encountered in determining the extent of these effects in the field is brought out. Studies under controlled conditions are suggested for the investigation of these important factors.

A laboratory experiment was directed toward finding (1) the proportion of the irrigation water that must be allotted to root-zone leaching in order to prevent the accumulation of soluble salts in the root zone, and (2) what proportion of the dissolved salts of the irrigation supply is absorbed by the crop

plant. With minimum salt concentrations of irrigation water of 991 p. p. m. during a 4.5-yr. period, it was necessary to allocate 22.5 percent of the input to root-zone leaching in order to prevent salt accumulation in the soil. In regard to the salts absorbed by the plant, it was found that for alfalfa during the period 13.7 percent of the total salts contained in the input water was so absorbed.

Aspergilli in the soils of Buenos Aires [trans. title], P. NEGRONI and T. NEGRI (*Physis*. 15 (1939), No. 47, pp. 193-212, figs. 11; *Eng. abs.*, p. 121).—About half of the 25 compound samples of soils (mostly from gardens) studied failed to reveal Aspergilli. Those obtained were *Aspergillus niger*, *A. terreus*, *A. fumigatus*, *A. sulphureus*, *A. flavus-oryzae*, and *A. nidulans*, named in the order of their frequency. A key and discussion of these species are included. There are 24 references.

Commercial fertilizers in 1939-40, G. S. FRAPS, T. L. OGIER, and S. E. ASBURY (*Texas Sta. Bul.* 593 (1940), pp. 47).—The statistics on fertilizers sold in Texas, information regarding the fertilizer law, and analyses of 1,086 samples of fertilizers are reported. The fertilizer grades adopted for Texas are given. Nonacid fertilizers should be used on soils having a pH of 5.5 or lower. However, since most Texas soils are generally only slightly acid, or even alkaline, the use of non-acid-forming fertilizers is not necessary at present. Under neutral or alkaline soils the ordinary fertilizers are preferable to non-acid-forming fertilizers.

Soft phosphate with colloidal clay has an availability to plants on the average of about 40 percent of that of the available phosphoric acid in 20 percent superphosphate. Manganese, magnesia, sulfur, calcium, boron, iodine, zinc, or other secondary fertilizing elements are reported as not being needed as additions to Texas soils at present. Claims for the beneficial action of vitamin B₁ in plant growth had to be revised, pending studies wherein vitamin B₁-response comparisons are made. Plant nutrients were found to cost less per pound in the more concentrated than in the less concentrated fertilizers. Available phosphoric acid cost slightly less in 20 percent superphosphate than it does in 18 percent.

AGRICULTURAL BOTANY

The Badianus manuscript (Codex Barberini, Latin 241), Vatican Library: An Aztec herbal of 1552, E. W. EMMART (*Baltimore: Johns Hopkins Press, 1940*, pp. XXIV+341, pls. [122], figs. 2).—Originally written by an Indian physician in Aztec and translated by another Indian into Latin, the present translation of this monumental work into English gives a true picture of certain aspects of Aztec medicine at the time of the Conquest. For the botanist, it makes available testimony as to the occurrence of definite plants at a given time in Mexico, and the facsimile color illustrations represent the earliest known plant pictures of American botany. For the pharmacologist and pharmacist, the interest will be largely in the use and preparation of drugs, among which are not only vegetable but also animal and mineral remedies. The foreword is by H. E. Sigerist.

Textbook of botany, E. N. TRANSEAU, H. C. SAMPSON, and L. H. TIFFANY (*New York and London: Harper & Bros.*, [1940], pp. XI+812, pls. 4, figs. 424).—"This textbook of botany represents the authors' ideas of some of the gradual changes in objectives, content, emphasis, sequence, and procedure in general botany that are necessary to incorporate effectively appropriate new discoveries in science and their various applications to human welfare. . . . Material from

all the artificial subdivisions of botany is included, not because we intended to survey the entire field but because the synthesis of material from all phases of botany is necessary to give a student a general perspective of his relations to his plant environment."

[Botanical papers] (*Bose Res. Inst., Calcutta, Trans.*, 13 (1937-39), pp. 1-254, pls. 2, figs. 17).—The following are included: Proteolytic Enzymes of the Leaves of *Clerodendron infortunatum*, by H. N. Banerjee (pp. 1-22); Investigation on the Catalase Activity of Jute Seeds (*Olitorius* and *Capsularis*), by A. Guha-Thakurta and B. K. Dutt (pp. 83-92); Catalase Activity of *Cajanus* Seed at Different Stages—Pre-resting, Resting, and Post-resting, by B. K. Dutt and A. Guha-Thakurta (pp. 93-103); Investigation on the Effect of β -Indolyl Acetic Acid on the Longitudinal Growth of Leaves of *Vallisneria spiralis* in Nutrient Solution, by B. K. Palit (pp. 139-157); Polarity of Hormone Transport in the Coleoptile of *Triticum*, by B. K. Dutt and A. Guha-Thakurta (pp. 203-214); and Effect of High Concentration Auxin on the Growth and Geotropism of the Coleoptile (*Triticum*), by A. Guha-Thakurta and B. K. Dutt (pp. 215-254).

Abstracts of dissertations presented by candidates for the degree of Doctor of Philosophy, summer quarter, 1939-40 (*Ohio State Univ., Abs. Doctoral Diss.*, No. 31 (1940), pp. VII+381, pls. 4, figs. 23).—The following are included: A Study of the Mineral Composition of Bluegrass as Influenced by Soil Type and Treatment With Special Reference to Certain Trace Elements, by M. H. McVickar (pp. 195-201); The Effect of Growth Substances on the Absciss Layer in Leaves of *Coleus*, by R. M. Myers (pp. 217-226); and Studies on the Life and Death of Bacteria, by E. A. Steinhaus (pp. 325-331).

Taxonomy and floristics of the Americas (July to December 1939), H. N. MOLDENKE (*Chron. Bot.*, 6 (1940), Nos. 6, pp. 129-131; 7, pp. 154-156).—A list of contributions arranged systematically and including paleobotany, algae, and fungi, as well as bryophytes and higher plants, family or generic names of the plants, and the names of authors. See also previous notes (*E. S. R.*, 81, p. 621; 83, p. 596).

The vegetation of Texas, B. C. THARP (*Houston: Anson Jones Press*, 1939, pp. XVI+74, pls. [2, figs. 17]).—The author of this publication, issued for The Texas Academy of Science, presents brief summaries of the dominant features of each of the 18 major vegetational regions (shown also on a map) and annotated lists of the ferns and flowering plants of the State, based on collections in the herbarium of the University of Texas.

Aquatic vegetation of the Allegheny and Chemung watersheds, R. McVAUGH. (Univ. Ga.). (*N. Y. State Conserv. Dept. Ann. Rpt.*, 27 (1937), Sup., pp. 176-195, fig. 1).—Appended to the text is an annotated list of species which gives the abundance and distribution of the 122 larger aquatic plants found in the area.

An annotated list of Utah grasses, B. F. HARRISON (*Utah Acad. Sci., Arts, and Letters, Proc.*, 16 (1938-39), pp. 23-35).

New and extended ranges for Utah plants, W. P. COTTAM, A. O. GARRETT, and B. F. HARRISON (*Utah Univ. Bul.*, 30 (1940), No. 16, pp. 11).—An annotated list.

Additions to the algae of Oklahoma, C. E. TAFT. (Ohio State Univ.). (*Okla. Acad. Sci. Proc.*, 20 (1940), pp. 49-54).—An annotated list.

Taxonomic relationships in the genus *Gossypium*, S. C. HARLAND (*Jour. Wash. Acad. Sci.*, 30 (1940), No. 10, pp. 426-432).—The author concludes that the Bourbon group is distinct from the upland group on both morphological and genetic grounds, and believes that the assemblage of Bourbons is a good

(taxonomic species, which should continue to be known as *G. purpurascens* pending a better name.

A new Polygonum from Garfield County, Utah, J. F. BRECKLE and W. P. COTTAM (*Utah Univ. Bul.*, 30 (1940), No. 15, pp. 7, figs. 5).—*P. utahense* n. sp.

New species and new names among Arizona Asteraceae, S. F. BLAKE (U. S. D. A.). (*Jour. Wash. Acad. Sci.*, 30 (1940), No. 11, pp. 467-472).

A phytosociological study of the herbaceous plants in two types of forests in central Indiana, J. E. POTZGER and R. C. FRIESNER (*Butler Univ. Bot. Studies*, 4 (1940), Papers 11-14, pp. 163-180).—A study of 9 stands of oak-hickory and 8 of beech-maple. Oak-hickory had 45-50 percent more species than beech-maple. Most species had a low frequency, fidelity, and density percentage, which may have been due to deficient soil moisture in the oak-hickory and to heavy leaf litter and reduced light in the beech-maple stand. The evidence indicates that if classification of forest types be made on the basis of herb layer, Indiana has various types of oak-hickory and beech-maple stands with similar arboreal crown cover. There are 13 references.

Ecology of species of grass and arable lands, V. M. CONWAY (*Chron. Bot.*, 6 (1940), No. 4, pp. 83, 84).—A discussion of recent work on factors changing grassland vegetation.

The effect of overgrazing and erosion upon the biota of the mixed-grass prairie of Oklahoma, C. C. SMITH (*Ecology*, 21 (1940), No. 3, pp. 381-397).—The effects of overgrazing on the plants and animals of this prairie are detailed in the text and in numerous tables and summarized.

Polygonal graphing of ecological data, A. H. HUTCHINSON (*Ecology*, 21 (1940), No. 4, pp. 475-487, figs. 5).—As a result of the detailed study presented (31 references), it is suggested that consideration of polygonal graphing as a method of estimating bioclimatic, bioedaphic, and biotic standards would facilitate the progress of ecology.

Exclosure technique in ecology, R. F. DAUBENMIRE. (Univ. Idaho). *Ecology*, 21 (1940), No. 4, pp. 514, 515).—The author points out a type of fault in technic and emphasizes attention to the problem of minimizing the effect of the barrier on wind movement, insolation, and precipitation. It is recommended that the exclosure be of the largest size and of the lowest, most open structure which can give the desired type of protection.

The interaction of higher plants and soil micro-organisms.—I, Microbial population of rhizosphere of seedlings of certain cultivated plants, M. I. TIMONIN. (N. J. Expt. Stas. et al.). (*Canad. Jour. Res.*, 18 (1940), No. 7, Sect. C, pp. 307-317, figs. 3).—"The microbial population in the rhizosphere of wheat, oats, alfalfa, and peas was studied, and the relative abundance of different types of micro-organisms recorded. By means of the plating method it was found that bacteria and actinomycetes were 7 to 71 times greater in the rhizosphere than in the soil distant from the roots, whereas fungi were but 0.75 to 2.1 times more numerous. Different varieties of plants affected the activity of the various groups of soil micro-organisms differently. Thus fungi were more numerous in the rhizosphere of oats, and bacteria in the rhizosphere of alfalfa. Seventeen genera of fungi were represented in isolates from the rhizosphere of seedlings and the soil distant from the roots. However, no marked difference was observed in the types isolated from the rhizosphere of different varieties of seedlings." A fungus isolated from the rhizosphere of alfalfa proved to be *Spicaria terrestris* n. sp., and the genus *Spicularia* Persoon was amended to include it.

Response of the peanut plant to inoculation with Rhizobia, with special reference to morphological development of the nodules, O. N. and E. K

ALLEN. (Univ. Hawaii). (*Bot. Gaz.*, 102 (1940), No. 1, pp. 121-142, figs. 11).—Each of 59 *Rhizobium* strains from various legumes proved infective to peanut roots, 17 strains markedly enhancing growth, 9 being effective to a less extent, and 33 proving decidedly nonbeneficial. All nodules were located in the root axils, those produced by the ineffectual strains being inconspicuous. Abnormal nodose formations, proving to be hypertrophied parenchymatous tissue containing heavy deposits of starch, were frequent at the rootlet bases of nitrogen-deficient plants. Root infection resulted from invasion through ruptured tissue at the site of lateral root emergence. No data were obtained supporting root hairs as avenues of infection. The origin of the nodule was in the pericyclic cells adjacent and in juxtaposition to the protoxylem strand from which the rootlet had emerged. Dissemination of the Rhizobia throughout the bacteroidal area was effected by passive transmission to new cells during the laying down of the cell plate. Differentiation of the nodule resulted from the formation of a peripheral meristem serving in the production of a nodule cortex and a bacteroidal area. A branched vascular system supplying the nodule surrounded the bacteroidal area and connected the xylem and phloem of the main root through a single connecting strand at the base of the nodule. Spherical plastid-like bodies, identified as aleurone grains, were abundant in the infected cells of the bacteroidal area. It is believed that aleurone is directly connected with the symbiosis, and is significant in the nitrogen-fixation process. Initial stages in nodule degeneration were characterized by the formation of a suberized layer of cells at the base of the nodule, thereby cutting off the vascular supply. Consequently, the bacteroidal area assumed a slimy consistency and Rhizobia invaded the intercellular spaces. The bacteroidal area of many nodules was absorbed by the plant prior to collapse of the old nodule cortex. There are 42 literature citations.

Studies on soybean nodule bacteria (*Rhizobium* sp.), I, J. A. AGATI and E. H. GARCIA (*Philippine Jour. Agr.*, 11 (1940), No. 1-3, pp. 271-283, pls. 3).—Although each of the seven isolates obtained was capable of producing nodules, only three proved desirable from the standpoints of both nodulation and nitrogen fixation.

Liebig and the organic nutrition of plants, H. R. KRAYBILL. (Ind. Expt. Sta.). (*Amer. Fert.*, 93 (1940), No. 6, p. 6).—An abstract.

The physiology of cell elongation, A. N. J. HEYN (*Bot. Rev.*, 6 (1940), No. 10, pp. 515-574).—A monographic review (162 references) on the plant cell, including considerable space devoted to the author's own work.

New research on growth and tropisms, H. G. DU BUY. (Univ. Md.). (*Chron. Bot.*, 6 (1940), No. 4, pp. 80-83).—A summary of recent work (about 50 references) on plant growth regulators, their origin, physical and chemical properties, translocation, mode of action, histological and cytological effects, and practical applications.

The effect of light, gravity, and centrifugal force on buckwheat seedlings, J. M. SMITH (*Okla. Acad. Sci. Proc.*, 19 (1939), pp. 65-67).—A brief summary of experimental results, with the conclusion that plants respond to these physical forces with a considerable degree of accuracy.

The relation between frost resistance and the physical state of protoplasm.—I, The protoplasm as a whole, J. LEVITT and D. SIMINOVITCH (*Canad. Jour. Res.*, 18 (1940), No. 11, Sect. C, pp. 550-561, pl. 1, fig. 1).—"The protoplasm of hardy and nonhardy cells was compared with regard to displacement by centrifuging, rounding-up time on plasmolysis, deplasmolysis injury, rate of Brownian movement, resistance to and recovery from distortion by micromanipulation. The conclusions are: (1) When the cells are in the normally hydrated (i. e.,

turgid) condition, there is either no difference in the consistency of hardy and nonhardy protoplasm, or else it is slightly less in the latter; (2) when the cells are plasmolyzed to the same degree (i. e., with a weaker plasmolyte in the case of the nonhardy), there is no difference in consistency; (3) when the cells are in equilibrium with one and the same concentration of plasmolyte, the protoplasmal consistency of the nonhardy is greater than that of the hardy; (4) the nonhardy are more susceptible to mechanical injury."

A form of low-temperature injury in detached leaves, E. R. ROUX (*New Phytol.*, 39 (1940), No. 3, pp. 271-276, figs. 2).—The author describes a form of borrowing following exposure to temperatures above the freezing point of the cell sap in detached leaves of evergreen loquat, *Viburnum* sp., and *Ficus* sp. Leaves picked in summer were not susceptible, and leaves otherwise susceptible were protected by previous exposure for a few days to a higher temperature before placing in cold storage. Attempts to relate this susceptibility to low-temperature injury in winter leaves to air temperatures, humidities, and light intensities at time of picking were unsuccessful.

Effect of sulphur dioxide on vegetation, M. KATZ (*Chron. Bot.*, 6 (1940), No. 6, pp. 131, 132).—A rather extensive digest of the contents of the book already noted (E. S. R., 81, p. 769).

Injection for the diagnosis of mineral deficiencies in the tomato, the potato, and the broad bean, H. HILL and W. A. ROACH (*Ann. Bot. [London]*, n. ser., 4 (1940), No. 15, pp. 505-521, pls. 3, figs. 6).—The authors studied the distribution following injection of an aqueous solution of acid fuchsin into an interveinal area of a leaf blade, the leaf tip, and the leaf stalk of the three plant species grown in sand culture deficient in one or more of the elements N, P, K, Ca, Mg, and B and injected with solutions containing the deficient element. The plants responded to all the elements injected, and the regions responding to the nutrient injections were similar to those colored by the dye. The response was general or local according to the injection method used. The distribution of the injected liquids could be explained by the arrangement of the vascular system. The methods described enable diagnosis of deficiencies to be made in 7-21 days and provide means of rapidly and without injury making good any deficiency to which the plant has been subjected.

Mineral nutrients in relation to flower development, W. F. LOEHWING (*Science*, 92 (1940), No. 2397, pp. 517-520).—A review of recent research on mobilization of materials and other phenomena associated with reproduction.

The role of potassium in plants, M. E. WALL. (N. J. Expt. Stas.). (*Chron. Bot.*, 6 (1940), No. 6, p. 133).—A discussion of recent findings and suggestions for future research (E. S. R., 83, p. 598).

Boron absorption by sunflower seedlings, C. S. SCOFIELD, L. V. WILCOX, and G. Y. BLAIE. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 61 (1940), No. 1, pp. 41-56, figs. 5).—Seedlings of *Helianthus annuus* were grown for 6 weeks in culture solutions differing only in B content. Without B or special purification of reagents growth was arrested before the first leaves had fully developed, but in solutions containing 0.05-2.5 p. p. m. of B growth was normal. The B content of the leaves increased progressively with its content in the culture solution. It is suggested that sunflower seedlings may be grown in samples of soil and the leaves analyzed for B as a means of estimating the available B content of the soil in cases of suspected deficiency. The new word "mitotrophic" is proposed to describe such elements as B, Mn, Fe, and Zn, which are essential to plant growth in lesser quantities than such elements as N, K, and P.

The effect of ringing and of transpiration on mineral uptake, E. PHILLIS and T. G. MASON (*Ann. Bot. [London]*, n. ser., 4 (1940), No. 15, pp. 645-650).—

Removal of a ring of bark of sea-island cotton between the foliage region and the root depressed the uptake of Br by the root within a period of a little over 2 hr. after ringing. The wood alone in the ringed plants transmitted as much Br up the stem as the bark and wood together in the normal plants. Increased transpiration caused increased uptake of Br in ringed plants, and a greater proportion of the absorbed Br was carried into the aerial parts of the plant under high transpiration than under low. It is believed the transpiration affects mineral uptake by altering the concentration in the absorbing region of the root and possibly also by oxygenating the root, while assimilation affects uptake by altering the solvent capacity of the root.

The effect of ringing on the upward movement of solutes from the root, E. PHILLIS and T. G. MASON (*Ann. Bot. [London], n. ser., 4 (1940), No. 15, pp. 635-644, figs. 4*).—Sea-island cotton plants consisting of two branches, a short main stem, and a root were used, in one group both branches being left intact and in a second group one branch being ringed. Ringing of one branch caused a small reduction in uptake of Ca and P by the whole plant. The ringed branch contained more P and less Ca than the normal branch of the ringed group and also more P and less Ca than the branches of the normal plant. It is concluded that the results harmonize with the view that the bulk of the soil solutes ascend the stem in the wood and, provided they are mobile in the phloem, are reexported down the stem in the phloem. It is suggested that the discrepancy between the results here described and those of Curtis (*E. S. R., 52, p. 125*) is due to the fact that the ringed branches in the latter case had to compete for water with a number of unringed branches, while in the present study the ringed branch had only one unringed branch with which to compete.

An observation of the effectiveness of root pressure in the ascent of sap, R. C. FRIESNER (*Butler Univ. Bot. Studies, 4 (1940), Papers 15-18, pp. 226, 227*).—A note on "bleeding" through bark unbroken save by the force of the exudate itself on sprouts of *Acer rubrum* from stumps made 4 yr. previously.

Investigations on the significance of ethereal oils in regulating leaf temperatures and transpiration rates, L. J. AUDUS and A. H. CHEETHAM (*Ann. Bot. [London], n. ser., 4 (1940), No. 15, pp. 465-483, figs. 12*).—Theoretical considerations indicated that vapor screens of ethereal oils around leaves can absorb at most less than 1 percent of the total incident heat radiations. Comparison of leaf temperatures of cherry laurel on irradiation through 15-in. screens of pure dry air and of air saturated with the vapors of anise, rosemary, thyme, verbena, peppermint, lemon, eucalyptus, and lavender oils indicated that differences between leaf and air temperatures tend to increase in the presence of vapor screens, presumably due to transpiration depression arising from the toxic effects of the vapors. Exposure of shoots to 1.5-cm. screens of air saturated with vapors of rosemary, thyme, and anise oils in both high and low light intensities failed to produce measurable effects on transpiration rate, leaf temperature, or stomatal resistance. Studies on the rates of evaporation of oils from filter paper and the associated cooling effects demonstrated that the latter are too small to have ecological significance. It is concluded that, in plants producing them, ethereal oils play no role in regulating water loss or leaf temperatures.

Nitrogen metabolism of the plant embryo, W. L. MCRARY (*Bot. Gaz., 102 (1940), No. 1, pp. 89-96, figs. 4*).—Protein disappearing from the lupine cotyledon was found to accumulate in the axis as amino acids and amides. Plants grown in darkness hydrolyzed more protein and transported the products to the axis sooner than plants grown in the light. Longitudinal plant growth may occur to a marked extent with little or no change in the actual protein content of the part affected. The amino and amide nitrogen concentrations in the water of the

tissues remained at the same order of magnitude throughout the first 15 days of germination, suggesting a dynamic relation between these two nitrogen fractions and protein hydrolysis.

Pectic substance of cotton fibres in relation to growth, R. L. WHISTLER, A. R. MARTIN, and C. M. CONRAD. (U. S. D. A. et al.). (*Textile Res.*, 10 (1940), No. 11, pp. 449-452, fig. 1).—Determination of the content of pectic substance at various growth periods suggested three distinct developmental stages of the cotton fiber. The first extended to about the eighteenth day and was characterized by a gradual decrease in pectic substance, the second extended to about the thirty-fifth day, during which time there was rapid decrease in pectic material, while the third extended to maturity, with only a slight decrease in pectic content. These three stages are said to agree well with the conclusions of other investigators from different types of data.

The formation of pyruvic acid in barley respiration, G. M. and W. O. JAMES (*New Phytol.*, 39 (1940), No. 3, pp. 266-270).—"Barley roots poisoned with 0.01-0.1 percent acetaldehyde or 0.3 percent solutions of certain aromatic sulfonic acids developed an ammonia-nitroprusside reaction for pyruvic acid which is not given by normal roots. Pure pyruvic acid was isolated as the 2,4-dinitrophenylhydrazone from cut and darkened leaves poisoned with 0.2 percent 1-naphthol-2-sulfonic acid. Since these poisons inactivate carboxylase, the above results suggest that pyruvic acid is continuously formed by barley tissues and is normally decarboxylated. Further evidence is thus provided for regarding it as an intermediate product in barley respiration."

Effect of phytohormone dust seed treatment on growth and yield of barley under greenhouse conditions, J. W. HOPKINS (*Canad. Jour. Res.*, 18 (1940), No. 10, Sect. C, pp. 507-512).—"Under controlled conditions of air temperature and soil moisture, the growth and yield of barley from seed dusted with 2.5 and 5 p. p. m. of indolylacetic acid in talc was compared with that from control seed dusted with talc only. Neither concentration affected germination. Both accelerated the incidence of tillering by 1 or 2 days, but did not increase the final number of shoots produced. With suboptimal soil moisture both phytohormone concentrations increased the height of the plants by about 3 percent and the dry weight of straw by about 10 percent, but did not increase the yield of grain. No demonstrable effect upon the yield of either straw or grain was observed in a parallel series of plants receiving a more plentiful supply of moisture."

Effects of vitamin B₁ upon the development of some flowering plants, C. L. HAMNER (*Bot. Gaz.*, 102 (1940), No. 1, pp. 156-168, figs. 4).—Vitamin B₁ was added to a number of different plants at 0.01 mg. per liter. No visible differences were detected between the control plants and those receiving B₁, and no significant difference was obtained in wet weight or in the accumulation of dry matter. Under neither a long nor a short photoperiod, nor at high or low planes of nitrogen nutrition, were there detectable differences ascribable to additions of vitamin B₁ to the cultures. Vitamin B₁ had no effect in hastening flowering, on size or number of flowers produced, or on color or quality of flowers in cosmos. Statistically, the differences which could be ascribed to the addition of B₁ as compared with controls under similar environment were never significant.

Chemical and histological responses of bean plants grown at different levels of nutrition to indoleacetic acid, O. SMITH, L. B. NASH, and G. E. DAVIS. (Cornell Univ.). (*Bot. Gaz.*, 102 (1940), No. 1, pp. 206-216, figs. 11).—One lot of kidney bean seedlings was grown under conditions of high nitrogen and low carbohydrate, and another lot under the reverse conditions. Treatment

with indoleacetic acid greatly increased the rate of root formation in the low-nitrogen, high-carbohydrate seedlings, but the response of the other lot was much slower. Apparently the carbohydrates were the limiting factor in the production of new roots after treating the high-nitrogen, low-carbohydrate seedlings with the acid. The high-nitrogen, low-carbohydrate seedlings were less responsive to changes in distribution of dry weight, probably due to the low-carbohydrate supply for transport to the treated region. In general, treatment with the acid was accompanied by greater nitrogen transfer from the upper to the lower parts of the seedlings. Nitrogen movement following treatment was greater from leaves to roots and lower hypocotyl in the high-nitrogen, low-carbohydrate seedlings. Treatment decreased the percentage of total sugars in all parts, and the percentage at both levels of nutrition was still lower at the end of the experiment than in those seedlings not treated with the acid. In general, the percentage of alcohol-insoluble acid-hydrolyzable carbohydrates increased in the hypocotyl and to a lesser extent in the leaves with the age of the seedling and to a greater extent in untreated than in treated plants. The percentage of hydrolyzable carbohydrates in the first internode of untreated seedlings was about the same at the end of the experiment as at the beginning, whereas internodes of treated seedlings decreased in this constituent.

The effect of beta-indole-acetic acid upon isolated plant embryos, M. S. GARDINER (*Mount Desert Isl. Biol. Lab. Bul.*, 1940, pp. 22, 23).—An abstract of studies on *Phaseolus* spp.

Effects of dusts containing indolylbutyric acid and oestrone on the rooting of dormant *Lonicera tartarica* cuttings, N. H. GRACE (*Canad. Jour. Res.*, 18 (1940), No. 7, Sect. C, pp. 283-288).—"Indolylbutyric acid and oestrone, separately and in combination in a series of talc dusts, were applied to dormant cuttings of *L. tartarica*. Indolylbutyric acid treatment, averaged over all oestrone treatments, increased the number of cuttings rooted, the number and length of roots per rooted cutting, the mean root length, and the green weight of leaf produced by the dormant cuttings. The average effect of oestrone on these responses was depressive throughout. Oestrone tended to offset the beneficial effects of the plant growth stimulating chemical, excepting the combination of 100 p. p. m. of each which increased root length. Oestrone alone did not reduce either the number or lengths of root per rooted cutting. The results indicated that the number and length of roots and the green weight of leaf produced are more sensitive responses for demonstrating differences due to indolylbutyric acid concentration in talc than is the percentage of cuttings rooted."

Starch hydrolysis in bean leaves following spraying with alpha naphthalene acetic acid emulsion, J. W. MITCHELL, E. J. KRAUS, and M. R. WHITEHEAD. (U. S. D. A.). (*Bot. Gaz.*, 102 (1940), No. 1, pp. 97-104, figs. 4).—A 1-percent lanolin and water emulsion of the growth substance was sprayed on the upper surfaces of attached bean leaves, and the starch digestion and sugar accumulation under darkness or low light intensity and the rate of starch and sugar accumulation under illumination were studied by quantitative determinations made at intervals after treatment. The percentage of starch and dextrin in treated leaves placed in darkness decreased more rapidly than in control leaves, but noticeable differences were not apparent for several hours. The percentage of sugar in leaves sprayed and placed in darkness increased during that period following treatment when starch digestion was most rapid, but later decreased as the starch reserve was depleted, finally reaching a value about equal to that of control leaves. Leaves depleted of starch, sugars, and

dextrin by holding in darkness and subsequently spraying with the growth substance and then placed in daylight accumulated less sugar, starch, and dextrin during the period of illumination than did comparable untreated leaves.

The role of growth substances in the regeneration of root cuttings, W. PLANT (*Ann. Bot. [London], n. ser., 4 (1940), No. 15, pp. 607-615, pl. 1*).—In root cuttings (thongs) of seakale (*Crambe maritima*) a growth substance was indicated by the *Avena* test. When thongs were treated with α -naphthaleneacetic acid (0.02 percent) roots were produced all along the thong. Repeated decapitation of apex and base eventually resulted in bud production at the base, and from these buds thongs with buds at both ends were produced. When thongs with buds induced basally by decapitation were then treated with β -indolylacetic acid (0.01 percent), roots were subsequently produced at the apex. When the vegetative growth of an "inverted" thong after 5 mo. is compared with a normal "control" thong, morphological differences are observed. Root systems arising from the mass of callus tissue or from the base of the parent thong showed secondary thickening, whereas apically induced root systems of the inverted thongs did not. Normal thongs had subsidiary roots, showing thickening, arising from the basal end only. It is concluded that the differentiation and behavior of the meristematic tissue is determined, in part, by specific concentrations of growth substance, relatively high and low concentrations influencing root and bud production, respectively.

Heteroauxin and the growth of meristems of Brassica, H. W. HOWARD (*Ann. Bot. [London], n. ser., 4 (1940), No. 15, pp. 589-594, figs. 5*).—The author's previous report¹ that a leaf initial had been converted into a root meristem by heteroauxin action he believes to be wrong, the true explanation apparently being that an extra external meristem had been formed in the cotyledon axil above the axillary bud and that this meristem had grown into a root. The problem of the two types of plant meristems is discussed, and it is concluded that root anlagen are formed where the concentration of auxin is high and that shoot anlagen are formed where it is relatively low.

Peptidase activity in the *Avena* coleoptile phytohormone test object, G. S. AVERY, JR., and K. LINDERSTRØM-LANG (*Bot. Gaz., 102 (1940), No. 1, pp. 50-63, figs. 9*).—*Avena* seedlings were grown in darkness at 25° C. on moist filter paper in preparation dishes. When the coleoptiles were 1.5, 4, 10, 17, and 36 mm. long, they were uniformly sectioned at 125 μ or 250 μ and peptidase determinations made on these segments. On a per segment basis, peptidase activity, reduced weight, and cell number were found to decrease in progressively older coleoptiles. For any given coleoptile 4 mm. or more in length, enzyme activity per unit weight or per cell was consistently greater at the tip. Correlations between morphology and auxin and peptidase gradients in the coleoptile are pointed out.

Oxidase systems in the tissues of the higher plants, J. G. BOSWELL and G. C. WHITING (*New Phytol., 39 (1940), No. 3, pp. 241-265*).—A comprehensive review (89 references).

Sexual substances in the algae, K. V. THIMANN (*Chron. Bot., 6 (1940), No. 2, pp. 31, 32*).—A review of recent advances.

Checking and adjusting the alignment of objectives in the binocular dissecting microscope, C. O. HATHAWAY and F. F. FERGUSON (*Stain Technol., 15 (1940), No. 4, pp. 173, 174*).

Combined fixing, staining, and mounting media, C. ZIRKLE (*Stain Technol., 15 (1940), No. 4, pp. 139-153*).—A number of nonvolatile, water-soluble substances can be added to the usual acetocarmine fixing fluids which do not alter

¹ Ann. Bot. [London], n. ser., 2 (1938), No. 8, pp. 933-942, figs. 12.

the fixation image and serve as mounting media when the volatile ingredients have evaporated. Formulas are given for solutions containing dextrin, dextrose, gelatin, pectin, sorbitol, and sucrose. Gum arabic can be incorporated in a formic acid-carminine fixative. The limiting factor in such media in fixing fluids is the osmotic value they give to the solution, but with certain precautions they can replace the usual acetocarmine treatment. Some of the natural balsams can also be incorporated in fixing fluids. Formulas are given for fixatives containing Venetian turpentine, sandarac, Canada balsam, and two synthetic resins. Addition of carmine to the fluids enables one to fix, stain, dehydrate, clear, and mount in one operation. Detailed procedures are presented, with 19 references.

Resins for sealing glycerin mounts, with a note on the use of Clarite (Nevillite V), J. L. MOHR and W. WEHRLE. (Univ. Calif.). (*Stain Technol.*, 15 (1940), No. 4, pp. 174, 175).

The acetocarmine method for fruit material, P. T. THOMAS (*Stain Technol.*, 15 (1940), No. 4, pp. 167-172, figs. 5).—The difficulty of making good acetocarmine preparations of plants with small chromosomes at meiosis is noted. The staining reaction depends on the composition of the prefixative, duration of fixation, strength of acetocarmine, and amount of iron used. Detailed procedures are presented, and suitable combinations of these factors for some fruit plants are described.

Preventing the curling of wood sections, F. HYLAND. (Univ. Maine). (*Yale Univ. School Forestry, Trop. Woods*, No. 64 (1940), pp. 41-43).—The tendency of wood sections to curl while being passed through the higher alcohols was obviated by placing them between fine wire screens, those made of stainless steel, Monel metal, and aluminum being found to withstand corrosion.

Notes on the technique of tree-ring analysis, I, A. E. DOUGLASS (*Tree-Ring Bul.*, 7 (1940), No. 1, pp. 2-8).

A container for growing plants for root studies, N. L. PARTRIDGE. (Mich. State Col.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 11, pp. 907, 908, figs. 2).—The galvanized iron containers described were 10 by 10 in. and 4 ft. deep, with one side detachable. Successful use in studying the relative depth to which certain grasses would root is reported.

A rapid method for excavating root systems of native plants, B. C. THARP and C. H. MULLER. (U. S. D. A. et al.). (*Ecology*, 21 (1940), No. 3, pp. 347-350, figs. 2).—In the "bisect-wash" method described in detail, a smooth face of soil is cut through the plant axis vertically to a depth and breadth to insure inclusion of all roots in the plane of bisection. Horizontal and perpendicular lines are marked off by a cord on this face, and by a jet of water the soil is removed from the whole face of the bisection to a depth of 1-2 in. A second bisection at right angles to the first provides a check on the first to insure a representative sample of the entire root system.

Methods for growing pollen tubes for physiological and cytological studies, O. J. EIGSTI (*Okla. Acad. Sci. Proc.*, 20 (1940), pp. 45-47, figs. 5).—The construction of a chamber for growing pollen tubes is described and the general procedure for its use outlined.

The morphology of pollen tubes in angiosperms, O. J. EIGSTI (*Okla. Acad. Sci. Proc.*, 19 (1939), pp. 105-108, fig. 1).—Twenty species of plants were studied, and the results are briefly summarized.

Comparative histogenesis of vegetative and floral apices in *Amygdalus communis*, with special reference to the carpel, R. M. BROOKS (*Hilgardia [California Sta.]*, 13 (1940), No. 5, pp. 249-306, pls. 4, figs. 11).—The marked histogenic differences found between leaf and flower buds in the almond apparently shed light on the general problem of carpel morphology in angiosperms

and fall to support the classical interpretation that the carpel is homologous with a foliage leaf. The results of this anatomical and developmental study are discussed in detail, and it is concluded that from a developmental standpoint the carpel is a distinct and unique organ among living angiospermous plants. Broad comparative histogenic studies are deemed urgent in order to test this interpretation. Over six pages of references are given.

Structure of end walls in differentiating vessels, K. ESAU and W. B. HEWITT (*Hilgardia* [*California Sta.*], 13 (1940), No. 5, pp. 229-244, pls. 4).—The differentiating vessel elements of the herbaceous angiosperms here considered (pumpkin, corn, tobacco, carrot, and beet) showed intact end walls until the future vessel reached its final diameter and developed secondary lignified layers on the longitudinal walls. Two superposed vessel elements were separated from each other by two cellulose layers—the two primary walls—cemented together by isotropic intercellular substance. There are 31 references.

Developmental anatomy of the fleshy storage organ of *Daucus carota*, K. ESAU (*Hilgardia* [*California Sta.*], 13 (1940), No. 5, pp. 175-226, pls. 14, figs. 12).—This study of the edible tap root of the carrot plant describes, in different stages of development, the tissues making up this organ and interprets its gross morphological features in terms of histological details. There are 38 references.

Anatomy of the vegetative parts of manihot [trans. title], A. P. VIÉGAS (*Inst. Agron. Estado* [*São Paulo*], *Campinas, Bol. Téc.* 74 (1940), pp. 30+[1], pls. 39).

Microbes in a changing world, S. A. WAKSMAN. (N. J. Expt. Stas.). (*Sci. Mo.*, 51 (1940), No. 5, pp. 422-427).—A general review of progress in the study of bacteria.

Proceedings of local branches of the Society of American Bacteriologists (*Jour. Bact.*, 40 (1940), No. 1, pp. 143-169).—Abstracts of the following papers of interest to botany are included: Bacterial-Fungus Antagonisms, by C. L. Porter (p. 144) (Purdue Univ.); The Implications of Variability on the Species Concept in Bacteriology, by R. E. Buchanan (p. 153), The Morphology and Physiology of Certain Myxobacteria of Iowa, by J. M. Beebe (pp. 155, 156), The Relationship of CO₂ Utilization to Succinic Acid Formation by the Coliform Bacteria, by H. G. Wood and C. H. Werkman (p. 158), and The Stimulative Effect of Glucose on the Anaerobic Dissimilation of Citrate by *Streptococcus paracitrovorus*, by H. D. Slade and C. H. Werkman (p. 158) (all Iowa Expt. Sta.); The Influence of Mineral Fertilizers on Symbiotic Nitrogen Fixation, by J. L. Roberts and F. R. Olson (p. 154) (Ind. Sta.); Percentage Utilization of Substrates by the Root Nodule Bacteria, by R. H. Burris and P. W. Wilson (pp. 154, 155), and The Respiration of *Lactobacillus bulgaricus* Near Its Maximum Growth Temperature, by R. M. Stern and W. C. Frazier (pp. 158, 159) (both Univ. Wis.); Bacteriology in the Paper Industry, by F. W. Tanner (p. 155) (Univ. Ill.); Formation of Acetylmethylcarbinol by Cell-Free Juices [from *Aerobacter aerogenes*], by M. Silverman and C. H. Werkman (p. 156), and Cellulose Decomposition by Some Aerobic Organisms, by A. G. Norman and W. V. Bartholomew (p. 156) (both Iowa State Col.); and A Wide-Range H-ion Indicator Produced by an *Actinomyces* Species, by J. E. and H. J. Conn (p. 168).

Cation adsorption by bacteria, T. M. MCCALLA. (Kans. Expt. Sta.). (*Jour. Bact.*, 40 (1940), No. 1, pp. 23-32).—*Escherichia coli* adsorbed cations, and the magnitude of this ability was demonstrated by four methods and measured. Other bacteria were also shown to adsorb cations, and a proposed mechanism is advanced. The adsorbed cations are exchangeable.

GENETICS

Gene and chromosome theory and cytology at the Seventh International Genetical Congress, Edinburgh, 1939, D. G. CATCHESIDE (*Chron. Bot.*, 6 (1940), No. 1, pp. 9-11).—A review of contributions to the congress.

Influence of female stock on the functioning of small pollen male gametes, W. R. SINGLETON. (Conn. [New Haven] Expt. Sta.). (*Natl. Acad. Sci. Proc.*, 26 (1940), No. 2, pp. 102-104).—Although earlier studies showed that when corn plants heterozygous for small pollen-1 sp_1 served as the male parent in crosses less than 1 percent of the sp_1 pollen grains usually functioned, when the sweet corn stocks Purdue 39 and Connecticut 81 received pollen of the constitution sp_1su Sp_1Su 39 and 17 percent, respectively, of the resulting kernels were su . Only about 6 percent (the cross-over ratio between sp_1 and su) would be expected if only Sp_1 grains had functioned. A considerable functioning of sp_1 pollen grains in competition with normal was shown. See also a note by Mangelsdorf (*E. S. R.*, 67, p. 225).

Translocations in maize involving chromosome 3, E. G. ANDERSON and R. A. BRINK. (Univ. Wis. et al.). (*Genetics*, 25 (1940), No. 3, pp. 299-309).—The 21 translocations in corn involving chromosome 3, for which data are reported, are distributed from the neighborhood of d_1 , well out on the short arm, almost to a_1 in the distal part of the long arm.

Genetical studies in cultivated raspberries.—I, Inheritance and linkage, D. LEWIS (*Jour. Genet.*, 38 (1939), Nos. 1-2, pp. 367-379, pl. 1).—Continuing the work of Crane and Lawrence (*E. S. R.*, 66, p. 435), the author describes five new genes— s , b , x , g , and d —controlling the following morphological characters: Spineless shoots, shoots without waxy bloom, red hypocotyl, pale-green leaf, and sepaloid flowers, respectively. In addition, he presents statistical analyses of all gene segregations and describes one linkage group of four genes.

Genetical studies in cultivated raspberries.—II, Selective fertilization, D. LEWIS (*Genetics*, 25 (1940), No. 3, pp. 278-286, fig. 1).—Continuing the series referred to above, the author describes a gene, w , causing differential fertilization in the cultivated raspberry and aberrant ratios and heterogeneity in linked marker genes T and G when the particular genes are segregating on the male side. The action of the pollen tube gene w is to inhibit completely or to retard pollen tube growth at some stage between pollen germination and fertilization. Cross-over values between W and the marker genes T and G are calculated, and a chromosome map with five genes is given.

Research on twins and animal breeding, F. A. E. CREW (*18. Internatl. Cong. Agr., Dresden, 1939, Sect. 9, Main Rpts.*, pp. 15-21).—A review of the occurrence of twinning in farm animals.

Methods of securing blood from rats, as developed in a study of blood groups and their inheritance, S. O. BURHOE. (Univ. Md.). (*Jour. Hered.*, 31 (1940), No. 10, pp. 445-448, fig. 1).—Securing blood in a sterile condition from etherized rats by clipping the tail or, more satisfactorily, by a cardiac puncture is noted.

The inheritance of resistance, demonstrated by the development of a strain of mice resistant to experimental inoculation with a bacterial endotoxin, A. BRADFORD HILL, J. M. HATSWELL, and W. W. C. TOPLEY (*Jour. Hyg. [London]*, 40 (1940), No. 5, pp. 538-547).—The resistance of mice was increased by 10 generations of selective breeding from the progeny of animals treated with a standard dose of 4 mg. of a bacterin of *Bacterium typhi-murium* (= *B. aertrycke*). In the fourth generation 36 percent of the survivors of treated ancestors survived. In the ninth and tenth generations 64 percent of the

selected stock survived, as compared with only 14 percent of the controls from nontreated parents. In the ninth and tenth generations a few animals from parents resistant to the toxin showed less than normal resistance to a living culture.

The inheritance of a tail abnormality in the house mouse, E. CASPARI and P. R. DAVID (*Jour. Hered.*, 31 (1940), No. 10, pp. 427-431, figs. 2).—A kink character involving a tail flexure in the house mouse was found to be inherited as a dominant, with the homozygote lethal. Inbred kinks crossed with normals produced about 50 percent showing the abnormality. Inter se matings of kinks (heterozygous) produced a 2:1 ratio in the progeny. A pure kink strain could not be established by inbreeding. The size of F_2 litters was reduced and there was a slight excess of normals, suggesting the possibility of a lowered viability of heterozygotes or the apparent failure of the kink character to show in some heterozygotes. Similarity of the character with fused (E. S. R., 77, p. 608) is noted but seems questionable.

Hereditary hypotrichosis in the rat (*Mus norvegicus*), E. ROBERTS, J. H. QUISENBERRY and L. C. THOMAS. (Univ. Ill.). (*Jour. Invest. Dermatol.*, 3 (1940), No. 1, pp. 1-29, figs. 16).—Continuing earlier studies by the Illinois Experiment Station (E. S. R., 60, p. 217), in which hypotrichosis in the rat was shown to be due to an autosomal recessive gene, the authors state that the total combined data indicate the production of 1,335 haired and 440 hairless young as the progeny of heterozygous animals. In reciprocal backcrosses there were 731 haired and 722 hairless, confirming the hypothesis as to the mode of inheritance of the character. Hypotrichosis was not linked with nonagouti, hooded, red eye, dilution, color, or curly characters for which suitable linkage tests were conducted. In further studies of the effects of the gene on mortality, weight, and vigor it was indicated that the length of life, growth rate, and fertility of hairless individuals were reduced as compared with normals. The basal metabolism was not significantly different. From skin transplantation experiments it was judged that the cause of hairlessness lies in the skin. No histological structure differences were noted in the pancreas, thyroids and adrenals, and spleen; and pituitary weights were similar.

Breeding small flocks of domestic fowl for high fecundity, F. A. HAYS. (Mass. Expt. Sta.). (*Poultry Sci.*, 19 (1940), No. 6, pp. 380-384).—Two lines of Rhode Island Reds from a common source were selectively bred for eight generations—one for plumage characters and the other for characters essential for high fecundity. Generally, less than 30 birds in each line completed the first year's production. These results were rather irregular, pointing toward the conclusion that selective breeding in such small flocks is not effective in establishing or maintaining characters associated with high egg production.

Breast ridge in domestic fowl, a new dominant character linked with pea comb, or another expression of the pea comb gene? S. S. MUNRO and I. L. KOSIN (*Amer. Nat.*, 74 (1940), No. 753, pp. 382-384).—A character designated as "breast ridge" consisted of a longitudinal formation running along the breast in the skin of Cornish and Cornish crossbred fowls. This character was found in crosses and in F_2 s between Cornish and Barred Plymouth Rock, White Leghorn, and Light Sussex fowls to behave as a dominant non-sex-linked character. In backcrosses there were produced 72 ridged to 67 nonridged progeny. Among 190 F_2 backcross progeny there were only 3 pea-combed individuals without the condition. Because of some variation in the character, and since the exceptions were at young ages, crossing over did not seem the probable explanation.

Note on the inheritance of yellow bill colour in ducks, J. M. RENDEL (*Jour. Genet.*, 40 (1940), No. 3, pp. 439, 440).—In the progeny from 13 matings, which

included some progeny with bright orange-yellow bills, there were 210 ducklings with normal bills and 66 with orange-yellow bills. This was thus an approximate 3:1 ratio in progeny from heterozygotes, assuming yellow bills to be caused by an autosomal, recessive gene.

Albinism in mockingbirds, E. A. McILHENNY (*Jour. Hered.*, 31 (1940), No. 10, pp. 433-433, fig. 1).—Of 43 young produced by normal-appearing mockingbirds, there were 18 full albinos. The other young were normal, but the sight of the albinos was deficient on bright days, probably resulting in lowered activity and lowered survival under natural conditions.

Interstitial cell stimulating hormone, I-III (*Endocrinology*, 27 (1940), No. 5, pp. 793-817, figs. 4).—Three papers in this series are presented.

I. *Biological properties*, H. Fraenkel-Conrat, C. H. LI, M. E. Simpson, and H. M. Evans (pp. 793-802) (Univ. Calif.).—The purified hormone was found to repair the interstitial tissue of the ovary of hypophysectomized rats, and to resemble the luteinizing hormone by increasing the weight of the accessories in ♂s and augmenting the effect of the follicle-stimulating hormone on the ovary alone in ♀s. More than 1 to 2 mg. of the interstitial-cell-stimulating hormone produced antagonistic antibodies when administered on 3 successive days. Pregnant-mare serum was reduced about 25 percent in its effects on ovarian enlargement in hypophysectomized ♀ rats. It appears that the extracted hormones may represent precursors of the actual secreted hormone, and differences in the responsiveness of strains of rats suggest that some are able to replace the active principle while others are unable to do so.

II. *Method of preparation and some physico-chemical studies*, C. H. LI, M. E. Simpson, and H. M. Evans (pp. 803-808) (Univ. Calif.).—The preparation of the highly purified interstitial-cell-stimulating hormone from sheep pituitary extracts is described.

III. *Methods of estimating the hormonal content of the pituitaries*, H. Fraenkel-Conrat, M. E. Simpson, and H. M. Evans (pp. 809-817) (Univ. Calif.).—Studies were made of the effect of implantation of total doses of from 10 to 200 mg. of fresh, stored, and frozen pituitary tissue on the development of the prostates, seminal vesicles, and testicles of normal and hypophysectomized immature ♂ rats and on the ovaries and uteri of ♀s. Marked responses in the weights of the accessories in ♂s and the gonads of ♀s produced by the fresh tissue implants were noted, but frozen and stored pituitaries produced markedly less stimulation of the adrenals as well as the accessories. A mechanism associated with the integrity of the cells may be necessary for the production of the maximum influence of fresh implants.

The isolation in pure form of the interstitial cell-stimulating (luteinizing) hormone of the anterior lobe of the pituitary gland, T. SHEDLOVSKY, A. ROTHEN, R. O. GREEP, H. B. VAN DYKE, and B. F. CHOW (*Science*, 92 (1940), No. 2382, pp. 178-180, figs. 3).—A purified hormone isolated from an extract of swine pituitary glands was found to cause interstitial cell stimulation in the ovaries or testes and caused the formation of corpora lutea in hypophysectomized rats.

Purification of the pituitary interstitial cell stimulating hormone, C. H. LI, M. E. SIMPSON, and H. M. EVANS. (Univ. Calif.). (*Science*, 92 (1940), No. 2390, pp. 355, 356).—Substances previously investigated at the California Institute of Experimental Biology and the Rockefeller Institute, noted above, did not seem identical.

Gonadotropic action of pituitaries from pregnant cows, A. NALBANDOV and L. E. CASIDA. (Wis. Expt. Sta.). (*Endocrinology*, 27 (1940), No. 4, pp. 559-566, figs. 2).—Pituitary glands removed from cattle at different stages of

pregnancy and with fetuses of different sexes were powdered, and definite amounts were implanted intramuscularly into immature ♀ rats. The potency was determined from the ovarian responses. There was a decline in gonadotropic potency of the cattle pituitaries from early to late pregnancy, giving a correlation of -0.46 between the fetal length and the gonad weight of the rats. This is considered due to the assumption that oestrogen secreted by the placenta has an inhibitory effect on the gonadotropic potency of the pituitary. Essentially the same effects were obtained on testis weight from injection of aqueous suspensions of the powder into chicks. The pituitaries from cows carrying ♀ calves had higher concentrations of gonadotropic hormone than those from cows carrying ♂ fetuses.

On the biological properties of highly purified gonadotropin from pregnant mare serum, H. H. COLE, R. I. PENCHARZ, and H. GOSS. (Univ. Calif.). (*Endocrinology*, 27 (1940), No. 4, pp. 548-553, figs. 8).—The gonadotropic response of immature normal and hypophysectomized ♀ rats and normal ♂ rats was not significantly different to varying doses of purified extracts and untreated pregnant-mare serum, leading to the conclusion that a high degree of purity can be obtained without disturbing the follicle-stimulating : luteinizing hormone ratio, or that the gonadotropic activity of mare serum is dependent on a single hormone. The latter view was favored, and the term "equine gonadotropin" was suggested for the hormone.

Non-specific augmentation with a highly purified follicle stimulating hormone fraction (Evans), F. BISCHOFF (*Endocrinology*, 27 (1940), No. 4, pp. 554-558).—In spite of efforts at purification, pituitary powder dissolved in water produced the same gonadotropic effects—follicle-stimulating, luteinizing, and antagonizing—in immature ♀ rats, further substantiating the multiple action of the follicle-stimulating hormone (E. S. R., 82, p. 469).

The quantitative determination of follicle stimulating and luteinizing hormones in mammalian pituitaries and a discussion of the gonadotropic quotient, F/L, E. WITSCHI (*Endocrinology*, 27 (1940), No. 3, pp. 437-446, figs. 7).—Analysis of the varying effects of gonadotropic substances administered to immature ♀ rats led to the discovery of four different measurable effects (1) ovarian weight, (2) luteinization, (3) uterus enlargement, and (4) cornification of vaginal epithelium. The last was found most adequate for the follicle-stimulating hormone and was little affected by the presence of the luteinizing hormone. An independent assay of the luteinizing hormone was developed by study of the activation of the melanophores in the germ of the feathers on the breast and abdomen of the African weaver finch. A black dot or bar on the newly developing feather with a white tip was indicative of a positive reaction. The amounts of dry hypophyseal powder from 14 mammalian species required to give positive rat vagina, rat luteinizing, and weaver finch units are tabulated, and calculations of the ratios (gonadotropic quotients) in the different species are presented.

Influence of chlorophyll on the activity of gonadotropic extracts tested on normal and hypophysectomized immature female rats, J. H. LEATHEM and U. WESTPHAL (*Endocrinology*, 27 (1940), No. 4, pp. 567-572).—The gonadotropic effects of pregnant-mare serum, anterior-pituitary powder, extracts of anterior-pituitary glands, normal ♂ urine, and Follutein (human pregnancy-urine extract), with and without chlorophyll and mixed before injection or simultaneously injected, were compared. The response was determined by the ovarian and uterine weights in normal and hypophysectomized immature ♀ rats. Chlorophyll caused a slight augmentation in pituitary extracts. Normal ♂ urine was not affected, whereas pregnant-mare serum was completely inhibited by chlorophyll. Chlorophyll injected alone had no effect on the ovaries. Variations in the results may have been due to inert material in the extracts.

Are gonadotropic hormones destroyed while they exert their action on the ovary? H. SELYE (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 2, pp. 404-406).—Subcutaneous injections of follicle-stimulating and luteinizing hormones in various doses administered to hypophysectomized rats from which one ovary was removed caused essentially the same increase in the remaining ovary as was produced per ovary in normal ♀s. It is concluded that there is no significant destruction of the gonadotropic hormones while the expected reaction on the ovaries is produced.

Does testosterone propionate inhibit ovulation? H. O. BURDICK (*Endocrinology*, 27 (1940), No. 5, pp. 825, 826).—Notation is made of ovulations that evidently occurred and corpora lutea formed in rats injected with 5 daily doses of 0.5 mg. of testosterone propionate (*E. S. R.*, 82, p. 613).

Reaction of immature female guinea pigs to gonadotropic extracts, J. H. LEATHEM and W. F. STARKEY (*Pa. Acad. Sci. Proc.*, 14 (1940), pp. 109-114).—Vaginal opening was induced in from 5 to 12 days in 8 of 12 immature ♀ guinea pigs by the daily administration of from 2.5 to 20 rat units of an extract of pregnant-mare serum. It was accompanied with uterine hypertrophy and ovarian stimulation. An extract of castrate urine produced similar gonadotropic effects.

Response of the immature female cat uterus to estradiol benzoate (estrone), W. F. STARKEY and J. H. LEATHEM (*Pa. Acad. Sci. Proc.*, 14 (1940), pp. 87-90, figs. 3).—Injection of immature cats with oestradiol benzoate caused a slight endometrial stimulation after 5 daily treatments with 100 rat units. Oestrous endometrium was induced when the treatment was continued for from 10 to 15 days, but larger doses for 5 days did not give this response.

Activity of progesterone in spayed females not pretreated with estrin, H. SELYE (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 2, pp. 343, 344).—The daily administration of 15 mg. of progesterone to spayed ♀ rats produced progestational changes in the vagina and mammary gland development in contrast to the failure of small doses to have this effect in spayed animals.² Thus, if a sufficient dose of progesterone is given, it exerts its characteristic effects without sensitization of the test animal.

Further studies on the androgenicity of progesterone, R. R. GREENE, M. W. BURRILL, and D. M. THOMSON (*Endocrinology*, 27 (1940), No. 3, pp. 469-472).—Progesterone administered subcutaneously in 10 daily doses of 2 mg. each to castrated immature rats was found to have androgenic effects as judged by material prostate increases in weight, but there was practically no change in the seminal vesicles. Intraperitoneal doses were not as effective as those given subcutaneously. Inadequate doses and intraperitoneal administration are suggested as reasons for failure to get androgenic effects from progesterone, as found in other studies.

The restoration of ovulatory cycles and corpus luteum formation in persistent-estrous rats by progesterone, J. W. EVERETT (*Endocrinology*, 27 (1940), No. 4, pp. 681-686, figs. 2).—Cyclic ovulation and corpus luteum formation were restored in rats exhibiting persistent oestrus by the daily administration of from 0.25 to 1 mg. of crystalline progesterone. Dioestrus occurred within 48 hr. in animals in which there was little likelihood of the occurrence of normal ovulation.

Induction of sexual receptivity in estrogen conditioned spayed female guinea pigs by orally administered progesterone and pregneninolone, A. L. SODERWALL (*Endocrinology*, 27 (1940), No. 5, pp. 840, 841).—Comparison

² *Soc. Expt. Biol. and Med. Proc.*, 34 (1936), No. 4, pp. 472-474.

of the effectiveness of progesterone in inducing copulatory response in spayed guinea pigs after oestrogen conditioning showed that 0.05 mg. was effective after subcutaneous injection, but 1 mg. was required when administered orally. Larger amounts of pregnenolone were required, and more was needed to produce progestational changes.

Production of persistent changes in the genital organs of immature female rats treated with testosterone, H. SELYE (*Endocrinology*, 27 (1940), No. 4, pp. 657-660, figs. 5).—The daily treatment of newborn ♀ rats with 1 mg. of testosterone propionate for 30 days caused uterine and ovarian atrophy and hypoplasia of the vagina without interference with somatic growth. A marked hypertrophy of the kidney and clitoris continued long after the cessation of treatment. Puberty was prevented.

The response of the testis to small doses of testosterone propionate, H. S. RUBINSTEIN and A. A. KURLAND (*Endocrinology*, 27 (1940), No. 3, pp. 461, 462).—Daily subcutaneous injections of 5γ of testosterone propionate to rats from 22 to 32 days of age not only did not have an inhibiting effect on testicular growth but there was some evidence of stimulation.

Inactivation of methyl testosterone in castrate male rats, G. R. BISKIND. (Univ. Calif. et al.). (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 2, pp. 259-261).—Pellets of methyl testosterone implanted in the spleen failed to excite androgenic effects. However, positive results were obtained when the androgen was implanted subcutaneously or in the transplanted spleen, showing that with normal blood supply the spleen destroys the hormone.

Experimental study on the transplantation of the rat hypophysis [trans. title]. **A. WESTMAN and D. JACOBSON** (*Acta Pathol. et Microbiol. Scand.*, 17 (1940), No. 3, pp. 328-347, figs. 5; *Eng. abs.*, pp. 346, 347).—Implantation of hypophyses from young rats into the eye chamber of hypophysectomized ♀s was found to prevent the appearance of eosinophilic and castration cells in the transplanted lobe, even after removal of the ovaries. However, the transplants seemed to exert no gonadotropic activity, the ovaries were atrophied, and there were no vaginal cycles. The transplants had the expected effect on growth and behavior.

Studies on thyroidectomized rats with special reference to lactation and growth, D. V. PREHEIM (*Endocrinology*, 27 (1940), No. 3, pp. 494-499, fig. 1).—Rats in three successive generations were thyroidectomized, and the effects on lactation were estimated from the growth of the young. Growth rate was reduced 12.13 percent, and litter size was 6.36 as compared with 7.03 in the controls, but the numbers raised to weaning were practically the same. Gestation periods of thyroidectomized animals were prolonged about 24 hr. No cumulative effects on the young in successive generations were noted.

Appearance of skeletal abnormalities in the offspring of rats reared on a deficient diet, J. WARKANY and R. C. NELSON (*Science*, 92 (1940), No. 2391, pp. 383, 384).—Among 164 young born to rats on the rachitogenic diet of Steenbock, Black, et al. (*E. S. R.*, 54, p. 489), there were 57 with multiple congenital abnormalities involving shortening of the mandible and deformed extremities. Only 1 abnormal animal occurred among 510 young from rats on antirachitic diets.

The effect of thyroxin on the social order in flocks of hens, W. C. ALLEE, N. E. COLLIAS, and E. BEEMAN (*Endocrinology*, 27 (1940), No. 5, pp. 827-835).—Employing White Leghorn hens from flocks previously studied for the influence of the sex hormones on social order (*E. S. R.*, 82, p. 614), the authors found that thyroxine injections caused no changes in the social order except

when sufficiently large doses were administered to cause molting. Following such treatment a lowering of the social position occurred.

A hormone study of dubbed and normal cockerels, H. W. MARLOW and L. F. PAYNE. (Kans. Expt. Sta.). (*Poultry Sci.*, 19 (1940), No. 6, pp. 401-403).—Assays of the ♂ hormone in the feces and testes of normal and dubbed White Leghorn cockerels after 4.5 mo. of age showed no significant differences, and the histological development of the testes was similar in the two groups although the weight of the testes of dubbed birds was about twice that of normals. The body weight of the dubbed birds was about 15 percent greater than that of normal cockerels.

The effects of testosterone-propionate on the growth of comb, testes, and ovaries in chicks, C. A. HORN (*Pa. Acad. Sci. Proc.*, 14 (1940), pp. 27-31, fig. 1).—Injection of New Hampshire Red chicks with 2.5 and 5 mg. of testosterone propionate in single and multiple doses caused comb growth in the treated birds. Administration in several small doses was more effective than in single doses. The growth of the testes and, to a lesser extent, the ovaries was retarded.

Peculiarities of hormonal determination in the process of feather development, A. A. WORTKEWITSCH (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 26 (1940), No. 7, pp. 713-716, figs. 3).—Studies of the effects of thyroid secretions on the character of developing feathers in pigeons showed within from 5 to 6 days of thyroidectomy no marked changes in development. On the fourteenth day a decrease in the rate of growth of the plumage occurred, with a gradual narrowing of the lower part of the vane. The normal rate of feather growth was restored in thyroidectomized birds by the oral administration of 100 mg. of thyroxine per day.

Effect of hypophysis on the process of moulting in birds, A. A. WORTKEWITSCH (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 26 (1940), No. 4, pp. 406-408, fig. 1).—Injection into quails of thyrotropic extracts prepared from different zones from the anterior pituitary was found to provoke molting, beginning in 3 days in some cases. Premolting was not induced in thyroidectomized birds, showing the importance of thyroid in stimulating the molting process.

Effects of X-rays upon the regeneration of feathers in the common fowl, B. DEBOER. (Univ. Mo.). (*Jour. Morphol.*, 67 (1940), No. 2, pp. 299-319, pl. 1).—Doses of from 2,000 to 3,000 roentgen rays caused the regeneration of plucked feathers in pigmented breeds to be white and continue white in subsequent regenerations. Feather follicles were destroyed or regeneration was delayed by longer exposures. Dried thyroid-gland extracts increased the rate of regeneration in feathers in nonirradiated regions or if irradiation was not sufficient to destroy the follicles.

The production of robin pigment in White Leghorn feathers by grafts of embryonic robin tissue, M. E. RAWLES (*Jour. Genet.*, 38 (1939), No. 3, pp. 517-532, pls. 3, figs. 3).—Grafts of small pieces of skin removed from robin embryos in early stages of development were made on 15 72-hr. White Leghorn embryos. Of 14 which lived beyond the nineteenth day of incubation, 5 showed colored down varying from blackish brown to pale cinnamon brown. In 1 which lived to sexual maturity, the colored down was replaced by juvenile mosaic-colored contour feathers and was later completely replaced by white (host) feathers. Feather structure was identical with that of the Leghorn host. Evidently the robin-colored feathers on the White Leghorn host arose from Leghorn feather germs, and the pigment was produced by robin melanophores which migrated

The relative potency of several estrogenic compounds tested on baby chicks of both sexes, S. S. MUNRO and I. L. KOSIN (*Endocrinology*, 27 (1940), No. 4, pp. 687-692).—Comparison was made of the effect of 10 daily injections of oestrone, oestradiol, oestradiol benzoate, and oestradiol dipropionate on the body, gonad, adrenal, comb, and oviduct (in ♀s) weights of chicks 1 week old. There was no effect on body weights of ♀s, but a slight depression in the weights of ♂s was evident. The gonads of both sexes were depressed. The oviducts were somewhat hypertrophied. The adrenals of ♂s were slightly stimulated, but in ♀s some depression was evident. The order of the effect of these hormones was as given above.

A modification of Riddle's method of prolactin assay, N. UYEI, M. ITOH, S. HAYATSU, and F. UYENO (*Science*, 92 (1940), No. 2393, pp. 435, 436).—A modification of the Riddle and Bates method for prolactin assay which involves the saving of a number of pigeons is described. If the crop sac of the pigeon proves transparent on incision of the skin, there is injected on 4 successive days a potent extract which will produce a degree of thickening of the crop sac on the other side also apparent after the skin is turned back.

Cold storage colts, V. R. BERLINER, F. E. COWART, and L. L. PHARIS. (Miss. Expt. Sta.). (*Jour. Hered.*, 31 (1940), No. 10, pp. 449-451, fig. 1).—Best results in the preservation of motility of stallion and jack sperm were obtained by storage of dilute semen with gradual cooling to from 40° to 45° F. The sperm showed a high degree of motility. However, only one of several mares conceived after insemination with 24-hr. stallion sperm and others after two inseminations with 24-hr. jack sperm. Pregnancy tests were positive for two further mares inseminated twice on successive days with jack semen. More success was indicated from the use of stallion and jack semen on successive days, even when division was made of the same sample, than when a larger amount was given in a single insemination.

An improved artificial vagina for the collection of stallion and jack semen, V. R. BERLINER. (Miss. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 96 (1940), No. 758, pp. 667-670, fig. 1).

Color markings in Rhode Island Red chicks as related to sex and adult color, F. A. HAYS. (Mass. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 61 (1940), No. 1, pp. 69-74).—The relation of down pigmentation to sex and adult color in 8,713 purebred Rhode Island Red chicks hatched from 1937 to 1939 showed that color markings and stripes in the down had no commercial value as indicators of sex in the stock studied. About 90 percent of the ♂ chicks and 56 percent of the ♀s showed no color markings. There was no sex difference in the appearance of black and brown markings, although the adult color of the ♂s averaged slightly lighter than that of ♀s. A darker adult plumage color was associated with black-pigmented areas in the down. There was also less mottling in such birds than in cases where the down color was solid or pigmented with brown.

Turkeys fertile under lights (*Pennsylvania Sta. Bul.* 399 (1940), pp. 53, 54, figs. 2).—Data collected by P. H. Margolf indicate that hen turkeys respond to artificial illumination and lay eggs in 21 days, but 30 to 35 days' lighting is required to induce sperm production.

FIELD CROPS

[Agronomic experiments in Connecticut] (*Connecticut [New Haven] Sta. Bul.* 438 (1940), pp. 513, 514, 520, 524, 528-530).—The progress of research with field crops is again (E. S. R., 81, p. 501) noted briefly from breeding work with

and testing of corn and corn hybrids; fertilizer tests with potatoes and sweet-potatoes; use of glass wool as a substratum in seed testing; and tobacco experiments at Windsor (E. S. R., 83, p. 485), including fertilizer tests, e. g., soybean oil meal v. cottonseed meal and urea v. organic nitrogen sources, tests of potash carriers and of sludge as a tobacco fertilizer, and placements, and irrigation and harvesting experiments.

[Field crops work in Pennsylvania], C. F. NOLL, C. J. IRVIN, H. B. MUSSER, C. O. CROMER, E. L. NIXON, W. R. WHITACRE, D. E. HALEY, S. I. BECHDEL, A. L. BEAM, J. W. WHITE, and C. C. WERNHAM (*Pennsylvania Sta. Bul. 399 (1940)*, pp. 14-18, 21-23, 24, 25, 48-51, figs. 2).—Brief reports are made on the progress of breeding work with potatoes, oats, and red clover; inheritance studies with red clover; variety tests with corn (and hybrids), oats, soybeans, alfalfa, and grasses for fine turf; combining v. binding wheat and oats; response of potato varieties to soil reactions and planting dates; study of degeneration of potatoes due to heat; defects in market potatoes, and timing of potato sprays; potato and tobacco rotations; fertilizer experiments with tobacco, especially in regard to potassium content; response of pastures to fertilizer and manure; and compost materials for maintenance of fine turf grasses, resistance of grasses to "melting out" disease (*Helminthosporium* sp.), and tests of fungicides for its control.

Possibilities and limitations in the use of irrigated land for forage production in northeastern Nevada: Improvements in cultural practices, seeding methods, and livestock husbandry, coupled with timely and well-balanced use of ranch and range forage, favor ranch stability, C. E. FLEMING and C. A. BRENNEN (*Nevada Sta. Bul. 154 (1940)*, pp. 34, figs. 7).—Experiments, 1934-39, made on a ranch in northeastern Nevada with the objective of increasing forage yields on irrigated, privately owned land in order to partly make up the inadequate productive capacity of available range lands in the congested grazing areas, included tillage and cultural practices, trials of introduced grasses and clovers and rotation, and intermittent grazing of pastures. A foreword by S. B. Doten describes the problem, and the application of the findings and their advantage in practice in the area are discussed.

In establishing introduced grasses and clovers, best results were obtained on a fine compact seedbed, by planting early to take advantage of available spring precipitation and a full growing and irrigating season, and by planting seed at a one-fourth-inch depth alone or with a light seeding (40 lb. per acre) of nurse crops, such as hull-less barley, which will not smother the seedlings. Seed mixtures of both clovers and grasses gave the best results for either pasture or hay production. Special combinations of Kentucky bluegrass, meadow fescue, timothy, orchard grass, white Dutch clover, mammoth red clover, alsike clover, alfalfa, redtop, crested wheatgrass, brome grass, and sweetclover are recommended for pasture alone and for hay and second-growth pasture on land of different levels of soil fertility, moisture supply, drainage, and elevation.

Intermittent grazing trials showed that pasture grasses irrigated and rested for 2 mo. before use had about double the carrying capacity obtainable when grazing began as early as livestock could use the forage beneficially. According to hay production records, good silty loam soils rich in humus and well irrigated with good drainage could produce from 1.75 to 2 tons of hay per acre, whereas light silty loams low in humus with inadequate control of overflow and drainage water yielded from 0.66 to 1.20 tons. Second-growth grazing trials indicated that good soils with an adequate moisture supply after haying or where irrigation water is available July 15 to August 15 might

produce stands of succulent second-growth grasses and clovers from 8 to 15 in. high if hay is cut early enough to insure about 1.5 mo. of good growing weather.

Grass investigations of the North Dakota Agricultural Experiment Station, W. WHITMAN (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 2, pp. 22, 23).—Grassland research at the station and substations is outlined.

Deferred grazing of bluestem pastures, K. L. ANDERSON (*Kansas Sta. Bul.* 291 (1940), pp. 27, figs. 3).—Deferred and rotation grazing of the bluestem grasses were compared, 1916–22, with season-long grazing by purebred Herefords. The carrying capacity was not increased by deferring grazing until September 1 because maximum or uniform utilization could not be obtained. However, when the deferred grazing period began June 15 a decided increase in carrying capacity occurred.

In comparisons 1927–38, the pasture with grazing deferred until July 1 had a higher carrying capacity than those grazed season-long either in terms of time actually grazed or when converted to a 6-mo. grazing season. The deferred pasture yielded an average of 65.1 lb. of beef per acre per grazing season, or 1.32 lb. of animal units per grazing day, compared to 37.4 and 42.5 and 1.17 and 1.09 lb., respectively, for the two pastures grazed season-long. Although seasonal gains per animal unit were somewhat smaller on deferred pasture, about twice the acreage and from 40 to 50 days longer each year were required on pastures grazed season-long to produce about one-third more gain per animal unit per grazing season. Stands of grass on deferred pasture were maintained in better condition, although it had been used much harder. At the end of each grazing season it had a better grass cover to afford protection against runoff and erosion during winter and spring. When the depleted grasses were replaced following severe climatic conditions during the later years of this experiment, considerable sand dropseed and buffalo grass appeared on pastures grazed season-long, whereas in deferred pasture, side-oats grama largely made up the replacement.

To permit deferred grazing it appears advisable to provide other forms of pasture during May and early June. Where the stand and vigor of the pasture vegetation are good, a plan of a deferred system of grazing is suggested which obviates supplemental pastures.

Abstracts of pasture literature, A. S. DAHL (*U. S. Dept. Agr., Soil Conserv. Serv.*, 1937, *SCS-TP-15*, pp. [2]+369).—Pasture publications by State experiment stations and extension services published up to 1934 and totaling 642, abstracted by C. R. Enlow, H. N. Vinall, M. A. Hein, and E. M. Coffman, are arranged by States and authors under 39 subject matter heads. Consult also related digests by Pieters (*E. S. R.*, 78, p. 619).

Is tripping necessary for seed setting in alfalfa? H. M. TYSDAL (Nebr. Expt. Sta. coop. U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 8, pp. 570–585, figs. 2).—In studies at Scotts Bluff, Nebr., and in several seed-producing areas of the United States in 1939, the respective percentages of alfalfa flowers tripped naturally ranged from 11 to 63 and of flowers forming pods (1) without tripping 0–6, (2) naturally 5–47, (3) artificially tripped 27–91, and (4) under bags 1–5 percent. The *Megachile*, *Nomia*, and *Bombus* sp. of bees were the most important insects in tripping alfalfa in different sections of the country. Honey bees tripped about 1.1 percent of the flowers visited, and when present in abundance might be beneficial. Cross-fertilized flowers produced about three times as much seed as self-pollinated flowers, and the three genera of insects are particularly adapted for cross-pollinating as well as tripping. Beneficial insects were found most active during the middle of the day and at the higher temperatures in bright dry weather. Many cases

of poor crops were found in seed-producing areas, yet all factors seemed favorable for a seed crop, including good bloom and no harmful insects. Under such conditions lack of tripping might be the determining factor.

Velvon, a new smooth-awned barley, R. W. WOODWARD and D. C. TINGEY. (Coop. U. S. D. A.). (*Utah Sta. Bul.* 293 (1940), pp. 11, figs. 2).—Velvon, a new smooth-awned barley with relatively stiff straw and a high degree of resistance to races or strains of covered smut found in Utah, was selected from a cross between Colorado selection 3063 (Coast × Lion) and Trebi. Comparative tests in Utah and other Western States showed Velvon to be equal in yield, quality, and other agronomic characters to the better of the adapted varieties of the region. It has largely replaced Trebi in Utah.

The analysis of lattice and triple lattice experiments in corn varietal tests, I, II. (Coop. U. S. D. A.). (*Iowa Sta. Res. Bul.* 281 (1940), pp. 66, figs. 3).—This study is in two parts.

I. Construction and numerical analysis, G. M. COX and R. C. ECKHARDT.—The field plans, statistical methods, experimental results, and mathematical theory are presented for two incomplete block designs, the lattice and triple lattice, which in addition to the lattice square designs (E. S. R., 81, p. 369) are well adapted to testing large numbers of varieties. Two experiments, consisting of yield tests of 81 double crosses of corn, are used to illustrate a new method of analysis in which the interblock information is recovered. The analysis is so presented that it can be adopted as the standard method of analyzing lattice and triple lattice experiments. Recovery of interblock information and reduction of block size from 81 to 9 plats per block resulted in a notable increase in precision when compared with the randomized complete block designs. The gain was 85 percent for the lattice and 73 for the triple lattice experiment. The use of covariance analysis is illustrated for the latter.

II. Mathematical theory, W. G. COCHRAN.—For each design the mathematical basis is given for the estimation of the varietal means together with their standard errors, the weights assigned to intra- and interblock error variance, and tests of significance. Tables indicate the efficiencies to be expected from the use of these designs instead of randomized complete blocks.

Grading hybrid seed corn for planting, R. H. REED. (Univ. Ill.). (*Agr. Engin.*, 20 (1939), No. 4, pp. 148, 152).—The method of seed grading described indicates the proper sizes of planter plate cells for planting corn of different kernel sizes.

Foxtail millet in Colorado, J. J. CURTIS, J. F. BRANDON, and R. M. WEIHING. (Coop. U. S. D. A.). (*Colorado Sta. Bul.* 461 (1940), pp. 12).—Cultural and varietal tests with foxtail millet at Akron, Colo., 1909–39, suggest drilling from 25 to 30 lb. of seed per acre between May 15 and July 1 just after a good rain and cutting for hay before or at first heading. The Siberian variety is recommended because of high hay yields and also good yields of seed, although Dakota Kursk, White Wonder, Goldmine, and German foxtail millets have closely approached it in yield tests. The crop is indicated for dry land in eastern Colorado, but it has not yielded well at high altitudes and alfalfa and other crops have produced more and better forage on the irrigated lands. The highest yields of foxtail millet were obtained on fallow, lowest on Sudan grass stubble land, and intermediate yields on winter wheat and spring-seeded small grain stubble land. Fallow or late spring-planted crops, as corn or sorghum, followed millet in rotations much better than did fall- or early spring-sown crops, as wheat, oats, or barley. Feeding trials at Akron showed that for fattening lambs foxtail millet hay slightly surpasses sorgo fodder if cut early, but is slightly inferior if cut when the seed is ripe. The seed is slightly less

palatable than proso and has about 83 percent of the feeding value of corn or proso, but for best results should be ground finely before fed to livestock.

The progeny test as a measure of the types of seed-development in *Poa pratensis* L., F. W. TINNEY and O. S. AAMODT. (Univ. Wis. and U. S. D. A.). (*Jour. Hered.*, 31 (1940), No. 10, pp. 456-464, figs. 5).—No variant types were found in 48 of 102 progenies grown as individual plants from seeds produced in single open-pollinated panicles of Kentucky bluegrass. In the total population, 1.6 percent were variant types, and the highest percentage of variants in any progeny was 21.9. Remarkable uniformity in type was observed among progenies collected in different climatic regions. The fact that a progeny is uniform throughout and practically identical with its seed parent indicates that the plants arose apomictically. Presence of atypical plants in an otherwise uniform progeny indicates that these plants may have arisen as a result of gametic union or mutation. The breeding studies described confirm cytological findings that apomixis is the predominant type of reproduction. This predominantly parthenogenetic origin of seeds evidently can be used to advantage by plant breeders and seedsmen.

Reproduction in some *Poa* species, V. ENGELBERT (*Canad. Jour. Res.*, 18 (1940), No. 10, Sect. C, pp. 518-521).—*P. arctica*, *P. alpigena*, and *P. alpina* from Greenland, *P. alpina* from Georgian Bay, Ont., and *P. pratensis* from Gaspé, Que., were observed to be all apomictic (parthenogenic) and pseudogamous. In pseudogamy the pollen tube enters the stigma and activates the apomictic embryo sac to development, but usually does not enter ovarian tissue to achieve fertilization of the ovule. Pollen from any one species germinated readily and with a high percentage on the stigmas of any one of the others. Pollen sterility did not exceed 2 percent.

Potato digger adjustment in relation to tuber bruising, E. V. HAEDENBURG and C. N. TURNER. (Cornell Univ.). (*Amer. Potato Jour.*, 17 (1940), No. 8, pp. 191-197, figs. 3).—Factors involving types of potato diggers, their adjustment, and operations in relation to tuber bruising were studied on 32 New York farms during 3 yr. On the basis of reduction in bruising obtained, speed of the apron, type of digger, and depth of digger point may be considered most important under prevailing conditions. However, attention to any one or a combination of several factors might result profitably to a grower according to his particular conditions. Other factors were agitation, apron tension, rear chain drive, and shaker-bar padding. See also an earlier note (E. S. R., 80, p. 478).

Photothermal induction of flowering in sugar beets, F. V. OWEN, E. CARSENER, and M. STOUT. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 61 (1940), No. 2, pp. 101-124, figs. 7).—"Photothermal induction" of flowering, suggested by E. J. Kraus, signifies induction of flowering by both light and temperature. The effect of photoperiod in beets was found to be associated intimately with and dependent upon temperature exposure. The favorable effect of low-temperature exposure to subsequent flowering was demonstrated with germinating seed, with beets after cold storage, and with growing plants. Certain factors influencing bolting in the field acted indirectly by altering the range or duration of effective temperatures. Thus, shade increased bolting by lowering the soil temperature and consequently that of the beet crown under conditions where unshaded soil was too warm. Irregularity in germination of seeds under temperatures conducive to induction of flowering resulted in variation in bolting because seeds retarded in sprouting escaped some of the low-temperature influence.

Both annual and biennial beets showed genetic variability in response to temperature and photoperiod. A factor for bolting designated *B'* and regarded as allelic to *B*, discovered by Munerati (E. S. R., 66, p. 816) and further described by Abegg (E. S. R., 76, p. 462), was identified by hybridizing selected parental material and testing backcross progenies under controlled environmental conditions.

Windrowing and storing of sugarcane in Louisiana following injury by freezing temperatures, J. I. LAURITZEN, C. A. FORT, and R. T. BALCH (*U. S. Dept. Agr., Tech. Bul. 736 (1940), pp. 44, figs. 4*).—The relation of different degrees of freezing injury to the behavior of sugarcane of the varieties Co. 281 (windrowing variety) and Co. 290 (near-windrowing variety) when standing, in the windrow, and stored at different conditions of temperature and humidity was studied at or near the United States Sugar Plant Field Station, Houma, La. See also earlier notes (E. S. R., 70, p. 614; 72, p. 471).

Under mild freezing conditions the regions of the sugarcane stalk in the spindle and at the tips of the leaves are first to be injured, and as freezing conditions become more severe the injury extends downward killing terminal buds, eyes, and stalk. The lower eyes are the last to remain sound. As long as any eyes are sound at the time of windrowing, Co. 281 and Co. 290 will windrow from 3 to 6 weeks under the usual weather conditions during the harvest in Louisiana without serious increase in acidity, decrease in pH value, and gum formation. When only an occasional eye remains sound or all the eyes are killed, considerable loss of solids, including sucrose in cane in the windrow, may occur, although the purity may remain high and the development of acidity and the formation of gum may be slow. Fermentation involving production of ethyl alcohol was associated with such destruction of solids. After all the eyes have been killed, the behavior of cane in the windrow or in storage seems to depend upon a degree of injury at present not measurable by physical symptoms. The development of acidity and gum formation may be slow or fast enough to make the cane unfit for sugar manufacture in a few days. Behavior of cane exhibiting different degrees of freezing injury when stored at different temperatures and relative humidities and when windrowed was similar as to the occurrence or nonoccurrence of fermentive changes. Cane showing no fermentive changes in the windrow showed none when stored at different temperatures (50°–80° F.) and relative humidities, whereas badly damaged cane showed fermentive changes under both sets of conditions. The data appear to justify, when possible and practicable, the windrowing of cane before injury by freezing temperatures, and also, as a protection against further injury, the windrowing of cane damaged by freezing temperatures in which sound eyes are found.

Sunflower as an indicator plant of boron deficiency in soils, C. E. SCHUSTER and R. E. STEPHENSON. (Oreg. Expt. Sta. coop. U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 8, pp. 607–621, figs. 4).—Sunflowers, heavy users of boron, could be employed successfully as indicators of the level of available B in soils. B deficiency is shown by cessation of growth of the terminal bud, reduced dry weight, and abnormal leaf characteristics, but the deficiency may be masked by other deficiencies unless the plants are supplied with enough available nutrients for good growth. Soils long clean cultivated and low in organic matter have contained less available B than uncultivated soils of the same type. Humus depletion seemed to aggravate B deficiency, which could be corrected by addition of enough compost to the soil. Soils varied widely in amount and distribution of available B, attributable to their origin and weathering, cultivating practices, erosions, humus supply, and other factors. Available

B was usually greatest in the upper 3 ft. of the soil, but the shortage was often extreme in depths below 3 ft.

Tobacco through three centuries, E. M. MATTHEWS. (Va. Expt. Sta.). (*Commonwealth [Va. State Chamber Com.]*, 5 (1938), No. 9, pp. 17-20, figs. 5).—An account of the development and status of tobacco production in Virginia.

Soil temperature and growth of Marquis wheat, D. J. WORT (*Plant Physiol.*, 15 (1940), No. 2, pp. 335-342, figs. 3).—When Marquis spring wheat was grown, 1937-39, in the greenhouse, the plant height, root length and extent, and tiller number decreased as the soil temperatures rose from 22° to 42° C. The greatest dry weights of tops and roots and total dry weight, at time of harvest, were found to result in plants grown at 22°, the lowest temperature maintained. The top:root ratio reached a maximum at from 30° to 34°, falling again as the soil temperature rose further. Leaves were largest at 22° and became lighter in color above 32°. Increasing soil temperatures from 22° to 34° accelerated heading by as much as 11 days, while temperatures above 34° retarded or prevented it.

Time of maturity and variety yields in 1940, T. E. STOA (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 2, pp. 20-22).—Growing conditions in North Dakota in 1940 generally favored wheat varieties that headed early. Drought and high temperatures in late July appeared to account for greater injury and less satisfactory yields in the late varieties. The earlier oats also were outstanding in localities where drought was a factor, whereas differences were not great in other localities, indicating performance over a period as a more dependable basis for judging a variety than performance in any one year. "Earliness alone is not a sufficient recommendation for a variety. But when earliness is combined with a good capacity for yield it can be a distinct advantage."

Proceedings of the Association of Official Seed Analysts of North America, 1938 (*Assoc. Off. Seed Anal. North Amer. Proc.*, 30 (1938), pp. 279, figs. 19).—Papers presented at the thirtieth annual meeting at Guelph, Ont., June 21-24, 1938, included The Training of Beginners in Purity Analysis, by E. F. Serrine (pp. 14-17), Fundamentals of Seed Control, by W. A. Davidson (pp. 87-90), Some Problems in Seed Marketing, by W. A. Wheeler (pp. 104-106), Germination Requirements of the Seed of Some Introduced and Native Range Grasses, by V. K. Toole (pp. 227-243), Moistening and Drying as a Pretreatment in Germinating Seeds of *Poa compressa*, by A. M. Andersen (p. 246), and The Germination of the Seed of *Alsine media*, by L. A. Kanipe (pp. 249-252) (all U. S. D. A.); The Occurrence of Weed Seeds in Commercial Vegetable Seeds, by C. A. Stahl (pp. 64-67); Variety and Varietal Purity (pp. 68, 69), and Seed Testing in Alabama (p. 97), both by L. N. Allen; Advisability Versus Inadvisability of Establishing Standards on Agricultural Seeds, by M. H. Snyder (pp. 71-73); Opportunity for Cooperation Between the Extension Services and Seed Laboratories of the United States, by F. A. McLaughlin (pp. 73, 74); The Unexplored Avenues of Crop Improvement, by W. T. G. Wiener (pp. 91-96); Seed Control in Tennessee, by F. H. Spanier (p. 98); Seed Price Versus Seed Quality, by J. E. Casey (pp. 99-103) (Ark. Expt. Sta.); Progress in the Seed Industry, by E. M. Page (pp. 107, 108); Seed Laboratory Record Card Data, by W. L. Goss (pp. 109, 110); The Seed Sample and Its Limitations (pp. 111, 112), and Selecting Beet "Seeds" for Germination Testing (pp. 269, 270), both by M. T. Munn, Some Observations Regarding Noxious Weed Seed Determinations, by M. E. Woodbridge (pp. 113-117), Chemical Control of Molds When Germinating Lima Beans, by W. Crosier and C. Nelson (pp. 189-194) (E. S. R., 82, p. 785), Hard-Shell Seeds in Peas and Beans (pp. 221-226),

and Injuries to Seedlings Induced by Chemicals Dissolving From Germinator Trays (pp. 253, 254), both by W. Crosier and S. Patrick, Canada Bluegrass Seed Is Sensitive to Germinative Conditions, by S. R. Patrick (pp. 247, 248), and Treatment of Seeds With Indolebutyric Acid and Its Effects, by D. E. Weimer (pp. 263-268) (E. S. R., 82, p. 750) (all N. Y. State Sta.); A Comparison of the Regular Method and a Fractional Method of Analyzing Orchard Grass Seed for Purity, by J. S. Jones (pp. 118, 119); A New Seed Blower (pp. 120-132), and Further Studies on the Distribution of Weed Seeds in, and of Results of Germination Tests on Replicate Samples (pp. 177-188), both by C. W. Leggatt; Uniform Techniques for the Analysis of Small-Seeded Grasses (pp. 133-171), and Detection and Classification of Seed-Borne Organisms, Their Effect on Germination and Their Control by Seed Disinfection in Laboratory and Field (pp. 195-213) (E. S. R., 82, p. 783), both by R. H. Porter (Iowa Sta.); Farm Demonstrations as a Measure of Seed Viability in Alfalfa, Red Clover, and Sweet Clover, by E. P. Sylvester (pp. 172-176) (Iowa State Col.); Abnormalities in the Germination of Lima Beans, by J. G. Fiske (pp. 214-217) (N. J. Stas.); Observations on Lima Bean Germination, by V. Drake and B. R. Atwater (pp. 218-220); Laboratory Germination Studies With *Agropyron smithii*—Preliminary Results, by W. D. Hay (pp. 244, 245), and Seed Value of De-hulled Oats—Preliminary, by W. O. Whitcomb (pp. 255-258) (both Mont. Sta.); Germination Studies of the Hull-less Seeds of Reed Canary Grass, by G. C. Morris (pp. 259-262) (Wis. Sta.); The Use of Trial Grounds for Variety Testing, by A. Hope (pp. 271, 272); and Classification and Germination of Herb Vegetable Seeds, by H. E. Vegiard (pp. 273, 274). Technical problems were also dealt with in committee reports. Earlier reports have been noted (E. S. R., 80, pp. 43, 44).

Proceedings of the Association of Official Seed Analysts of North America, 1939 (*Assoc. Off. Seed Anal. North Amer. Proc.*, 31 (1939), pp. 143, figs. 5).—The papers presented at the thirty-first annual meeting at Madison, Wis., August 1-4, 1939, included A Decade of Progress in Seed Testing in Alabama, by L. N. Allen (pp. 10-15); Comparison of Time Required for Complete and Modified Analysis of Seeds (pp. 28-34) and A Suggested Policy for the Evaluation of Hard Seeds (pp. 86-94), both by W. O. Whitcomb (both Mont. Expt. Sta.); Application of Tolerances to Seed Analysis and Law Enforcement, by C. W. Leggatt (pp. 94-101); Testing of Native Grass Seeds at the Kansas State Seed Laboratory, by E. L. Norris (pp. 101-104); Identifying the *Festuca* Species in Commerce, by M. T. Munn (pp. 104, 105), The Ineffectiveness of Certain Seed Treatments To Reveal Origin of Red Clover Seed, by D. E. Weimer (pp. 106-108), Influence of Chemical and Thermal Treatments on Infection of Cruciferous Seedlings by *Alternaria* spp. and *Rhizopus nigricans*, by W. Crosier and S. Patrick (pp. 116-120), and Some Fungi Associated With Grass Seed, by W. Crosier and D. E. Weimer (pp. 120-121) (all N. Y. State Sta.); The Pubescent Characteristic of Red Clover, *Trifolium pratense*, as Related to the Determination of Origin of the Seed, by E. A. Hollowell (p. 109), and Notes on the Viability of the Impermeable Seed of *Vicia villosa*, Hairy Vetch, by V. K. Toole (pp. 109, 110) (both U. S. D. A.); Notes on Flower Seed Germination, by B. R. Atwater (pp. 111-113); Boiling-Water Treatment an Aid in Germinating Bur Clover Seed, by J. E. Casey (pp. 114, 115); The Hemocytometer Method for Detecting Fungous Spore Load Carried by Wheat Seeds, by W. N. Rice (pp. 124-127), and Laboratory and Field Germination of Treated and Untreated Beet Seed, by R. H. Porter and W. N. Rice (pp. 127-130) (both Iowa Sta.); and State Seed Laws and Their Application to Dealer and Grower, by R. U. Crouley and C. P. Bull (pp. 130, 131). Technical problems were also dealt with in committee reports.

Chemical control of annual weeds in flax and grain fields, E. A. HELGESON and D. GERBRACHT (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 2, pp. 7-10, figs. 2).—Sinox (E. S. R., 83, p. 55) when sprayed on Bison flax nearly in bloom was most satisfactory for general use in a 1 : 100 concentration and particularly for mustard, whereas purslane and prickly lettuce were injured little. Sprayed flax averaged 10.63 bu. per acre, and untreated 4.59 bu. The pigweed and Russian-thistle infecting Thatcher spring wheat about 25 cm. high were not affected much by sprays, although pigweed sprayed July 24 was injured more severely and the few mustards present were killed. Plants readily killed included water pod (*Ellisia nyctelia*), marsh-elder, ragweed, field mustard, French weed (*Thlaspi arvense*), wild buckwheat, and the potato. Other plants showing varying degrees of injury are listed.

Western bitterweed control studies, W. H. DAMERON. (Tex. Expt. Sta.). (*Tex. Agr. Workers' Assoc. Mtg., Papers, 1939, pp. [122-126]*).—The history of bitterweed (*Actinea odorata*), causes and prevention of its spread, control measures, and prevention of poisoning of livestock are reviewed from station studies on the plant (E. S. R., 68, p. 673; 78, p. 247).

HORTICULTURE

[**Horticultural studies by the New Haven Station**] (*Connecticut [New Haven] Sta. Bul.* 438 (1940), pp. 514-516).—Included are brief reports on studies in the development of sweet corn hybrids; environmental factors affecting the color and sugar content of beets; improvement of squash by inbreeding and recombination; the breeding of disease-resistant cantaloups and cucumbers, blight-resistant celery, and strawberries; and the genetics of corn (coop. Univ. Mo. and U. S. D. A.).

[**Horticultural investigations by the Pennsylvania Station**], E. I. WILDE, R. P. MEAHL, C. B. LINK, R. D. ANTHONY, H. K. FLEMING, C. O. DUNBAR, W. S. CLARK, JR., N. F. FARRIS, F. N. FAGAN, W. R. WHITACRE, G. J. STOUT, C. E. MYERS, A. L. HASKINS, M. T. LEWIS, E. M. RAHN, W. B. MACK, W. THOMAS, J. W. SINDEN, and H. W. POPP (*Pennsylvania Sta. Bul.* 399 (1940), pp. 25-27, 40-44, 61-65, 66, figs. 3).—Included are brief reports on variety tests with iris; the use of growth-promoting substances in stimulating root development in cuttings; effect of native peats in the culture of roses; effect of incorporating sand with soil in growing Better Times roses; the value of Malling rootstocks in apple culture; deep planting as a means of inducing rooting from the scions of apple grafts; the value of growth substances in promoting the rooting of apple cuttings; the value of selecting relatively frost-free orchard sites; harmful effects of continuous cultivation of orchards; sod as a prevention of erosion in peach orchards; cover crops for peach orchards; new varieties of cherries and peaches; the need for standardizing apple packages; irrigation of vegetable crops; improvement of tomatoes, peppers, rhubarb, and lettuce; testing of sweet corn hybrids and varieties; testing of vegetable varieties; placement of fertilizer for vegetable crops; foliar diagnosis as an indication of the nutritional needs of greenhouse tomatoes; gypsum as an amendment for mushroom composts; and light requirements of *Brassica rapa* seedlings.

Effect of hormodin A, a growth substance, on the rooting of cuttings, M. A. MAXON, B. S. PICKETT, and H. W. RICHEY (*Iowa Sta. Res. Bul.* 280 (1940), pp. 929-973, figs. 56).—In cooperation with the Boyce Thompson Institute, a total of approximately 50 species and varieties of horticultural plants were used over a 2-yr. period in testing this proprietary growth substance, said to contain indolebutyric acid. Herbaceous cuttings almost without exception responded favorably to treatment at one or more of the concentrations used, unless old

woody tissue was employed or decay had entered the picture. The optimum concentration for herbaceous cuttings ranged between 2.5 and 10 p. p. m. The rooting response of greenwood cuttings of many species of deciduous trees and shrubs was variable and was influenced by prevailing climatic conditions. Some species, notably the apple, failed to root with any treatment. The spread of effective concentrations, 1.25 to 80 p. p. m., was much wider for greenwood than for herbaceous cuttings. However, only a few of the species withstood treatments stronger than 40 p. p. m. Evergreen cuttings were generally slow to root and sometimes decayed before the roots were initiated. Treated cuttings were more subject to injury by high temperatures and moisture fluctuations than were the untreated controls. The concentration required for evergreens tended to be high, most of the species ranging between 20 and 80 p. p. m. In general, results with hardwood cuttings were unfavorable. Practical suggestions are offered.

The use of copper resinate as a treatment for paper pots, M. LEATHERMAN and V. R. BOSWELL. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 951-955).—To test the effect on plants of copper resinate incorporated in paper containers used for growing vegetable plants, paper cups dipped in carbon tetrachloride solution with different concentrations of copper resinate were filled with soil and planted with small Marglobe seedlings. Part of each lot of the pots was plunged into soil. In a test conducted in December growth in the treated pots was not significantly different from that in clay pots, but was significantly greater than that in the untreated paper pots. In a second test the copper resinate treatment was again beneficial with respect to growth. The differences were greater in the case of paper pots planted in soil than in those above the soil. Noting no apparent correlation between the amount of copper resinate in the pots and growth, the authors suggest that the lowest concentration was adequate to suppress the activity of microorganisms. In no case was there any evidence that any of the amounts of copper resinate used were toxic to tomato plants.

[**Results of variety tests**] (*Pennsylvania Sta., Jour. Ser. Papers* 930 (1939), pp. 7, figs. 12; 932, pp. 10; 934, pp. 9, figs. 61; 940, pp. 7; 942, pp. 8; 998 (1940), pp. 8; 999, pp. 7; 1002, pp. 8, figs. 13; 1007, pp. 7; 1008, pp. 6, figs. 25).—There is presented in mimeographed form the following papers: No. 930, Bean Variety and Strain Trials, 1939; No. 932, Pepper, Celery, Spinach, Muskmelon, and Watermelon Trials, 1939, and No. 934, Pea Variety and Strain Trials, 1939, all by E. M. Rahn; No. 940, Tomato Variety and Strain Trials, 1939, and No. 942, Sweet Corn Variety and Strain Trials, 1939, both by E. M. Rahn and G. J. Stout; and No. 998, Sweet Corn Variety and Strain Trials, 1940, No. 999, Tomato Variety and Strain Trials, 1940, No. 1002, Pea and Edible Soy Bean Variety and Strain Trials, 1940, No. 1007, Cabbage Variety and Strain Trials, 1940, and No. 1008, Cucumber and Celery Variety and Strain Trials, 1940, all by E. M. Rahn.

The Golden Gopher muskmelon, T. M. CURRENCE, C. J. ELDE, and J. G. LEACH. (Minn. Expt. Sta.). (*Minn. Hort.*, 68 (1940), No. 9, p. 171, fig. 1).—A description is presented of a new muskmelon developed by the station.

The Essary tomato, D. M. BAILEY (Tennessee Sta. Cir. 71 (1940), pp. 4, figs. 3).—Obtained by mass selection from the Marglobe variety, the Essary tomato is described as to vine and fruit characters and yielding capacity. Over the 3-yr. period, 1938-40, at the Mericourt substation, Essary outyielded both Certified Marglobe and Certified Indiana Baltimore in average total yield and average yield of U. S. No. 1 fruit.

New methods of fertilizing tomatoes, J. B. HESTER (Amer. Soc. Hort. Sci. Proc., 36 (1939), pp. 935-938).—Based on a series of field experiments conducted

in 1938 and 1939, the author suggests that tomatoes should be supplied liberally with P in the row under the plant before, or at, the time of planting, but that N and K should be used sparingly at this time. It is suggested that the abundant fertilization with N and K should be in the form of side dressing on sandy soils and broadcast or plowed under on heavy soils. By delaying the application of N and K the plants receive these materials at the time they need them.

The effect of the size of the fertilizer application on yield of greenhouse tomatoes, I. C. HOFFMAN. (Ohio Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 927-929).—With the so-called standard fertilizer treatment as a control, greater and lesser amounts were used to determine whether deviations from the standard treatment might be profitable. With the Globe tomato set in greenhouse beds about January 20 the plot which received the standard application yielded the largest amount of marketable fruit. Where the amount of fertilizer was trebled or quadrupled yields became progressively less. Much the same type of results was secured with the Marhio tomato planted at a different period.

The effect of calcium and potassium fertilizers on the solidity and the calcium and potassium content of canned tomatoes, C. B. SAYRE, Z. I. KERTESZ, and J. D. LOCONTI. (N. Y. State Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 5, pp. 389-394).—Using the Nystate variety, it was found that on a soil containing abundant natural supplies of calcium, but insufficient potassium for maximum crop yields, the addition of calcium salts or potassium salts had no appreciable effect on the calcium or potassium content of the tomatoes produced nor on the firmness of the canned fruits as measured by their drained weight.

Some effects of maturity on the marketability of Florida tomatoes, W. M. FIFIELD. (Fla. Expt. Sta.). (*Fla. State Hort. Sci. Proc.*, 52 (1939), pp. 143-146).—With practically all of the Florida tomato crop harvested in the green-ripe stage, the author studied the effects on yield and market quality of leaving tomatoes on the vines until they began to change color. Total yields of the green-ripe and "turning" plots were about the same, but the yield of No. 1 fruit was almost twice as great on the green-ripe plots due to overripe rejects and a greater incidence of cracking and other injuries on the turning plots. However, in ripening tests following harvest the turning fruits ripened from 95 to 100 percent of salable tomatoes within a 6- or 7-day period as compared with an average of only 68 percent for green-ripe tomatoes. When shipped to northern markets consignees stated that the turning fruit compared favorably with home-grown tomatoes.

The interaction of nitrogen, potassium, and phosphorus on growth of young apple trees in sand culture, L. P. BATJER, W. C. BAYNES, and L. O. REGEIMBAL. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), p. 43).—Observations on 1-yr. York Imperial and Delicious apple trees grown in sand cultures in the greenhouse showed that the concentration of P and K in the nutrient solution had no significant effect on growth at a low N level, 10 p. p. m., but at higher levels (25 and 100 p. p. m.) growth increased with increasing supplies of P and K. No visible K or P deficiency symptom was noted in any treatment. Increased growth resulted from increased N supply at all levels of both P and K. The contents of N, P, and K in the leaves were directly influenced by the supply in the nutrient solution. High P increased the N content of the leaves, but K had no significant effect. With all three levels of K, 100, 10, and 4 p. p. m., the amount of K in the leaves tended to increase with the decrease of N. P content of the foliage also increased

with decreasing N. In the high P cultures there was a tendency for the P content of the foliage to increase with decreasing K.

Correlation of fruit color in apples to nitrogen content of leaves, J. R. MAGNESS, L. P. BATJER, and L. O. REGEIMBAL. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 39-42, fig. 1).—Utilizing a group of 8-year-old Rome Beauty trees just coming into fruiting and embraced in a nitrogen fertilizer study, there was observed an inverse relationship between the amount of N in the leaves at harvesttime and the amount of color development of the fruit. It was evident that to obtain best color in the apples N applications should be as light as was consistent with satisfactory growth and yield. Trees that received N applications after leaf fall the preceding autumn developed high color in their fruit, but the N content of the trees was low suggesting a possible loss from the soil by leaching. Under the conditions of the experiment the addition of K was apparently without effect on color development.

Tree girth and yield as indicators of subsequent apple tree productivity, A. F. YEAGER and L. P. LATIMER (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 101-105; also [*New Hampshire Sta. Sci. Contrib.* 76 (1939)], pp. 101-105).—An analysis of yield and growth data taken on a block of Northern Spy with McIntosh fillers at Durham and in a McIntosh orchard near Pittsfield revealed many correlations that might be useful in estimating future yields of the trees. Girth proved to be a fairly good measure of the average productivity of trees in the succeeding 2 yr., but was not so accurate for estimating yield of each of the 2 yr. The average yield for any 2 yr. was correlated closely with average yield in succeeding years. Attempts to utilize both girth and yield by the multiple correlation technic proved effective, but this method was very little better than that of average yield alone. Selection of a group of the more uniform trees, based either on growth or yield, resulted in considerably smaller coefficients of variability.

Catalase activity and nitrogen content of apple buds in relation to advance in season, A. J. LOUSTALOT. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 363, 364).—In lateral buds collected at different intervals from February 16 to May 8 from 1- and 2-year-old shoots of 18-yr. McIntosh trees there was noted little or no change in catalase activity until March 27, when there was a marked increase which continued until the last sampling date. Nitrogen content showed no appreciable change until April 20, with a continued rise thereafter. A gain in catalase activity preceded any apparent change in dry weight and nitrogen content of the buds.

Catalase activity in relation to after-ripening of apple seeds, A. J. LOUSTALOT. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 361, 362).—Parts of two lots of McIntosh apple seeds, one of which had been kept dry in an open container at room temperature for 1 yr. and the other freshly extracted from the fruit, were afterripened in damp peat moss at a temperature of 32°-36° F. Catalase determinations after removal of the seed coats showed little or no change in the nonafterripened lots of both ages. The afterripened seeds showed a gradual increase in enzyme activity, accompanied by increased germinability. At the last sampling date, 85 days following afterripening, the old and the fresh seeds were about alike in catalase activity. The older seeds seemed to yield a somewhat higher and earlier germination than did the fresh seeds.

Cover crops and fertilizers for Georgia peach orchards, E. F. SAVAGE (*Georgia Sta. Cir.* 122 (1940) pp. 10, figs. 2).—Pointing out the potential value of cover crops, the author warns that certain kinds of cover crops may compete seriously for water and thereby injure the peach trees. Winter types, such as rye and vetch mixtures, Austrian Winter peas, and crimson clover, are desirable

because they grow in the season of abundant moisture. Lespedeza is also valuable because it makes its greatest growth in late summer and early autumn when the tree has less need for water. Information is given as to contour planting of trees, fertilizers and their use, and the effect of fertilizers on the fruit.

The phosphate nutrition of fruit trees.—II, Continued response to phosphate applied at the time of planting, O. LILLELAND and J. G. BROWN. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 53-57, figs. 2).—This second contribution (E. S. R., 76, p. 334) discusses the results of three treatments applied to Elberta peach trees planted in March 1937—(1) no fertilizer, (2) 10 lb. of treble superphosphate in the planting hole, and (3) the same as (2) plus $\frac{1}{2}$ lb. of ammonium sulfate. Part of the trees were dug in February 1938 and part in December 1939. Definite response to N was evident in June 1937 and to phosphate in July 1937. At the end of the first growing season the trees receiving phosphate and phosphate plus N were 245 and 322 percent larger, respectively, than the no-fertilizer trees. At the end of three growing seasons the percentages were 107 and 138, respectively, despite no further fertilization. Leaf symptoms of P deficiency did not appear in the no-fertilizer trees, but analyses of the leaves did show a marked increase in the P content during the first season, and only slight increments in the second and third seasons.

Studies on the use of certain dinitrophenol compounds to break the rest period in peach trees, J. H. WEINBERGER. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 353-358, figs. 2).—Of some 25 chemicals tested in Georgia as agents for breaking the rest period of peach trees, only 1, dinitrophenol, compared favorably with dinitro-*o*-cyclohexylphenol in effectiveness. Most of the materials proved no more effective than the oil emulsion carrier used alone. The time of application of rest-breaking chemicals was found highly important, with the optimum date varying widely with variety, latitude, and the severity of the winter. The optimal time extended apparently over only a few days and was governed by the number of hours of low-temperature (below 45° F.) exposure that the trees endured prior to treatment. In the orchard trials, chemical treatments appeared to be equivalent to 200-300 hr. of low-temperature exposure. The farther south that peaches are grown, the more significant was the rest-breaking treatment.

Summer pruning of peach trees in the nursery row, W. H. UPSHALL (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 343, 344).—Over a 3-yr. period no significant differences in trunk or height growth were noted in peach budlings whether the lower laterals were removed at weekly or biweekly intervals or once in September. However, frequent removal of laterals gave a smoother trunk with better-healed wounds.

Peach spraying experiments, 1938-1939.—Progress report, H. W. THURSTON, JR., and H. J. MILLER (*Pennsylvania Sta., Jour. Ser. Paper 952* (1940), pp. [1]+16).—This is a condensed report in mimeograph form.

A quantitative survey of eight mineral elements by a spectrographic method and of total nitrogen in young leaves of twenty-five varieties of American grapes, B. C. BRUNSTETTER, A. T. MYERS, I. W. DIX, and C. A. MAGOON. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 635-638).—The second leaves from the base of new thrifty shoots, after drying and grinding, were analyzed spectrographically for K, Mg, Ca, P, Al, Fe, Mn, Cu, and N. Outstanding differences were determined in the mineral and nitrogen contents of the different varieties, the differences in some instances amounting to 100 percent or even several hundred percent. Marguerite was characterized by a high content of Al, Fe, and Mn; Niagara by a low content of K and Ca; Massasoit by a low content of Mg and Mn; and Caywood No. 50 and Columbia Imperial by

a high N content. In Lindley and Marguerite only was the Fe content higher than that of the Mn. The biological significance of the findings is not discussed.

Rootstocks for the Oriental persimmon, R. W. HODGSON. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 338, 339).—Propagated on *Diospyros lotus*, *D. kaki*, and *D. virginiana*, Hachiya trees made their largest growth on *D. lotus* and their smallest on *D. virginiana*. Fuyu trees made their greatest growth on *D. virginiana* and their least on *D. lotus*. In general, *D. kaki* exhibited the widest range of compatibility with Oriental persimmon varieties and may prove the most desirable stock.

Fertilizer investigations with the Gros Michel banana, H. H. CROUCHER and W. K. MITCHELL (*Jamaica Dept. Sci. and Agr. Bul.* 19, n. ser. (1940), pp. [1]+30, figs. 11).—Stating that there is a paucity of published information relating to fertilizer studies of bananas and that the available data suggest that N is the most important limiting element, the authors discuss experiments with the Gros Michel variety in Jamaica. The results varied greatly with the type of soil involved. On a soil derived from Richmond Beds, favorable effects were secured only from N. On a soil derived from calcareous deposits of the Bowden Beds, benefits were secured from N, P, and K. On a soil of the Terra Rossa type, P proved the limiting factor, but when this element was supplied adequately K also became beneficial. On another soil of the Terra Rossa type, no yields were secured in the absence of applied K, and doubling the K fraction further increased yields. There was an apparent correlation between vigorous growth and yield. An excess of P without an increase in K resulted in short-fingered fruits and distortion of the fingers.

Investigation on the development of color in citrus fruits, E. V. MILLER and J. R. WINSTON. (U. S. D. A.). (*Fla. State Hort. Sci. Proc.*, 52 (1939), pp. 87-90).—Stating that there are two types of ether-soluble pigments in orange rinds, namely chlorophylls and carotenoids, the authors assert that degreening on the tree results in a loss of chlorophylls and an increase in carotenoids. Degreening by the use of ethylene tended to remove chlorophyll without increasing the carotenoids. Limes, lemons, and grapefruit differed somewhat from oranges in that carotenoid pigments tended to decrease along with chlorophyll as the fruits lost green color whether in the normal ripening process on the tree or when treated with ethylene.

Seasonal variation in juice and acid content of Persian limes, S. J. LYNCH. (*Fla. Expt. Sta.*). (*Fla. State Hort. Soc. Proc.*, 52 (1939), pp. 81-83).—Top-grade fruit obtained at 2-week intervals from packing houses was found to contain 50 percent or better of juice, except for one picking in June and one in December when there was a slight decline. Peaks occurred in August and early September and again from the middle of October to the middle of December. Acid content of the juice was more constant, with a range from 5.37 to 6.13 percent. The largest fruits were picked during November and December.

Gardenia culture, G. E. YERKES, F. L. MULFORD, L. McCULLOCH, and F. F. SMITH (*U. S. Dept. Agr. Leaflet* 199 (1940), pp. 8).—In compiling general information, the authors discuss the cultural requirements in the field, greenhouse, and home and the control of various physiological, pathological, and entomological conditions.

The culture and forcing of Easter lilies, H. E. WHITE (*Massachusetts Sta. Bul.* 376 (1940), pp. 20, figs. 3).—Presenting general information relating to the horticultural importance of lilies, foreign and domestic production of bulbs, culture, propagation, fertilization, temperature requirements for growth and physiological, pathological, and entomological problems, the author discusses

the results of certain experiments. The removal of from 20 to 25 scales from 7- to 9-in. bulbs reduced the vitality of the plants. Lilies grew equally well in soils with and without the addition of amendments of such materials as manure, peat, and sand. *Lilium longiflorum giganteum* bulbs rooted better at temperatures above than below 60° F., and the rooting temperature influenced the subsequent rate of stem development. Lilies rooted at from 80° to 82° and from 52° to 55° required approximately 100 days and from 140 to 150 days, respectively, to bloom. Bulbs rooted at from 60° to 70° produced slightly more blooms than those rooted below 60°. The 8- to 10-in. bulbs bloomed approximately 20 days earlier than the 7- to 9-in. bulbs. Erabu lilies bloomed 16 days earlier and produced more blooms per plant when rooted and grown at from 62° to 65° than at from 52° to 55°. Supplemental lighting was effective in hastening the blooming of Easter lilies, and cut blooms were held successfully for a period of 8 weeks in storage at from 38° to 40°.

Light and heat intensity not explanation of fading of rose blooms: Pruning, defoliation, carbohydrates are factors, J. C. RATSEK. (Tex. Expt. Sta.). (*South. Florist and Nurseryman*, 50 (1940), No. 11, pp. 3, 4, figs. 2).—Where Talisman roses were pruned to 4-, 12-, and 20-in. heights there was noted a great difference in the color of the blooms of the first crop. The petals of the blooms of the 4-in. plants were almost white, while those of the less severely pruned plants showed more and more of the normal color. Unpruned plants produced deep-red blooms of the true Talisman form. Where stems were completely defoliated, within 4 days the developing blooms were white to pale pink. The application of a sugar solution to the defoliated plants improved the color. By defoliating plants to different degrees and controlling the number of blooms it was possible to produce a whole range of colors. It is concluded that carbohydrate supply is concerned with development of color, and light intensity is also a factor.

The ferns and related plants native to North Dakota, O. A. STEVENS (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 2, pp. 13-15, figs. 3).—Descriptive notes are presented on a number of ferns and related plants.

Coniferous tree seed testing and factors affecting germination and seed quality, C. E. HEIT and E. J. ELLASON (*New York State Sta. Tech. Bul.* 255 (1940), pp. 45, figs. 8).—Based on studies with 34 different species of conifer seed, the authors report that the various species have characteristic requirements for successful germination. Mature, well-filled seeds freshly collected and extracted properly should be practically 100 percent viable, and any material reduction from this figure suggests improper handling during collection, extraction, and storage. In the study, average germination percentages varied greatly with genera and species. Most of the pines were between 70 and 90 percent viable, while larch seed seldom gave over 50 percent. Moist prechilling was found essential for certain pine and larch species and for eastern hemlock, and may be desirable for other species. Daylight was necessary for satisfactory germination of some species, and artificial light may be helpful in securing complete germination in certain Scotch pine stocks. Temperature and moisture were critical factors in the germination of some species, and alternating or cool temperatures were more stimulating to the dormant seed than were constant or high temperatures. Pine seed had longer life in ordinary dry storage than did other genera. The ideal long-time storage for all conifer seeds was in sealed containers at a temperature of about 2°-4° C., and with a moisture content not exceeding 5-8 percent.

FORESTRY

The Society of American Foresters—an historical summary, R. S. HOSMER (*Jour. Forestry*, 38 (1940), No. 11, pp. 837-854).—This historical summary by a charter member covers the 40 yr. of life of the society during which the membership has increased from 7 to 4,600, distributed in 19 sections of the United States and Canada.

[**Forestry studies by the New Haven Station**] (*Connecticut [New Haven] Sta. Bul.* 438 (1940), pp. 509-511, 513).—Brief reports are presented on the salvaging of lumber destroyed by the hurricane in the Rainbow Forest, measurements on fallen timber, preservative treatment of fence posts and other wood products, and the distribution of forest planting stock.

Forestry [studies by the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 399 (1940), pp. 27-29).—Brief reports are presented on studies of the distribution of trees by diameter classes in virgin timber stands, by H. A. Meyer and D. D. Stevenson; the value of different chemicals for killing "weed" trees, by Stevenson; and factors affecting the sugar content of maple sap, by Stevenson and H. O. Triebold.

Forestry on private timberlands (*U. S. Dept. Agr., Misc. Pub.* 381 (1940), pp. [25], figs. 80).—This is a pictorial record, with annotations, of what some private timberland owners in the United States are doing to keep their forest lands in a productive condition.

Simple method for determination of range distance, R. R. PATON and Z. W. WHITE. (Ohio Expt. Sta.). (*Jour. Forestry*, 38 (1940), No. 10, pp. 818, 819).—Herein is outlined a simple method based on triangulation for determining horizontal distances.

The viability and collection of seed of *Liriodendron tulipifera* L., R. E. WEAN and A. T. GUARD. (Purdue Univ.). (*Jour. Forestry*, 38 (1940), No. 10, pp. 815-817, fig. 1).—Discussing seed formation in the tulip tree, the authors report that in examining a total of 11,161 samaras collected from cones from 7 trees only 19.08 percent were found to contain endosperm. This suggested that some 81 percent of the embryos had apparently aborted following fertilization. There appeared to be no significant variation in the number of seeds per cone or in the number of embryos developed from cones collected at different heights from the trees. The individual trees differed in the percentage of viable seeds per cone, suggesting the desirability of examining sample cones from a given tree prior to harvesting the fruits for seeding purposes. It is suggested that a transverse cut through the middle of a cone will indicate the value of the parental tree as a source of seed.

Multiple seedlings of pines and Douglas fir, A. R. GRAVATT, D. H. LATHAM, L. W. R. JACKSON, G. Y. YOUNG, and W. C. DAVIS. (U. S. D. A. et al.). (*Jour. Forestry*, 38 (1940), No. 10, p. 818, fig. 1).—A record is presented of the frequency of occurrence of multiple seedlings in *Pinus banksiana*, *P. ponderosa*, *P. resinosa*, *P. sandergergeri*, *P. strobus*, and *Pseudotsuga taxifolia*. (= *P. douglasii*).

Propagation of white pine by cuttings, W. L. DORAN, R. P. HOLDSWORTH, and A. D. RHODES. (Mass. Expt. Sta.). (*Jour. Forestry*, 38 (1940), No. 10, p. 817).—Cuttings taken in March from the upper and lower portions of a tree about 30 yr. old were treated variously with indolebutyric acid and sucrose and placed in a sand-peat moss bed in a warm greenhouse. At the end of 3 mo. the untreated controls were mostly dead, but the cuttings which had been given a preliminary treatment with sucrose and a final treatment with a solution of 50 mg. of indolebutyric acid per liter of water had rooted 20 percent

in the case of cuttings from the lower part of the tree and 10 percent in those from the upper portion. Cuttings treated with sucrose prior to the indolebutyric acid treatment lived longer, rooted or not, than did those treated with the acid alone.

Effect of high rate fertilizer treatments of nursery stock upon its survival and growth in the field, S. A. WILDE, R. WITTENKAMP, E. L. STONE, and H. M. GALLOWAY. (Wis. Expt. Sta. et al.). (*Jour. Forestry*, 38 (1940), No. 10, pp. 806-809, figs. 2).—The application by broadcasting or in solution of a balanced NPK fertilizer to nursery beds of average fertility resulted in an average increase in survival of from 10 to 15 percent following transplanting of 2-year-old jack, red, and Scotch pine seedlings to a podzolic outwash sandy loam. However, no statistical significance could be attached to survival data because of the variability among individual sample plats. The average increase in height growth ranged from 20 to 30 percent in favor of the fertilized stock and was found statistically significant. A seasonal effect was evident, with spring planting giving somewhat better survival and height growth than did fall planting.

A new method of pruning, B. H. PAUL and S. A. WILDE. (U. S. D. A. and Univ. Wis.). (*Jour. Forestry*, 38 (1940), No. 10, pp. 819, 820, fig. 1).—A Russian method of disbudding the lateral shoots from the leader so as to secure a branchless trunk of from 6 to 7 m. in length is described. During the process, some of the lower laterals are allowed to remain to nourish the branchless leader.

The role of soil organic matter in reforestation, S. A. WILDE and W. E. PATZER. (Wis. Expt. Sta. et al.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 8, pp. 551-562, figs. 7).—In studies conducted in Wisconsin there was noted a pronounced increase in the rate of height growth of *Pinus banksiana* and *P. resinosa*, correlated with a higher content of organic matter in the soil. A close relationship was established between the content of organic matter and that of total N, available P, and available K in outwash and pitted outwash sandy soils derived from granitic rocks. There was noted a general tendency for the increased survival of seedlings on soils high in humus, but the correlation was not significant.

The effect of a compact subsoil horizon on root penetration, D. I. CROSSLEY. (Minn. Expt. Sta.). (*Jour. Forestry*, 38 (1940), No. 10, pp. 794-796, figs. 2).—Under conditions prevailing in central Minnesota, permanently compacted subsoils restricted rooting mainly to the superimposed soil horizons, with the degree of confinement depending on the degree of compaction. The irregular growth habit exhibited by the roots of bur oak growing under normal soil conditions is attributable to hereditary characteristics rather than to any external factors. It was evident that the uniformity in the position and size of the structural elements in the roots of the bur oak make it impossible to distinguish any seasonal growth periodicity.

Tested methods of grafting pines, N. T. MIROV. (U. S. D. A. and Univ. Calif.). (*Jour. Forestry*, 38 (1940), No. 10, pp. 768-777, figs. 8).—In grafting experiments, pines belonging to rather widely distant groups were successfully united. On the basis of the 15 species employed, it appeared possible to intergraft any of the species. Treatment of the grafted seedlings with colchicine tended to increase survival. Shoots of older trees were grafted successfully on young transplants, and needle bundles of ponderosa and Coulter pines were grafted successfully. Inarching was found the most successful method for grafting pines under the semiarid conditions of California summers. The value of the findings for experimental work is emphasized.

Shade effects in ponderosa pine, G. A. PEARSON. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 10, pp. 778-780, figs. 2).—In experiments with seedlings and transplants grown under lath shades of different densities and with root competition eliminated, it was found that "ponderosa pine does not develop normally in the Southwest if overhead cover intercepts as much as half of the insolation. Side shade improves the form and is, on the whole, beneficial if the tree receives full sunlight from above during most of the day. Sapling and pole stands, even under dense stocking, need the side shade of larger trees in order to develop a form suitable for saw timber."

Forest products statistics of the Northeastern States, R. V. REYNOLDS and A. H. PIERSON (*U. S. Dept. Agr., Statis. Bul. 70* (1940), pp. 109, figs. 3).—This, the fifth in a series of six bulletins planned to cover the entire United States (E. S. R., 82, p. 494), presents statistics for 11 Northeastern States and the District of Columbia. The subjects covered include lumber production, distribution, and consumption; pulpwood consumption; and stumpage, log, and lumber prices.

DISEASES OF PLANTS

Bureau of Plant Pathology, D. G. MILBRATH (*Calif. Dept. Agr. Bul.*, 28 (1939), No. 10, pp. 567-577).—Included are brief reports of work with western celery mosaic, bacterial ring rot of potato, peach mosaic eradication, decline disease of date palm, white pine blister rust, vetch disease of unknown cause, chestnut blight eradication, Pierce's disease of grapevines, European grape diseases, crown gall, crinkle disease of cherry, a disease of *Pittosporum tobira* suggestive of virus etiology, bud shattering of almond, Winters disease of peach, a new peach trouble resembling the "X" disease, and a summary of causes of plant diseases on specimens received during 1939.

[Plant disease work by the New Haven Station] (Partly coop. U. S. D. A.). (*Connecticut [New Haven] Sta. Bul.* 438 (1940), pp. 511-513, 516-520, 528).—Progress reports are included on white pine blister rust and Dutch elm disease control; new copper compounds for downy mildew of cucumber and cantaloup; new sprays and schedules for defoliation diseases of tomato and other vegetables; new squash foot rot due to *Fusarium* sp.; studies of "X" disease of peach; apple spraying for cedar rust, scab, and insect pests; foliar nematode on chrysanthemums; and seedbed control of tobacco downy mildew.

Some recent records of plant pathogens in Missouri, W. E. MANEVAL. (Univ. Mo.). (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 1940, Sup. 125, pp. 151-164).—This annotated list supplements one previously noted (E. S. R., 78, p. 809), and contains numerous new records of pathogens on wild and crop plants, nearly half of the fungi being new reports for Missouri and most of the others being new host records. There are 50 references.

[Plant disease work by the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 399 (1940), pp. 23, 24, 47, 65).—Brief progress reports by W. S. Beach, J. J. Reid, D. E. Haley, H. W. Thurston, Jr., and D. E. H. Frear are included on tobacco leaf spot diseases (*Pseudomonas fluorescens* and *Bacterium tabacum*) and their control; specific gravity of commercial and home-boiled lime-sulfur fungicides; and *Trichoderma* spp., *Diplocladium* spp., and *Conidiobolus villosus* in relation to mushroom diseases and their control.

[Papers of interest to phytopathology] (*Assoc. Off. Seed Anal. North Amer. Proc.*, 31 (1939), pp. 116-127, figs. 5).—The following are of interest: Influence of Chemical and Thermal Treatments on Infection of Cruciferous Seedlings by *Alternaria* spp. and *Rhizopus nigricans*, by W. Crosier and S. Patrick (pp. 116-120), and Some Fungi Associated With Grass Seed, by W. Crosier and D. E.

Weimer (pp. 120-124) (both N. Y. State Expt. Sta.); and The Hemocytometer Method for Detecting Fungous Spore Load Carried by Wheat Seeds, by W. N. Rice (pp. 124-127) (Iowa).

Mycological notes [trans. title], J. B. MARCHIONATTO (*Physis*, 15 (1939), No. 47, pp. 133-144, pls. 9).—Descriptions and local notes on 27 species of fungi of phytopathological interest.

[Proceedings of Central New York Branch of the Society of American Bacteriologists] (*Jour. Bact.*, 40 (1940), No. 1, pp. 165, 166, 168, 169).—Abstracts of the following papers of interest to plant pathology are included: The Selective Disinfection of Seeds, by H. S. Hamilton and A. W. Hofer (N. Y. State Expt. Sta.); and Seed-Bed "Sterilization" and Tobacco Wildfire, by J. Naghski, D. E. Haley, and J. J. Reid (Pa. Sta.).

A review of latent infections caused by *Colletotrichum gloeosporioides* and allied fungi, R. E. D. BAKER, S. H. CROWDY, and R. K. MCKEE (*Trop. Agr. [Trinidad]*, 17 (1940), No. 7, pp. 128-132, figs. 3).—The object of this review (17 references) is to summarize existing data on this and allied species of *Colletotrichum*, and to indicate problems still requiring elucidation.

The genus *Fusarium* in Argentina [trans. title], C. J. M. CARREBA (*Physis*, 15 (1939), No. 47, pp. 21-77, figs. 24).—A general and taxonomic study, discussing the genus, its importance from the standpoint of plant infections, the types of lesions induced, pathogenicity, culture studies and media, keys to the generic groups, and detailed treatment and illustrations of the specific groups and species. Three pages of references are included.

Argentine species of *Peronospora* [trans. title], J. C. LINDQUIST (*Physis*, 15 (1939), No. 47, pp. 13-20).—A taxonomic study of this plant-parasitic fungus genus.

A quick method of isolating certain phycomycetous fungi from soil, C. H. MEREDITH. (Iowa Expt. Sta.). (*Phytopathology*, 30 (1940), No. 12, pp. 1055, 1056).—Phycomycetous fungi were isolated by touching the soil on a flamed cover slip to the surface of an inverted Petri dish of nutrient-free agar. The tip of the most rapid-growing organism was freed from bacteria by placing it under nutrient-free agar in a Petri dish and removing the fungus when it grew to the surface. Cultures of *Pythium debaryanum*, *P. ultimum*, *P. rostratum*, *P. echinulatum*, *P. pulchrum minden*, and *P. vexans* were identified in northern Iowa, and of *P. debaryanum*, *P. pulchrum*, and *P. rostratum* in southern Iowa.

Morphogenetic aspects of virus diseases, M. SHAPOVALOV. (U. S. D. A. and Utah Expt. Sta.). (*Utah Acad. Sci., Arts, and Letters, Proc.*, 16 (1938-39), pp. 55-58, pl. 1).—The author concludes from this review that systemic viruses can alter the normal morphology of plants, that these morphogenic effects may be either depressive or stimulative, that many of the morphological changes are teratological, and that the induced malformations may furnish valuable material to experimental morphology. Some of the virus-induced morphogenic changes in plants have been used for practical purposes in ornamental horticulture, and the possibilities of further developments along such lines are noted.

Acquired immunity from plant virus diseases, W. C. PRICE (*Quart. Rev. Biol.*, 15 (1940), No. 3, pp. 338-361, figs. 5).—A critical review (118 references).

The value of testing fungicides in the laboratory before use in the field, F. L. HOWARD. (R. I. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 409-414).—Tested on glass slides, bordeaux mixture at full or half strength almost completely inhibited germination of the peach brown rot fungus. Commercial brands of "dry" bordeaux and of certain "insoluble" copper fungicides when used at the recommended dilution proved inferior to bordeaux, but some of them

at double strength approached it in effectiveness. Liquid lime-sulfur 2-100 proved slightly more toxic than 1-100 dilution, but somewhat less so than bordeaux. A wide range in the efficiency of commercial dry lime-sulfurs was found. Many of the "wettable" sulfurs and the sulfur dusts exhibited a relatively low toxicity. An apparent sharp reduction in the toxicity of bordeaux to *Alternaria solani* spores occurred at dilutions greater than 5-5-50, and certain dry bordeaux preparations failed to check germination materially. Less fungicidal potency of some chemicals was evident on the living leaf than on glass. A small amount of wheat flour increased the effectiveness of some fungicides. Some insoluble coppers and liquid lime-sulfur had little effect on the spore germination of the tomato early blight fungus. Malachite green and some other organic dyes at great dilutions were potent against *A. solani* spores. Caution in selecting adjuvants is advised, since some combinations render the fungicide practically innocuous.

A rapid method of testing the effects of fungicides on fungi in culture, B. W. HENRY and E. C. WAGNER. (Univ. Wis.). (*Phytopathology*, 30 (1940), No. 12, pp. 1047-1049, fig. 1).—Dusts or sprays are applied directly to Petri dish cultures, from which a preliminary estimate of the fungicidal value of compounds is obtained.

Silver as a fungicide, L. W. NIELSEN and L. M. MASSEY. (Cornell Univ.). (In *Silver in Industry*, edited by L. EDDICKS. (New York: Reinhold Pub. Corp., 1940, pp. 431-450).—The text includes the toxicity of silver to plants, plant organs, and plant pathogens; and silver as a protective fungicide, seed disinfectant, and soil disinfectant.

Host specialization in the head smut of grasses, *Ustilago bullata*, G. W. FISCHER. (Wash. Expt. Sta. and U. S. D. A.). (*Phytopathology*, 30 (1940), No. 12, pp. 991-1017, figs. 2).—Cross-inoculation studies (1936-39) with 44 collections of *U. bullata* (including *U. bromivora* and *U. lorentziana*) from 36 species of *Agropyron*, *Bromus*, *Elymus*, *Festuca*, *Hordeum*, and *Sitanion* are presented. Eight physiologic races were recognized by the reactions of 14 differential species selected from the many inoculated. The supposed specialization of the smut from *Agropyron* and *Hordeum* spp. to grasses of the *Hordeae* and of the smut from *Bromus* spp. to grasses of that genus was found untenable. Certain collections from *Agropyron* and *Elymus* spp. proved virulent on *Bromus* spp., and certain collections from *Bromus* spp. proved virulent also on *Agropyron*, *Elymus*, and *Hordeum* spp. Five of the 8 races have highly susceptible hosts in both the bromegrasses and the *Hordeae*. The most common race, widespread in the Pacific Northwest on *B. tectorum*, proved capable of infecting a number of species of *Agropyron*, *Elymus*, and *Festuca*, as well as a few other *Bromus* species. Of the economic grasses, the most susceptible to this race of *U. bullata* is *E. glaucus*. Another race also common in the Northwest on the weed *B. mollis* is virulent on *E. canadensis*, also an economic species. The author's earlier recommendation that *U. bullata*, *U. bromivora*, and *U. lorentziana* be consolidated on morphological grounds is now fully substantiated by the fact that they are not even separable on a host specialization basis. The recognition of each physiologic race as a species is considered undesirable. Instead, the 8 races are given numbers, in accordance with the common practice of designating physiologic races in the rusts and smuts.

Variability in association effects of other soil fungi on the virulence of *Helminthosporium sativum* on wheat seedlings, G. B. SANFORD and M. W. CORMACK (*Canad. Jour. Res.*, 18 (1940), No. 11, Sect. C, pp. 562-565).—"Random isolates of *Penicillium*, *Actinomyces*, and certain miscellaneous soil-inhabiting fungi were tested in steam sterilized soil, under pure culture conditions, for their association effects on the virulence of *H. sativum* P. K. and B. on wheat

seedlings. Certain isolates of the first two genera mentioned exerted a marked degree of suppression, some had no effect, while others increased the virulence. Similarly, these effects varied widely within certain species of *Penicillium*. This preliminary study indicates that the random isolates of many genera and species of fungi may differ widely in ability to affect the virulence of certain plant pathogens."

Airplane spore traps for studying the annual migration of wheat rust, K. S. CHESTER. (Okla. A. and M. Col.). (*Okla. Acad. Sci. Proc.*, 19 (1939), pp. 101-104).—The additional evidence presented on the long distance movement of the rust diseases of wheat is believed to bring further indication that the rust problems are not purely local. Ultimate control must depend on the widespread use of resistant varieties.

The control of truck crop diseases in Tidewater Virginia, H. T. COOK and T. J. NUGENT (*Virginia Truck Sta. Bul.* 104 (1940), pp. 1661-1717, fig. 1).—The purpose of this bulletin is to furnish the truck crop growers of this region with definite programs for controlling the important diseases of the vegetable crops grown there. These programs are not necessarily applicable in other parts of Virginia or in other States. Part 1 considers the importance of vegetable diseases and the nature, causes, and methods of controlling plant diseases; part 2, disease control programs for specific crops; and part 3, the preparation and use of fungicides.

The effect of some mineral nutrients on the development of clubroot of crucifers, D. E. PRYOR. (Wis. Expt. Sta. et al.). (*Jour. Agr. Res. [U. S.]*, 61 (1940), No. 2, pp. 149-160, figs. 4).—Methods are reported for securing effective clubroot infection in sand culture. The plants were grouped into those with no symptoms, those with clubs, and those with galls. The clubs were of the usual type mentioned by other workers. The effect of S, N, and K nutrition on the development of clubroot in susceptible, resistant, and immune crucifer strains was studied, the proportions of nutrients being adjusted to produce plants with deficiency symptoms, plants growing moderately, and plants pronouncedly vigorous from an extra supply of N and K.

The percentage of susceptible plants with clubs was in general increased slightly over that in the complete solution by an abundance of K, more by an abundance of N, and most by the absence of S or N. The percentage was decreased markedly in plants deficient in K. A smaller proportion of susceptible plants developed galls in nutrient solutions with S or N withheld than was the case with resistant plants. The percentage of resistant plants with clubs was increased somewhat by high N, but it was greatest in the cases of S or N deficiency. With an extra amount of K the results were inconclusive. The proportion of plants with clubs was decreased definitely by lack of K. Gall formation was usually increased by the absence of S or by high N and was generally decreased by high or low K. No signs of clubroot appeared regardless of the variation in nutrient supply on the immune Purple Top Milan turnip. Deficiency of S lowered the S oil content greatly, while N starvation did not. On a given variety, the number of plants with clubs was increased to about the same extent by the absence of either of these elements. It would thus appear that S oils are unessential in preventing or retarding clubroot development in its tissues.

Agglutination test applied to strains of *Phytomonas stewarti*[i], G. L. McNEW and A. C. BRAUN (*Bot. Gaz.*, 102 (1940), No. 1, pp. 64-77).—Three of the 90 single-colony isolates studied failed to agglutinate in either of 2 serums used, some in one or the other but not in both, and the remainder in both serums at dilutions of 1:20 to 1:2,560. No consistent serological properties of isolates

from susceptible v. resistant inbred lines of corn were noted. Some isolates from the same leaf lesion were as different from one another as those from different plants. Strains from the same culture were found to differ in serological characters. Study of 15 strains showed that the serological properties were not correlated with any particular colony character, physiological ability, or degree of virulence. Strains from different localities in the United States and Mexico proved no different from one another than some of the variants derived from one of the strains. Some strains agglutinated in all serums as high as 1:1,280 to 1:5,120. These strongly agglutinating strains usually induced immune serums that failed to agglutinate 5 of the strains. The poorly agglutinating strains, on the other hand, produced serums that were effective against all the cultures tested. Several other species of wilt-inducing bacteria failed to agglutinate in antiserum for 3 strains of *P. stewartii*. There are 28 citations to the literature.

Agglutinin absorption by different strains of *Phytomonas stewartii*[1], A. C. BRAUN and G. L. McNEW (*Bot. Gaz.*, 102 (1940), No. 1, pp. 78-88).—Strains of *P. stewartii* differing in virulence, colony type, physiology, and agglutination reaction were tested for ability to absorb agglutinins from immune serums. All strains tested absorbed most of the agglutinins from both homologous and heterologous serums, showing that they were similar in most essentials. The failure of some strains to agglutinate after absorbing agglutinins appeared to be due to their resistance to this reaction. Some differences were noted between the strains from Mexico, New York, and New Jersey. The differences in serological properties were not closely correlated with any other character observed, such as virulence or colony type.

Studies of the etiological agent (*Phytomonas malvacearum*) of angular leaf spot of cotton in Argentina [trans. title], L. HALPERIN (*Physis*, 15 (1939), No. 47, pp. 99-102, fig. 1).—This is a preliminary report.

The susceptibility of cotton seedlings to *Phymatotrichum omnivorum*, L. M. BLANK. (Tex. Expt. Sta. coop. U. S. D. A.). (*Phytopathology*, 30 (1940), No. 12, pp. 1033-1041, fig. 1).—Under favorable conditions, infection of cotton seedlings from inoculation with sclerotia occurred to a greater extent with older than with very young seedlings. Inoculation at time of planting resulted in a longer incubation period and a much lower percentage of disease than did inoculation at 10 days or more after germination of the seed. Carbohydrate accumulation in the seedling tissues at approximately the time of a sharp increase in susceptibility to infection suggests the importance of the host-parasite nutritional relationship. Addition of starch to autoclaved soil or to an agar substrate increased the virulence to such an extent that seedlings were readily infected immediately after germination.

Sodium hypochlorite shows promise as a seed treatment, R. WEINDLING. (U. S. D. A. and S. C. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 12, pp. 1051, 1052, fig. 1).—Considerable control of damping-off of cotton due to *Glomerella gossypii* was obtained by treating seed with a commercial sodium hypochlorite preparation (B-K) at 1.5-4 oz. per bushel. The practical possibilities of such treatment are suggested for use where metallic germicides are undesirable.

Pea seed treatment with chemical dusts, J. C. WALKER, E. J. DELWICHE, and P. G. SMITH. (Wis. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 61 (1940), No. 2, pp. 143-147).—In 4 years' trials of red copper oxide and 2 percent Ceresan in Wisconsin, the benefits varied with season and location. Soil conditions inducing stand reduction of sugary-cotyledoned varieties were not detrimental to the starchy-seeded Alaska variety, and the latter was thus not benefited by seed treatment. There were significant increases in only 1 of 4 yr. at

Marshfield, and then only with red copper oxide. During a 2-yr. period, more consistent beneficial results were obtained by seed treatment at Sturgeon Bay than at Madison. In a majority of cases for all tests the increased stand was greater with red copper oxide. There was no clear correlation between soil moisture and effectiveness of treatment.

Anthracnose of black pepper (*Piper nigrum* Linn.), Y. Y. VIMUKTAN-ANDANA and M. S. CELINO (*Philippine Agr.*, 29 (1940), No. 2, pp. 124-141, figs. 5).—This reports a general study of a minor disease due to *Glomerella cingulata*, including the cultural characters of the fungus, climatic influences, and control.

Mildew or blight of peppers due to *Phytophthora capsici* in Argentina [trans. title], E. F. GODOY (*Rev. Facult. Agron. La Plata*, 24 (1939), pp. 235-280, pls. 7, figs. 2; *Eng. abs.*, p. 280).—This paper discusses the incidence and serious economic importance of the disease in Argentina; its symptoms, including fruit rot and killing of seedlings; characters of the fungus as isolated from stems, fruits, and seeds; its pathogenicity and seed transmission; the pathogenesis and epidemiology of the disease; and its control by soil disinfection, seed treatment, and spraying.

Potato naturally infected with California aster yellows, H. H. P. SEVERIN. (Calif. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 12, pp. 1049-1051, fig. 1).—A newly discovered variety or physiological race of the aster leafhopper (*Macrostelus divinus*) recovered the virus of California aster yellows from a spontaneously infected potato plant and transferred it to healthy asters.

Bacterial soft rot of potatoes in southern Florida, G. D. RUEHLE (*Florida Sta. Bul.* 348 (1940), pp. 36, figs. 6).—As a result of an investigation (begun in 1936) of the causative factors in a bacterial soft rot often causing heavy losses in shipments of washed potatoes from southern Florida, the causal organism (*Erwinia carotovora*) was isolated and its pathogenicity proved. Development in the field is closely associated with rainy weather causing waterlogging of the soil; is favored by other diseases, particularly late blight; and, in transit or storage, is increased by washing the tubers and crating them while wet, without rapid drying. Infection may start in the presence of free moisture at cuts, bruises, or cracks and may be spread by contact. The bacteria may enter from wet soils through lenticels or lesions.

From laboratory tests using a specially constructed apparatus for maintaining temperature and humidity, it was found that rapid drying of the tuber surfaces before or soon after packing controlled the disease in storage or shipment. Ordinary air blasts from fans or blowers proved insufficient, but washed potatoes were dried without damage by 4 min. in air heated to 150° F. The effect of the heated air on the temperature of the tubers was considerably offset by the cooling effect of evaporation. Tested on a commercial scale since 1938, bacterial soft rot has failed to develop sufficiently to cause rejection of a single shipment from the packing houses using the method. Precooling washed potatoes after loading the car eliminated most of the decay in shipments, but this method proved more costly and less reliable. Washing tubers by spray jets was less conducive to rot development than washing in tanks. The desirability is stressed of planting seed pieces in well aerated soil, of controlling diseases of the growing crop with copper fungicides, and of reducing mechanical injuries in harvesting to a minimum.

Problems in breeding for disease resistance, D. REDDICK. (Cornell Univ.). (*Chron. Bot.*, 6 (1940), No. 4, pp. 73-77).—A discussion of potato (*Solanum tuberosum*) breeding for resistance to *Phytophthora infestans* by the use of *S. demissum*.

The reaction of sorghum varieties and hybrids to milo disease, L. E. MELCHERS and A. E. LOWE. (Kans. Expt. Sta.). (*U. S. Dept. Agr., Bur. Plant*

Indus., *Plant Disease Rptr.*, 1940, *Sup.* 126, pp. 165-175).—This disease, also known as root, crown, and shoot rot of milo and *Pythium* rot of milo, is said to be of increasing economic importance in those States where it occurs. The reactions of a large number of sorghum varieties and hybrids to it are here presented.

The action of electrolytes on solutions of tobacco mosaic virus nucleoprotein (Marmor tabaci var. vulgare Holmes), R. J. BEST (*Austral. Jour. Expt. Biol. and Med. Sci.*, 18 (1940), No. 3, pp. 307-312, fig. 1).—The critical coagulation concentrations of a number of electrolytes for aqueous solutions of the pure virus nucleoprotein were determined at pH 7 and 30° C. The precipitating power of cations paralleled their valency. The virus was precipitated in the form of paracrystalline needles and fibers which retained their infectivity. The nature of the anion markedly influenced the precipitating power, a lyotropic series being evident. The order of effectiveness on a molar basis was (NO₃)' < (CNS)' < I' < Br' < Cl', succinate, acetate < phthalate < phosphate < oxalate < tartrate < malate < sulfate < citrate. Salicylates behaved anomalously and denatured the virus protein.

Stony pit of pears at Hood River, J. R. KIENHOLZ. (U. S. D. A.). (*Oreg. State Hort. Soc. Ann. Rpt.*, 31 (1939), pp. 21, 22).—A note summarizing the results of a survey and of studies of this virus disease in Oregon.

The "X" disease, or yellow-red virosis, of peach, E. A. WALKER. (Univ. Md.). (*Md. State Hort. Soc. Proc.*, 42 (1940), pp. 50-52).—A review, with 10 references.

Little leaf control demonstrations, O. T. MOWHORTER, W. W. LAWRENCE, and G. LEAR (*Oreg. State Hort. Soc. Ann. Rpt.*, 31 (1939), pp. 110-115).—A summary of the results of demonstrations of the past few years with zinc sulfate sprays in combination with boron and spreaders for controlling this disease in sweet cherry trees.

Checking fruit decay with ultraviolet lamps, E. R. DE ONG (*Blue Anchor*, 17 (1940), No. 9, p. 7).—An improved type of germicidal lamp has been recently developed which at short distances is said to be capable of killing both bacteria and the spores of fungi causing fruit decay.

Control of crown gall of raspberries, H. F. WINTER. (Ohio Expt. Sta.). (*Hoosier Hort.*, 22 (1940), No. 11, pp. 168-170).—Use of crown gall-free stock is advocated, to be secured through propagation by sucker plants selected as far away as possible from the parent plants and transferred to new crown gall-free soil each year for 4-5 yr.

Cultivation of bananas under shade for the control of leaf spot disease, C. A. THOROLD (*Trop. Agr. [Trinidad]*, 17 (1940), No. 11, pp. 213, 214).—*Cercospora musae* leaf spot, major factor in reducing banana exports from Trinidad from ±170,500 stems in 1937 to ±66,500 in 1939, is effectively checked by providing cocoa and immortal trees (*Erythrina* spp.) as overhead shade for the bananas. Undesirable characteristics render objectionable the use of the resistant Imperial College hybrid I. C. 2, and under Trinidad conditions spraying and dusting are considered economically impracticable although experimentally demonstrated as efficacious in Jamaica. It is recommended that the susceptible Gros Michel banana be grown under shade in spite of the resulting higher incidence of fruit scarring.

Melanose of citrus and its commercial control, G. D. RUEBLE and W. A. KUNTZ (*Florida Sta. Bul.* 349 (1940), pp. 54, figs. 7).—A study was begun in 1931 at the Citrus substation to obtain more information on the life history of *Diaporthe citri*, the fungus causing this important disease, and to develop more practical methods of control. The purpose of this bulletin is to present the known facts regarding the cause, factors influencing infection, and recommenda-

tions for avoiding losses in commercial groves. These data are discussed in detail. Abundant infection shortly after blooming results in severely blemished fruits, which are graded out at packing time. It was found that most of this melanose infection could be prevented by applying an efficient copper fungicide 2-3 weeks after petal fall, following a normal bloom. Single applications of 6-6-100 bordeaux spray have given better control than single applications of lower concentrations, especially under conditions of severe infection, but when infection is expected to be severe two spraying with a 3-3-100 formula at a 3- to 4-week interval are to be preferred. Several of the proprietary "insoluble" copper fungicides may be substituted for the bordeaux with nearly equal control, and insecticides compatible with bordeaux may also be used with them. Wettable or bentonite sulfurs appeared to be the most practical spreaders for use with post-bloom copper fungicides. They controlled mites and killed many scale crawlers when added at 5-10 lb. to 100 gal. of spray. Whenever efficient copper sprays are used for melanose, some extra spraying for scale will be necessary, and in most cases oil emulsions will be found most satisfactory. Certain precautions must be observed in applying the different sprays used in the recommended schedules if spray injuries are to be avoided, and modified schedules are suggested for special conditions. Keeping the trees reasonably free of dead wood by pruning in early or midspring is said to be a valuable supplement to spraying for melanose control.

Catalog of the bacteria and fungi of the coffee tree (*Coffea* spp.), J. GONÇALVES CARNEIRO and D. BENTO PICKEL (*Catálogo das bacterias e dos fungos do caféeiro*. São Paulo: Sec. Agr., Indus. e Com. Estado São Paulo, 1940, pp. 184).

Mango anthracnose [trans. title], G. G. RADA (*Min. Fomento, Dir. Agr. y Ganaderia [Peru], Cir. 50 (1939), pp. 7, pls. 2*).—An informative leaflet on the disease due to *Glomerella cingulata*, including control.

Further studies on the comparative efficacy of bordeaux mixture, copper oxalate, and some other "insoluble" copper sprays for the control of walnut blight, P. W. MILLER. (U. S. D. A.). (*Oreg. State Hort. Soc. Ann. Rpt., 31 (1939), pp. 127-132*).—Continuing his studies (E. S. R., 81, p. 535) of various fungicides for control of *Phytophthora juglandis* on Persian walnut, the author found that at a sufficiently strong concentration copper oxalate gave almost as good control (1939) as bordeaux mixture and without injuring the foliage, as is often the case with the latter. Yellow cuprous oxide, copper oxychloride, and copper acetate also caused no detectable injury and gave good control, whereas zinc ammoniacal copper silicate, brown cupric oxide, and a proprietary copper fungicide gave poor to fair control and were noninjurious.

What can be done about lily mosaic? P. BRIERLEY. (U. S. D. A.). (*Amer. Lily Yearbook, 1940, pp. 10-19, figs. 4*).—The author attempts to define the lily mosaic problem in some detail, to weigh more recently discovered information, and to consider what lines of procedure are likely to control the disease satisfactorily in garden lilies. The discussion includes the new evidence and new views on lily mosaics, their prevalence in garden lilies, the wild host and latent virus hazards, and two possible methods of control—growing virus-free lilies from seed or use of varieties which resist, escape, or endure the disease.

Living with lily mosaic, G. L. SLATE and E. P. IMLE (*Amer. Lily Yearbook, 1940, pp. 27-32, fig. 1*).—Following a brief discussion of control by detection and destruction of diseased lilies to prevent spread of the virus to healthy plants, and by planting bulbs of known freedom from infection and isolating them from diseased lilies, the author suggests growing only those varieties which for one reason or another are able more or less successfully to escape infection.

Toward this end, annotated lists are presented of lilies which nearly always escape mosaic infection, those which usually escape, those which remain moderately free, those which are tolerant, and those which are very susceptible.

Importance of *Verticillium* as a pathogen of ornamental plants, A. W. DIMOCK. (Cornell Univ.). (*Phytopathology*, 30 (1940), No. 12, pp. 1054, 1055).—Over a 2-yr. period the author isolated *Verticillium* strains from 17 species of ornamental plants (listed) showing symptoms of hadromycosis, including what were apparently first records for fall monkshood, bachelor's-button, larkspur, common foxglove, mignonette, salpiglossis, and African marigold, and the first report in North America for annual and perennial phlox and Oriental poppy. Inoculations on various hosts are noted, and additional susceptibles from Europe are listed. Limited cross-inoculations failed to indicate any host specialization in the strains used. Since the organism is present in most varietal plantings of florists' chrysanthemums, the desirability of sterilizing chrysanthemum soil before replanting with other ornamentals is emphasized.

Apparent recovery of American elms inoculated with *Ceratostomella ulmi*, S. J. SMUCKER. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 12, pp. 1052-1054).—The results of studies of 115 successfully inoculated trees indicated that the fungus had gradually died out in some of them. In such trees recovery had progressed from apparent to real. Subsequent inoculations of 10 each of the infected, recovered trees and of the noninfected controls indicated that failure of the infected trees to develop external symptoms during seasons following the original infection could not be attributed to any lack of pathogenicity of the fungus or to any immunity acquired by the trees.

Dutch elm disease and its control, D. S. WELCH and D. L. COLLINS (N. Y. State Col. Agr., Cornell Ext. Bul. 437 (1940), pp. 19, figs. 8).

Note on a heart rot of oak trees caused by *Polyporus frondosus* Fr., K. S. CARTWRIGHT (*Forestry*, 14 (1940), No. 1, pp. 38-41, pl. 1, figs. 3).

Mycelial extent beyond blister rust cankers on *Pinus monticola*, J. EHRLICH and R. S. OPIE. (Univ. Idaho.). (*Phytopathology*, 30 (1940), No. 7, pp. 611-620, fig. 1).—*Cronartium ribicola* mycelium in the distal ends of 116 cankers on green stems and branches and proximal ends of 146 cankers on green stems and green and flagged branches from three ecologically comparable areas in one northern Idaho locality was found to extend 0.5-3 (mean 1.66) cm. beyond the externally visible canker margins. No practical mean difference was found between distal and proximal measurements, or, for each type of canker, between measurements for the different areas. Mean extents were about 2.3 cm. for cankers on green stems, 1.5-1.6 cm. for cankers on green branches, and 1.2 cm. for cankers on flagged branches. Of 4 possibly related and readily determinable canker characters studied, diameter of cankered internode at the outer limits of surface discoloration was found to be most closely correlated with mycelial extent and to be most readily and accurately determinable in the field.

White pine blister rust control—Michigan.—Annual Reports, 1938, E. C. MANDENBERG; 1939, J. K. KROEBER ([Lansing]: Mich. Dept. Agr., 1938, pp. [4]+38, figs. 2; 1939, pp. [5]+53, figs. 3).

The presence of *Fusarium bulbigenum blasticola* in Argentina [trans. title], M. J. FREZZI (*Physis*, 15 (1939), No. 47, pp. 87-97, figs. 6).—This reports a study of the fungus and the damping-off of pine seedlings which it causes, and includes discussion of the symptoms, the fungus and its pathogenicity and cultural characters, and control of the disease by soil and seed disinfection.

The watermark disease of willows.—I, Host-parasite relationships, G. METCALFE (*New Phytol.*, 39 (1940), No. 3, pp. 322-332, pl. 1, figs. 2).—In addition

to *Bacterium salicis*, a white, a yellow, and a green-fluorescent bacterium were found constantly associated in watermarked willow wood. The bacterial population of diseased wood was found to change with time, *B. salicis* being inactivated after the first year, followed by a second invasion of the wood by the three associated bacteria and leading to the complete permeation of all the tissues. The distribution of the bacteria in the wood and the pathological effects are described. The infection of healthy wood and the spread of the bacteria in such wood are discussed in relation to the persistence of the disease in the tree from year to year.

Colorado rusts of woody plants, P. F. SHOPE (*Colo. Univ. Studies, Ser. D, Phys. and Biol. Sci.*, 1 (1940), No. 2, pp. 105-127).—An annotated list of 58 species, with key.

The effect of *Peniophora gigantea* and *Schizophyllum commune* on strength of southern yellow-pine sapwood, C. A. RICHARDS and M. S. CHIDESTER. (U. S. D. A.). (*Amer. Wood-Preservers' Assoc. Proc.*, 36 (1940), pp. 24-31, figs. 5).—The results of the tests reported are believed to indicate clearly that these two fungi, and particularly *P. gigantea*, should no longer be regarded as harmless. In large timbers in which they have not permeated the wood thoroughly the strength would be affected to a much less extent, but the tests have definitely shown that *P. gigantea* may reduce the strength of the wood considerably. The necessity for storage under as favorable seasoning conditions as possible and for limiting the length of the storage period is emphasized.

Proceedings of the Third National Plant Nematode Conference, edited by H. P. BARSS (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 1940, Sup. 124, pp. 135-150).—Abstracts of the following papers are presented: Inducing Uniform Soil Infestations of the Nematode *Heterodera marioni* as an Aid in Breeding for Resistance to Root Knot, by K. C. Barrons (Mich. State Col.); Remarks on Additions to a List of Hosts of the Root-Knot Nematode, by E. M. Buhner; Resistance to Root Knot Nematode in *Nicotiana*, by E. E. Clayton; The Bulb Nematode (*Ditylenchus dipsaci*) in Narcissus Plantings in Western Oregon, by C. A. Cole; Some Observations on the Development of Root-Knot Nematode Diseases in Virginia, by S. [B.] Fenne; Some Suggestions for Quick Testing of Nematode Resistance in Plant Breeding Programs, by G. H. Godfrey (Tex. Expt. Sta.); Controlling Root-Knot Nematodes in Potatoes in the Klamath Basin by Means of Irrigation, by A. E. Gross (Oreg. Sta.); Control of Root Knot in Florida Cigar-Wrapper Tobacco Fields, by R. R. Kincaid (Fla. Sta.); Comparison of Crop Rotation and Fallowing as Methods of Control for Root Knot of Cotton Under Irrigation, by C. J. King; The Reniform Nematode [*Rotylenchulus reniformis*] as a Root Parasite, by M. B. Linford, J. M. Oliveira, and F. Yap (Univ. Hawaii); A Comparison of the Root-Knot Nematode and the Meadow Nematode, by C. W. McBeth; Recent Root Knot Damage in Potatoes, by J. T. Middleton (Calif. Citrus Sta.); The Effect of Crop Rotation on the Control of *Heterodera marioni* on Norfolk Sandy Loam Soil, by K. J. Shaw; Recent Field Observations on Tomato and Cotton Root-Knot Nematodes, by C. D. Sherbakoff (Tenn. Sta.); The Distribution and Relation of the Meadow Nematode, *Pratylenchus pratensis*, to Fusarium Wilt of Cotton in Georgia, by A. L. Smith; On the Occurrence of the Banana Nematode (*Pratylenchus musicola* [Cobb] Filipjev) in the United States, and The Root-Knot Nematode Attacking Stems and Leaves of Plants, both by G. Steiner; Some Further Observations on the Nematode Fusarium-Wilt Experiments at Lumberton, North Carolina, by A. L. Taylor, H. D. Barker, and P. H. Kime; Nematode Population and Species Determination Studies on Soils From the Regional Cotton Wilt Plots, by A. L. Taylor and A. L. Smith (coop. Ga. Sta.); Suggestions Arising From an Analysis of "Plants Reported Resistant or

Tolerant Toward Root-Knot-Nematode Infestation," by J. Tyler; Outline for Reports on Root-Knot Infestations With Particular Reference to the Resistance of Certain Plants; Nematode Studies at U. S. Regional Vegetable Breeding Laboratory [at Charleston, S. C.], by B. L. Wade; and Chemical Treatment of Soil to Control the Root Knot Nematode, by P. A. Young (Tex. Sta.).

Effect of blue stain on specific gravity and strength of southern pine. A. D. CHAPMAN and T. C. SCHEFFER. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 61 (1940), No. 2, pp. 125-133).—The effect of blue stain on the specific gravity and strength of pine wood artificially inoculated with four fungus species (*Ceratostomella* spp. and *Graphium rigidum*) was essentially the same as reported for prior similarly controlled studies. Although all strength properties appeared to be lowered generally, only the effect on toughness was of general practical significance. The fungi did not affect the wood with equal severity, nor was their relative order of superiority in this respect entirely the same for all properties tested. There was some evidence of a broad relation between abundance of direct cell-wall penetration and reduction in toughness. The intensity of discoloration was not indicative of the severity of attack or of the comparative weakening. The frequency of association between a particular blue stain fungus and a certain kind of wood apparently does not necessarily indicate its inherent ability to attack the wood or to affect its strength.

Variation in *Helminthosporium sativum* induced by a toxic substance produced by *Bacillus mesentericus*. J. J. CHRISTENSEN and F. R. DAVIES. (Minn. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 12, pp. 1017-1033, figs. 4).—*B. mesentericus* isolates grown on artificial media produced a substance suppressing growth, increasing conidial production, inhibiting or retarding germination, causing abnormal hyphal growth, and inducing mutation in certain races of *H. sativum*. This substance was thermostable, although prolonged heating tended to weaken its potency. It was diffusible, passed through a Berkefeld filter, was adsorbed on infusorial earth, withstood freezing and desiccation, tolerated acid, and was inactivated by alkali and by certain bacteria and fungi. Added to solid nutrient media, the sterilized bacterial cultures suppressed growth of many fungi but failed to increase the frequency of sectoring, except in *H. sativum* and possibly one species of *Penicillium*. Races of *H. sativum* responded quite differently to the toxic substance, and the frequency of sectoring was associated with its concentration, with certain types of medium, and with relatively high temperatures. *B. mesentericus* did not induce sectoring when grown in close association with *H. sativum*. A race of *H. sativum*, while growing on potato dextrose agar containing the toxic substance, gave rise to numerous variants differing in cultural characters, general physiology, pathogenicity, and to some extent in morphology. By means of mutation, *H. sativum* may adapt itself to a new environment, giving the appearance of increased tolerance to the toxic substance.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Blasting to improve wildlife environment in marshes. T. G. SCOTT and W. L. DEVER. (Iowa Expt. Sta. et al.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 4, pp. 373, 374, pls. 2).

Utilization of oaks by birds and mammals. W. R. VAN DERSAL. (U. S. D. A.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 4, pp. 404-428).—A review of the literature, a seven-page list of which is included, has shown 186 different kinds of birds and mammals to feed on oak products. Acorns have been recognized as preferred or staple foods of a great many of these animals, and oak browse is shown to be of outstanding importance to wild herbivores.

A study of deer populations by use of pellet-group counts, L. J. BENNETT, P. F. ENGLISH, and R. MCCAIN. (Pa. Expt. Sta. coop. U. S. D. A. et al.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 4, pp. 398-403).

A study of monthly variations in the nutritive value of several natural winter deer foods, H. HELLMERS. (Pa. Expt. Sta. et al.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 3, pp. 315-325, pl. 1, figs. 8).—In this study samples of eight species of woody plants browsed by deer were collected at monthly intervals and analyzed chemically to detect variations in their composition. Marked differences were found, especially in protein, nitrogen-free extract, and crude fiber, all of which exhibited trends indicating a reduction in nutritive value through the winter. The findings indicate that a representative index to the nutritive value of winter browse may be most easily and most satisfactorily obtained by collecting material monthly and analyzing composite samples made by mixing the original samples of each species in equal proportions. A few of the species analyzed compared very favorably in chemical composition with bluegrass and timothy. Most species, however, were considerably below these two grasses in nutritional qualities.

Territorial behavior and populations of some small mammals in southern Michigan, W. H. BURT (*Mich. Univ., Mus. Zool. Misc. Pub.* 45 (1940), pp. 58, pls. 2, figs. 10).—The study presented, commenced in the spring of 1935, was conducted in the attempt to secure information on the breeding seasons and populations of certain small mammals in southern Michigan. In concentrating on one species, the wood mouse (*Peromyscus leucopus noveboracensis*) was selected because of its common occurrence throughout wooded areas. Other forms observed were *Tamias striatus lysteri*, *Glaucomys volans volans*, *Blarina brevicauda talpoides*, *Pitymys pinetorum scalopsoides*, and *Synaptomys cooperi cooperi*. A list of 30 references to the literature cited is given.

Studies on a population cycle of snowshoe hares on the Lake Alexander area.—II, Mortality according to age groups and seasons. III, Effect of reproduction and mortality of young hares on the cycle, R. G. GREEN and C. A. EVANS. (Univ. Minn.). (*Jour. Wildlife Mangt.*, 4 (1940), Nos. 3, pp. 267-278, figs. 2; 4, pp. 347-358, figs. 3).—Included are details concerning the mortality among snowshoe hares, with special reference to age groupings, additional to those previously noted (E. S. R., 83, p. 791). On this area in Minnesota, the proportion and the absolute number of yearling hares were markedly lowered during the years when the population was most drastically reduced, and rose sharply when the population began to increase. The mortality among adult hares was maintained at a relatively constant rate, irrespective of the cyclic changes in population measured by the annual census.

The changing mortality among immature hares during the first 9 mo. of life was found to be the principal factor in the fluctuation of the population of snowshoe hares on the Lake Alexander area during the recent cycle. A high mortality among the young hares caused the decline in population; a low mortality in young hares resulted in the increase in population before and after the period of decline. Neither the mortality among adult hares nor the rate of reproduction appear to have varied enough to be of major importance as a cause of the cycle. The role that shock disease plays as a cause of some of the phenomena described has been considered in an earlier contribution (E. S. R., 82, p. 825).

Notes on the food and parasites of the rabbits of a lowland area in Oklahoma, C. C. SMITH (*Jour. Wildlife Mangt.*, 4 (1940), No. 4, pp. 429-431).

Food habits of the raccoon in eastern Iowa, L. W. GILES. (Iowa Expt. Sta. et al.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 4, pp. 375-382).

The woodchuck as a soil expert, A. E. MOSS. (Univ. Conn.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 4, pp. 441-443, fig. 1).

A systematic classification for the birds of the world, A. WETMORE. (*Smithsn. Misc. Collect.*, 99 (1940), No. 7, pp. [2]+11).

Autumn birds of an Eastern Bob-White Experimental Game Management Area in southern Iowa, E. SANDERS. (Iowa Expt. Sta. et al.). (*Iowa Bird Life*, 10 (1940), No. 3, pp. 39-42).

Birds of Oregon, I. N. GABRIELSON and S. G. JEWETT (*Corvallis: Oreg. State Col.*, [1940], pp. XXX+650, figs. [118], map. 1).—The introductory part of this work, based upon personal observations and the literature, includes a check list of the birds of Oregon, a general account of birds as a group, a discussion of the topography and life zones of the State, Federal bird refuges therein, a history of Oregon ornithology, and list of birds originally described from Oregon. The main part of the work, which consists of an annotated list of the birds of the State, includes a description of each form, its distribution, and notes on its occurrence and habits. A hypothetical list and a bibliography of 30 pages are included. A map of the life zones of the State, indicated in colors, by V. Bailey, is attached.

The phenology of some bob-white food and cover plants in Brazos County, Texas, T. P. CHENAULT. (Tex. A. and M. Col. et al.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 4, pp. 359-368, fig. 1).

Food habits of the sharp-tailed grouse by analysis of droppings, G. SWANSON. (Minn. Expt. Sta.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 4, pp. 432-436).—A contribution presented with a list of 22 references to the literature.

Seasonal food habits of the marsh hawk in Pennsylvania, P. E. RANDALL. (Pa. Expt. Sta. et al.). (*Wilson Bul.*, 52 (1940), No. 3, pp. 165-172).—Observations of the food habits of the marsh hawk during the course of a management study of the ring-necked pheasant in Pennsylvania are reported. Mice were the staple food during 10 mo. of the year, with juvenile birds the most important items of food during June and July. The effect of marsh hawks upon the pheasant population was negligible, and there was no reason to believe that the hawks were a limiting factor on other game species in the study area. It is concluded that the general food habits of the marsh hawk are beneficial to man, and that this hawk is a decided asset to an agricultural community.

Winter observations on pheasants in southeastern Minnesota, U. C. NELSON. (U. S. D. A.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 4, pp. 369-372).—Deficiency in food and cover resulting in a high winter mortality is considered by the author to be the limiting factor in the management of ring-necked pheasants in southeastern Minnesota.

Turkey vultures in central Iowa, T. G. SCOTT and R. MOORMAN. (Iowa Expt. Sta.). (*Iowa Bird Life*, 10 (1940), No. 3, pp. 34-37, fig. 1).

Comparative psychology.—II, Plants and invertebrates, C. J. WARDEN, T. N. JENKINS, and L. H. WARNER (*New York: Ronald Press Co.*, [1940], vol. 2, pp. XIII+1070, figs. 168).—Included in this work is a chapter on the Platyhelminthes, Nemathelminthes, Trochelminthes, and Annulata (pp. 440-540), also one on the Arthropoda (pp. 581-810). Examples cited represent, in the main, types that have been most widely used in behavior investigations. They are presented with bibliographies (pp. 898-915, 928-1021).

The feeding habits of larval newts with reference to availability and predilection of food items, W. J. HAMILTON, JR. (Cornell Univ.). (*Ecology*, 21 (1940), No. 3, pp. 351-356, figs. 2).

Brown snail infestations, A. J. BASINGER. (Calif. Citrus Expt. Sta.). (*Calif. Citrog.*, 25 (1940), No. 7, p. 226).—Reference is made to control measures for the European brown snail, of which there was an enormous increase in numbers in 1939.

Common names of economic insects in different countries, VI, VII [trans. title], G. SCHMIDT (*Ent. Beihefte Berlin-Dahlem*, 6 (1939), pp. [1]+160; 7 (1940), pp. [1]+161-364).—The first part of this compilation (pp. 1-119) lists the common German names of insects and includes alphabetical indexes of the species and genera and a four-page list of references to the literature. Part 2 (pp. 120-354) lists the common English, French, Italian, Spanish, and Dutch names of insects, followed by alphabetical indexes of the species and genera and a four-page list of references to the literature. A supplement to part 1 is appended.

The value of a State collection of insects, H. S. TELFORD (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 2, p. 19).—Attention is drawn to the value of a State insect collection in the ready identification of injurious and beneficial forms.

Insect life without vitamin A, R. E. BOWERS and C. M. McCAY. (Cornell Univ. et al.). (*Science*, 92 (1940), No. 2387, p. 291).—It is considered evident from experiments conducted that the German cockroach needs no vitamin A in its diet, since its body can function normally throughout its life cycle without this vitamin.

[Contributions on economic insects, insecticides, and insect control] (*U. S. Dept. Agr., Bur. Ent. and Plant Quar.*, 1940, E-496, pp. 5; E-497, pp. 9, pls. 4; E-498, pp. 6, pls. 3; E-499, pp. 8, pl. 1; E-500, pp. 5; E-501, pp. 3; E-502, pp. 13, pls. 2; E-503, pp. 2; E-504, pp. 56; E-505, pp. 7, pls. 6, fig. 1; E-506, pp. 19, pl. 1; E-507, pp. 5; E-508, pp. 21, pls. 5; E-509, pp. 33; E-510, pp. 5; E-511, pp. 4, pl. 1; E-512, pp. 4; E-513, pp. 4; E-514, pp. 43).—The following contributions are in continuation of this series (E. S. R., 83, p. 216); The Use of Derris and Cube Washes in the Control of Cattle Grubs, by R. W. Wells (E-496); The Use of Oil or Oil Containing Pyrethrins for Earworm Control in Sweet Corn, by G. W. Barber (E-497), which supersedes E-476 (E. S. R., 81, p. 806); A Cattle Fly Trap for the Control of Horn Flies, by W. G. Bruce (E-498); Control of Insects on Growing Tobacco Plants of the Flue-Cured Type, by W. A. Shands, N. Allen, and J. U. Gilmore (E-499); Weevils Which May Attack the Bases and Roots of Conifers in the Lake States and Methods of Preventing Injury, by H. J. MacAloney (E-500); Suggested Control Recommendations for Tobacco Insects on Sun-Grown Cigar-Type Tobacco in the Georgia and Florida Producing Region, by F. S. Chamberlin (E-501); The Periodical Cicada, Brood XIV, by J. A. Hyslop (E-502); Methods Used to Combat the White-Fringed Beetles (E-503); A List of Commercially Available Detergents, Wetting, Dispersing, and Emulsifying Agents, by H. L. Cupples (E-504); The White-Fringed Beetle, by L. J. Padget and K. S. Littig (E-505); Investigations in Control of Hemipterous Cotton Insects in Arizona by the Use of Insecticides, by T. P. Cassidy and T. C. Barber (E-506); The Bulb Scale Mite, by C. F. Doucette (E-507); Concentrated Spray Mixtures and Their Application by Ground and Aerial Equipment as Compared With Standard Spraying and Dusting Methods, by S. F. Potts (E-508); Bibliography of the Codling Moth, 1935, by F. M. Wadley (E-509); Some Deterrents as a Control for the Melonfly, by R. H. Marlowe (E-510); Standard Method for the Distillation of Geraniol, by L. Koblitsky and R. D. Chisholm (E-511); Fumigation of Bulk Soil With Methyl Bromide for the White-Fringed Beetle in New Orleans (E-512) and Methyl Bromide Fumigation of the White-Fringed

Beetle Larva in Small Flowerpots in New Orleans (E-513), both by E. M. Livingstone; and Abstracts of Recent Foreign and Domestic Patents Relating to Derris, Lonchocarpus, Tephrosia, and Rotenone (First supplement to E-446), by R. C. Roark (E-514) (E. S. R., 80, p. 365).

[Contributions on economic entomology] (*Assoc. South. Agr. Workers Proc.*, 41 (1940), pp. 110-119).—Contributions presented at the annual meeting of the Cotton States Branch of the American Association of Economic Entomologists held in February 1940 include the following: History of the Cotton States Branch of the American Association of Economic Entomologists, by O. I. Snapp (pp. 110-112), Calcium Arsenate Dusting of Cotton and Its Influence on pH of Cell Sap and Aphid Populations, by E. W. Dunnam, and J. C. Clark (pp. 112, 113), A Field Test of Timed Poisoning Schedules for the Protection of Sea Island Cotton From the Cotton Boll Weevil (p. 113) and A Possible Alternative Method of Measuring Boll Weevil Injury to Cotton (p. 114), both by P. M. Gilmer, Combination of Insecticides for Boll Weevil and Cotton Leaf Aphid Control, by C. F. Rainwater and F. F. Bondy (p. 114), Progress Report (1939) on Mixtures of Calcium Arsenate and Sulfur for Control of the Boll Weevil at State College, Mississippi, by R. L. McGarr (p. 114), The Effect of Several Insecticides Used in Boll Weevil Control Tests Upon Aphid and Mirid Infestations, by R. C. Gaines, M. T. Young, and G. L. Smith (p. 115), The Amazon Fly *Metagonistylum minense* Towns., a Promising Parasite of the Sugarcane Borer, by T. E. Holloway and R. Mathes (p. 116), Lateral Migration and Depth of Pupation of the Larvae of the Primary Screwworm (*Cochliomyia americana* C. & P.), by B. V. Travis, E. F. Knipling, and A. L. Brody (p. 116), Biology of *Pantomorus peregrinus* Buch., by J. B. Gill and H. C. Young (p. 117), Biology and Habits of *Pantomorus taeniatus* Berg., by H. C. Young and H. S. Hollingsworth (p. 118), Recent Notes on the Biology of the White-Fringed Beetle, by H. S. Hollingsworth, B. A. App, and H. C. Young (p. 118), A System of Classifying Cabbage According to Extent of Caterpillar Injury and The Occurrence and Relative Abundance of the Various Species of Cabbage Caterpillars on Cabbage in the Charleston, S. C., Area, both by W. J. Reid, Jr., and C. O. Bare (p. 118), and Results of Tests With Benzene, Paradichlorobenzene, and Other Insecticides Against the Tobacco Flea Beetle (*Epitrix parvula* (F.)) in Plant-Beds, by N. Allen and W. A. Shands (p. 119) (all U. S. D. A.); Boll Weevil Control Tests With Calcium Arsenates Containing Different Percentages of Water-Soluble Arsenic Pentoxide, by R. C. Gaines (p. 113); Boll Weevil Control Tests With Several Insecticides, by M. T. Young, G. L. Garrison, and R. C. Gaines (p. 113); A New Method of Mounting Insects for Student Collections, by F. E. Guyton (p. 115); The Pest Control Division, the University of Florida, Gainesville, by J. T. Creighton (p. 115); Some Extension Experiences With the New Type of Ant-Bait Containers, by W. C. Nettles (p. 116); Insecticides for Greenhouse Pests, by S. H. Coleman and C. Lyle (pp. 116, 117); Insecticide Tests Against the Striped Cucumber Beetle (*Diabrotica vittata*), by C. Lyle (p. 117) (Miss. Expt. Sta.); Second Report on the Host Plants and Parasites of the Cowpea Curculio and Other Legume Infesting Weevils, by T. L. Bissell (p. 117) (Ga. Sta.); and A Progress Report on the Use of Rotenone Dusts for the Control of the Pickleworm and Melonworm in Alabama, by F. S. Arant (p. 119) (Ala. Sta.).

[Report of work in entomology by the New Haven Station.] (Partly Coop. U. S. D. A.). (*Connecticut [New Haven] Sta. Bul.* 438 (1940), pp. 500-508).—The work of the year reported upon (E. S. R., 81, p. 540) relates to the Japanese beetle, biology and control of termites, European corn borer, wireworms, squash bug and squash vine borer, smaller European elm bark beetle,

oriental fruit moth, European red mite, substitutes for lead arsenate for the control of the apple maggot, a comparison of adhesives for the special curculio spray, and an investigation of oil sprays.

The ninth annual insect population summary of Kansas, 1939, R. C. SMITH and E. G. KELLY. (Kans. Expt. Sta.). (*Jour. Kans. Ent. Soc.*, 13 (1940), No. 3, pp. 65-85).—This annual report (E. S. R., 83, p. 217) gives a summary of weather conditions in Kansas during 1939, followed by a descriptive account of the more striking insect activities and climatic relationships for the year.

[Work in economic zoology and entomology by the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 399 (1940), pp. 25, 29-34, 44-47, 51, 52, 66, 67, figs. 2).—The work of the year reported upon (E. S. R., 82, p. 353) includes notes on the worst enemies of cottontails, by J. D. Buehle; mortality of ring-necked pheasants, crippled pheasant losses, food of marsh hawks, and nesting habits of pheasants, all by P. E. Randall; fall foods of ruffed grouse, by T. M. Kuhn; pellet group counts for determination of deer population, by L. J. Bennett, P. F. English, and R. McCain (coop. U. S. D. A.); banding of American woodcocks, by A. T. Studholme, Buehle, and R. T. Norris; winter browse poor deer food, by E. B. Forbes; tagged trout taken by anglers, by G. L. Trembley; migration of trout, by R. L. Watts; flea beetles on tobacco, sod webworms, and hairy chinch bugs, all by H. N. Worthley; codling moth control, by Worthley and D. E. H. Frear; pistol casebearer control, by H. M. Steiner; dormant spray for scale and mites, by Worthley and Steiner; new and safer spray materials, by H. W. Thurston, Jr., and H. Miller; spray schedule for the grape berry moth, by Worthley and B. D. Gleissner; and control of cecidomyiid larvae in mushroom houses, garden centipedes, and red spiders, all by C. A. Thomas.

A summary of the sugarcane insect investigations conducted at the Houma Laboratory of the Federal Bureau of Entomology and Plant Quarantine during 1939, J. W. INGRAM. (U. S. D. A.). (*Sugar Bul.*, 19 (1940), No. 4, pp. 4-6).—The results of work in Louisiana during 1939 with the sugarcane borer, insect transmission of mosaic, and the sugarcane beetle are reported.

[Notes on work with cranberry insects in 1940], C. S. BECKWITH. (N. J. Expt. Stas.). (*Amer. Cranberry Growers' Assoc., Proc. Ann. Conv.*, 71 (1940), pp. 12, 13, 16, 17).—A brief reference is made to the application of pyrethrum by ground dusters and of oil from airplanes for the control of the leafhopper causing false blossom.

Studies of the tip worm have shown the occurrence of two generations a year, one working in early June and the other in early July, and that it overwinters in a cocoon attached to a fallen leaf or stem and is not affected by the winter flood. Fifty-five first-generation flies emerged between May 23 and June 4 and were captured in a cage which covered 16 sq. ft. of surface on an infested bog. A small second generation appeared starting on June 13 and continued to emerge over a period of 20 days. Oviposition apparently commenced when the flies were less than 3 days old. A definite advance was made during the year in the determination of the 2-day (24 to 48 hr.) incubation period, the feeding of the insect on one leaf before moving to one of the new tips, and the probability of at least 2 days open feeding on the tip leaves.

Relation of cover crops to citrus insects, J. R. WATSON. (Fla. Expt. Sta.). (*Citrus Indus.*, 21 (1940), No. 7, pp. 11, 18).

Annual report of the forest insect survey, 1939, A. W. A. BROWN (*Canada Dept. Agr., Forest Insect. Survey Ann. Rpt.*, 1939, pp. 37, figs. 14).

Insect pollinators of toria (*Brassica napus* Linn., var. *dichotoma* Prain), and sarson (*B. campestris* Linn., var. *sarson* Prain) at Lyallpur, K. A.

RAHMAN (*Indian Jour. Agr. Sci.*, 10 (1940), No. 3, pp. 422-447).—A study was made of the habits and usefulness of insect visitors to toria and sarson flowers. Of the more than 100 different insect species collected, representing 55 families of 9 orders, *Apis florea*, *Andrena ilerda*, *Halictus* sp., and *Eristalis tenax* were found to be the most important pollinators. A study of the hourly frequency of the insect visitors confirmed this conclusion.

Insect transmission of plant diseases, J. G. LEACH (*New York and London: McGraw-Hill Book Co.*, 1940, pp. XVIII+615, [pl. 1], figs. 238).—This work brings together the present status of knowledge of insects as relates to their transmission of plant diseases. Each of the 17 chapters includes a quite complete list of references to the literature consulted.

Entomophagous insects, C. P. CLAUSEN (*New York and London: McGraw-Hill Book Co.*, 1940, pp. X+688, figs. 257).—The present knowledge of insects as parasites or predators of other insects is brought together, arranged by orders and families. Entomophagous forms of the orders Hymenoptera (pp. 3-342), Diptera (pp. 343-484), Lepidoptera (pp. 485-498), Strepsiptera (pp. 499-524), and Coleoptera (pp. 525-584) are of particular importance. Such forms of 11 additional orders also considered include Hemiptera (pp. 585-590), Thysanoptera (p. 591), Trichoptera (p. 591), Mecoptera (p. 592), Plecoptera (p. 592), Neuroptera (pp. 593-607), Odonata (p. 608), Corrodentia (p. 609), Orthoptera (pp. 610, 611), Dermaptera (p. 612), and Thysanura (p. 612). A 47-page list of references to the literature cited is included.

Recent records of the introduction of beneficial insects into the Hawaiian Islands (*Hawaii. Ent. Soc. Proc.*, 10 (1938), No. 2, pp. 349-352).

Recent contributions of insect physiology to insect toxicology and control, W. M. HOSKINS (*Hilgardia [California Sta.]*, 13 (1940), No. 6, pp. 307-386).—This discussion of the subject is accompanied by a 15-page list of references to the literature cited.

A simple apparatus for the determination of thermal death points, E. T. ROUSE and R. O. CHRISTENSON. (Ala. Expt. Sta.). (*Amer. Micros. Soc. Trans.*, 59 (1940), No. 3, pp. 275-278, figs. 2).—The apparatus here described for determining the point of irreversible coagulation of the protoplasm of animal parasites records the temperature of the culture itself. The apparatus which supplies the heat consists of a steam aspirator which forces the steam into a water bath containing the culture vial with its inserted thermometer.

The scientific principles of plant protection, with special reference to chemical control, H. MARTIN (*London: Edward Arnold & Co.*, [1940, 3. ed.], pp. X+385).—Among the 16 chapters of this work, those which relate particularly to entomology are: Plant resistance (pp. 9-33), the influence of external factors on the susceptibility and liability of the plant to attack (pp. 34-52), biological control (pp. 53-69), fungicides and insecticides (pp. 70-103), insecticides (pp. 156-238), fumigants (pp. 245-257), soil treatment (pp. 276-294), toxic action and chemical constitution (pp. 295-310), traps (pp. 311-326), and the treatment of the centers and vectors of infection (pp. 327-343).

Prolonging toxicity of pyrethrum insect sprays, R. B. TRUSLER (*Soap and Sanit. Chem.*, 16 (1940), No. 1, pp. 115, 117, 119).

Pyrethrum deterioration, A. WEED (*Pests*, 8 (1940), No. 9, pp. 11, 12).

Deposition and retention of sprays on apples, II, D. E. H. FREAR and H. N. WORTHLEY (*Pennsylvania Sta. Bul.* 400 (1940), pp. [2]+22, figs. 5).—The results of a further investigation (E. S. R., 78, p. 365) of the amounts of lead and arsenic retained upon the fruits and foliage of apples sprayed in 1937 and 1938 with acid lead arsenate in various schedules and mixtures are reported. It was found that the lead and arsenic deposits were greater on fruits from the

bottoms of the trees than on those from the tops. "Calculations of the Pb : As₂O₃ ratio in the data collected gave no consistent figure for either fresh or weathered deposits nor consistent differences in the ratios exhibited in different spray mixtures. The ratio in treatments to the Jonathan variety was greater in 1937 than in 1938 (3.52 and 2.15). In treatments applied to Stayman Winesaps and to Jonathans from the same tanks of spray mixture in 1938 the ratio was nearly twice as great in the former variety (4.16 and 2.15). In 1937 the spacing of spray applications at progressively longer intervals to compensate for the diminishing growth rate of the fruits, 'growth schedule' applications, did not maintain a consistently higher level of spray deposits than the spacing of applications at uniform intervals, when both schedules consisted of five cover sprays ending on the same date. In 1938 the deposits produced by a growth schedule of three cover spray applications ending on June 9 were much reduced by subsequent growth of the fruit before the cessation of codling moth attack, as compared with a schedule of four uniformly spaced applications ending on June 30. In 1937 it appeared that the addition of 1 pt. of fish oil per 100 gal. of spray mixture resulted in greater deposits of lead and arsenic than the addition of 1 lb. of soybean flour. Retention of lead but not of arsenic was greater with soybean flour.

"As compared in four-cover spray schedules in 1938, soybean flour at 1 lb. and skim milk powder at 0.5 lb. per 100 gal. of spray mixture showed little difference in their effect on the deposit and retention of lead and arsenic. In 1937 a schedule of three cover sprays ending on June 26, the last two of which were inverted or 'Washington State College dynamite' spray mixture, built up considerably higher deposits of lead and arsenic than any noninverted spray mixture. On July 28, however, after 32 days of exposure, the deposits were lower than in treatments receiving two additional noninverted spray applications ending on July 17, and thus analyzed after 11 days of exposure. In 1938 a treatment involving two cover sprays, the second of which was applied on June 6 and comprised a double concentration of lead arsenate in a 'modified Washington State College dynamite' spray mixture, applied at a double dosage per tree, showed deposits of lead and arsenic nearly as great as those in treatments receiving the last of four lead arsenate sprays in noninverted mixtures on June 30, when fruit samples were analyzed on July 1. The 'dynamite' treatment . . . afforded as good codling moth control as more extended spraying schedules."

Plant galls and gall makers, E. P. FELT (*Ithaca, N. Y.: Comstock Pub. Co., 1940, pp. VIII+364, pls. 41, figs. 344*).—This book is planned to give a general idea of insect galls and their producers and to facilitate identification of the nearly 2,000 plant deformities listed in North America. Part 1 (pp. 3-35), which is introductory, discusses gall types, the principal gall producers, the various ways in which galls are developed, the biology and the economic importance of galls, and their alternation of generations. Included is a list of the known agamic and bisexual forms of American gall wasps. Part 2 (pp. 39-338) lists and classifies the galls according to their plant hosts and describes them concisely. There is a general account of the gall makers and of their preferences under each of the plant families especially favored by gall insects. The book is a greatly extended and more comprehensive account of the author's key to American insect galls previously noted (*E. S. R., 40, p. 554*). A selected bibliography of recent publications is included.

Grasshopper injury among wheat varieties, R. W. SMITH. (U. S. D. A.). (*6. Hard Spring Wheat Conf., Minneapolis, 1939, Rpt., pp. 53, 54*).—Tables are given of the results of observations of grasshopper injury and stem rust made

in the spring wheat nursery in the Dickinson region of North Dakota in 1938. Reference is made to several theories that have been advanced as to why badly rusted varieties should be injured more by grasshoppers than those having but little rust.

Grasshopper populations (Orthoptera: Acrididae) of typical pastures in the Bluestem region of Kansas, D. A. WILBUR and R. F. FRITZ. (Kans. Expt. Sta.). (*Jour. Kans. Ent. Soc.*, 13 (1940), No. 3, pp. 86-100, fig. 1).

The toxicity of yellow phosphorus to cockroaches, T. H. CHENG (*Ohio State Univ., Abs. Doctoral Diss.*, No. 31 (1940), pp. 39-48, figs. 2).—Through quantitative feeding of phosphorus paste diluted with sirup, the medium lethal dose of phosphorus for the American cockroach was determined to be 0.02 mg. per gram, showing that it is a highly toxic stomach poison for this species. For this cockroach it was much more toxic than was sodium arsenite or sodium fluoride when the latter were fed in the same viscous medium, and the phosphorus was imbibed more rapidly and with less regurgitation than were the other two poisons. Sodium arsenite was more toxic in water than in sirup, but even in water it was less toxic than phosphorus. The German cockroach was less susceptible to phosphorus in paste diluted with sirup than was the American cockroach, the medium lethal dose for the former being 0.13 mg. per gram as compared with the 0.02 mg. per gram for the latter, but it is pointed out that the larger medium lethal dose for the German cockroach cannot alone account for the failure of phosphorus paste to control this species in practice. It is likely that the German cockroach does not imbibe diluted paste as freely as does the American cockroach. The practical control of cockroaches with phosphorus paste may be attributed not only to its action as a stomach poison but possibly to its effect as a contact poison and fumigant.

Effect of pH on the toxicity of nicotine injected into the cockroach *Periplaneta americana* (L.), C. H. RICHARDSON and L. O. ELLISOR. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 14 (1940), No. 3, pp. 305-316, figs. 4).—In order to determine whether molecular nicotine is more effective than ionic nicotine when injected into the American cockroach, relatively large doses and sublethal, paralytic doses of the alkaloid at several H-ion concentrations were administered to adult insects. Injection was made into the body cavity by puncture at the base of a posterior leg, the method resembling intraperitoneal injection of vertebrate animals. No significant difference was observed in the mortality from relatively large doses of injected nicotine that could be related to the pH of the solutions; nor did the paralytic and recovery times after injection of sublethal doses vary consistently, throughout the experiments, with the H-ion concentration. Such differences as did occur did not support the hypothesis that injected nicotine molecules are more active than injected ions. Male cockroaches are more susceptible than the females to large doses of injected nicotine, but no sex difference was observed in the reaction times or recovery times of insects injected with sublethal, paralytic doses. Twenty-four references are given to the literature cited.

Effects of liquid household insecticides on the oothecae of the German cockroach, B. M. PARKER (*Ohio State Univ., Abs. Doctoral Diss.*, No. 31 (1940), pp. 257-264).—It was found in tests conducted that pyrethrum and thiocyanate were highly toxic to the females of the German cockroach. Pyrethrum caused a majority of the females to drop their oothecae and apparently had some toxic effect on the oothecae. Of roaches sprayed with thiocyanate (Lethane 384) the majority of females retained their oothecae after death, and this insecticide appeared to be less toxic to the oothecae than pyrethrum although it exercised some control over hatching. Rotenone and cresylic acid, at the concentrations

used, had no marked effect on either the adult females or the oothecae. When the total percentage of oothecae failing to hatch was calculated for each spray at each dosage and compared with the total percentage of adult females killed, it was apparent that, in general, the oothecae were decidedly more resistant to the pyrethrum and thiocyanate sprays than were the adult females.

The selenium content of grasshoppers found feeding on seleniferous vegetation, A. L. MOXON. (S. Dak. State Col.). (*S. Dak. Acad. Sci. Proc.*, 19 (1939), pp. 69, 70).—A report is made of the selenium content of grasshoppers, infestations by which have been severe in the seleniferous as well as in non-seleniferous areas of South Dakota during the past few years. The selenium content of grasshoppers and of the vegetation upon which they were feeding indicates a direct correlation between the selenium content of the insects and that of the vegetation upon which they fed. Since selenium toxicity is prevented by arsenic and arsenic toxicity is more or less prevented by selenium, the effectiveness of arsenic as a poison for grasshoppers in seleniferous areas is questionable.

Controlling rose thrips, A. C. DAVIS. (U. S. D. A.). (*Amer. Rose Ann.*, 1940, pp. 106, 107).—Experimental control work with the flower thrips on roses during two seasons led to the conclusion that in gardens where roses are grown for cut flowers tartar emetic-brown sugar sprays, consisting of tartar emetic 1, 1½, and 2 oz., brown sugar 7½ oz., and water 3 gal., may be used to advantage in reducing the number of thrips per rosebud. Application of the spray every 2 or 3 days is necessary to protect the opening buds adequately. It was found that picking all open flowers apparently does not give any great degree of protection to the buds.

Cocoon-spinning Thysanoptera, S. F. BAILEY. (Univ. Calif.). (*Pan-Pacific Ent.*, 16 (1940), No. 2, pp. 77-79).

Some unexpected species of Arthropoda found in South Dakota, H. C. SEVERIN. (S. Dak. State Col.). (*S. Dak. Acad. Sci. Proc.*, 19 (1939), pp. 86-88).

Say's stink bug, J. A. MUNRO and F. G. BUTCHER (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 2, pp. 11-13, fig. 1).—A brief account is given of Say's stinkbug, which has been increased in abundance in North Dakota during the past few years. An outbreak in 1940 resulted in severe injury to more than 10,000 acres of wheat in one southwestern county, with damage in many fields being so high that the grain was not worth harvesting. Its injury to flax was also extensive in that area. As yet no practical method has been developed for its complete control. Mention is made of several practices of value, including the burning of weeds and trash in which the bugs hibernate, plowing of infested stubble fields during the usual course of summer-fallowing, early spring burning of trash cover in narrow strips, especially along margins adjoining cultivated cropland, and working the stubble fields shortly after harvest with various types of subsurface tillage implements to inhibit heavy weed growth late in the season.

Some Tingitidae (Hemiptera) from the Eastern Hemisphere, C. J. DRAKE and M. E. POOR (*Hawaii. Ent. Soc. Proc.*, 10 (1938), No. 2, pp. 203-207, fig. 1).—The genera *Cetiocysta* and *Corythauma* are erected and seven species described as new. Notes and revisions on several species from India, Australia, and Africa are included.

Synonymy and distribution of the Lantana lace bug [Teleonemia scrupulosa] (Hemiptera Tingitidae), C. J. DRAKE and D. M. FRICK (*Hawaii. Ent. Soc. Proc.*, 10 (1938), No. 2, pp. 199-202, fig. 1).

Influence of planting date on potato leafhopper population and hopperburn development, T. C. ALLEN, G. H. RIEMAN, and J. S. McFARLANE. (Wis. Expt. Sta.). (*Amer. Potato Jour.*, 17 (1940), No. 11, pp. 283-286, figs. 2).—It was found in work in Wisconsin that the percentage of hopperburn development was greater in early maturing potato varieties than in late maturing varieties, regardless of the planting date. Percentage hopperburn development was reduced by deferring the planting date with both early and late varieties of potatoes. Nymphal leafhopper population is closely correlated with percentage hopperburn development in respect to time of planting. The results indicate that the relative earliness or lateness of a variety is not the prime factor in determining its resistance or susceptibility to hopperburn.

Studies of methods and materials for the control of the leafhopper *Empoasca fabae* as a bean pest, D. M. DELONG (*U. S. Dept. Agr., Tech. Bul.* 740 (1940), pp. 64, figs. 25).—Laboratory and field tests for the control of the potato leafhopper under way at Columbus, Ohio, in 1926, 1927, and 1928, with additional studies in Florida and Ohio in 1932 and 1933, are reported upon.

Pyrethrum sprays were found to be immediately effective but lacked residual effect. Bordeaux mixture, both in laboratory and field plat tests, was not immediately effective but gave a high percentage of control in 4 or 5 days after application and a residual effect against hatching leafhoppers for 10 days or more following application. It is concluded that the plant physiology is changed by bordeaux residue in such a way that a temporary resistance is brought about in the plant. Several forms of sulfur were used on plants as sprays and dusts. All these showed some residual toxicity to leafhoppers, but some types were much more effective in this way than others. Flotation sulfur, wettable dry sulfur, and dry-mix sulfur used as sprays and dusting sulfur gave the best results. Dusting sulfur was also used with pyrethrum dusts which contained different amounts of pyrethrins (1, 0.5, and 0.05 percent). Combinations of sulfur and pyrethrum (0.5 percent) 90-10, sulfur and pyrethrum (1 percent) 95-5, and sulfur and pyrethrum (0.05 percent) 75-25 gave good toxicity and good residual value. Fifty-four references cited are listed.

Derris infusion as a poultry dip for louse eradication, R. B. GAPUZ (*Philippine Jour. Anim. Indus.*, 7 (1940), No. 2, pp. 153-161, pls. 2).—Infusions in water of crushed fresh roots of *Derris philippinensis* in the proportion of 1:100 and over were found effective against all kinds of chicken lice. In view of the variation in the toxic constituents of derris roots, it is recommended that the strength of the infusion to be used in the eradication of lice be 2 percent or more. Concentration as high as 5 percent was used safely in this study.

A list of the genera and subgenera of the Aleyrodidae, E. A. DREWS and W. W. SAMPSON. (Univ. Calif.). (*Bul. Brooklyn Ent. Soc.*, 35 (1940), No. 3, pp. 90-99).—Sixty-nine genera and subgenera of Aleyrodidae are listed, with the authority, genotype, date, and place of description of each.

Biological control of mealybugs in greenhouses, W. D. WHITCOMB (*Massachusetts Sta. Bul.* 375 (1940), pp. 22, figs. 2).—Report is made of studies of *Cryptolaemus montrouzieri* Mulsant, a ladybeetle first introduced from Australia into California in 1892, where it has become one of the important natural enemies of mealybugs infesting citrus trees. This coccinellid has been reared on the citrus mealybug and the long-tailed mealybug on gardenias and on the Mexican mealybug infesting chrysanthemums under normal conditions in Massachusetts greenhouses. Its larvae were shown to eat about 1,325 mealybug eggs, the equivalent of 3 or 4 mealybug egg masses, during their life and to eradicate completely an average mealybug egg mass in 9 or 10 days. "A constant temperature of 60° F. definitely retarded the development and activity

of the beetle so that it did not hold the mealybug in check, but satisfactory results were obtained at 70° and 80°. Practical control of mealybugs by this predatory beetle was secured (1) from April 1 to September 1, when a temperature above 70°, which would stimulate the development and activity of the beetle, could be maintained; (2) when the infestation of mealybugs was great enough to provide adequate food without causing unprofitable injury to the plants; (3) on plants which will tolerate warm growing conditions favorable to the activity of the beetle; (4) when the beetles were liberated at the rate of one for each gardenia plant or one for each two chrysanthemum plants; [and] (5) when the use of insecticides necessary to control other pests did not kill the majority of the beneficial predators. When these conditions were provided, as described in detail, *C. montrouzieri* controlled or eradicated a heavy infestation of mealybugs within 9 or 10 weeks after they had been successfully liberated and a normal number of second-generation larvae had developed."

A new Pergandeida from the Colorado desert (Homoptera: Aphididae), R. C. DICKSON. (Calif. Citrus Expt. Sta.). (*Pan-Pacific Ent.*, 16 (1940), No. 2, pp. 57, 58, fig. 1).—*P. cahuillae*, an aphid collected on *Suaeda suffretescens* near Indio, Calif., is described as new.

Three aphids of the genus Brevicoryne Van der Goot, C. F. SMITH and G. F. KNOWLTON. (N. C. Expt. Sta. coop. Utah State Agr. Col.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 404, 405, fig. 1).—The cabbage aphid, *B. salixutis* n. sp., and *B. symphoricarpi* (Thos.), are noted, with a table for their separation.

The emergence of a neotropical mantispid [Mantispa interrupta Say] from a spider egg sac, H. E. MILLERON. (Minn. Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 357-360).

Control of pineapple caterpillar, C. A. THOROLD and A. PICKLES (*Trop. Agr. [Trinidad]*, 17 (1940), No. 11, pp. 215, 216).—Report is made of an experiment with derris preparations in an attempt to control the injury to pineapple fruits by the larva of the lycaenid butterfly *Tmolus echnion* L. The results suggest that some control of its attack is achieved through the use of Derrimac dust applied to the fruits at intervals of 2 weeks.

Biology and control of strawberry leafroller *Ancylis fragariae* Walsh & Riley, R. L. PARKER and P. G. LAMERSON (*North Cent. States Ent. Proc.*, 18 (1939), pp. 97, 98).

Differential injury within varieties, inbred lines, and hybrids of field corn caused by the corn earworm (*Heliothis armigera* (Hbn.)), R. H. PAINTER and A. M. BRUNSON. (Kans. Expt. Sta. and U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 61 (1940), No. 2, pp. 81-100, figs. 3).—The results of an investigation conducted at Manhattan, Kans., to determine the range of injury caused by the corn earworm to various strains and varieties of corn and to classify the varieties, hybrids, and inbreds on the basis of the amount of injury sustained, are reported, the details being given in six tables. A consistent tendency toward resistance or susceptibility to earworm damage to ears was shown to be transmitted by certain inbred lines of corn. "Length of husk extension and date of flowering have some influence on the amount of damage to ears, particularly in heterogeneous material, but many marked breaks in the correlations occur, suggesting other and more subtle causes of differences in severity of injury. Under conditions at Manhattan the relatively susceptible strains appear more sensitive to the influence of date of flowering and length of husk extension than do the relatively resistant strains. The greater influence of these factors in open-pollinated varieties may be due to the high proportion

of susceptible individuals present in the material studied. Differences in resistance and susceptibility to injury to the developing curl or bud of young corn plants are also inherited. Such differences appear to be independent of the differences in resistance to damage to ears caused by the same insect. There are indications that resistance to earworm injury may be increased by mass selection within an open-pollinated variety." Twenty references to the literature cited are included.

Parasites of the oriental fruit moth in Japan and Chosen and their introduction into the United States, G. J. HAEUSSLER (*U. S. Dept. Agr., Tech. Bul.* 728 (1940), pp. 62, figs. 3).—The present contribution reports upon the results of the first 2 yr. (1932-33) of the search for parasites of the oriental fruit moth that has been in progress continuously in Japan and Chosen (Korea) since it was inaugurated in January 1932. Following a brief introduction and description of field investigations and scope of work, the methods used in conducting parasite surveys, species of parasites reared from the oriental fruit moth in Japan and Chosen, parasitization of the various stages of the fruit moth in these two areas, and collection, rearing, and shipment of the oriental fruit moth parasites are dealt with. Sixty-one species of parasites were reared from this pest in many of the important peach-, pear-, and quince-producing regions of Japan and Chosen. *Trichogramma minutum* was the only true egg parasite reared, although the braconid *Phanerotoma grapholithae* also oviposits in that stage of the host. Twenty-two species, including *P. grapholithae*, were reared as primary parasites of twig-infesting larvae. Thirty-eight species were reared as parasites of oriental fruit moth stages within the cocoon.

Studies on the life history of the codling moth in southwestern Quebec, A. A. BEAULIEU (*Sci. Agr.*, 20 (1940), No. 11, pp. 624-631, figs. 2).—Life history studies of the codling moth, details of which are given in the tables and charts, have shown a gradual decrease of the partial second generation from 1937 to 1939. The data indicate that the second generation is of importance only in certain years, the decrease having been closely related to a similar decrease of the mean daily temperature over these years.

Transference of hessian fly resistance and other characteristics of Marquillo spring wheat to winter wheat, R. H. PAINTER, E. T. JONES, C. O. JOHNSTON, and J. H. PARKER. (Coop. U. S. D. A.). (*Kansas Sta. Tech. Bul.* 49 (1940), pp. 55, figs. 18).—The hessian fly resistance of Marquillo spring wheat has now been transferred to winter wheats by means of crossing. These Marquillo hybrids are important for two reasons: (1) They are the first winter wheats to show marked resistance to the hessian fly in experimental tests in both hard and soft wheat belts wherever so far tested; and (2) they have given several different combinations of resistance to fly, tolerance to jointworm, resistance to leaf rust, stem rust, bunt, and mildew. Preliminary data indicate that they (particularly various lines of Marquillo × Oro and Marquillo × Tenmarq) may equal or excel the yield of standard varieties of winter wheats such as Turkey and Tenmarq.

Fly resistance derived from Marquillo was incidentally carried over from the durum parent along with stem rust resistance, for which the cross was originally made. The fly resistance tends to be recessive, although apparently more than one genetic factor is involved. In hybrids there was no evidence of linkage between fly resistance and resistance to disease, winter hardiness, spring or winter habit of growth, or other visible agronomic characters on which records were taken. The total difference in fly resistance between Marquillo or its hybrids and susceptible winter wheat varieties appears to be the result of the interaction between three or more separate heritable mechanisms: Low larval survival, ability to withstand infestation, and under some conditions low oviposition.

Midge control by soil fumigation, W. E. BLAUVELT. (Cornell Univ.). (*Amer. Rose Ann.*, 1940, pp. 108-110).—In the preliminary tests of soil fumigants here reported, in which naphthalene, paradichlorobenzene, nicotine, carbon disulfide, ethylene dichloride, dichloroethyl, and the proprietary products Soilogen, Astogen, and Fumogen were used, dichloroethyl ether was found to be the most promising material, considering effectiveness, safety to the plant, cost, and other factors.

The Rocky Mountain "black fly" *Symphoromyia atripes* (Diptera: Rhagionidae), H. H. ROSS (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 254-257, figs. 9).

The genus *Sympycnus* in Utah (Dolichopodidae: Diptera), F. C. HARMSTON and G. F. KNOWLTON. (Utah Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 395-403, figs. 28).

The growth of the head capsule of the Japanese beetle larva, D. LUDWIG and W. F. ABERCROMBIE (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 385-390, figs. 2).

Investigations of the parasites of *Popillia japonica* and related Scarabaeidae in the Far East from 1929 to 1933, inclusive, T. R. GARDNER and L. B. PARKER (*U. S. Dept. Agr., Tech. Bul.* 738 (1940), pp. 36, fig. 1).—This report, covering the work of the 5-yr. period from 1929 to 1933, inclusive, in Japan, Chosen (Korea), India, and Taiwan (Formosa), supplements earlier reports (*E. S. R.*, 70, p. 511). It presents additional information relative to the parasites previously listed, as well as accounts of other species found attacking the genus *Popillia*. Investigations were also made of parasites of the oriental beetle, Asiatic garden beetle, and *Serica peregrina* Chapin, 3 additional beetles that have become established in the northeastern part of the United States in recent years. Four species of Tachinidae and 1 of Pyrgotidae parasitic on adult *Popillia* beetles and 2 species of Dexiidae and 5 of Scoliidae parasitic on the larvae of *Popillia* were investigated. Investigations were carried on with a large number of *Tiphia* parasitic on the grubs of *Anomala* and *Serica*, but only 11 species were considered of sufficient importance to warrant introduction into the United States against the oriental beetle, Asiatic garden beetle, and *S. peregrina*. Large shipments of these parasites in the adult and immature stages were sent to the United States.

Two new spore-forming bacteria causing milky diseases of Japanese beetle larvae, S. R. DUTKY. (U. S. D. A. and N. J. Expt. Stas.). (*Jour. Agr. Res. [U. S.]*, 61 (1940), No. 1, pp. 57-68, figs. 6).—Two spore-forming bacteria responsible for type A and type B milky diseases of the larvae of the Japanese beetle, respectively, are described as *Bacillus popilliae* n. sp. and *B. leutimorbus* n. sp. They produce a disease condition in the larvae of the Japanese beetle that is not readily distinguishable on gross examination. Only the type A organism has as yet been cultured on artificial mediums.

Status of the milky diseases of Japanese beetle larvae, R. T. WHITE. (U. S. D. A.). (*Turf Cult.*, 2 (1940), No. 2, pp. 84-87, fig. 1).

The feeding of ground beetles, W. W. SHOUGH (*Amer. Midland Nat.*, 24 (1940), No. 2, pp. 336-344).—Cage observations of the feeding habits of carabid or ground beetles, largely predaceous, are reported. It was observed that among the types of living animal food offered, the beetles had little or no food selectivity. Any form that can be penetrated is eaten, although larval forms are given a wide preference, due, it is believed, to ease of capture and softness of body. Certain of the beetles, notably *Calosoma* sp. and *Pasimachus* sp., are definitely carnivorous; others, as *Harpalus* sp., *Evarthrus sodalis*, and *Nothopus grossus*, feed to a varying extent on plant food, though none seek plant food exclusively.

A revision of the North American Necydalini (Coleoptera: Cerambycidae), E. G. LINSLEY. (Univ. Calif.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 269-281).

A new species of *Hippodamia* from Mt. Rainier (Coleoptera: Coccinellidae), P. H. TIMBERLAKE (Calif. Citrus Expt. Sta.). (*Hawaii. Ent. Soc. Proc.*, 10 (1938), No. 2, pp. 265, 266).—A coccinellid from Longmire Springs, Mt. Rainier, Wash., is described as *H. washingtoni* n. sp.

Two new species of *Batrisodes* from South Carolina (Coleoptera: Pselaphidae), M. W. SANDERSON. (Univ. Ark.). (*Ent. News*, 51 (1940), No. 6, pp. 169-172).

The bionomics of the yam beetle *Galerucida bicolor* (Hope), a pest of cultivated yam in S[outh] India, T. V. R. AYYAR (*Jour. Bombay Nat. Hist. Soc.*, 41 (1940), No. 4, pp. 874-876, pl. 1).

Relative prevalence of potato flea beetle injuries in fields adjoining uncultivated areas, D. O. WOLFENBARGER. (U. S. D. A.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 391-394, fig. 1).

Experiments in Great Britain with wood preservatives for the prevention of *Lyctus* attack, F. R. CANN (*Forestry*, 14 (1940), No. 1, pp. 27-37).—An investigation aimed at determination of the value of water-soluble salts and other preservatives for the prevention of damage by *Lyctus* powder-post beetles in the sapwood of hardwoods is reported. The different types of preservatives and their suitability for the prevention of *Lyctus* are briefly discussed. Materials, methods of treatment, and testing technic are described and classified under the headings effective and ineffective. It is shown that water-soluble preservatives are effective only when applied by an impregnation treatment. Certain preservatives of the oil and solvent types are effective when applied by short-period dipping treatment.

Uninfected elm wood as a source of the bark beetle *Scolytus multistriatus* Marsham carrying the Dutch elm disease pathogen, D. L. COLLINS, K. G. PARKER, and H. DIETRICH ([New York] *Cornell Sta. Bul.* 740 (1940), pp. 14, fig. 1).—Of collections made in the field in southeastern New York State, as high as 15 percent of the specimens of the smaller European elm bark beetle, now generally considered to be the most effective agent in its transmission in the United States, were found, by culturing, to be carrying the Dutch elm disease fungus *Ceratostomella ulmi*. When cultured directly after emerging from diseased wood, as high as 100 percent of the beetles were positive for this fungus, but usually they averaged considerably less than 50 percent. "When beetles were artificially infested with spores and allowed to enter healthy wood, as high as 74 percent of their progeny emerged carrying spores of *C. ulmi*. Healthy cut logs exposed to normal beetle attack in the field produced as high as 62 percent of positive beetles in the progeny of parents which probably averaged much lower when entering. Pieces of uninfected beetle wood found in the field produced as high as 25 percent of positive beetles. Uninfected elm wood in farmers' wood piles also produced positive beetles. Diseased wood cut in short lengths and piled produced as high as 16 percent of positive beetles when stored out-of-doors and as high as 9 percent when stored in sheds. Healthy wood cut and stored in a similar way, but subjected to entry by spore-bearing beetles, produced 14 percent of positive beetles when stored out-of-doors and 19 percent when stored in a shed." The findings indicate that dead or dying elm wood of whatever origin, if suitable for the breeding of the smaller European elm bark beetle, is a potential source of inoculum from which this fungus may be spread by emerging beetles. Since the beetles can carry the fungus into uninfected wood and their progeny can carry it out, such wood serves as a reservoir for continuing local dissemination of the disease organism. It may also act as a bridge for the transfer of the fungus from the disease area to regions where the disease does not occur.

The shot hole borer *Anisandrus pyri* (Peck) in British Columbia (Coleoptera: Scolytidae), W. G. MATHERS (*Canad. Ent.*, 72 (1940), No. 10, pp. 189, 190).

Longevity and egg production in the common bean weevil (*Acanthoscelides obtectus* (Say)), R. J. BUSHNELL and D. C. BOUGHTON. (Univ. Conn. et al.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 361-370, figs. 3).

A new Fijian Diathletes injurious to Pandanus (Coleoptera: Curculionidae), E. C. ZIMMERMAN (*Hawaii. Ent. Soc. Proc.*, 10 (1938), No. 2, pp. 335-338, figs. 2).—*D. pandanae*, the larvae of which were taken from the trunk and limbs of a *Pandanus* tree near Loma Loma, Lau Province, Fiji, in August 1938, is described as new. That it may become a pest of considerable economic importance is indicated since the fruits are eaten by some people, the fibers of the aerial roots are used for cordage, and the wood itself is used in various ways. In some islands probably one of the most important sources of monetary income is the sale of *Pandanus* mats and other plaited goods.

Biochemical aspects of the differentiation of the female honeybee (*Apis mellifera* L.), R. M. MELAMPY, E. R. WILLIS, and S. E. MCGREGOR. (U. S. D. A. and La. State Univ.). (*Physiol. Zool.*, 13 (1940), No. 3, pp. 283-293, figs. 7).—The findings in a differential study of the female castes of the honeybee from the biochemical standpoint show that the queens and workers have the same approximate growth rate during early larval life, and then the growth of the worker caste is retarded, as indicated by the nitrogen, total lipid, total reducing substance (calculated as glucose), and calorific value. A list of 36 references to the literature cited is included.

Studies on the poison system of the honeybee, J. E. ECKERT. (Univ. Calif.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 258-268, figs. 12).

Environmental resistance to the establishment of parasitic Hymenoptera, S. E. FLANDERS. (Calif. Citrus Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 245-253).—It is shown that the establishment of parasitic Hymenoptera may be resisted by environmental factors which affect the activity of the ovipositing females or the development of their progeny. A parasitic species may fail to become established because it does not frequent host habitats or because it frequents habitats which lack hosts. The use of insecticides may reduce the host density below that required for the maintenance of the parasite population. Establishment may fail if the deposition of fertilized eggs of colonized adult parasites is inhibited by a change in condition of the host, the presence of predators, or the lack of food, or if the development of the parasite progeny is inhibited by the unsuitability of its normal host or by the competition of other parasites, either primary or secondary. The contribution is presented with a list of 27 references to the literature cited.

Some egg parasites of *Oecanthus quadripunctatus* Beut. and of a species of *Orchelimum*, E. J. UDINE and J. S. PINCKNEY. (U. S. D. A.). (*Pa. Acad. Sci. Proc.*, 14 (1940), pp. 81-84).—In the search for other hosts of some of the parasites of the hessian fly, various insects which in some stage of their development resembled the hessian fly puparium were reared at the Carlisle, Pa., laboratory. Notable among these was the four-spotted tree cricket, the eggs of which were found in abundance in the stems of wild carrot, or Queen Anne's lace (*Daucus carota*). From a total of 5,849 eggs of this cricket reared from various localities in Pennsylvania, Virginia, and North Carolina, nine species of parasites were obtained, namely, *Cacellus oecanthi* (Riley), *Leptoteleia oecanthi* (Riley), *Polynema bifasciatipenne* Gir., *Tetrastichus* sp., *T. oecanthivorus compar* Gahan, *Eupelmus* n. sp., *E. allynii* French, *Eurytoma* sp., and *Macrorileya oecanthi* Ashm. Eggs of an unidentified species of *Orchelimum* were also collected, though less

abundantly, from the stems of wild carrot. From the 153 eggs reared from localities in Pennsylvania and Virginia, four species of parasites were obtained, namely, *Eupelminus* sp., *Tumidiscapus orchetimumis* Gahan, *Eupelmus* n. sp., and *Macrotcleia* n. sp. The distribution and abundance of the parasites, tabulated by localities, is shown in accompanying tables. *E. allynii* was the only species parasitic on the hessian fly that was reared from the eggs of the two orthopterons.

A revision of the Pimplini of eastern North America (Hymenoptera: Ichneumonidae), H. K. TOWNES, JR. (Cornell Univ.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 283-323, figs. 10).

The hornworm parasite *Apanteles congregatus* Say and the hyperparasite *Hypopteromalus tabacum* (Fitch), B. B. FULTON. (N. C. Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 33 (1940), No. 2, pp. 231-244, figs. 3).—Report is made of a study of *A. congregatus*, a common braconid parasite of Sphingidae and an important enemy of the tomato worm, the percentage of parasitism of hornworms by which increases during autumn. This parasite "deposits a large number of eggs in the host in a few seconds. The eggs increase greatly in size before hatching. There are two larval instars in the host. During the first instar the larvae increased five-fold in dimensions. The second instar larvae molt as they are leaving the host. The third instar larvae spin cocoons on the host. Until about October 1 the pupae are formed in a few days; after that time the larvae hibernate and pupate in the spring. Several species of hyperparasites were reared from *Apanteles* cocoons. The most important enemy of *Apanteles* in tobacco fields is *H. tabacum*, which may almost eliminate the primary parasite in certain fields in late fall. Its larvae feed externally on *Apanteles* larvae within the cocoons."

Some parasites and hyperparasites of the cecropia moth, O. P. BRELAND (*Jour. N. Y. Ent. Soc.*, 48 (1940), No. 3, pp. 259-264).

***Anystis agilis* Banks, a predacious mite on eggs of the artichoke plume moth,** W. H. LANGE, JR. (*Pan-Pacific Ent.*, 16 (1940), No. 1, p. 30).

The tropical rat mite *Liponyssus bacoti* in Minnesota, W. A. RILEY. (Univ. Minn.). (*Jour. Parasitol.*, 26 (1940), No. 5, p. 433).

ANIMAL PRODUCTION

[Abstracts of papers on animal nutrition presented at the seventh annual meeting of the American Institute on Nutrition] (*Jour. Nutr.*, 19 (1940), No. 6, Sup., pp. 7, 11, 13, 14, 15, 17, 18, 19, 20).—Abstracts of the following papers are noted: Pantothenic Acid and Its Nutritional Significance, by R. J. Williams: Comparative Activities of Certain Antihemorrhagic Quinones, by H. J. Almquist and A. A. Klose (Univ. Calif.); Muscular Dystrophy in Rabbits and the Autoxidation of Animal Fats, by H. A. Mattill; Relation of Perosis to Unrecognized Vitamins, by A. G. Hogan, L. R. Richardson, and H. Patrick (Univ. Mo.); A Deficiency Disease in Chicks Prevented by *dl*-alpha Tocopherol, by H. R. Bird and T. G. Culton (Univ. Md.) (*E. S. R.*, 83, p. 812); Studies of the Vitamin B-Complex With Chicks, by T. H. Jukes, and Anti-grey Hair Vitamin Deficiency in Dogs and Silver Foxes, by A. F. Morgan (both Univ. Calif.); and Availability of Phosphorus in Hays, by D. E. Williams, F. L. MacLeod, E. Morrell, and H. R. Duncan (Univ. Tenn.).

[Livestock investigations in Pennsylvania] (*Pennsylvania Sta. Bul.* 399 (1940), pp. 34-40, 54-56, figs. 2).—Studies for which results are briefly noted include a comparison of corn silage, alfalfa hay, and alfalfa-molasses silage as roughages for fattening steers, by F. L. Bentley and P. T. Ziegler; breeding superior type lambs for hothouse lamb production, by W. L. Henning; optimum

protein levels for growing fattening pigs, by T. B. Keith and R. C. Miller; pumping as an aid in the pickle curing of hams, and the curing of frozen hams, both by Ziegler; the destruction of vitamin C during bovine digestion, by C. A. Knight, R. A. Dutcher, N. B. Guerrant, and S. I. Bechdel; the function of manganese in animal nutrition, the synthesis of vitamin C by rats, and the effect of exercise on the vitamin B₁ requirements of rats, all by Guerrant; the effect of anterior pituitary extract on energy and protein metabolism, and methods of computation of energy factors, both by M. Kriss and L. F. Marcy; the dynamic effects of protein, carbohydrate, and fat, by E. B. Forbes, J. W. Bratzler, et al.; the relation of protein to heat production, by Forbes; and measurement of spoilage of certain edible fats, by M. L. Shaner and H. O. Triebold.

From poultry investigations, results are noted on the inheritance of egg shape, by D. R. Marble; the value of whole oats for turkeys, by P. H. Margolf; the vitamin A requirements of chicks, the riboflavin requirements of White Leghorn and Barred Plymouth Rock chickens, and the value of molasses as a partial substitute for corn in chick rations, all by R. V. Boucher; and the use of dried yeast to reduce the incidence of perosis.

Feeding farm livestock, E. W. SHEETS (*Chicago: Breeder Pubs.*, [1940], pp. 192, figs. [31]).—Practical directions are given for livestock feeding.

The impairment in nutritive value of corn grain damaged by specific fungi, H. H. MITCHELL and J. R. BEADLES. (Ill. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 61 (1940), No. 2, pp. 135-141).—The fungi used in this study were *Diplodia zeae*, *Fusarium moniliforme*, and *Gibberella zeae*. Ears of corn were artificially inoculated with pure spores of these organisms. Corn showing damage of 94-98, 100, and 53 percent by *Diplodia*, *Fusarium*, and *Gibberella* organisms, respectively, were used in the analytical studies and the paired rat feeding tests. Damage to corn by *Diplodia* ear rot or *Fusarium* ear rot definitely reduced the digestibility of the nitrogen and energy and the nutritive value of the protein and energy for promotion of growth in the rat. Damage of the latter type appeared somewhat more severe. Infection with any of the organisms caused definite changes in the chemical composition of corn, particularly loss of the ether-extractable constituents. A sample of corn containing 53 percent of kernels damaged by the *Gibberella* organism proved extremely toxic to young albino rats.

Stabilization of iodine in salt and feedstuffs, F. F. JOHNSON and E. R. FREDERICK (*Science*, 92 (1940), No. 2388, pp. 315, 316).—The newly devised method for stabilizing the iodine supplement of comestibles consists of milling 100-mesh alkali iodide with a small amount of nontoxic metallic soap. When 92 parts of potassium iodide were milled with 8 parts of calcium stearate, a stable free-flowing powder, coated with the stearate and practically insoluble in water, resulted. Loss of iodine from mineralized salt containing the stearate-coated iodide was very little as compared with the loss from the same formula without the calcium stearate. The stearate also functioned to prevent caking of table salt when used at a 0.2-percent level.

Vitamin content of distillers' by-products, C. S. BORUFF, A. F. LANGLYKKE, and S. BLACK. (Univ. Wis. et al.). (*Indus. and Engin. Chem.*, 32 (1940), No. 9, pp. 1237-1239, fig. 1).—Three feed products representing distillers' residues including (1) the insoluble portion removed on screens, (2) the insoluble fraction removed by centrifuges, and (3) a soluble fraction removed by evaporating the thin slops, were assayed. The dried centrifuge sludge was relatively poor in water-soluble vitamins. The dried sirup contained from 26 to 40 μ g. of flavin and from 2 to 3 International Units of vitamin B₁ per gram, also a significant amount of the chick antidermatitis factor and factor W. A composite sample of the feed contained only small amounts of vitamins A and D, but from 13.3 to

15 μ g. of riboflavin and from 1 to 1.3 I. U. of vitamin B₁ per gram, as well as sufficient chick antidermatitis factor to protect chicks at a feeding level of from 30 to 40 percent.

Factors affecting the stability and estimation of carotene in artificially dried grass and hays, S. K. KON and S. Y. THOMPSON (*Jour. Agr. Sci. [England]*, 30 (1940), No. 4, pp. 622-638, figs. 3).—The loss of carotene in finely ground, artificially dried grass amounted to about 23.9 percent during the first month of storage and 31.4 percent over a 6-mo. period (August to February). Little difference in rate of loss was noted between samples stored in the light v. the dark, at ordinary temperature v. 70° to 80° F., and in paper bags v. jute bags. The carotene loss in baled artificially dried grass amounted to from 30 to 40 percent over a period of 13 months' storage. Methods of estimating carotene in forage are discussed.

The hematology of avitaminosis A in dogs and rabbits, M. W. EMMEL (Fla. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 761, pp. 145-148, figs. 2).—Three groups of young pups were fed on vitamin A-deficient, low vitamin A, and adequate vitamin A diets, respectively. Those on the deficient diet developed acute A avitaminosis after 9 weeks, at which time the normal numerical relationship of small to large lymphocytes was reversed. Those on the low vitamin A intake for 18 weeks developed mild symptoms of vitamin A deficiency and showed an increase in total lymphocyte count, with a preponderance of the large lymphocytes. The normally fed controls showed no significant blood changes. When 37,500 International Units of vitamin A in shark-liver oil were fed on alternate days to the deficient groups, the deficiency symptoms disappeared within 2 weeks and a normal blood picture was restored in 4 weeks. Rabbits of varying ages subjected to vitamin A-deficient feeding all exhibited blood counts indicative of chronic vitamin A deficiency. Blood counts returned to normal within 7 weeks when 7,500 I. U. of vitamin A in shark-liver oil daily was added to the diets.

Directions for the ascorbic acid therapy of slow-breeding bulls, P. H. PHILLIPS (Univ. Wis.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 761, pp. 165, 166).—It is reported that the subcutaneous injection of ascorbic acid (E. S. R., 84, p. 173) caused marked recovery in from 60 to 75 percent of the impotent bulls which were so treated. The response to ascorbic acid therapy may be in the form of greater sexual interest or more viable sperm, or both. Distinct improvement of the semen generally occurred. The recommended treatment consists in dissolving from 1 to 2 gm. of crystalline ascorbic acid in from 5 to 10 cc. of sterilized buffer solution (distilled water or physiologic saline solution may be used) and injecting the ascorbic acid solution subcutaneously at from 3- to 4-day intervals for 5 or 6 weeks, or until the bull shows definite improvement.

Legume and grass silage for beef cattle, K. L. TURK (*Id. Agr. Soc., Farm Bur. Rpt. 24* (1939), pp. 219-224).—A general discussion regarding the preparation and use of such silage.

Beet-top silage for fattening steers, F. W. CHRISTENSEN (*North Dakota Sta. Bimo. Bul.*, 3 (1940), No. 2, pp. 3-5).—Study of the comparative gains of 1,000-lb. steers on an 82-day feeding trial suggested that good clean beet-top silage was worth from one-third to one-half as much as corn silage.

History of the breeds of cattle in Canada [trans. title], L. DE G. FORTIN (*Bonne Terre*, 18 (1940), pp. [337], figs. 57).—Principal sections of this treatise include the history of the cattle breeds in Canada, formation and preservation of the breeds, and improvement of the cattle.

Levels of protein for pigs, T. B. KEITH and R. C. MILLER (*Pennsylvania Sta. Bul. 401* (1940), pp. [2]+22, figs. 7).—There are reported the results of experi-

ments in which swine were fed on corn supplemented with soybean meal, tankage, and alfalfa meal to provide mixtures containing 10, 12, 15, 17, 20, 22, 25, and 27 percent protein. The results summarized for rate and economy of gains for different weight intervals showed the higher protein levels to stimulate the more rapid gains in the younger animals, but under certain conditions of high-priced protein and low-priced corn the 17-percent protein ration was most economical. Above 125 lb. live weight, 15-percent protein rations were most economical, but the amount of protein recommended for weight above 100 lb. depends on the use to be made of the pigs. Cod-liver oil was added as a supplement to rations containing 15 percent protein, with the result that the average daily gains were less rapid. The feed requirements were also greater with the cod-liver oil.

A series of nomographic tables is presented for ready calculation of the costs per 100 lb. of gain at different prices for the feeds included.

Growth rate and carcass quality in bacon pigs: A study of polynomial coefficients fitted to growth rate data, H. P. DONALD (*Jour. Agr. Sci. [England]*, 30 (1940), No. 4, pp. 582-597, fig. 1).—A statistical analysis of growth data and carcass reports for 75 bacon-type pigs are described. By means of standard partial regression coefficients, the dependence of each of six carcass measurements on growth rate, rate of change of growth rate, carcass weight, and weaning weight was determined. The various degrees of correlation are described at length. It is concluded that, since the influence of growth rate on carcass measurements appears to be expressed in a variable way according to the type of pig concerned, it is not possible to make detailed predictions of the relation between growth rate and carcass quality.

The "restricted" feeding of bacon pigs: A co-ordinated experiment at centres in Great Britain and Ireland, R. W. SHORROCK (*Jour. Agr. Sci. [England]*, 30 (1940), No. 4, pp. 598-621).—In 22 uniform experiments, bacon pigs were fed in all cases at a uniform rate to 100 lb. live weight and at 3 levels of feeding thereafter. Restricting the daily feed intake to 5 lb. 3 oz. per head increased the efficiency of feed utilization with no pronounced effect on carcass quality as compared with the feeding of 6 lb. 5 oz. or 7 lb. 8 oz. per head daily. The feed saving between the lowest and highest levels amounted to 50 lb. per head over the period from 100 to 200 lb. live weight.

The quality of hams and bacons prepared from carcasses of hogs fed with different feed mixtures, D. S. BOLONG (*Philippine Jour. Anim. Indus.*, 7 (1940), No. 4, pp. 321-333, pls. 3, fig. 1).—Four pairs of pigs were fed rice bran plus (1) kitchen refuse, (2) corn meal, (3) copra meal, and (4) a balanced mixture including corn meal, copra meal, and tankage over a fattening period of 285 days. Studies were conducted on the cured hams and bacons. Feed mixture 3 containing an excess of copra meal resulted in relatively slow growth and in the production of soft oily fat. Well-marbled meat of good quality was produced by all other lots. The highest shrinkage during drying, smoking, aging, and cooking occurred in the lot fed rice bran and copra meal, while the least shrinkage occurred in meat obtained from animals fed the balanced mixture. The meat from lot 4 also contained the highest percentage of protein and yielded the most savory finished product.

Rabbit feeding for meat and fur, W. KING WILSON and W. McCARTNEY (*Imp. Bur. Anim. Nutr. [Aberdeen]*, *Tech. Commun.* 12 (1940), pp. 36).—General principles of feeding, with special reference to the nutrient requirements by rabbits of different size and for the production of meat and skins.

[**Poultry Science Association, thirty-second annual meeting**] (*Poultry Sci.*, 19 (1940), No. 5, pp. 345, 346, 347, 348-352, 353, 354, 355-361, 362, 363, 364,
