## INDEX TO VOLUME VI.

## CONTRIBUTORS.

## A.

Abell, Irvin, 115, 122, 204, 240, 366, 399, 614.  
 Adair, J. M., 341.  
 Albrecht, F. H., 761.  
 Aleorn, Ed, 114, 636.  
 Albright, G. H., 53.  
 Allen, E. S., 153, 455, 694.  
 Allen, M. K., 193.  
 Allen, W. E., 339.  
 Anderson, E. C., 309, 318.  
 Anderson, S. J., 60.  
 Anderson, W. W., 31, 585, 594, 645, 679, 717, 720.  
 Armstrong, M. W., 56.  
 Armendt, L. G., 682.  
 Arnold, J. H., 31, 60.  
 Asman, Bernard, 150.  
 Atkinson, J. L., 288, 580.  
 Austin, Curtis, 362.  
 Austin, J. H., 318.  
 Aud, C. Z., 107, 203, 204, 366, 559, 583, 591, 644.

## B.

Backus, J. J., 318.  
 Bailey, G. P., 606.  
 Bailey, Steele, 553.  
 Bailey, William, 19, 41, 335, 457, 573, 584, 601, 609, 614, 676, 728, 754.  
 Baird, Foster, 701.  
 Baltzer, L. P., 266.  
 Barber, I. Z., 605.  
 Barbour, Philip F., 7, 78, 123, 158, 213, 242, 296, 401, 660, 667.  
 Barkley A. H., 320, 647.  
 Barnes, J. S., 322, 364.  
 Barnette, W. T., 365.  
 Barrow, David, 741.  
 Barr, Ed., 276, 450.  
 Barr, G. L., 410.  
 Bates, R. A., 159, 457, 683, 764.  
 Bates, S. W., 335, 353, 605.  
 Bean, A. J., 116, 774.  
 Beard, F. M., 314, 339, 367, 379, 586.  
 Beard, S. L., 340, 633.  
 Beazley, H. C., 266, 317.  
 Best, I. D., 450.  
 Bird, R. L., 367.  
 Bizot, A. R., 359.  
 Blackburn, J. H., 289, 365, 341.  
 Blackerby, P. E., 604.  
 Blair, William, 311, 317, 681.  
 Blanton, J. W., 613.  
 Bloch, O. E., 149, 296.  
 Bloom, I. N., 40, 322.  
 Blythe, Vernon, 160, 230, 313, 366.  
 Board, Milton, 648.  
 Boggess, W. F., 16, 160, 225, 595, 601, 673, 680.  
 Boone, J. C., 54.  
 Botts, A. T., 265, 448, 604.  
 Botts, J. W., 116, 338, 703.  
 Botts, S. T., 265, 335, 448.

Bowen, D. C., 96, 204, 321.  
 Boyd, Frank, 550.  
 Brady, A. S., 109, 450, 571.  
 Brandeis, Florence, 157, 218.  
 Brice, J. C., 140, 148.  
 Bronner, Herbert, 695.  
 Brooks, J. G., 432.  
 Brown, J. S., 109.  
 Bruner, W. T., 158, 364.  
 Buchanan, J. B., 288.  
 Bullock, T. S., 570.  
 Bullock, W. O., 604.  
 Burk, G. H., 56.  
 Burnett, E. D., 257.  
 Burr, W. R., 408.  
 Burrow, R. C., 605.  
 Bushong, G. W., 229.  
 Butler, F. L., 353, 368, 376, 378.

**Home Treatment of Scarlet Fever.**—On the basis of an experience of many hundred cases of scarlet fever, Milne is satisfied that the method of anointing the patient with 10 per cent. carbolic oil or eucalyptus oil, day by day, and a plentiful supply of fresh air, prevents the disease from spreading. After a few days his patients were allowed to mingle freely with other people. He reports many instances in which this practice has been followed—notably one in which he brought such a patient as a guest into his own home, allowing him to mingle freely with his children at meals and at games—without ill results. Milne now prefers eucalyptus oil which is rubbed in over the entire body from the crown of the head to the soles of the feet, including the roots of the hair, the axillae, and other flexures, both morning and evening for the first four days, then once daily until the tenth day. The throat is swabbed with carbolic oil, 10 per cent. every two hours for the first twenty-four hours. Milne has never known nose, ear or kidney trouble to follow, and the severity of the attack appears to be always mitigated. Cold must be avoided for three weeks and the children warmly clad. At first he allows only soda water or hot water and milk in equal quantities; in a few days, he permits light diet, and by the tenth day, ordinary meals. He has applied this method also in measles. This method, he asserts, dispenses with the need of elaborate disinfection afterward, the course of the disease being destroyed. Of course, it protects only against contact infection, and would not check an epidemic arising from a common source, such as infected milk.—British Medical Journal.

**Prevention of Tropical Liver Abscess.**—Rogers urges the reinstatement of the ipecacuanha treatment, 30 grains (1.95), or in less acute cases, 20 grains (1.30), of chloral hydrate. No food or fluid should be given for three hours before or after the dose. He compares the rejection of the ipecac treatment to the substitution, early in the nineteenth century, of venesection and salivation for the empirical quinin treatment, which was not restored to use again till 1847. Amebic ulcer of the great bowel is readily curable by ipecacuanha, and on this ulcer, Rogers holds, the liver abscess depends.—Medical Press.

## ABOUT THE NOSTRUM MATTER.

Postal card replies have been received from 1883 out of our 1904 members, and from 1555 of the 1776 physicians in the State not yet affiliated with our Association. Out of this total vote seven wrote for further information and seven voted in the negative. Five of the first class, and two of the latter have since written, changing to the affirmative.

This is a wonderful showing. It indicates that the profession of Kentucky is awake and ready to do its duty. It has required considerable study for us to find that Liquor Antisepticus as made by a competent pharmacist better meets our needs than listerine; that Liquor Antisepticus Alkalinus is in almost every way preferable to glyco-thymoline. When the Mist. Chloral et Potassii Bromid Comp. of the National Formulary is indicated, why not use it, rather than a secret proprietary? In fact, it is wholly unnecessary to prescribe or use any nostrum. It is to be regretted that all the members of the profession have not availed themselves of the liberal offer made by the JOURNAL, and procured the Manual of the Pharmacopeia and National Formulary. These are not only useful, but are almost essential, since, under the federal pure food and drug law, these publications furnish the legal standards for drugs.

Another thing is equally essential. Be sure your druggist is an honest and capable man. If he is, he will be delighted when you stop using nostrums about which he knows as little as you do. The standard preparations cost less than the nostrums to the patient, and yet the druggist's margin of profit is greater.

## THE NEGATIVE VOTE.

The intelligent objector who finds himself

in the minority is entitled to all credit. It is he who keeps the pendulum from swinging too far. It is in this spirit that we analyze the negative vote in our general referendum on the nostrum evil.

Two of the fourteen negative votes could not do without the American Journal of Clinical Medicine. Under these circumstances they voted conscientiously as it is certainly put under the ban as a trade journal. That it is a vivacious and attractive commercial journal goes without saying, but members of our profession who are unable to dispense with this indefatigable therapeutic guide, certainly should vote in the negative on the resolutions.

Two of the votes were registered by Eclectics. We appreciated their letters and it is a pleasure to correct an impression they had received from an error in the letter accompanying the resolutions. No member of the profession objects to the use of the specific tinctures by those who prefer them to the ordinary galenicals. These are standard preparations whose composition is known. We think it would probably be well for our Eclectic brethren to have those preparations listed and submitted for inclusion in the U. S. P. Some of these preparations are of undoubted value and the whole profession should have easy access to them. We thank Drs. Fuller and Morrill for calling these preparations to the attention of the profession.

## RECIPROCITY.

The State Board of Health announces the establishment of reciprocity in medical licensure with Utah, Texas and New Hampshire. Our list now includes Maine, New Jersey, Virginia, West Virginia, Tennessee, Georgia, Missouri, Michigan, Minnesota, Kansas, Vermont, the District of Columbia, Indiana, Iowa, Nebraska, Nevada, South Caro-

lina, Wisconsin, New Mexico, Colorado, Mississippi, Maryland and North Dakota, making twenty-six States and Territories. Negotiations are pending with other States. We intend in the near future to publish a resume of the conditions in the various States. At present these can be now obtained by sending 25 cents to the *Journal of the American Medical Association*, 103 Dearborn Avenue, Chicago, and securing their book, "The Laws."

It is to be remembered that, in all of the Kentucky agreements, it is required that the applicant shall have been a member of the county, State and National medical society of the school or system of medicine with which he affiliates for at least one year, and that he shall be commended as a fit subject for reciprocity at a stated meeting of his county society. Some States require that the applicant shall have passed our State Board examination, others accept all of our licentiates.

---

#### JANUARY 1, 1908.

Another year with all of its possibilities and responsibilities confronts us. Let each of us collect up our accounts as closely as possible. Let us resolve that we will attend the deserving poor more closely than ever, and that we will *point blanc* decline to do practice at all for that numerous class who can pay, but will not. Let us be a little more liberal with our wives, a little more careful with our children; and, above all, let us never give a sick person any sort of drug or mixture about whose contents or indication we know nothing except what some interested manufacturer—lay or medical—has told us.

---

### SCIENTIFIC EDITORIALS.

#### THE VALUE OF VITAL STATISTICS.

BY GEORGE P. SPRAGUE, LEXINGTON.

Like all other branches of human endeavor, medicine has been so long engrossed with results, that it has had small opportunity to consider causes. Thus it is that our profession, while bending every energy to the relief and cure of the sick, has, as a whole, given little attention to the prevention of disease. The attitude of the medical profession has been so universal that the sanitarian and his work have been, for generations, looked upon by physicians with good-natured indifference. In recent years, however, during the last decade particularly, it has been more and more forced upon us that the physician's duty to his individual patient is but a minor part of his life-work, while the larg-

er share of his reason for being a physician consists in his ability to prevent disease and preserve health in his community and, by combination with others, throughout the State. To this end, the world's foremost investigators are found in the bacteriological laboratory, in the amphitheatre and at the bedside, while the search for new remedies has been largely relegated to the financially-interested chemist. In this great warfare of disease, prevention, one valuable aid—a study of vital statistics—has been singularly neglected. It is often thought that vital statistics are merely a register of births and deaths, and were that all, they would still be worth keeping, but that is not all. Abbott defines vital statistics as the science of numbers applied to the life histories of populations, and says "The facts which are collected from different nations, communities, and populations, and which are embraced in the term 'vital statistics' constitute the basis of definite and accurate knowledge upon many of the fundamental principles of public hygiene, sociology, and of preventive, as well as therapeutic medicine." Thus it is that in a system of vital statistics, the registration is largely for the purpose of securing statistics for analysis, and it is in the analysis that conditions are found out of which grow means of protecting property, safeguarding lives, and preventing deaths with a co-incident enormous financial saving to the State.

A year or two ago, when the Kentucky State Board of Health made an inquiry into infectious and contagious diseases in Kentucky, it was found that the preventable diseases alone, cost our State millions of dollars yearly. A system of vital statistics would soon so analyze the conditions surrounding these diseases, that a campaign of prevention could be inaugurated against them. This illustrates but one side of the value of such statistics, for properly kept, they are a record of birthright, of property inheritance, and of identity after death, and intelligently studied, they furnish the necessary data for life insurance calculations, lead to a more definite knowledge as to the value of vaccination, antitoxic sera, etc., the need of protecting streams from pollution, the effects of climatological conditions in health and disease, and in certain definite diseases, and not to go further into details, enable us to more clearly see the special causes of disease and death in both urban and suburban communities.

In a paper on vital statistics at the 25th. Annual meeting of the Public Health Association held at Atlantic City from Sept. 30th to Oct. 4th, 1907, Dr. Cressy L. Wilbur,

chief statistician, Bureau of the Census, Washington, stated that in 1895 there were only eight registration states for deaths, and no registration states for births, and that even in 1907 there were but fifteen registration states for deaths, while the registration area for births was limited to Massachusetts, Pennsylvania and Michigan, so that a law providing for a department of vital statistics of our State Board of Health, passed by the present legislature would keep Kentucky where she has ever been in matters medical—in the front rank of progress. A subject which is so seldom considered by the medical profession must, naturally, be little understood by the average legislator, but if each reader of the JOURNAL will but present the facts in the case to the members of the General Assembly from his county, or even write a note to them, urging the need of such a law, its passage should be an easy matter.

### SURGERY OF THE CHEST.

JNO. R. WATHEN, LOUISVILLE.

It is a strange fact that, with all the advances in recent years made by American surgeons in the abdomen and other parts, they have given little attention to the surgical diseases of the chest.

With an increased knowledge of its physiology and its pathology, a better understanding of aseptic technique, the employment of Rontgen methods in diagnosis, and many other aids, at present the chest is receiving much attention from surgeons in both this country and abroad.

Sir William Macewen, in a recent lecture (Brit. Med. Jour. 1907) in London has said: "The admission of air to the pleura and its results has been, and according to some authors is still considered, the greatest barrier to the surgery of the lung." Thus we have an excellent surgeon and experimentalist stating in a recent paper that "the pleura do not remain in contact when air is admitted into the pleural cavity, even by a pin-hole opening," and that "when openings large enough to admit the hand are made into the pleura, the lung, in two or three expirations, collapses to its hilum and remains there stationary, without the slightest effort at expansion." Having been taught that the lung always collapsed on opening the pleural cavity when there were no organic adhesions present, the phenomena presented by some cases which came under my observation in the early seventies caused me to consider the question and to doubt that collapse of the lung was always so absolute as it was supposed to be. Inquiry was also made as

to whether there were modifying circumstances which could avert that collapse, or others which could rectify it when it did occur."

Macewen has clearly demonstrated after a vast experience, that if the patient is placed on the affected side before opening the pleura, allowing the action of gravity to aid in fixing the mediastinal septum and causing a closer adhesion or cohesion between the visceral and the parietal layers of the pleura, that the lung will not collapse as formerly believed.

When this adhesion of capillary attraction is lessened by position or the lack of fluid between the layers of the pleura it tends to reach from the thoracic wall and can only be returned to normal by firm pressure on the thorax, bringing the parietal layer of the pleura into contact with the visceral and causing the extrusion of air between the layers.

This collapse of the lung has been prevented in Germany by the air-chamber, constructed by Sauerbruch, the essential feature of which is to cause a negative pressure over the exposed lung equal to the pulmonary retractility. Carl Beck has recently written (Surgical Diseases of the Chest 1907): "This ingenious invention eliminates the possibility of pneumothorax in interthoracic operations by excluding the atmospheric pressure, thus preventing collapsing of the lungs after being opened to the air. In a lower animal Sauerbruch opened the thorax on both sides, and removed sternum and ribs without seeing the respiration interfered with in the slightest degree. The Sauerbruch chamber is air-tight. Its size permits of the presence of surgeon, assistant, patient and operating table. The head of the patient may project outside, while a rubber cuff is tightened around the neck. Regulation of the air-pressure is done by an air-pump a valve in its wall permitting the entrance of a sufficient amount of air to keep up continuous negative pressure inside the chamber. Von Mikulicz and his assistant, who did work inside of the air chamber for an hour, did not suffer any discomfort."

Other types of apparatus have for their principle the maintenance of a positive pressure by placing the patient's head in a closed box under increased air pressure and there administer the anesthetic. All these mechanical methods have as their basic principle the establishment of a constant difference in air pressure between the interior and the exterior of the lung equal to the pulmonary retractility.

Dudley Tait (Surgery, Gynec. and Obstetrics 1907) has recently written:—

“Delageniere’s method is unquestionably the most valuable of the surgical methods for controlling pneumothorax. The technique of Delageniere’s procedure is as follows: U-shaped incision in the axillary line, and resection of the eighth, ninth, and tenth ribs. Make a small opening (1 to 1 1-2 cm.) in the most dependent part of the pleura, allowing air to enter. If any respiratory disturbance supervene, close the wound with compress, or seize the lung with forceps and bring it into the wound. As soon as the breathing becomes normal remove the compress or gradually release the lung until the pleural cavity becomes accustomed to the presence of air. The operator may thus witness the gradual development of “complete” collapse of the lung. The pleural incision is then enlarged so as to permit either visual, digital, or manual exploration of the cavity and its contents. The pulmonary lesions having been located, the lung is sutured to the edges of the pleura, or to a second incision if the affected pulmonary area is situated higher than the exploratory incision. The air remaining in the hermetically sealed pleural cavity is then removed with an aspirator.”

While the above methods are a fair presentation of the modern views of the mechanics of chest surgery, the fact remains that we are just beginning to fully appreciate the possibilities of future operative intervention.

The treatment of pyothorax dates back to remote antiquity; the operation was performed as early as the time of Hippocrates. Nevertheless, little of real value has been added to the original principles of drainage established by this early pioneer in surgery of the chest.

One of the greatest aids to accurate diagnosis of surgical diseases of the chest has been the use of the Roentgen rays, with which we can clearly demonstrate abscesses, aneurisms, tumors, and many other conditions.

Killian, of Germany, has devised an instrument called the bronchoscope, which can be introduced into the bronchi and foreign bodies as bones, buttons, beans, etc., can be easily seen and removed, without doing a tracheotomy.

As our experience ripens, the real value of these newer methods in surgery of the chest will be more fully demonstrated and be of greater good to practical surgery.

## THE PUERPERIUM. CARE OF THE CHILD.

BY EDWARD SPEIDEL, LOUISVILLE.

It is very important that the baby cry lustily, immediately after its birth, in order that the lungs may be fully inflated. Accordingly, before the cord is severed, the child should be grasped by the feet with a towel, its head hanging downward, when a few smart slaps on the buttocks will generally bring about the desired result. This manœuvre will at the same time clear the bronchi and trachea of mucus, which may readily be wiped out of the mouth with a soft piece of gauze, when the baby is laid upon its right side to favor the closure of the foramen ovale. Late ligation of the cord is now generally practiced, as described in a previous article, “The Conduct of Labor” (KENTUCKY MEDICAL JOURNAL, July, 1907), and the rubber elastic funis band that is applied with the applicator, a nickle-plated instrument resembling a small hollow ten pin, is the neatest and perhaps safest means of ligation.

The cord should then be temporarily wrapped with a piece of absorbent cotton, so that it may not be infected in the succeeding manipulations.

The child should be taken to a warm place and thoroughly anointed with warm olive oil, to remove the vernix caseosa. If this is done before an open fire, then the nurse should be cautioned to protect the baby’s eyes from the direct glare. In thus passing over every portion of the baby’s body, the nurse should be on the look-out for blemishes or deformities, as invariably the mother’s first question is as to whether there are any. In most instances none will be found and the mother can at once be so assured. If a serious deformity is noticed, then, of course, it would be unwise to inform the mother at this time and the physician must satisfy her inquiries temporarily.

The excess of oil having been removed with a soft cloth, the baby is ready for the permanent dressing of the umbilical cord. In applying the permanent dressing, a piece of gauze 8 inches square is folded twice like a handkerchief and a corner clipped, leaving a small hole in the center, when it is again opened up. This gauze is laid flat upon the baby’s abdomen, the cord is drawn through and turned to the left or upward. There is a popular superstition, that if the cord is placed to the right, that the baby will be liver grown. One of our text books on Obstetrics, treats the matter seriously, stating that when the cord is dressed to the right and held in place by the belly band, that its pres-

sure against the abdomen, will bring about adhesion of the liver.

If the cord is dressed to the left, then it should be thoroughly dusted with stearate of zinc and balsam peru, a fine white palpable powder that answers the purpose admirably. It is superior to powdered boric acid, in that it does not cake, it is superior to an oily dressing, as mumification of the cord takes place faster. After dusting the stump of the cord, the lower third of the piece of gauze is folded upward, the upper third downward and the belly band placed over this, flat upon the abdomen. The ends of the gauze should not be folded over, or the pressure of the belly band upon this mass will cause the baby much discomfort. A still better way, is to dress the cord upward in the median line, the gauze is then folded upward once toward the stump of the cord and the belly band placed over it. The advantage of the latter method, rests in the fact, that the dressing is high up and not subject to accidental contamination by urine. The belly band may be changed as often as needed in the succeeding days, but ordinarily the gauze dressing should not be disturbed at all until the cord drops off. If the gauze is accidentally soiled by urine, then it must be carefully removed and reapplied. After the cord drops off, any granulations persisting, should be touched with 20% argyrol solution, and a castor oil dressing applied, ordinarily a dusting with a borated talcum powder will be all that is required.

It is unwise to bathe the baby at once. At birth it is ushered into an atmosphere, at least 20 degrees lower than that which it has been existing in and any chilling of its body as may occur by giving it a bath at this time, will impair its vitality. As a general thing, there is more or less commotion in the household in consequence of its arrival and the bath had better be postponed, until a convenient time later on. One author suggests, oiling the baby's body daily and not giving it the bath until the cord drops off.

The baby should be dressed warmly, laid in its crib well covered and in cold weather kept warm by hot water bottle, placed near it carefully wrapped in a towel.

A daily sponge bath should be given, until the cord drops off, thereafter the immersion bath is used, more than one bath daily is injurious.

The doctor must give the baby as much attention upon his post partem visit as he gives the mother. If he neglects it, then he is very apt to offend the mother and neglect of this kind may often result seriously to the infant. Jewett in the 1907 edition of his Ob-

stetrics, page 285, gives the following causes of sudden death in the infant:

*Sudden Deaths*—It should be remembered that new-born infants are liable to sudden and unexpected death. It is not uncommon for an infant apparently doing well to suddenly die, with or without convulsions. The most common causes of sudden death are the following:

1. Acute bronchitis or broncho-pneumonia with heart failure.

2. Cerebral hemorrhage, with or without eclampsia.

3. Acute indigestion with autointoxication, with resultant eclampsia.

4. Asphyxia, caused by vomiting and aspiration of the vomited matters into a bronchus, or from laryngeal spasm.

5. Congenital weakness, as in cases of hereditary syphilis, premature birth, etc.

6. Nephritis, septicaemia, anomalies of the brain or cord, congenital cardiac malformation or atelectasis.

7. Status lymphaticus, as from enlarged thymus or other gland. Other causes may give rise to sudden death, but the above are those most often met with. The fact that such an accident is liable to occur should cause the attendant to carefully watch a new-born infant.

The eyes of the baby should be examined daily, the Crede treatment having been given immediately after delivery, and the nurse having been instructed to cleanse the lids once daily with warm saturated solutions of boric acid.

The physician should pass his hand over the child's head and get his finger tips educated to the size and shape of the fontanelles, as this will aid him greatly in future diagnosis during labor.

The action of the bowels and kidneys should be noted. In the first two days, the tarry stools, the meconium will be passed. Thereafter the stools will gradually change in color until the light yellow feces of infancy will pass. The baby should have from 2 to 4 defecations daily, but one natural action of the bowels is better than several if dependent upon the use of purgatives.

It may be advisable if the condition calls for it, to give the baby a teaspoonful of olive oil once or twice as a laxative, but all natural means to relieve constipation should be resorted to before drugging a baby with the various laxatives, castoria, etc.

The habits of an infant can be regulated very early in life, to the great comfort of both child and mother. If the baby's napkin is removed a short time after its morning nursing and it is held for a few min-

utes in the squatting position and this practice is continued from day to day at a definite time, defecation and micturition will become definitely established at that time. The insertion into the rectum, of a small piece of cocoa butter or of twisted toilet paper anointed with vaseline, may be necessary at times to stimulate peristalsis. Pieces of soap should not be used for this purpose, as irritation of the rectum follows. The nurse will often claim that the baby's kidneys have not acted on the first day. It must be remembered that only a very small amount of urine is naturally secreted during that time and that may escape unnoticed with the liquid stools that are passed. In case of doubt, the question must be settled by administering warm water to the baby and fixing a piece of absorbant cotton around the penis or against the vulva of the infant. If red stains appear upon the napkin, they are due to an excess of uric acid and indicate the administration of water to the baby.

Before dismissing the case, the penis of a male child should be examined and if necessary the prepuce should be forcibly dilated with artery forceps until it can be retracted behind the corona and the parts then anointed with vaseline. By thus retracting the foreskin and the use of vaseline several times a week for a short time, the necessity for a circumcision may be avoided.

Proper habits of nursing should be instituted from birth. The baby's entire future depends upon it, health, strength, and personal appearance. The baby should be put to the breast four times in the first 24 hours, every three hours on the second day, then on the third day the systematic nursing should be instituted. Thereafter the baby should be nursed every two hours from 6 A. M. to 10 P. M. and only once during the night. If it awakens more than once during the night, then it should be given a little warm water and kept in its crib. In a short time it will learn to accommodate itself to these regulations and in many instances will sleep all night. If the baby shows an inclination to turn night into day, then it must be waked regularly for nursing during the day and be taught to sleep at night.

The baby should receive its first nursing about 6 A. M., then at 8 and before its third nursing at 10 A. M. it should receive its bath, thereafter it should be allowed to sleep as long as it will. When it awakens the two hour nursing should be kept up regularly until 10 P. M. If it sleeps over time then, it should be given a half hour's grace. It should then be roused, should be allowed to cry for a few minutes and then nursed. Af-

ter each nursing the baby should receive a teaspoonful of warm water—to clean the mouth of any milk remaining in it and if it cries between nursing times, warm water should also be given it. One or two weeks of a determined effort on the part of the nurse or mother to carry out the above rules, will prove of such benefit to all concerned, the baby, the mother and even the father, who usually complains loudest if his night's rest is disturbed by a squalling infant, that they will feel abundantly repaid for their effort.

The baby gets no nourishment in the first 48 hours, the breasts only containing the colostrum, nature's purgative, intended to clear the infant's gastrointestinal tract of the accumulations of fetal life and to get ready for the assimilation of its natural food on the third day. It is necessary for the baby to nurse this material, for the above reason, secondly because it brings about the true milk formation and, lastly, because its nursing favors involution in the organs of generation. The latter argument may often be used to induce the young mother to nurse her offspring.

The baby practically receives no food in the first 48 hours, because its system is not ready for it and it is very unwise therefore to try to improve upon nature by giving it, whiskey toddies, sugar teats or milk mixtures during that time. It can only result in deranging the infants delicate organs and when its true food finally arrives, it is unable to take care of it. It is only in instances in which the milk formation is tardy in the breasts of the mother, that it becomes necessary to temporarily tide the infant over this period with a little diluted cream, a teaspoonful to an ounce of warm water. The necessity for this is generally indicated by quite a rise of temperature, the starvation temperature, which quickly subsides upon the administration of a little nourishment.

The baby generally loses from six to eight ounces in weight in the first four days, but it should regain this by the end of the second week. Thereafter a healthy child should gain from four to six ounces a week and the frequent question as to whether the mother's nourishment is sufficient for the baby, is readily ascertained by a systematic weighing of the baby.

After the first month, if the infant is doing nicely, it is well to allow the mother to give the baby one artificial feeding a day in case she is absent from home. In this way she is not prevented from attending some social functions. The baby is nursed before she leaves; receives the artificial food at

the proper interval next, and then can readily wait for the return of its mother for its next nursing.

The baby should be compelled to nurse slowly. If there is a tendency to gulping down its nourishment, then it should be removed from the breast at the end of each five minutes and allowed to rest. Fifteen to twenty minutes should be enough for a nursing; the breasts should be nursed alternately and the infant should not be allowed to lie at the breast for a longer time, macerating the nipple.

The baby should not lie in bed with its mother. This leads to frequent and indiscriminate nursing, especially at night, when it is so convenient to quickly quiet it in that way instead of listening to its prolonged wailing. It is dangerous, because the baby may be smothered either by the coverings interfering with its respiration or the mother overlaying it in her sleep. A case of this kind occurred in my practice only recently. The baby should have its own crib or a basket can be fixed as a temporary bed for it. It should not be shaken or churned about in a cradle, neither should it be picked up the minute it cries. A good cry several times a day is splendid exercise for the baby. It produces deep respirations and aids in its digestion.

If the baby suffers from colic, then careful questioning will generally prove that the trouble is due to indiscriminate and too frequent nursing. A good opportunity is thus given the physician to impress the necessity of such regulations upon the mother.

It is astonishing how well the babies get along in the large maternity hospitals in which the infants are taken to the mothers for nursing at stated intervals and kept away from them at night.

The mother should be cautioned not to give the baby paragoric or Dewee's Mixture, for the colic. These remedies whilst relieving the pain temporarily, cause constipation and an early return of the colic.

A little hot water, fennel tea or catnip tea, will usually answer the purpose, if not, a little bicarbonate of soda in hot water or five drops of chloroform water will prove effective. Warm applications to the abdomen and perhaps a small warm rectal injection, will aid in bringing relief.

### BRONCHO-PNEUMONIA.

PHILIP F. BARBOUR, LOUISVILLE.

Broncho-pneumonia is not only one of the most frequent, but also one of the most dangerous diseases of infancy and childhood. It

is amenable to proper treatment, but the physician must have a very clear idea of what condition is present and what object he must have in view.

Broncho-pneumonia is practically always secondary to an acute bronchitis, which in its turn may be secondary to some other disease as measles or influenza. Of course in forming a prognosis in such cases the gravity of the original disease must be taken into consideration. If the treatment of broncho-pneumonia is not thoroughly understood it is a very fatal disease, and among the poor and ignorant its mortality runs very high. In children's and babies' hospitals and asylums the death rate may average as high as seventy-five per cent. In private practice the record will be very much better.

Every bronchitis in children tends to extend to the smaller bronchi and bronchioles. In adults as is well known this inflammation usually does not extend deeper than the third or fourth dichotomous division of the bronchi. Therefore bronchitis never assumes serious proportions in the adult, except in very old people. Here we find conditions analogous to childhood. In watching a case of bronchitis we often can observe a spreading of the inflammation to the smaller tubes as evidenced by the rales becoming finer and finer, more and more sibilant in character.

When the rales become very fine we know that the bronchitis has invaded the bronchioles and now a new factor enters the case and that is that the inflammation no longer tends to limit itself to the mucous membrane as was the case when the inflammation was in only the larger tubes. The walls of the bronchioles are so much thinner, the mucous membrane having changed to a very delicate flattened epithelial layer, so that it is an easy matter for the inflammatory process to invade the contiguous tissues, which in this case would be the infundibula. Thus the bronchitis advances into a broncho-pneumonia, an extension which is readily recognized. For as soon as the air cells are invaded the clinical symptoms immediately become more serious and alarming. The temperature which had been running about 101° or possibly 102°, the natural temperature for bronchitis, now jumps up to 104° or thereabouts. The respiration increases by 20 or 30 to the minute and the pulse also becomes more rapid. The elevation of the temperature alone is almost sufficient to enable the practitioner to make a positive diagnosis. In fact, when the temperature rises that high in the course of bronchitis one must make a very thorough examination before he can exclude pneumo-

nia,—the probabilities are so strongly in its favor.

There are two stages in this disease which call for entirely different methods of treatment. The first stage is characterized by the extensive involvement of the smaller tubes, by the interference with breathing which comes from the mechanical interference with respiration that follows the swelling of the mucous membrane and a certain amount of diminution in the calibre of the tube that is produced by the spasm of the muscular fibres in the wall of the bronchioles. This spastic state is analogous to the spasm of the muscles of the larynx in croup and like croup it is greatly relieved by steam inhalations. For the relief of the congestion in the bronchioles there are a number of agents which may be used. There is no agent as potent to relieve congestions of mucous membranes as aconite or preferably aconitin which is a definite compound whose effect can be easily determined and watched. Hot poultices of various kinds will draw the blood from the congested area and make the breathing easier. Other therapeutic agents will readily suggest themselves.

The second stage of broncho-pneumonia is characterized by the excessive amounts of mucus which form a very great obstruction to the aeration of the blood because they fill up the bronchioles. There are several agents which will be of service here. Emetics will remove the superabundant mucus, belladonna or atropine will lessen the free secretion and strychnine will stimulate the peristaltic wave by which nature normally empties the bronchioles. Alkalies diminish the viscidities and thereby enable the child to cough up the mucus with far less effort. It is not necessary to dwell on these points which are well known.

There is another aspect of broncho-pneumonia which is often overlooked and that is that this disease may present symptoms which are characteristically bronchial in type, as has been suggested in the former part of this paper and a treatment corresponding to this idea outlined. But there are other cases in which the bronchial element may almost wholly be ignored. In these cases the pneumonic element, or perhaps it is better to say the toxemic element is the one to be considered. These cases run a very high temperature and show all the evidences of an overwhelming poisoning of the system and this toxemia must be combatted *secundum artem*. Here strychnine, whiskey, and other stimulant must be pushed to physiological limits. One other agent will prove of service in such cases—*echinacea*.

These observations are offered as suggestions and at a somewhat later time will be amplified.

## THE OCULIST AND THE OPTICIAN.

BY ADOLPH O. PFINGST, LOUISVILLE.

Although medical literature contains numerous contributions in which the difference between the optician and the oculist is clearly defined the indifference of the profession as to the position each should occupy in the community and the relation that should exist between them is offered as an apology for the appearance of the communication. The optician has been defined as one versed in optics or in other words a refractionist. Before the study of the diseased conditions of the eyes became a branch of medicine all cases of defective vision, whether induced by errors of refraction or by disease of the eyes, came under the same category and were entrusted to the optician for the "fitting of glasses." After the development of ophthalmology to a science much of which was made possible through Helmholtz's important invention of the ophthalmoscope about 50 years ago, the physician was enabled to detect very minute and consequently very early changes in the interior of the eye. The graduate physician, versed in the diagnosis and treatment of eye disease is the oculist. In the present day two distinct kinds of optician are found in the larger cities. The one whose chief aim is the sale of glasses as prescribed by the oculist and the proper adjustment of the frames. He assumes no responsibility as to the satisfaction of the lenses. The optician of this class is usually supplied with proper appliances for grinding his own lenses, enabling him to fill oculist's prescriptions promptly and accurately. He stands in the same relation to the oculist that the pharmacist does to the practitioner of medicine. Catering as he does to the oculist he does not attempt to refract other than simple cases of presbyopia, the condition of persons beyond a certain age in which lenses are required for reading, writing, etc. The other class is the optician who, after a course in refraction of from four to six weeks considers himself a refraction expert or often goes further and believes in his ability to diagnose diseases of the eye. Representatives of this class are found in charge of optical departments in the large department stores and drug stores, many of whom have adopted the title "doctor" and all of whom head their advertisement with the familiar "Eyes tested free." Their lenses are ordered from jobbers away from home and dispensed in stock

frames whose proper adjustment is neglected on account of attention to "greater things." It is of this class of optician with much confidence and little ability that we can rightfully say they do harm in a community by leading the non-suspecting public astray by their alluring ads. Every practicing ophthalmologist can cite numerous cases where the ill-advised use of lenses in cases of defective vision due to pathological conditions of the eye have been the cause not only of discomfort, but of increase in the existing disease, and the cause of delay in the discovery of the real trouble. To illustrate the writer need only refer to cases from his practice of chronic glaucoma, chroiditis, and retinitis pigmentosa in which strong lenses had been given to the detriment of the patient. Aside from the importance of detecting diseases of the eye it is a fact well recognized that the proper determination of errors of refraction can only be accomplished by paralyzing temporarily the muscles of accommodation by the aid of optics or some other cycloplegic agent which would preclude the probability of proper examination by the optician. Although a large part of the medical profession appreciate fully the importance of advising patients with suspected eye troubles to consult the physician skilled in the detection of diseased conditions or errors of refraction there is still a large percentage who are careless about such cases. It can surely be attributed only to thoughtlessness when a physician advises a patient with headache, eyeache, or defective vision to go to some optician to have his eyes examined or in an off-hand way simply tell him to have his eyes examined without enlightening him as to the proper place to have it done. He could just as well say to his patient with suspected appendicitis "go have yourself examined relative to the advisability of an operation" without advising with the patient as to whom to consult. It would seem that in a case of suspected eye trouble the patient should at least be warned by his physician against the promiscuous consultation of opticians who are not in a position to detect and interpret changes in the eyes or to pass scientifically upon errors of refraction or muscular troubles.

#### NOTES ON THE THERAPEUTIC USES OF ARSENIC.

BY T. C. HOLLOWAY, LEXINGTON.

Grouped under the family name of Alteratives are several drugs which occupy a most important place in the armamentarium of the successful physician.

Although their exact physiological action has not been satisfactorily worked out, yet it has been shown that in certain diseases, most intimately connected with the processes of nutrition, their administration is attended with decided benefit. Our present knowledge of their action may be summarized in the statement that they alter or modify the processes of nutrition in such a way as to overcome the morbid conditions present.

In the dosage usually employed no very definite symptoms are at once apparent, but when exhibited for a considerable length of time the effects become definite and well marked. Of this group the drug under consideration is a conspicuous member. It is with the purpose of emphasizing certain well known facts in connection with the therapeutic uses of arsenic that the following brief review is presented.

*Physiological Action.*—Locally arsenic is powerful though slowly acting, escharotic, when in concentrated form, while even when well diluted it acts as an irritant. A small quantity placed in the cavity of a tooth causes within twenty-four to thirty-six hours, necrosis of the nerve; and when applied to the skin, as it frequently is in the form of some quack "cancer cure" employing a paste to remove the growth, an extensive slough of the affected part follows after a variable length of time. When taken into the alimentary canal, in powder or in the form of soluble salt it is rapidly absorbed. It is also readily taken up when applied to the skin, or inhaled in the form of a vapor. It is eliminated principally by the kidneys, when taken in medicinal doses. In toxic amount it acts as a violent gastro-intestinal irritant and is therefore freely thrown off by the bowel as well as by all the excretory glands and mucous membranes.

When small medicinal doses are given for a considerable time a certain degree of tolerance is established, so that it is necessary to gradually increase the dose. As there is a tendency for the drug to accumulate in certain organs under these conditions, it is best to stop its administration for ten days at frequent intervals, whenever it is desired to give arsenic for a long time.

Many interesting experiments upon animals have been made to determine the effect of arsenic upon tissue-change. While the results have not been absolutely conclusive, they nevertheless indicate that small repeated doses of arsenic retard tissue-change and decrease nitrogenous elimination, while toxic doses produce the opposite effect.

Small repeated doses of arsenic as shown by the investigations of Stockman and Char-

teris tend to increase the number of leucocytes by stimulating the formation of the leucoblastic cells of the bone-marrow, but the number of red cells, and the percentage of haemoglobin are not markedly affected.

It is supposed that the value of arsenic in such diseases as malaria, pernicious anaemia, and leukaemia, is due to its specific action on the parasites causing these diseases rather than to any direct action on blood-formation.

When arsenic is given internally in small medicinal doses, the mucous membrane is stimulated, the appetite sharpened, and by its favorable effect upon nutrition the tone of the nervous and circulatory systems is improved. Viratelle states, that in small doses, the elimination of uric acid is augmented and nutrition is increased because chloride of sodium, the stimulant par excellence of nutrition and the preservative of the red corpuscles is retained in the organism in larger quantities than normal.

One of the first noticeable symptoms produced by medicinal doses of arsenic, which have been repeated and gradually increased, is a slight puffing of the eyelids, which appears particularly in the early mornings. As a general rule this symptom should mark the physiological limit of administration for that particular case. Some individuals exhibit a marked intolerance of the drug, and the beginning doses should therefore be small.

*Therapeutic Uses.*—In the treatment of uncomplicated anaemia arsenic is particularly useful. Next to the preparations of iron, it is the most reliable remedy we have. In progressive pernicious anaemia it is far superior to iron. Speaking of its use in this connection Osler says: "Of medicines, arsenic is the most important, and in the form of Fowler's Solution should be employed in small and increasing doses. We are indebted to Bramwell for pointing out the great value of the medicine, and in certain cases it acts almost as a specific. In 8 of the 20 cases of recovery noted by Pye-Smith the improvement seemed due to arsenic. Padley has collected in the literature 48 cases treated without arsenic of which 42 were fatal, while of 22 cases treated by arsenic 16 recovered, 2 improved and only 4 proved fatal." (2)

By other more enthusiastic observers it is claimed that arsenic is as much of a specific in pernicious anaemia as mercury is in syphilis. (3)

The best clinical experience has shown that arsenic is of special value in the treatment of chronic malaria. In those cases which have not yielded to quinine, and in which there is present cachexia with marked evi-

dence of disturbance of nutrition arsenic is most serviceable. It should be administered in small doses gradually increased until the physiological effect is produced. While not indicated as a rule in ordinary intermittent fever it may be employed with benefit whenever for any reason the preparations of eichona are not well borne. When used in such cases the first doses should be large in order to overcome the paroxysms, as much as 5 to 10 drops of Fowler's solution, properly diluted, may be given every two or three hours until the desired result is obtained or until some decided symptoms are produced.

It has been claimed by some observers that arsenic possesses decided value as a prophylactic against malaria, being superior in this respect even to quinine. (4)

In leukaemia, and in chronic congestion and enlargements of the spleen, the administration of arsenic, on account of its anti-malarial influence, is advised. In Hodgkin's disease, according to Osler, arsenic is of decided value. He says in discussing the treatment of this malady: "Arsenic is the only medicine which has seemed to be of positive value, and under its use I have seen the gland tumors decrease greatly in size. It should be given in increasing doses until some of the unpleasant effects of the drug are manifested, when a return should be made to the small dose, and again gradually increase.

When well borne, large doses 20 to 25 minims of the liquor arsenicalis should be taken three times a day for many weeks. In two cases with moderate enlargement of the cervical and axillary glands the progress of the disease seemed arrested and the glands certainly become smaller and softer." (5)

Others have borne testimony to the value of arsenic in this disease, especially when its administration is begun early, and full doses are kept up for months; three recoveries reported by Karewski. (6)

In the treatment of various chronic affections of the skin arsenic is almost indispensable. By reason of its stimulating action it is not indicated in acute inflammatory stages, but in the chronic conditions, especially when the superficial strata of the integument are involved, its administration is attended with the greatest benefit.

In the squamous and papular varieties of eczema and in psoriasis it is indicated and may prove beneficial in urticaria of the chronic type.

In many pulmonary conditions, especially after they have passed through the acute stages and have assumed a slow chronic form, arsenic may be used with great benefit.

By its important action in increasing the nutrition of the body, the vital resistance is correspondingly raised and the morbid processes are overcome.

Chronic bronchitis, and chronic pneumonia, the so-called fibroid phthisis, and asthma are among the diseases of this class in which arsenic may be of value.

In some manner not well understood, arsenic exerts a decidedly favorable influence in certain nervous diseases, particularly chorea. In this disease the full physiological effect of the drug must be reached, with due caution as to the development of toxic symptoms.

In many forms of neuralgia arsenic is a remedy of very decided value.

Among other conditions in which arsenic has been recommended and used with more or less success may be mentioned, infantile diarrhoea, gastralgia, vomiting of pregnancy, chronic rheumatism, and rheumatic gout.

The toxicology of this drug is both interesting and important; as cases of acute or chronic arsenical poisoning are not uncommon.

The following preparations are official:—

Arsenous Acid, of which the beginning dose is one-thirtieth of a grain, should be given in pill or capsule after meals, and slowly increased.

Liquor potassii arsenitis. U. S. Fowler's solution (one per cent.) is nearly colorless and odorless, with a faint taste of the compound spirit of lavender, which is in it. Dose, five to ten drops in a wineglassful of water after meals, to be increased and used with the same precautions as arsenic.

Sodii Arsenas. U. S. Sodium Arsenate occurs in transparent, slightly efflorescent, soluble crystals, and is solely used in making the Liquor Sodii Arsenatis, U. S. Solution of Sodium Arsenate (about four and a half grains to one fluidounce) is equivalent to Fowler's Solution.

Liquor Acidi Arseniosi. U. S. Solution of Arsenious Acid is in strength and therapeutic use equivalent to Fowler's Solution.

Arsenii Iodidum. U. S. Arsenic Iodide. This is an orange-red, crystalline solid, wholly soluble in water and entirely volatilized by heat. It has been used as an alterative, and also an external application in lupus and chronic tubercular affections. Dose— one-sixtieth to one-fifteenth of a grain.

## ORIGINAL ARTICLES.

### SOME THERAPEUTIC FACTS, FADS AND FANCIES.\*

BY W. L. HEIZER, NEW HAVEN.

Skoda said "We are able to diagnose and describe and understand a disease (when it runs a well known and typical course I would add), but we must not believe that we are able to cure it by any of our remedies." Böhmer on the other hand, who treated diseases by symptoms alone, when having treated a case in his clinic would exclaim to his audience: "Hear ye, and admire the power of the medicaments. We have conquered all the symptoms." These two men, Skoda and Böhmer, represent the two schools of therapeutic belief of all time, and yet, not more than 150 years elapsed between the advent of the two. And so it has been throughout the history of medicine. The facts, that medicine is not an exact science, that medicines have so many and variable uses, that drugs have not been of uniform strength and efficacy that our views concerning therapy are constantly changing, are responsible for these ever-changing views of medication and schools of medicine.

Just now there is a great tendency to advance the art of medication. Surgery, pathology, bacteriology, anatomy and physiology have made wonderful strides in the last few years. Diseased conditions that meant invalidism and death before the days of antiseptics and asepsis and a perfected study of pathology and diagnosis, are now readily and permanently cured by the skillful use of the knife. The results have been so fascinating and astounding in certain classes of conditions, and so quick in their production that there has been a tendency on the part of the professors in medical colleges, medical publications and our societies to leave in waiting the slower, uncertain and disappointing measure of therapeutics. And hence it is, that we have the alluring surgical specialties for the young graduate, and the aspirations for surgery as a natural result of the very atmosphere of practically all our teaching in medical colleges. We have the test-tube expert and microscopist, the research

\* Read before the Kentucky State Medical Association  
Louisville, October 15-17, 1907.

man, but how few fully-developed men do our colleges graduate who are filled to the brim with a knowledge of the proper action, preparation and uses of drugs, and with a confiding faith in their efficacy under proper dispensation.

From the truly scientific in the aforementioned branches of medicine we have drifted and been led into a distinctly pseudo-scientific system of therapeutics, into employing high-sounding German synthetics, into employing drugs which we are confidently told possess miraculous powers, and serums of various kinds and doubtful actions.

It is well, sometimes for us lest we forget, to recall some of the varied principles of a course of study in order to withdraw our minds from the alluring deductions and courses of reasoning that we have been following more or less blindly. Some forgotten fact of anatomy or truth of physiology will sometimes change our entire course of procedure. As we know, the very basis of drug therapeutics rests upon at least three fundamental conditions: First, purity and uniformity of the strength of a drug; second, a thorough knowledge of that drug's uses, alone or in combination; third, a proper appreciation of the pathological or morbid conditions warranting its use. These three short principles properly acted upon would eradicate all our evils in therapy. Drugs acting as they do by chemical affinity, exert their force in various ways falling into more or less well-defined classes which we recognize as narcotics, anesthetics, antispasmodics, tonics, astringents, stimulants, sedatives, cathartics, diaphoretics, diuretics, hematics, and topical remedies. Under each of these divisions there are from three to a dozen drugs whose action is well and positively known, whose strength, purity and uniformity are unquestioned when made by certain of our manufacturing concerns. Hence two of the three simple propositions of practical therapeutics are readily complied with. The third, that of a proper appreciation for their indication seems to be the error into which we fall, either unwittingly or carelessly. This leads us to consider a few specific errors into which we, or some of us have been led.

About the worst abused set of drugs on the market and the one that has been outraged most often is that class known as digestive ferments. The Council on Pharmacy and Chemistry examined a large number of articles widely advertised as digestants. Nearly all of them failed to show the results claimed for them. Grutzner's demonstrations are significant. He fed animals with

differently colored food with short intervals, between feedings. After variable times the animals were successively killed and the stomach and contents frozen so as to prevent any disarrangement of contents. When this was cut open, it showed that the greater portion of the gastric contents remained unmixed for several hours. The various colors of the different foods remaining separated, while at the pyloric end the colors and food were thoroughly mixed. He concluded, therefore, that only the first portion of a meal is at once exposed to the digestant action of the acid and pepsin and each successive portion of food being deposited as a successive layer within the preceding portion. He further found by the use of litmus that within the mass of food it remained alkaline or neutral for about two hours while only that portion of food which actually touched the walls of the stomach and in the pyloric end underwent pepsin digestion. He further found, upon testing for diastase, that it remained present for several hours, especially in the fundus, though it was destroyed before digestion was complete.

Acids, alkalies, salts, metals, antiseptics, tannins, chloroform, ether and alcohol injure, hinder and destroy the digestive ferments.

The results of recent experiments by reliable workers, epitomized, are as follows:

At a temperature of 104° F.—

Trypsin, is greatly injured by .056 per cent. HCl, and destroyed by .56 per cent. It is completely destroyed by pepsin in .112 per cent. HCl. It is remembered normal HCl present during digestion is .2 per cent.

Pepsin is largely destroyed by .01 per cent. NaOH and completely destroyed by trypsin.

Diastase (in nine hours) is considerably injured by .03 per cent. and destroyed by .1 per cent. NaOH. It is almost completely destroyed by .009 per cent. HCl. It is greatly weakened by pepsin, even in neutral solution, but it resists trypsin fairly well.

Applied practically it follows, from these demonstrations as premises, that solutions of digestive ferments are practically worthless owing to their mutual destructibility upon one another. It is more so if preserved by acid, alcohol antiseptics or any of the substances named. If made fresh and given in solution, the action of diastase and pancreatin would be destroyed by the action of HCl of the stomach.

Triturates of pepsin, diastase and pancreatin keep well unchanged and fairly active, but unless *intimately mixed with the food* before reaching the stomach will act only at

the place of landing in the stomach due to lack of peristalsis only in the pyloric end as proved by Grutzner. And if they were mixed their action is suspended and destroyed by HCl present.

To give pancreatin successfully requires it to be given in a salol-covered capsule or some form of capsule which insures its delivery into the duodenum before solution. And yet, how many prescriptions for Panoptic Elixir, Peptenzyme, Elixir Lactated Pepsin, and similar preparations go from the physicians of this city and State to the pharmacists every day?

This brings us to a very important item of this paper, which, owing to its frequent and extensive elaboration will be handled as briefly as its importance will allow. All of us now have been pinched and awakened so that we realize how extensively proprietary medicines have been used and are being used. It seems an insatiable desire for us to get something new, with a new name and a new action when we know it is impossible, with any fancy combination that a money-mad and conscienceless nostrum-maker can concoct, to produce any action other than laid down in our works on therapy.

The extent of their use can be best exemplified by an experiment conducted by one of the pioneers in eliminating this evil. Edward Bok, Editor of the Ladies' Home Journal. He says, in a paper before a Philadelphia county medical society, December 12, 1906, "Conditioned that I should not reveal my source of information, nor give names of medicines or physicians, I was given an opportunity to examine one hundred prescriptions that had been filled. Of these one hundred prescriptions, 42 prescribed a proprietary drug, or article in part or in whole. I selected 30 of these and called on each of the physicians who had written the prescriptions." He said the physicians were men of excellent standing, some very high in the profession and out of the 30, two gave an accurate account of the ingredients of the medicine, while the 28 either did not know, or what was more dangerous, thought they knew when they did not. Here in the city of Philadelphia of the first 100 prescriptions examined 40% contained proprietaries, 95% of the writers of which did not know what they were giving their patients. One contained morphine unknown to the prescriber, and was given to a restless infant who was quieted so successfully that the parents became alarmed and changed doctors who gave another remedy, a proprietary, which, unknown to the second doctor contained morphine, and caused a second stupor.

Another was an exploited Beef, Quinine and Iron Tonic, which was claimed to be non-alcoholic, but it was found to contain no beef, quinine and iron and did contain 22% of alcohol.

Carelessness and blind credulity on the part of the doctors, are part of the causes of these great wrongs inflicted upon the people by the doctors. Our medical colleges are partly to blame in that they do not teach enough pharmacy and therapeutics. Our medical press is to blame largely, more so than anything else, except possibly, a smooth-talking, high-salaried medical ignoramus, who in the most suave and matter-of-fact way, assures us of ingredients contained, palatability, pleasing appearance, wonderful effects produced and ending up by leaving a few samples for us to try on our patients. We bow and treat him politely, when, if we would but think what an insult he has offered to our knowledge of therapy, we would give him a verbal chastising and send him out with a feeling of respect for our knowledge, instead of a feeling of contempt for our gullibility.

To come right home, pick up last number of Louisville Journal of Medicine and Surgery. The first page of lovely green, in brazen impudence is this: "Ingluvin—a specific for the vomiting of gestation. Superior to the pepsin of the hog." (Which hog? The maker of the stuff?) "Fully endorsed by the medical fraternity." (Who, the hog? Very likely, or he wouldn't keep running that advertisement.) On the very next side of that same emerald cover in glaring headlines, and occupying a full page, comes this: "A Delightful Revelation." You settle yourself down to have it revealed and it takes up that most delectable and wondrous medicine, assuring us of its "ethical" character, Syrup of Figs, made by California Syrup of Fig Company, and made up as per formula: Syrup of California Figs—75 parts. Aromatic Elixir of Senna, manufactured by our own original method, known only to California Fig Syrup Company,—25 parts.

This "offense is so rank that it smells to Heaven." This "ethical" has small chances of undergoing that precise and wonderful metamorphosis, at this day, as did Fellows Syr. Hypophosphites, which at one time was sold exclusively to the laity, and being unprofitable was then advertised to the profession as ethical. Through the journal there is Seng and Chiona, etc., battle-scarred and worn, still uttering its piping cry to be heard by an awakened and fighting profession.

The American Practitioner and News, of

Louisville of August 1907, contains the same "Delightful Revelation" of California Fig Syrup fame, also Passiflora, Sal Hepatica, and a barred gate, tight and unsurmountable with some women's aches and ills, Lagrippe, headaches, neuralgia and insomnia, shot at it and in it, while towering above as a rising sun of hope, in a glorious blaze of light, and rising like a benediction over all this motley array of physical confusion is our old friend Antikamnia, with a soothing phrase to ns baffled doctors, "No pain beyond this Gate."

There are at least twenty other advertisements of an objectionable nature in these journals, including Kutnow's Powder, which a microscopist of this city uses and so reported in one of his discussions, while in both are write-ups and glowing reports in which some of these drugs have done the ideal thing.

Now, gentlemen, there may be some money in doing this kind of frandulent business, but in justice to their readers it should be stopped. Of course, those of us who use our brains and conscience are not going to be mislead by any such absurd claims, but some brother who is still in trespasses of sin may still further pave his way to perdition by means of such articles and advertisements.

Hydroeine, that wonderful "cure for consumption" as advoeated by Dr. C. S. Roberts, member of A. M. A., N. Y. State Medical Society, member of Onondaga County Medical Society, writer of various articles for nostrums, promoter two years ago for the doctors' benefit of a water-still, which he says netted him \$3,200 on a \$300 investment. This new cure, (which for 15 cents will be sent \$3 worth) has the following interesting formula:

- Hyper-oxidized, hydro-carbon (vegetable) . . . . . 28 gr.
- Pure rock sugar . . . . . 8 gr.
- Powdered Pancreatin . . . 1-20 gr.

The oxides are liberated in the stomach and thrown into the circulation.

The veriest nonsense! Nobody ever knew or will know the identity or existence of that hyper-phonetic first substance, and if there could be any such thing, that and a little pancreatin and rock sugar thrown into a big bag like the stomach is not going to give off any oxygen or oxides, and if it did, what would it amount to? It reminds you of that wonderful "synergistic whole" tablet of 1-4 gr. morphine, 1-1000 gr. pure hyoseine hydrobromate, 1-100 gr. eactin (whatever that is) put out by that indefatigable, hard working bare-armed, coatless and perspiring, W. C. Abbott. In his last issue of the American Journal of Clinical Medicine, which is mail-

ed to every doctor whose address he can secure in Kentucky, on account of the exposition of him made in July number of Ky. S. M. J., he breathes defiance to his enemies, comes armed to the teeth, and with blood in his eye, hurls imprecation after imprecation into his fellow doctors, and, backed up by his interested co-workers, Drs. Lanphear, Waugh, W. J. Robinson, A. S. Burdick, tells all our chemists that eactin is a crystalized essence of the cactus grandiflorus (which our chemists assert is practically inert and has no active isolated principle); that his brand, and his alone of hyoseine hydrobromate is the only one to use. He admits, further on that he purchases it from one of our well-known pharmaceutical houses. He grows purple in the face, assuring us that it differs from scopolamine and morphine anesthesia (which has been weighed and found wanting through too frequent fatalities and hair-raising escapes from dissolution on the part of the patients). The facts are, that he is financially interested in manufacturing that tablet and being a doctor is licensed to use the methods of our nostrum friends in our councils and societies. It is also a fact that scopolamine and hyoseine are practically identical and that the combination has been tried, especially in Germany, and found to be unsafe. The eactin is added pretty much for the same purpose that Kargon Comp. was added to that prescription advertised to the laity last winter for a little of everything, telling them to buy the ingredients and mix them at home. The Kargon Comp. was made by a firm in Cincinnati, and found to contain some diuretic potash salts and buchu, but which was a patent in itself. So with the eactin. No one else makes eactin, hence, the H. C. M. per brother Abbot is the thing to use. Accept no substitute.

Dr. VanMeter, of Lexington, reports in an August issue of the J. A. M. A., a fatality from the use of the H. C. M., Abbot, in the removal of a small tubercular cyst of the parotid gland.

Now what is the purpose of these expositions of some facts, fads and fancies in therapeuties? Simply to recall to our minds that it is unwise to use a single drug, or combination of drugs, with which we are not familiar; to accept none but the standard authorities for the actions of drugs, or indications; to use none but pure drugs of uniform strength made by manufacturing houses of repute; to decry the advertising on the part of our medical journals of these nostrums, and to advocate the use of our knowledge of diseases at all times for the relief of morbid condition and their symptoms.

## DISCUSSION.

Dr. George H. Simmons, of Chicago (Secretary-Editor American Medical Association) was asked to open the discussion. He said:

MR. PRESIDENT AND GENTLEMEN:

I only wish I had the power of oratory, that you Kentuckians have, to impress you with the importance of this subject. There is no bigger curse afflicting our profession than this commercialization of our therapeutics, and there is not a single thing in the whole realm of commercialism that is so difficult to attack, that has so much money back of it. If you attack it as the proprietary medicine business, you will find this means the patent medicine business, as they are linked together as has been shown time and again.

Dr. Heizer spoke of the digestive ferments. He told you one thing that every citizen of Louisville ought to know, and that is, that at one time, one of the best chemists in this country, Professor Scheffer, of Louisville, investigated a nostrum—laetopeptin, and read the report of his investigation before the American Pharmaceutical Association in 1877. It was published in the Transactions of that association the same year. Scheffer not only reported on it from a chemical, but from a clinical standpoint. He showed conclusively that it had absolutely no effect as a digestant; that the only value it possessed as a therapeutic agent was that which belonged to the alcohol it contained. He demonstrated that the composition claimed for it was absolutely impossible, and that pepsin and pancreatin are incompatible. Yet the attention of physicians was not called to this expose until it was done by the report of the Council on Pharmacy and Chemistry on digestants. Why did the Council on Pharmacy and Chemistry take up this matter? Because it ran against two or three preparations that looked to be all right. The formulae were given, and the remark was made, "If that is not ethical, what is ethical? It is advertised and put out by a house of standing; it is scientifically presented; it is not advertised to the public; it is all right." The Council is working in the interest of the physician, but it is all the time afraid it will go further than physicians will follow. That is the trouble. The question, therefore, arose as to what should be done with these digestives. The Council on Pharmacy and Chemistry took up the whole matter, a sub-committee was appointed to look into the subject, which it did and made a report covering the whole matter. This report was published. It showed the impossibility of such combinations, as, for instance, the combining of pepsin and pancreatin; it showed that their combinations were inert as digestives, and appealed to the medical profession not to prescribe them, and to the manufacturers not to

put them out. What was the result? Some of our leading firms instructed their detail men how to answer this report of the Council on Pharmacy and Chemistry, and so far as we know only one firm—Armour & Company—has complied with the request and stopped putting out these monstrosities; and they will not stop so long as physicians will prescribe them.

About forty year ago Garrod, of England, suggested carbonate of lithium as a dissolvent of uric acid. The suggestion was taken up and the drug was used for some time. It was finally shown, however, that Garrod's theory was not correct: it was proven that as soon as it reached the stomach the carbonate became a chloride which was but slightly absorbable. Later came that remarkable monograph of Hague on "Uric Acid," in which he attributed to uric acid about all the diseases that flesh is heir to. And all of us were talking and writing of "Uric acidemia," and were crediting to uric acid about every disease imaginable. Now, if you put the Garrod theory and the Hague idea together, you have a splendid foundation on which to exploit nostrums, because if lithia will prevent uric acid, and uric acid is a disease breeder, then all we have to do is to give lithia. As a result, nostrum makers have pushed this idea and are pushing it to-day for all it is worth. We have hundreds of nostrums based on this idea, i. e., containing lithia, which are advertised as "Curealls." Not only this but the idea is being used to promote the sale of waters. If some mineral water is discovered that will reveal with a spectroscope the millionth of a milligram of lithia, it is immediately put on the market as a lithia water and advertised as a remedy for all diseases imaginable.

Cod-liver oil, thirty or forty years ago was considered a great reconstructive and was used especially for consumption and other wasting diseases. But cod-liver oil tastes bad and patients would not take it. So there was a demand for a palatable cod-liver oil, and the demand was at first supplied by emulsions in which there was cod-liver oil. But the taste of the cod-liver oil was present. Gradually, however, the point was reached where the manufactures supplied us with tasteless cod-liver oil. The idea that cod-liver oil is valuable as a reconstructive has been played on, and intelligent physicians are to-day accepting and prescribing cod-liver oil in the form of proprietary medicines which contain no cod-liver oil. They have taken the word of the manufacturers of these preparations without a question. At one time manufacturing chemists attempted to give us quinine without the bitter taste, and attempts were kept up until finally one enterprising firm did put on the market a tasteless quinine, but it was shown up to be nothing but

gypsum, and that ended this tasteless quinine business. It is exactly the same to-day with the tasteless cod-liver oil preparations. But although this fact has been published, these preparations are still being prescribed by physicians.

**Dr. W. S. Boggess**, of Louisville — When our distinguished secretary wrote and asked me to discuss the paper of Dr. Heizer, I accepted the invitation with a great deal of pleasure because I knew it would be one well worthy of discussion and well worth thinking about. Dr. Heizer is one of my boys. I helped to educate him.

He has presented to us a subject that is of vital importance to the profession, and no more important topic will be presented at this meeting.

I want to say to you in all frankness that I am a therapeutic optimist. There is nothing pessimistic about me when it comes to therapeutics. I believe in the efficacy of drugs; I believe in the efficacy of therapeutics other than the administration of drugs, and until the profession gets away from the idea that drugs and drugs alone are all we to depend upon, for the cure of diseases and the relief of symptoms and pain, it will never do for patients what the patients expect it to do. There are numerous other therapeutic methods which can be used, such as hydrotherapy, massage, electrotherapy, and suggestion, and a number of other remedies which we can use with patients other than the more administration of drugs. A commentary on the profession I should like to make is this: How many members of our profession are anything but calomel and quinine doctors? In other words, there are many physicians who rely on nothing for the cure of disease except calomel and quinine, with possibly a few patent medicines? That blessed old liver is more abused than all the rest of the human economy. If it were not for liver trouble, malaria and the menopause, the average doctor would not make his diagnosis, and would not cure the disease.

Just a few words about iron. The profession will have to get away from the idea that any of these new iron preparations have any great medical efficacy. The profession has to go back to the old-fashioned remedies, Bland's mass and tincture of chloride of iron, and what preparations you choose to make from them. The so-called vegetable irons, egg irons, predigested irons, are not worth much. If there is a physiological indication in the system of iron, you can get the medicinal effects alone from the administration of Bland's mass, properly and freshly made tincture of chloride of iron, made into that combination known as Bashan's Mixture.

With reference to cod liver oil, which was referred to by Dr. Simmons, there is no drug that has been flaunted into the face of the profession and laity more than cod liver oil. Years ago I

abandoned its administration, and there is absolutely no efficacy in tasteless cod liver oil.

Primarily the fault lies with our medical schools; I do not have reference particularly to the medical schools of the South, but to those of the whole country. As Dr. Heizer has said, more time is devoted to specialism and surgery than to the more important, the cardinal branches of the profession. Therapeutics is a subject that is very much neglected. It ought not to be taught in the way it is taught, that is, giving the student the physiologic and therapeutic efficacy of drugs without giving him applied therapeutics. Pharmacology is not taught, and unless a man knows something about pharmacy he cannot fully appreciate therapeutics, and is all the easier a victim for nostrum houses. He should be taught pharmacy. He should be taught prescription writing, and he should be taught also that the administration of one drug of a certain class is not always the best way to administer it. You can take drugs like the heart tonics, and you can get better results sometimes from a combination of heart tonics than from the use of any single heart tonic. You can get better results by exercising good judgment in the selection and administration of drugs for individual cases. There is an art as well as a science in prescription writing, and in the combination of drugs. You can take three or four drugs of one class and get better results from them than any one drug of that class. So prescription writing and pharmacology and therapeutics are subjects that are very much neglected in our medical colleges.

**Dr. A. B. Cooke**, of Nashville: While my work has not been so much along the line of medical journal advertising of proprietaries and nostrums, I am deeply interested in this subject; but after the skilful and masterly manner in which the subject has been presented by Dr. Heizer, there is very little to be said. The proprietary medicine interests have nothing to stand on that I can see, and I am sure the subject as presented by the doctor leaves nothing upon which they can stand.

I was glad to hear Dr. Boggess make some of the remarks he did, and I was especially glad to hear him say that he was not a therapeutic nihilist, but a therapeutic optimist. When we begin to look around for the cause of the proprietary medicines advanced, and especially during the later years, I think we will find it is due to the teaching and opinions of certain members high in the councils of the medical profession, especially our teaching profession. I make bold to mention names in this connection, because only a few days ago I saw this comment from a clinic that was being conducted by Dr. Osler, formerly of Baltimore, whom you all know, who, after explaining the malady under consideration, and giving his ideas, or rather the accepted therapeu-

tic teaching as to the proper remedy to be applied in these cases, said:

"Now, gentlemen, these are the drugs that are said to be given for this affection; but I want to tell you frankly, that in my opinion the sooner you forget what little you know about drugs, the better off both you and your patients will be."

It is that kind of teaching coming out from a man high in authority that is making therapeutic nihilists and pessimists in our profession, and putting us in an attitude to be gulled. Back of it all stands this consideration, that the average patient expects to be given something in the way of medicine, and the doctor, not having very much faith in medicine himself, will say, "This won't do any harm, and perhaps it may not do the patient any good, but we will give it anyway, as it may do as much good as anything else."

When you go a step further you get to this one fact, and upon which I would lay more blame than upon our medical colleges, although the Lord knows they are at fault along this line, and that is the laziness of our profession as individuals. We are not willing to take the trouble to learn therapeutics, to study the actions of drugs, to make ourselves masters of them, and consequently we prescribe in a haphazard way because we have not the proper knowledge. This is a broad field and a great deal can be said on it.

A few years ago, in preparing a paper or report I wished to present before the Nashville Academy of Medicine, I had occasion to go to several druggists in our city, and interview them along the same lines that Dr. Heizer did the druggists in Lexington. I went to one of our prominent druggists in Nashville, and got his permission to go over his files for six months previously. The prescriptions filed in that drug store contained proprietaries, or were composed exclusively of proprietaries, or even worse, of nostrums in the proportion of fifty-five per cent. of the total. So you see, this is not a Kentucky shortcoming. It is broadest; it is all over our country, and the magnificent work the Council on Pharmacy and Chemistry is doing through the Journal of the American Medical Association gives us a real hope, a bright spot in the situation.

Only a few weeks ago a well-dressed, pleasant gentleman, came into my office and asked me if he might take a few moments of my time. Not knowing what he had in store for me, he began to unfold the beauties and advantages of sulpholithia, which was exposed in the columns of the Journal of the American Medical Association Dec. 17, 1906. I went to my files, brought out a copy of that issue of the Journal, and told him that if he could answer the statements made therein, in any way that would appeal to an in-

telligent man, I would listen to what he had to say on this subject. But he could not do so. That calls to my mind one more thought, namely, that Dr. Heizer, in reading his paper, went too far in one respect. He said that when these men come into our offices and take up our time, we should dress them down with a tongue-lashing and fire them out by the seat of the pants. We cannot afford to do that, not because of the respect we owe to them or their calling, but because of the respect we owe to ourselves. (Applause). We must treat them courteously, but we can do it in such a way, as a rule, that they can be made to see that they are trespassing and are unwelcome.

I regret very much to have consumed so much of your time on this subject, and as there are others to follow me, I trust you will excuse me from making any further remarks.

**Dr. T. C. Holloway, of Lexington:** I appreciate the honor done me by our president in calling on me to discuss this paper. I do not know exactly why this honor is thrust on me unless it is that I have been especially interested in the subject, and as no one of the previous speakers has discussed one point which possibly is in the minds of many, it is perhaps up to me to say again what I have already said about it. There is one phase of the subject which, it seems to me, goes one step farther than that of the detail man coming into our offices and trying to convince us that a nostrum is good for our patients. That is bad enough, but the doctor who cannot read his medical journals enough to know how to defend himself against these men, should go back to school. But when a man, who is a member of the American Medical Association; a man who commands a certain respect as a doctor; uses his position as such to go to our little county medical societies away from the medical centers and there present for our use things which are condemned and which are known to be harmful, and when he uses his position to teach us how to use these things, it seems to me that such a man deserves to be repressed, good and hard. Such an unpleasant incident happened, as many of you know. It was unpleasant to us. I am not blood-thirsty and quarrelsome so as to lead me to make enemies. I cherish the reputation of Kentucky for hospitality with the rest of you. But such an unpleasant thing happened at one of our little societies some distance from Louisville, and that was in connection with hyosein-morphin-cactine anesthesia. What we had to say has been presented to the doctors in Kentucky, and what I wish to emphasize in as strong language as possible is that we should not allow men who are interested in the manufacture of drugs to become teachers of therapeutics; nor should we allow men who are interested in the sale of drugs to come upon the floor of a meeting of

this kind and try to teach us how to use them. That is about all there is to that phase of the subject. A careful examination of the merits of the question along the lines already indicated in the discussion will take care of it. I happen to know that the offense committed at one of our little county medical societies has been repeated once or twice. The gentleman concerned in that particular product has since attended several meetings of physicians, some of them said to be meetings of international importance, for the purpose of exploiting this anesthetic, and I thought it was worth while to bring this matter to your attention.

**Dr. Virgil E. Simpson**, of Louisville: I wish to state my position with regard to proprietary medicines. My position, so far as my own practice goes, with reference to the great majority of these cases is really summed up in a remark that was made by a physician in this city to a detail man not long ago. This detail man said to the doctor, when he entered his office, "Do you use this preparation?" calling it by name. The doctor answered, "I do not." The detail man asked him why, and the doctor replied, "Because my patients usually have used it before they called me." If there was any other objection to the use of these preparations, that would be the most potent one against their use, so far as I am concerned. The majority of these preparations can be easily procured by patients, and as a consequence they become more or less familiar with them. How many patients are there among your clientele who are not familiar with glycothymoline? How many are there who do not know something about antiphlogistine, and various other things I might mention?

So far as the cause of the use of these things is concerned, it is certainly a complex proposition. There are a number of reasons which might be mentioned which have entered largely into the present condition of affairs, and one of them is that the medical profession as a whole has signally neglected to inform themselves upon the real pharmacological actions of drugs. No mechanic would purchase and keep in good order free from rust a tool which he knew absolutely nothing about or could not use; but you as medical men will continue to prescribe drugs about which you know little or nothing. You are not familiar with their pharmacological action. You give a preparation to a patient which is supposed to do a certain thing, but you do not know anything about the real action of the drug or drugs given in the system. You give these various preparations that are advertised to contain different drugs, some synthetical in character. You are prescribing names and not drugs. Let us suppose that I am treating a case of rheumatism in which there are complications developing, necessitating consultation. Let us suppose that Dr.

Bailey is called in consultation. We examine the patient; we consult about the matter; I tell Dr. Bailey what I know about the case, and he concludes probably that I have made a correct diagnosis, and says, "What are you doing for the patient?" And I reply that I am giving so-and-so, a preparation made by such and such a pharmaceutical house, and that this preparation (guaiacol) is said to contain strophanthine iodide, strophanthine salicylate, etc., and I have got the literature of it over at the office. Dr. Bailey would go away feeling that while I had made a correct diagnosis, and had a proper appreciation of the pathological conditions, but still he would feel that I had not been treating the patient in a scientific manner as if I told him that I was giving strophanthine salicylate, and he is thoroughly familiar with the action of the preparations because descriptions of them have been given in all our standard text-books.

If we would make a proper study of the pharmacological and physiological action of drugs, it would increase materially our feeling of self-dependence and self-reliance, so far as the management of the conditions that present themselves at the bedside are concerned. If we knew more about drugs we would not feel so helpless, and our cases oftentimes would appear less hopeless than they really seem. I rarely use these preparations. Very few of them do I use now, nor have I been using them for more than two years. I am not willing to engage in any attack upon pharmaceutical houses as a general proposition, because we need them. We are in sympathy with scientific dosage and things of that kind which can be worked out and given by pharmaceutical houses. It is true, and I am aware of the fact, that many druggists are incompetent, and that substitutions are made. But I want to say to you, that substitution can not be made if you prescribe tincture of digitalis. I am in sympathy with pharmaceutical houses that are spending much time and a great deal of money in finding more palatable products, in finding more potent preparations, in elaborating or getting rid of impurities which certain preparations may have, in isolating the alkaloidal principles of drugs, in getting them in definite form, size and shape. I am also in sympathy with pharmaceutical houses that exploit synthetical preparations within certain bounds. Urotropin has a certain definite physiological action in the human economy. Why such preparations as this, properly handled and properly advertised, when the composition of the product is thoroughly known to the profession, should have war waged against them, I do not know. I have no war to wage against urotropin. But the combinations of well known drugs, put up under different trade names, and which can be procured only from certain pharmaceutical houses, are to me objectionable, and I

believe will become more and more objectionable as time goes by.

**Dr. William Bailey**, of Louisville: It is not often that I had had occasion to differ with my friend, Dr. Boggess. I want to say that, being a Kentuckian, I believe that our purpose should be to study disease and get the indication, and then by the knowledge of the physiological action of drugs select that drug which we think will remedy the defect or difficulty by overcoming the pathological conditions and restoring the physiological function of the part. I have seen a distinguished man in one of our medical colleges write a prescription with twenty different drugs in it, and I have asked which one of them accomplished any good.

It has been my purpose largely in my work in the last fifteen years to prevent doctors from giving medicine. I don't mean by that, I am a therapeutic nihilist. I am like Dr. Boggess, an optimist in therapeutics; but I believe that we should have knowledge both of disease and of the physiological action of drugs we give, in order that we may intelligently prescribe. That is my firm conviction, and we need to go back to it. The reason why so many proprietary remedies are used to-day in the practice of medicine is simply because the average doctor does not wish to spend the time in making proper preparation for his work. You will find some men giving most of the drugs that are on the market. In consultation work I find that practitioners are using drugs a great deal without knowing what they contain.

When these detail men come to my office, I receive them, and kindly ask them to place their preparations in a certain part of my office, and I may say that I have as many as six hundred and fifty preparations lined up that have not been touched. Occasionally, I have been seduced into the use of drugs, because I did not know what better else to do. But I am inclined to limit myself to the strictly ethical, well-known drugs, have a clear indication for the disease, and give one drug. If I combine anything with it, it is either to assist that drug in its physiological function, or to make it more palatable for the patient. I do not believe in combining the various heart tonics that have been mentioned. I do not believe in combining digitalis and nitroglycerine, although they are both heart stimulants, one causing contraction of the capillaries, and the other dilatation of them.

These few remarks I present to you and ask you to study disease, have your indications for medical treatment, and then select those drugs that are indicated, whose physiological action was well-known, and then we will get better results than we do from the polypharmacy used at the present time.

**Dr. Clarence H. Vaught**, of Richmond: I am very much pleased to have heard this discussion

on one of the most important subjects that this society will probably have to deal with. It occurs to me, however, that there are a great many things to be considered before we can do anything radical along these lines. Most of us have been using proprietary medicines so long that I believe we have forgotten the art of prescription writing and the dosage of the crude drugs, and it will require a longer time than we would think at first to regulate a matter of so much importance.

I am not in accord with one of the speakers who preceded me in ordering detail men from our offices, because that would not be the correct thing for a Kentucky doctor to do, at least. But you can treat him cordially, and, at the same time let him know that you are competent and fully capable of judging of the medicine that your patient should take, and as you have done that in the past, you will do it more forcibly and fully in the future. That is the most effective way to deal with them. I cannot conceive how a physician can insult any man, especially when he comes in only to tell him how to treat his case, because that is the thing he wants to know. He does not tell him, perhaps, just exactly how the case should be treated, but treated according to the medicine he has, and many of these enterprising houses bring prescriptions already written, and many of the members of this Association have used them. But it will be an impossibility for us to get at this problem quickly. The schools will have to pay more attention to materia medica and prescription writing, and these post-graduate courses, it seems to me, could employ four-fifths of the time in instructing us which of these preparations are ethical, and which are not. The idea is to separate the wheat from the chaff. There are many of these proprietary medicines that are so much more palatable than the forms druggists can make them, and it appears to me we would have to have a new class of druggists to put up these prescriptions, because they have been so accustomed to pouring from one bottle to another. If we write a prescription consisting of two drugs and the pharmacist takes considerable time in putting it up, assure him that he can charge the victim for all the time he is taking, so long as he gives what we write. But the pharmacist does not want you to return to that method of practice; but I believe the time has come when we should go back to the crude drugs.

**Dr. T. J. Shoemaker**, of Morganfield: I agree with Dr. Boggess as to the importance of studying materia medica and therapeutics more thoroughly than has been done in the past.

Our medical journals have been weeding out some of these most offensive proprietary medicines from their advertising columns, and yet if we will examine some of these journals carefully, we will still find that they continue to publish

such objectionable advertisements. Preparations like antikamnia, syrup of figs, etc., are still being advertised in these medical journals, and they ought to be cut out.

**Dr. George P. Sprague**, of Lexington: This excellent paper and the discussions have, it seems to me, logically led to a point I have not seen mentioned as yet—a point I believe the medical profession must come to eventually, and that is, some method of endorsing the drugs that we do use should be devised. The various speakers have mentioned the preparations that are considered fraudulent, that have not been accorded to the formulæ printed; but they did not go further and tell us about what our best manufacturing chemists and pharmaceutical houses are doing. Several of them have been weighed in the balance by the Council on Pharmacy and Chemistry of the American Medical Association, and found wanting. There has been nothing said about our druggists all over the land, who are continually letting their undergraduate assistants put up tinctures and fluid extracts, anything they can extemporize at a less cost than can be bought from wholesale companies with resulting inequality of the standard drugs contained therein, so that we do not know to-day, when we write a prescription for most standard remedies, what we are getting. We do know, when we are getting a sealed bottle from one of our best manufacturing pharmaceutical houses to-day, what it contains, and as a result of the work that has been done there will grow up some system by the National Association of endorsing the drugs we use. I wanted to call the attention of this Association to that one point.

**Dr. Heizer** (closing the discussion): It was impossible for me to treat this subject in an exhaustive manner. However, I am glad that the paper brought out such an excellent discussion, and am especially gratified that the resolutions which have been adopted will enable us to carry this work from this Association into our county medical societies and thereby inform the members of those societies what has been and is being done in regard to these proprietary and patent medicines. If these resolutions carry out what we intend, we will gradually be able to eliminate all these evils from our practice.

#### THE LEADERSHIP IN MEDICAL ORGANIZATION.\*

BY W. W. RICHMOND, CLINTON.

Rufus Choate, the great forensic advocate, in an address delivered on the birth day of Daniel Webster in 1859, said,—“I have read that in a certain hard battle, when the tide

was running against him and his ranks were breaking, some one in the agony of a need of generalship, exclaimed,—“Oh, for an hour of Dundee!””

Now, in the language of Jack Bunsby, the incomparable philosopher, “The bearing of this observation lies in the application of it.” Beyond evil, the need set forth in this instance is one that will cry to us as long as time shall last,—the need of good generalship.

It is providential, it is a condition of all movements and organizations, independent of argument or advocacy. It is a law which speaks to the instinct like that of self-preservation or avoidance of adverse elements. It is as old as time. All ancient civilizations were subject to it and the great God Himself may be said to have ordered it, in building His Nation.

Associated with that thought was the need of a leader that should marshal His people to victory. (Will say in passing that he held his office until death.) The first historic world power, though cruel and intractable in the extreme, submitted to the law of leadership, holding sway until overcome by greater power, and thus down the ages.

However, leadership, unsupported by the sympathy and confidence of followers, is barren of results. There should co-exist such a spirit of unity and loyalty as inspired the Puritan, whose hand Queen Elizabeth, in a tyrannous freak, had cut off. He waived his hat with the hand that was left and shouted, “God save the Queen.”

So far as this association and the medical profession in Kentucky are concerned, you may at first blush, wonder wherein I have discovered any lack of generalship, for have we not an army of generals? And I think few “Sawyers late Noekenorfs” among us.

It has been written, “There are no accidents in the economy of Providence” and well may I say there are no accidents in the science of medicine. The paramount and pre-eminent truths, which guide us in our practice, are wholly resultant from the deep and earnest researches, experimentations and experience of the master minds of our cult, and in the exploration and uncovering of these invaluable truths, brave and unselfish men have sacrificed their time, their labor and even jeopardized their lives, with no thought save to throw light into dark places and serve mankind an altruistic scheme of life, that is not always valued at the present day.

The leadership in the past has been good, which is evidenced by the organization of this association many years ago. The names

\* Read before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

of those excellent and learned men, whose generous impulses and pathetic hearts first planned and then brought out medical organization in Kentucky, should be honored and revered.

“Who does the best his circumstance allow  
Does well, acts nobly, angels could do no  
more.”

But time brought about a necessity for still greater work, (or advancement in the work), and loftier achievements. A higher state of organization became necessary. It is a formative power that must be commensurate to its needs. Every department in life has grown and developed. Shall the medical profession stand still or retrograde, while all other activities climb aloft? Never let it be so. Rather let us study to forge to the front and occupy the position made possible by the incalculable progress attending the profession.

The principles of organization, which were established by the founders of this association, have not been destroyed, but magnified into one solid compact of county, State and Nation, so that now we cannot be insensible to the excellence and beauty of order, method, uniformity of action, or in brief, effective organization. We are realizing our most sanguine hopes in the organization of the medical profession in Kentucky.

*Organization.*—Organized effort calls for leadership and only through organized effort, ably generated, can we expect to reap the fruits of victory and see the full fruition of the purposes of the founders of this association. All men are not leaders. All men cannot be generals in the marshaled army. The majority must constitute the rank and file of the organization, in which its strength and influence lies. There is a fitness that must be considered in government. As Goldsmith's ‘Traveler’ has it,—‘Just experience tells in every soil, that those who think must govern those who toil.’ Therefore to these men, who constitute the rank and file of medical organization, is accredited the honor and glory of victory and conquest, these make up the grand counter part that goes to complete the strength and power of the body, useless each without the other.

“No man can end with being superior, who will not begin with being inferior.” Let us bear in mind that upon the men, who have been willing to sacrifice both time and money and have devoted to the subject the deepest thought and most earnest study, has fallen the responsibility of leadership. Therefore, to accomplish most for the greatest good, we must get in line and in obedience to the rules and regulations of the body stand by

and hold up the hands of the leaders, whom we have chosen and in whom we have trusted. Obedience welds the chain that binds together the composite factors of good government. The qualities of submission and service are indispensable to all great enterprises. He is the patriot, he is the hero, who goes to life's battle girded with the spirit of obedience and the high resolve to make the world more complete by fulfillment of his own appointed duty. “He who is false to present duty, breaks a thread in the loom and will find the flaw when too late to remedy it.”

In the organization of the medical profession, reaching as it does from the County Medical Society, to the American Medical Association, there are many places of honor and trust to be filled, demanding ability, integrity, honesty, and good leadership. The selection of these officers and leaders should be carefully and wisely made without personal preferment and for the greatest good of the organization. The very suggestion of place or domination carries with it to the minds of many, a feeling of resentment.

Now, since we assume that leadership is necessary in the great medical movement, let us fix a lofty ideal and strive to reach it, Phillip Brooks beautifully expresses it, “The ideal life, the life of full completion haunts us all. We feel the thing we ought to be beating beneath the thing we are.” There is nothing more practical than a high and relentless ideal, the man, who renounces mediocrity and uplifts the average of the world, is the full man.

Returning to the matter in hand, when a leader is chosen, he should have the endorsement of the entire body and should be aided in every way possible to make the term of his office successful, for in his success, in a great measure, lies the corresponding success of the organization. It is difficult to find men, who are infallible. This is an exemption that I believe not many of us will claim. I dare say that some mistakes have been made in the management and leadership of the present organization. Be that as it may the great good that has been so far accomplished has so immeasurably exceeded its opposite, that we feel justified in applying Pope's aphorism, “To err is human, to forgive divine.” On the other hand it is not difficult to find men of discontent who, actuated by a spirit of envy and jealousy, are disposed, through the press and otherwise, to criticise the acts and ruling of those in authority, and offering suggestions as to the better way. These malcontents even go so far as to question the integrity of the officials of the organization, insinuating mismanage-

ment, dishonesty and even graft upon the part of certain ones, and advocating independence of the member in the sense that he should not submit to the resolutions and recommendations made by the organization. Now this incipient disaffection should arouse every loyal instinct of the true brotherhood. It should warn us of the insidious poison evil and selfish minds would inject into our organization. Perfection we cannot expect, but absolute well doing men have a right to require, and this we think, as far as possible, has been brought to the work.

All worthy and capable men in the profession have an equal chance. The layman is likened, by Richard C. Trench, to building stone, and is thus advised, "Fit, square, polish thyself, thy turn will come, the wall will have need of thee." Co-operation we must emphasize. Whoever consents to less than his thorough best is neither shrewd nor good. To put only a part of ourselves into a given task is but to add to the general bulk of confusion. Let us look into the work of organization past and present, and note the progress that has been made. The past we admit has not been entirely guiltless of mistakes, but we should allow that to act as discipline.

"Nor deem the irrevocable past as wholly wasted, wholly in vain.  
If rising on the wrecks at last,  
To something nobler we attain."

The present glows with the balmy effulgence of the morning, and is only an earnest of what we shall do, but who is able to prognosticate the future? Let us aspire to such a majestic scope for our organization that the delicate fabric of form itself may hang thereon. Away with petty complaints, and let us overcome every obstacle, like the magnificent oak, which was seemingly detained in its growth by a boulder, but easting its roots around the same, anchored itself to withstand the storm of centuries. Opposition, if it be honest and manly, is not in itself undesirable. It is the whet-stone by which a highly tempered nature is polished and sharpened. At first the work of organization was confined to a few physicians in the cities and larger towns in the State and was patronized by them mostly on account of its social features. Through the influence and untiring energy of a few of the most enthusiastic of these members, the work of the organization has been broadened and its benign power so extended as to reach the rank and file of the doctors throughout the State. Therefore, in the past four or five years, the membership of this association has been increased from 555 to 1845, and it is undergo-

ing a steady and substantial growth. It is with a pronounced degree of pride that I record this fact. All movements to succeed must contain some intrinsic worth. It is true, bad things sometimes prosper, but such glory is ephemeral. This, however, is destined to outlive all opposition, and in its improved and perfected state to bless mankind by its existence. It has taken ages to bring the world to its present standard. We are the fruitage of many generations, and may hasten the Elysian period by making the most of ourselves. Johnson says, "We want not time, but diligence for great performances."

The standard of medical education has been raised to a notable degree. Our medical colleges have been strengthened by more masterful faculties, greater facilities and better equipage. The two years' course has been supplanted by a four years' course, and a higher order of preliminary qualification is demanded of pupils entering medical schools with the prospect of still greater proficiency being required. The time is at hand when the worn joke of buying a diploma will no longer pass current. The profession is exalted and dignified to that extent by existing requirements that a young man cannot lightly form the determination to enter the profession. Looking at the matter in its present phase, he needs to examine himself and see whether or not he possesses the requisite qualifications to pursue the course.

One can no longer choose the medical profession as he would choose a fabric in a shop. It is more nearly correct to say the profession chooses the man. To become a successful physician requires something more than to desire and resolve. It calls for painstaking and arduous study, pure morals and an over average brain. The conditions to be met are such that only those adorned with the noblest qualities of mind and heart need apply. Better laws governing the practice of medicine have been enacted, to the extent that we have not an unlawful practitioner in the State, whereas, before the higher organization, Kentucky was the home of many illegal practitioners of medicine, and the dumping ground of quacks and charlatans of every kind and order. The patrons can no longer allege that the relation is one-sided. Every reasonable protection in the training of the future physician has been vouchsafed. Better and more effective laws governing the health of the people, a system of sanitation and hygiene has been established by our State Board of Health and operated by it through a health board and health officer in every county in the State. County medical

societies have been organized in 108 counties in the State, and the most of them are doing active work. A four years' course of study has been provided for them, and ere long a post-graduate course of medicine will be conducted in every county society in Kentucky. Why these changes? It is the mysterious unrest of those who feel themselves capable of better things. Lander asserts that it is those who are not quite satisfied who are the sole benefactors of the world.

The doctor, as a rule, is studying medicine as he has never done before. He recognizes the difference between a reputable medical journal and an advertiser of patent medicines and proprietary nostrums. He knows a reputable physician from an imposter; in brief he has learned to differentiate honest medicine and fraud. This uprise in the profession minimizes the dangers of spurious practitioners. It produces in the natural course of things, a penetrating acumen and solid judgment upon the part of the young aspirant, which is of the weightiest importance. He learns to read men. The real doctor now has the latest literature of his profession on his desk, new books in his library, new instructions in his case and in every way a better equipage in his office for the successful practice of medicine and surgery.

How has all of this been brought about? The answer comes sharp and quick, by leadership in a united medical profession. Who are these leaders? What have they done? and what are they doing? They are men who have been willing to make the greatest sacrifice and do the most work for the least pay. They are those whom the recording Angel will put beside, Abou Ben Adhem, and whose deeds will say, "Write me as one who loves his fellow men."

High-minds are as little affected by unworthy returns for service as the sun is by those fogs, which the earth throws up between herself and his light. These are the men who have studied faithfully and profoundly, for the good of all concerned, the great purposes of medical organization, and the principles involved in its successful operation. Where did this new order of things have its beginning? In the hearts of the leaders of the great American Medical Profession, the American Medical Association, through good leadership, has become the greatest organization of doctors known to the world. What has placed this association upon the heights? The unparalleled excellence and mastery of its leaders. These giving freely of themselves foresaw the destined greatness to which it might attain, and their very power of will moved steadily to

that goal. Thus has the seed planted by them grown and expanded into a vigorous and beautiful tree. Thus has the offspring nourished by this unremitting toil become a sturdy giant. Truly has it been said "No great measure should consent to be restricted within limited bounds, but like the flow tide of the ocean rush forth to water the thirsty land." The medical association possesses this distinctive feature. All other organizations reserve within their own domain all benefits for their own members. In fact, they are formed as a protection against society at large, but ours confers its bounty upon all classes alike.

With its magnificent Board of Trustees composed of the best men of the profession, men of such sterling worth in honesty, in economy, and in integrity and capability, as to enable them to provide the ways and means for the substantial and successful operation of the association, it has broadened and enlarged upon every line and in every direction, so that it has become a star in the constellation of success. Its influence is felt in every State in the Union. "Good the more communicated, the more abundant grows."

The light cannot be hid; rather it sheds its beneficent rays upon the furthest limits of our land. With its council on education a better system of medical education is being established.

With its council on organization the medical profession of the nation is being so cemented together as to become world famous for its power and influence. With its council on Pharmacy and Chemistry patent and proprietary medicines are having a difficulty to maintain the hold they once had upon the people. No department has been overlooked. The enlightenment deduced from a sustained study of these subjects has extended to the people so that error in regard to old and vicious customs in medicine is being uprooted.

Lastly, with the greatest and most powerful medical magazine known to the world, "*The Journal of the American Medical Association*," edited by one of the most distinguished journalists of his day, the organization has extended its influence to the homes of the fifty thousand subscribers, who read this Journal, and is so advancing the cause of medical education, medical legislation, and medical ethics, as to place the medical profession upon a higher plane and command for it a profound respect and greater recognition by the people. In this age of push and progress, the man who will sit down and think for others is to be honored. Thought is one of the most valuable forms of property,

since it makes possible the greatest achievements. Thought put in action swings the club of reform. Thought races with the swift footed ideas as they run through the world of change. Think, conclude, act, this is the philosophy of mental growth. Raise difficulties and then remove them. These are the innumerable forces, animate and inanimate, to be brought under man's power. The best does not spring into existence, but is evolved. It took John Milton forty years to produce "Paradise Lost." William Cullen Bryant rewrote his "Thanatopsis" more than one hundred times and then was not satisfied with it. Burke rewrote his speech against Hastings thirteen times, and so should we ever reach upward for what is highest and noblest.

In conclusion, every realm of action requires the combined powers of leaders and followers to constitute success. If the necessary virtues be furnished by each, who shall be made to measure the consequent strength and usefulness?

Let every doctor in Kentucky strive to become a leader, and in doing so let him be willing to be led, and let him use his greatest efforts to uphold and encourage, those who are leading and who have done so much and who are doing so much for the good of the organization. Let each one be able to say, I have pressed to this heart my brother's woe until like the ancient legend, they have grown into pinions, whereby to soar toward the illimitable region of good deeds rewarded, and let him work to the purpose that the world can say:

"There grows no laurel green enough, there is quarried no marble fair enough, the sky kissing Himalayas boast no peak high enough, to pedestal the monument of these philanthropic and universal benefactors of mankind."

#### DISCUSSION.

**Dr. J. G. Carpenter**, of Stanford: Mr. President: There was a time when general practitioners were the leaders of the medical profession; but since we have had a multiplicity of medical schools in the last ten or fifteen years, these schools have assumed leadership, and may God have mercy on their poor souls. The trouble is not so much in regard to leadership in Kentucky, but the great evil lies with our medical schools that are sending out such inferior men, and the Boards of Health ought to be rapped, too, in reference to this matter. Whenever we have a good man from a medical school he becomes a leader. It is those who are insignificant that are in the way. There should be a school of leadership, and if we were more partic-

ular in examining the men who matriculate, in examining those who are trying to make doctors, each private in the profession will soon be a leader. Let us, above all things, begin at the foundation and purify the medical schools; have them send out better men, more competent men, better raised men, men who have been born gentlemen, and leadership will soon take care of itself. The man who has not practiced medicine out in the country cannot conceive of the conditions and things that our Councilors have had to contend with. Let us take, for instance, the territory that Dr. Wesley has gone over and worked in. He has been a leader, and a grand leader in his profession, and I believe he has done the best work of any councilor in the State, and were all councilors like Dr. Wesley, practitioners of medicine would soon be whipped into line or led into better ways.

**Dr. J. Garland Sherrill**, of Louisville: I am sorry that Dr. Carpenter has been a little harsh in his criticism of medical schools, for I am sure that when he and I went to school they did not teach us as well as they do now. I am also sure, that our schools are not attempting especially to lead, excepting in one thing, namely, to turn out better doctors than they have done in the past. We all know that a doctor is not made by a medical college. He is simply put in a position where he can become a doctor, and the greatest part of his learning must come after he is a doctor and not while he is at school. This is a little departure from the subject under discussion, but I am sure the body of this Association all desire to have good leaders, and that we are willing to have first-class leaders, no matter where they come from, whether from the mountains, from the East or West, or from the North or South of the State.

**Dr. G. A. Hendon**, of Louisville: There is one important lesson that ought to be drawn from the paper to which we have just listened. If there is anything in the world that the medical profession ought to be proud of, it is of her leaders, both in peace and in war. We cannot find any fault with our leaders that we have had heretofore, and their high standing only makes it imperative upon those of us who occupy a younger sphere to come up to that standard, and we ought to remember that if we lower that standard, then we are retrograding. When I listened to the address of our president, I could not but conclude immediately that such noble thoughts could only come from a man who is capable of thinking such thoughts and who is thoroughly imbued and interested in the work in which he is engaged. What are the qualities of a leader? A man without vanity, one who is willing to undergo self-effacement in the interest of the cause he espouses, and in the selection of our leaders it

would be well for us to keep in mind the selection of men without vanity, and men who are willing to suffer self-abnegation.

**Dr. Richmond** (closing the discussion): In my paper I spoke of the organization from its beginning to the present time. I did not cast any reflection upon any defects or mistakes that were made especially, only in general, and I think we owe just as much to the founders and leaders of this Association at its beginning and all the way through from year to year as we owe any leader at the present time. Each leader did the best he could. So I may say, that no reflection was cast on any medical college. Our medical colleges are teaching to-day as they never taught before. As I said in my paper, our medical colleges have been strengthened with stronger faculties, better facilities in every way for teaching than they had a few years back. Our advantages are greater. We are progressing, hence there can be no reflection cast on any school, any leader, or anything in connection with the organization from the past to the present, but only to congratulate ourselves upon the present outlook. I thank you very much for your attention.

TECHNIQUE AND ADVANTAGES OF  
THE MODIFIED BLOOD CLOT  
METHOD OF CLOSING THE  
WOUND IN THE MAST-  
OID OPERATION AS  
USED IN FIFTY-  
THREE CAS-  
ES.\*

BY J. A. STUCKEY, LEXINGTON.

When Blake of Boston, Reik of Baltimore, and Sprague of Providence followed by Sohier Bryant of New York, advocated the use of the blood-clot method of closing the wound after the mastoid operation, I was one of the large army of "doubters and kickers," and questioned seriously the safety of the procedure. After talking personally with these gentlemen, all of whom are of unquestioned and well recognized scientific ability, and seeing several cases with Blake, I cautiously tried the method with slight modifications, and with such gratifying results that I call attention to them now for your consideration with no small degree of confidence.

As advocated by Blake and others the object of the method is to encourage physiological repair of the mastoid wound, and not treat it as an open sore to heal by slow granulations, but to allow it to close by the most

rapid method Nature provides.

This method requires more careful technique as to preparation of the patient, in the operation itself, and in the after care, and means you must have a clean wound with healthy or clean walls.

The preparation of the patient in my hands includes (1) the thorough emptying and cleansing of the alimentary canal, the placing of the skin in good condition by at least two baths followed by brisk rubbing of the body, and liberal use of water to drink, to within two hours of beginning the anesthetic. (2) The preparation of the operative field in the most careful manner. (3) The administration of the minimum amount of ether and the avoidance of everything which produces shock. (4) The minimum amount of traumatism, laceration of tissues especially the periosteum, the removing of all rough edges and ledges of overhanging bone, and the avoidance of unnecessary contusions

caused by ligatures, forceps, clamps and retractors.

"The chemico-physiological factors of success are still more important and depend on the following facts, namely, the blood has a decided bactericidal action; that living tissues cannot stand great changes of temperature or desiccation; that the normal reaction of these tissues is alkaline, and that any chemical substance which tends to lower the vitality of the tissues, whether it has a bactericidal action or not, has a retarding effect on Nature's reparative work. It follows, then, that nothing more active than dry wiping or physiological salt solution, at the temperature of the body, should be used in the wound for cleansing purposes." (Bryan.)

I have found less infection from silk worm gut sutures than any other.

In all my cases where this method was used, except two, the Stacke-Schwartz, or the so-called radical operation was done, consisting of converting the tympanic cavity, mastoid antrum, cells and auditory canal into one cavity.

The difference in my technique and method of operation from that used by most otologists consist (1) in not using the chisel and mallet except in rare instances where the bone is so eburnated the rongeur and eurettes cannot

\* Read before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

be used, (2) in doing first the Stacke operation of removing the superior wall and going through the aditus ad antrum into the antrum, then in to the mastoid cells. In other words doing the major part of the operation first instead of last. This is done almost entirely with two sizes of the Kerrison's forceps and a modified Jansen's rongeurs, cortex rougues and curettes.

Briefly, the method consists of making the usual post-aural incision, going well through the periosteum, separating this membrane carefully, at the same time detaching the membranous auditory canal from the superior and posterior walls. This membranous canal is then tied back with strip of gauze so that it will not obstruct the view of the tympanic cavity.

The tissues including the periosteum, covering the rest of the mastoid process are separated and the retractors applied, with a clear view of the lower part of the auditory canal and tympanum, remnants of the tympanic membrane are removed with the curette. The necrosed ossicles are removed with the forceps which I devised (Fig. 1), then the Kerrison rongeurs are used for removing all of the superior wall and uncovering the facial ridge. The advantages of these rongeurs are they cut up and forward, away from the facial nerve, the danger points.

After carefully exposing the middle ear cavity and aditus, these are thoroughly freed of all granulations and diseased bone with the curette, the orifice of the Eustachian tube cleansed with the conical burr which I also devised (Fig. 2), and which answers the purpose most satisfactorily. Care must be taken that the edges of the tympanic ring are cut away, the bottom of the middle ear cavity, and orifice of the Eustachian tube are made clean and smooth.

Up to this stage of the operation, surgical anesthesia is necessary, but after finishing the middle ear cavity, there is little need of the anesthetic and practically no more ether is given until the sutures are taken, which finish the operation. I have several times removed two-thirds of a large mastoid process, uncovering the sinus and removing the tip of the mastoid, requiring much time and careful manipulation and no other given after finishing the operation in the middle ear. By this method of operating, the patient not only receives the minimum amount of ether, but is practically awake by the time the operation is finished.

During the entire operation, the operative field is frequently irrigated with sterile normal saline solution of temperature 115° F., this effectually controlling the bleeding,

washes away chips of bone and detritus, keeping the parts clean, warm and moist. cut of sterile normal saline solution.

Before finishing the operation, a careful search should be made for diseased cells in root of the zygoma and those posterior to the bony covering of the sinus, as well as the extreme tip of the mastoid process. When satisfied a clean operation has been done, the canal is slit well back into the external meat-

us, making an opening large enough to admit introduction of the rubber perforated drainage tube of 1-4 in. in diameter, the upper flap is anchored to the edge of the temporal muscle with 10 day chromicised cat gut, the lower to the sterno-cleido mastoid. The entire field is now irrigated with normal salt solution at temperature of 115° F., being careful to wash out all the bone dust and small clots, tags of muscle or tendon sheath should be cut off, and soft parts examined for evidence of infection, this if found, is removed with curette. The perforated rubber tubing cut proper length and containing a narrow strip of gauze is inserted well back in the tympanic cavity, the periosteum is pulled forward and allowed to drop over edge of bony cavity, and the lips of the wound closed with silk worm gut suture. Between the last two sutures in the bottom of the wound, a small cigarette drain or a small perforated rubber tubing, about an inch long, is inserted to give freer drainage. The usual dressing of gauze and cotton are applied externally.

At the end of the first 24 or 36 hours, the external dressing is removed as well as the posterior drainage, also the strip of gauze from the tube in the canal, a fresh strip is inserted and capillary attraction maintained. No irrigation of the wound is done until the large tube in the canal is removed on the third or fourth day, when the canal is wiped out gently or syringed with 1-1000 solution of Alphazone in normal salt solution, then dried with absorbent cotton and a strip of narrow gauze is inserted. After the fourth day the canal is wiped out daily, if exuberant granulations threaten, these are to be touched with 25 to 50% alcohol, the parts allowed to dry thoroughly, then to be dusted with a powder of equal parts of aristol and boric acid. The sutures are usually removed on the fifth or sixth day, the patient allowed to sit up on the fourth day, leave the hospital as soon as he feels able to do so, which is usually on the sixth or eighth day. The auditory canal is not packed with cotton

or gauze, but allowed to remain open as soon as the serous discharge ceases. Dermatitis is usually complete in from 16 to 30 days, the patient able to resume customary duties in two weeks. If a clean operation has been done, there is danger of overtreating the cavity favoring the formation of excessive granulations and delaying dermitization, by syringing and packing. Early exposure of both the wound and the patient to air, and a bit of scientific neglect, are often of great assistance to nature.

In the fifty-three cases referred to, I have had infection of part of the clot in the lower portion of the wound in seven, but the infection was walled off and gave very little more trouble than an ordinary furuncle. In the two cases where the classical mastoid operation was done, for acute infection, the healing of both middle ear and mastoid was complete within ten days. In all the cases the convalescence was shortened at least one-half, there was no disagreeable, painful and prolonged packing and after-treatment.

In none of these cases was the hearing made worse in the ear operated upon than it was before the operation. In all the cases there has been little or no scar or deformity. In the majority only a slight pitting behind the ear which is visible only on close inspection. In four cases the upper flap sagged and packing of the canal with gauze for two or three days had to be resorted to.

The advantages of the perforated tube drainage are (1) it can be removed without disturbing the granulations of healing, (2) it can be removed without pain to the patient, (3) a fresh one can be introduced without discomfort.

The indications for the non-use of this method are in those cases where the soft parts covering the mastoid are infected or where an extra or sub-dural abscess or sinus thrombosis has been encountered.

### DISCUSSION

**Dr. George P. Sprague**, of Lexington: Mr. President: I am not an otologist, but I have seen a good many of these operations done, and I want to commend the absence of the use of the chisel and the use of a forceps instead. I do not believe the chisel in brain operations, or in operations about the brain and head, is justifiable in most cases, and it certainly is made, in this radical operation on the mastoid, a very much safer operation with biting forceps than ever has been done in the past with chisel.

**Dr. D. M. Griffith**, of Owensboro: This is an especially interesting paper to those who are engaged in this work. The essayist has varied

from the original Staacke-Schwartz operation of going into the antrum and then into the aditus ad antrum and into the middle ear, and has revised the order. I am rather inclined to think that it is a safer procedure.

I have never practiced the blood clot operation, because I believe many of us attain as near perfection as possible by the frequent performance of a certain line of work. The blood clot operation as yet, if it is not in the experimental stage, is certainly not accepted by otologists all over the country. There are many who claim that they get a much greater percentage of cases of infection from blood clot union—that is, suppuration of that part that is not infected—than Dr. Stucky reports. If the operation eventually should become as highly a successful procedure in the hands of other operators as it has in Dr. Stucky's individual work, there is no question but what it in the future will become the procedure. But as for my own patients, without in the least desiring to discredit the doctor's judgment or his technique, I shall pursue the policy of treating it as an open wound, because I know when I have that, I am acting in accordance with the fundamental principle of surgery, that is, as long as we furnish an outlet, the danger of infection is greatly minimized, although we may have secondary infection of the wound.

The doctor's instrument is very ingenious, and from that point of its advantage of approaching above and leaving the facial ridge visible, there is no question about its feasibility. The man who has not done a radical mastoid operation has no conception of what a hard operation it is. I have done a great many operations for different conditions, and I am free to say that the mastoid operation is the hardest I have ever undertaken. I have done many of these operations, and as it is my practice to be candid, I will say that I have had one case of facial paralysis, and I want to qualify the doctor's statement that the operator ought to be censured for having been the cause of such a condition. I am like the Irishman, I do not think I ought to be censured.

**Dr. Stucky**: I stated in my paper that if, after exposing the facial ridge, you cut down on the facial nerve, and injure it, you are to blame when you can see it. But there are some cases in which this nerve cannot be seen.

**Dr. Griffith**, (resuming): After hearing the delightful description which Dr. Stucky has given us, we would naturally think that the facial nerve in this operation can be clearly seen by anyone who has eyes; but such is not the case, gentlemen. The question of hemorrhage comes in there, which is not always easy to control. We clean it away and more blood comes, but after you have gotten all the granulations and

dead bone out, then you cease to have hemorrhage. But after you have done all that you have seen the necessity of keeping away from the facial ridge because you have completed the bone part of the operation. Hemorrhage so persistently obscures the field of operation that it requires more care and more courage to proceed in this operation without doing harm than any other operation, in my judgment, in the realm of surgery. As Dr. Stucky has told you, in the operation of appendectomy, when you cut down, you can see what you are doing. If you go further into the anatomy, there is no great danger of injuring the surrounding tissue because you are going to get a latitude of several inches in which to work; but in operating on the mastoid you are working in a cavity the limits of which will not exceed three-quarters of an inch, and, as he has pointed out, this bone varies more than all other bones of the body. And that is true. No man, who does mastoid work, can feel absolutely certain, when he goes down into the bone, just what he is going to find. He may find an abnormal position of the lateral sinus, which may be jammed square up against the posterior wall of the external auditory canal. He may strike an anatomical vagary. I have not been able to make a triangular opening into the bone and find the spine of Henle. I never saw it until two or three weeks ago, and yet I failed to find it. So far as it was within my power to determine, it was not there.

The essayist has emphasized one point that is highly gratifying to me, and that is, there is a difference between the performance of the simple mastoid operation and the radical mastoid operation. We cannot perform a radical mastoid operation, entailing the serious consequences which may follow in its wake, subjecting ourselves to the adverse criticism of an unfortunate result, for the same compensation that a man can do a simple mastoid operation; and yet it is hard to instill into the minds of the laity, and oftentimes into the mind of the general practitioner, the fact that there is a vast difference between the two operations, and that the operator ought to have compensation for one that is far in excess of the other. I have gone up against that a number of times, and I have no doubt Dr. Stucky has. He has brought out that important point from our standpoint very clearly, and I want to thank him for his excellent paper.

**Dr. Arthur T. McCormack**, of Bowling Green: While I was at Rochester, Minnesota, I saw Dr. Charles Mayo do some of his operations for mastoid trouble, and what was of greater value and interest to me was in hearing him discuss the general subject. I was surprised to hear him say that all cases of pain in the ear, which continued for longer than twenty-four hours,

should be subjected to a mastoid operation, whether the drum membrane was punctured or not, as he was confident that many of the obscure nervous diseases, especially those which disturb the equilibrium, were due to chronic mastoid trouble of long standing frequently, the patient having entirely forgotten having had the original trouble. He insisted that but one operation is done for mastoid trouble where fifty are indicated or needed in practice in the best localities, and he urged this upon the doctors who not only listened to him, but upon the doctors of the United States. The operation was done by Dr. Mayo exactly in accordance with the description given by Dr. Stucky. He quoted Dr. Stucky in doing the operation, and said that he only differed from his with reference to the modified blood clot dressing. Dr. Mayo said that blood outside of the arteries had no germicidal powers; but, on the other hand, was a culture medium of great value; that the mastoid that was really infected should be cleaned out absolutely at the time of operation, and that no blood should be left in there, but the dressing should be applied from the bottom, with drainage in accordance with the suggestion of Dr. Stucky.

**Dr. Stucky** (closing the discussion:) In replying to our honorable president's remarks about the danger of this method, he said he wanted a free outlet. Well, with the canal split well back to the middle meatus and made so that you can put your finger through it (and that is my guide as to size); with the whole of the mastoid tip cleaned out, with the addition of this little strip between the last two sutures, I do not see how it is possible to have freer drainage.

**Dr. Griffith:** Did you have that in these two simple cases?

**Dr. Stucky:** In all of them. I started with a small tube, but now I have gotten down to one-third of a tube, and in the last two cases I got along with two strands of catgut. Another point: the moment gauze is saturated with the secretion, it ceases to be much of a drain. You watch the wound every day, and if there is any puffiness, any evidence of infection going on, you have got nothing to lose, you are where you were when you started; you cut a stitch, and turn it out. I have done that seven times and had no trouble. If the proof of the pudding is in the eating of it, I have eaten it in fifty-three cases. And I do not know about the bactericidal action of the blood. Wright says it is true; Blake, of Boston, the father of otology, and Sprague, of Providence, say it is true, as do Bryant and others, and I know it has delivered the goods so far, and I have no reason to regret using it.

I am glad Dr. Griffith made the remark he

did lest some of you had gotten the impression that I said any man was culpable who injured the facial nerve. It is the most uncertain thing I know of. The point I made is this: With this method, with the Kerrison forceps, by removing the superior wall first, and then removing the external wall covering the aditus ad antrum with a forceps that goes up and out away from the facial nerve, when you see your danger, and with your eye wide open, if you go ahead and take a chisel and carelessly cut the facial nerve, I don't know but what you are culpable.

In my first series of cases I had three instances of palsy. I had living monuments of the chisel walking around, and I wished the Lord would call them up higher. [Laughter.] The palsy did not last long, but every day seemed a month. I could see that eye that never closed in slumber on that side of the face, and never responded to a smile. I did not cut clear through the nerve. The longest time the palsy lasted was nine weeks. But I have had no facial palsy, no trouble in a hundred and some odd cases of radical operation where I have used the Kerrison forceps. I speak feelingly on this subject. The patients are all right now. In one case, to which I have already referred, the facial palsy lasted nine weeks, and in another twenty days. In those cases where an extensive operation is required, if we have osteomyelitis or erosion of the canal, if we injure the facial nerve, facial palsy is likely to follow and exist for a time. I think Dr. Clark saw the facial nerve exposed in one of my cases; I could run over it with a cotton probe and make the face of the patient twitch. I have seen nine cases in which the spine of Henle is absent. I have seen cases in which I could not find any evidence of a suprameatal triangle.

There are two landmarks for the mastoid operation, and when you go in the other way, doing the Stacke-Schwartz operation, first, you know where you are going.

I am glad Dr. McCormack said what he did about Dr. Mayo. We all have the most profound admiration for the work of the Mayos. One of the great lessons Dr. Charles Mayo taught me is the advantage of clean work, and if any of you want a mastoid operation done, let me beg of you not to have it done in the house. I do not care how sick the patient is, it is better, if possible, to have him transferred to a hospital. I remember very well a patient who had otitic meningitis, with convulsions, who was placed on a cot in a baggage car and carried sixty miles before being operated on. We want a well-regulated hospital for these operations, and assistants who know what we are going to do, and who know how to help us. That is where everything counts.

I am specially glad that Dr. McCormack

quoted Dr. Charles Mayo with reference to recurring mastoiditis, although I differ with him. I believe the average otologist will differ with Dr. Mayo as to the length of time a patient should suffer from earache before submitting to operation. I do not let them suffer three hours before I incise the drum membrane. I do not believe in paracentesis. That word has been tabooed and cut out of our transactions. We are not allowed to use it in our otological society; but we do a myringotomy, and that is cut the membrane clear around in the form of a half moon. Where we wait longer than twenty-four hours the patient may have an acute neuralgia or osteitis. There may be pain in the mastoid without suppuration; but I take it, that Dr. Mayo had reference to an infected mastoid, and an infected mastoid leaves the same tract that an infected appendix does. You may have a recurrent mastoiditis; you may have a recurrent appendicitis, but the appendicitis gets the patient after a while, and a mastoiditis is going to get the patient after a while. An appendicitis leaves adhesions; while a mastoiditis leaves you with sclerosed bone, and the point of least resistance after each attack of mastoiditis is diminished from without and increased from within, and you have nothing within between you and the vital centers but the tegmen tympani, and the eburnated and sclerosed mastoid process which is similar to an appendix that is bound down by tight or dense adhesions.

#### THE DOCTOR—HIS BUSINESS SIDE— AND HIS RELATIONS TO HIS FELLOW DOCTORS.\*

BY M. B. STEDMAN, VERSAILLES.

In the very beginning we wish to state that there are many doctors who do not possess a "business side" and are, therefore, one-sided. In fact it is almost proverbial that the average physician possesses little or no business qualifications.

This absence of qualification along business, or commercial lines, is due to a lack of training in business, for, up to the time of graduation in medicine, about the only business transactions the young doctor has engaged in have consisted of business appeals to the "old man" for a remittance, which remittances have not led to a very complicated experience in book-keeping.

Hence, I state that without some degree of training, there cannot be a very accomplished business side to any one.

In order to make a financial success out of the practice of medicine, two things are essential, namely: 1st—to so equip ourselves

for the practice that we may be able to earn a competency—2nd, to see to it that what we have earned shall within a reasonable time be paid to us. In other words, we must be good collectors.

How many physicians there are within the knowledge of each of us, whose extensive practice justifies a liberal income for the benefit of their families, and yet who are always "hard up", simply through a lack of the application of business methods in making their collections.

If the unusual should occur, and a doctor should be able to accumulate a surplus, we should advise against any speculative investments, or even those of a commercial nature, but would advise, first of all, the provision for life insurance to the utmost of his capacity to carry without burdening himself. This character of investment amply and securely provides for his family and does not require any time taken from his professional duties to look after it.

Enough for the business (or lack of business) side of the doctor.

#### HIS RELATION TO HIS FELLOW DOCTORS.

There should always be a close and cordial relation between physicians, second only to the relation between brother and brother.

Why should not this relationship obtain in every community?

Is there, in this pleasing and cordial relationship between gentlemen who have the same purpose in view, who are traveling, as it were, the same road, aught that would work a hardship upon any gentleman? Is there any rule of conduct required that is not embodied in that grandest of all principles covered by the golden rule? In fact, would not the path of our professional life be much more pleasant to tread if there were no stones of discord, bickerings and back-bitings strewn along our path?

If we conscientiously lived up to these high ideals, would not our beloved profession be elevated, not only in our own esteem, but within the laity as well?

A few words as to consultation:—

When a consultation has been suggested by the family, it is the duty of the attending physician to give his cordial assent at once. He should remember that "all that a man hath will he give for his life." The patient feels that there is wisdom in counsel whether there is or not. He realizes that one may suggest something which the other has overlooked, though both may be equally competent. It is wonderful how many excellent medicinal measures are shelved away in a man's brain and are forgotten, but may be brought to light by suggestion of another,

and then we wonder how we could have overlooked the suggestion with which we were perfectly familiar. The patient feels grave apprehension with regard to his condition, desires that everything shall be done for his welfare and calls one whom he supposes can give valuable assistance in the case. Such a consultant ought to be cheerfully called and accorded the highest courtesy and kindness. The patient does not always name the physician to be called in consultation, but leaves this to the attending physician, and this is best. The physician in charge is the most competent judge of the qualifications of those he may desire to assist him. He knows the needs of the patient and should try to meet them in his consultation. A consultation may be called in the interest of the physician. In these perilous times when damage suits seem to be the order of the day, it is often well for the attending physician to call in a consultant, especially in cases of fractures and dislocations for his own protection. When a consulting physician has been called, whether at the suggestion of the attending physician or of the family, he should be received as a gentleman and confrere, and treated with courtesy and consideration. To a right thinking physician—one devoid of suspicion and jealousy, this sharing of responsibility brings no small amount of comfort and help. To the self-satisfied and self-sufficient, it brings nothing but an attack of jealousy and sulkiness. If you desire real benefit to accrue to yourself or to your patients, meet your consultant cordially and cheerfully. If you bring nothing else to the sick room and the patient in a consultation, at least bring cheer and hope and sunshine. Let it manifest itself in your voice, in your countenance, in the grasp of your hand. After examining the patient the consultation between the physicians should be entirely private. The case should be thoroughly gone over and discussed in all its bearing, the consultants keeping continually in mind that they meet alone in the interest of the patient and should not allow themselves to drift into discussions of questions not germane to the case in hand. Matters of diagnosis, prognosis and treatment having been settled the result should be communicated to some member of the family or to the patient himself, if the family desire it, both physicians being present. The treatment should go to the patient and family at the recommendation of both physicians, unless he should desire the consultant to do so. The consultant should hold no communication with the patient or members of the family about the case, unless the attending physician is present. This is im-

portant. Just here trouble often arises; the attending physician rightfully or wrongfully imagines the consultant does not always speak with the same voice to the family when he is not present as when he is present. Protect the attending physician as far as you possibly can; make no unfavorable criticism of his conduct of the case to any one. Indeed never mention your differences at all unless the welfare of the patient demands it, and then only to patient or his family. Protect the consulting physician always to the limit of conscience, but the patient must never be allowed to suffer from withholding the whole truth. When a consultation is concluded, arrangements should be made for the next visit of the consultant, provided it is thought necessary to have him see the patient again. This being done, consultant should take his departure at once, never lingering to discuss the situation with the neighbors or with the family. He should never remain after the attending physician has gone. The consulting physician should never consent to take charge of the case by request of the family alone. It is doubtful if it ever should be done at all, but never unless by the earnest request and desire of the attending physician. Whenever a physician, be he attendant or consultant, feels that he is the soul and body of medical wisdom and that none can be found who is capable of rendering him any assistance, right then and there you have a case well-nigh ready for the fool-killer. If physicians when they meet in consultation would ever be kind and courteous and generous, frank and honest toward one another, forgetting self, then there would be no place for envy, jealousy, dissension or bitterness. Remember that "charity suffereth long and is kind, charity envieth not, is not puffed up, doth not behave itself unseemly."

In many communities our noble profession is discredited and spoken of with sneering contempt, by the laity, simply because we have, by our bickerings, back-bitings and contention, dragged it far below that high plane it should occupy.

Doctors should often be seen in each others' company and thus let the public be convinced that there is not that animosity and estrangement between them that they had been led to believe.

In conclusion, let me urge that we strive to promote unity and harmony between the members of our profession and ere long we will have the proud distinction of being members of the grandest profession on the face of the earth.

## DISCUSSION.

**Dr. Arnold:** Thought it best, having an honest and honorable consultant, that the latter see the patient and make his comments and recommendations to the family, all without the presence of the attending physician. He thought that whatever might be said by the consultant would thus be received at its fact value and not subject to the discount of a supposed bias in favor of the attending physician. In this way, he thought that much responsibility would be lifted from the attending physician.

**Dr. Crawford** thought if we would all act on the suggestions of the reader, we would get along better.

**Dr. Anderson** endorsed the paper in toto. "Let us be men, not boys."

**Dr. Worthington** thought we should think first of the patient's welfare; that suggestions by the consultant need not be to the injury or prejudice of the attending physician.

**Dr. Parrish** thought the consultant was called for one visit only, and not as a joint attendant; that consideration could only be had once and that after that one or the other really controlled the management of the case; that doctors do not call consultation nearly often enough for their own protection and the patients' welfare; that hereafter he would always have some one present, whenever it might become necessary to use forceps in labor.

**Dr. Sleet** thought that the consultant could never later with propriety take charge of the case.

**Dr. Morgan:** "What if the attending physician and family both want him?"

**Dr. Parrish** granted that possibly there might be circumstances justifying the consultant's taking charge of the case, but averred that he, himself would never, under any circumstances so supersede the attending physician.

The Committee on Subjects for the next meeting reported:

"How to Keep Our Patients at Home"—Dr. Arnold.

Subject of his own selection—Dr. Anderson.

The society passed resolutions of regret at the prospective loss of Dr. Crawford by removal.

## DIFFERENTIAL DIAGNOSIS AND METHODS FOR PREVENTION OF SPREAD OF DIPHTHERIA.\*

By A. L. WAGONER SCOTTSVILLE.

I have chosen for my subject Differential Diagnosis and Methods for the Prevention and Spread of Diphtheria, not because that I

\* Read by title before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

have anything new to offer, but because of its seasonableness and because, notwithstanding all that has been said and written about it, this disease is not well understood by a large number of physicians in active practice today. Doubtless there is no disease that demands a more early recognition than diphtheria, and probably there is no disease that the mortality is effected more than this one by the failure to recognize it early.

It might be presumed that a disease which is so characteristically developed, with local symptoms, might be easily diagnosed, but this is not the experience of able diagnosticians in certain class of cases. As it is only a comparatively few physicians that have access to bacteriologists, and so few that are equipped to do the work themselves, the great bulk of doctors have to rely upon clinical history, local symptoms and constitutional involvement in making their diagnosis rather than the culture.

Fortunately there are not many diseases that we confuse with diphtheria, but in the absence of an epidemic, with a negative history, a positive diagnosis can only be made by the clinical history proven by the culture.

Those who have studied diphtheria closely notice that it divides itself into two classes, the mild and the severe, and of the two divisions the milder is the most dangerous, 1st, because, they are usually not recognized at once; 2nd, they infect others; 3rd, they may be followed by sudden and severe laryngeal involvement.

As a rule in sporadic cases the membrane in the throat is the first thing we notice that causes suspicion, which should not be so, for in some cases there is no membrane, in others it is so situated you can not see it.

This membrane is formed by three different organisms; namely, staphylococcus pyogenes, streptococcus pyogenes and the Klebs-Loeffler bacilli. None save the skilled diagnostician can differentiate a membrane formed by the staphylococcus from the streptococcus infection, but all should be able to differentiate staphylococcus and streptococcus infection from Klebs-Loeffler infection.

A membrane with sudden constitutional disturbances, pulse very rapid, and temperature rising to 103° or over quickly, and returning to normal about the second or third day, condition ushered in with chill or slight rigor, pain in back and limbs, considerable pain on deglutition, tonsils red, congested and swollen, and follicular ulcers are seen here and there over tonsils, this condition denotes staphylococcus infection.

In streptococci infection we have the most painful of the throat infections. In this

form the temperature rises more gradually to 102 or 103 and remains stationary for several days. The inflammation is not confined to the tonsils, but extends usually to the pharynx, posterior nares, and all the tissues of the fauces, and by invasion of the Eustachian tubes causes a difficulty in hearing. Sometimes there is swelling of the glands of the neck, and there is great pain on deglutition, and often much prostration. The membrane does not usually cover all the inflamed surface and is thin, of a yellowish white or grayish white appearance, which disappears in a few days, but the swelling of the tonsils and other tissues remain for several days and recovery is slow.

A membrane when first seen that is of a thin grayish color, and as it ages becomes more gray, brown or even black, and with a tendency to spread, and is not readily removed and when force is employed bleeding is the result, this indicates Klebs-Loeffler infection.

The fact that a membrane is present is not of as much importance as the fact that it spreads, and particularly where it spreads to. If it spreads beyond the tonsil it may be regarded with almost absolute certainty as diphtheria or if it is limited to the tonsil, but with little or no surrounding inflammation, it is most likely diphtheria. If during the onset there is a nasal discharge streaked with blood or there is tenderness of the cervical glands even without their being enlarged is strongly suggestive of diphtheria.

If upon examination of a throat we find there is an intense degree of inflammation, and there is some swelling of the uvula and faucial pillars, or that the membrane that is present is easily removed or broken we are quite sure in assuming that we are not dealing with diphtheria.

Its the low temperature and the persistence of the deposit upon one or both of the tonsils that leads us to suspect diphtheria, and with this a grayish or white deposit on one or both tonsils, in a patient between 2 and 12 years can be safely classed as highly suspected case of diphtheria.

A wise plan is to consider all acute inflammations, whether nasal, faucial or pharyngeal as suspicious until proven otherwise, by clinical course or bacteriologic examination. Many cases of mild diphtheria is diagnosed as follicular tonsillitis, and there is nothing but a culture which will at times positively make the distinction. But unless the symptoms are so developed that doubt is practically removed beyond all question, tonsillitis should be looked upon with doubt.

High temperature, sudden onset, intense inflammation, painful deglutition, membranes

easily removed, has no tendency to bleed or return, inflammation extending beyond deposit, membrane sloughs in a few days, but the inflammation remains; this condition does not indicate diphtheria.

A membrane that extends beyond the tonsil should always be regarded as diphtheria, which has always been my experience, save in one case, in this the tonsils were so swollen that from contact there was deposit upon uvula which was not diphtheria. High temperature coming late in a case denotes secondary infection, usually of the streptococcus variety.

Differential diagnosis in a nut-shell in the absence of culture, which should be resorted to for confirmation, is as follows: Low temperature, gradual onset, persistence of deposit, membrane of a grayish-white color, as it ages becomes darker, not easily removed, and when removed has a tendency to return, and when force is applied bleeding is the result. Very little or no inflammation beyond the membrane. In the pharyngeal, there is very little pain on deglutition, and in the laryngeal, there is hoarseness, harsh cough and the voice probably reduced to a whisper. Urinary analysis shows the presence of albumin in small quantities, this condition denotes diphtheria.

When a diagnosis has been made of the disease, what is our duty to prevent its spread, what are the mediums through which this germ is carried. How can we fight the enemy successfully if we fail to familiarize ourselves with every phase of the enemy's life.

Chapin, Hill, Weichard, Welch, Garman and many others have shown that fomites rarely contain the germ, Osler, Anders and others claim that the poison is never given off in the breath; the same authors also claim that infection by contagion does not extend beyond a radius of a few feet from the patient.

If these men that claim fomites not to be a medium for conveyance, should be correct, and infection by contagion should be limited to the area of a few feet from the patient, then is it not highly probable that the great danger is through the agency of a third person in some way. That the poison is given off in the pharyngeal secretions and the saliva there is no doubt.

Many of our late writers designate a class of people who have some form of throat involvement, whereby the bacilli from the throat either in the form of shreds of the membrane or expired air of a diphtheritic patient finds lodgment and a suitable soil for their propagation, yet does not produce the disease. This class of people are designated

as carriers, who tramp the streets, and enter homes, spreading the disease. Solis-Cohen, of Philadelphia, says that these germ-laden throats of the infected constitutes a far greater source of danger than do their garments. This same man states that healthy persons who have been in contact with diphtheria may carry the germs on their mucous membranes without becoming sick themselves, though they are capable of transmitting the disease to others.

Another cause for the dissemination of this disease, is the fact that only well-marked cases are isolated and placarded, while persons suffering from the milder forms of diphtheria are permitted to walk the streets, attend school and frequent public places. A graphic description of these mild cases of diphtheria and of their danger was given by Jacobi in 1897 and as his views have been confirmed by many of our later writers. His description of these mild cases and their portrait so clearly drawn, that we think it well to quote him in this connection: "The symptoms are often but few, a little muscular pain and difficult deglutition are, perhaps, all that is complained of. Women will quietly bear it, men will go about their business. There is as much diphtheria out of bed as in bed; nearly as much out of doors as in doors. Many a mild case is walking the streets for weeks without caring or thinking that some of his victims have been wept over before he was quite well himself. Diphtheria is contagious. Severe forms may beget severe or mild forms. Mild cases may beget mild or severe cases."

The report of the Secretary of the Board of Health of Kentucky for the year commencing April 1st, 1906 and ending April 1st, 1907, states there were 1,068 deaths in Kentucky from diphtheria, while there were only 119 from scarlet fever, and the death rate was so low from small-pox it was not mentioned.

This same report contains the statement that diphtheria as well as other contagious diseases is a preventable disease, and ought to be prevented. While this is true the statistics of boards of health and sanitary workers show that in spite of the ever-increasing knowledge as to its bacteriology and methods of propagation, diphtheria still remains a fairly common affection.

Why is this? As has already been stated one reason is the fact as a rule only well marked cases are isolated and placarded, while persons suffering from milder forms of diphtheria are permitted to go at large. And another unguarded avenue of contagion, according to Solis-Cohen is kept open through the false sense of security given by rules now

in vogue as to disinfection. He states that fomites as proven by Chapin, Hill Weichard and Welch rarely contain the germs, are required to be disinfected, while no attention is paid to the virulent bacilli which so frequently are present and persist for long periods in noses or throats of persons with whom the patient has been in just as intimate contact.

Ignorance of the character of the disease upon the part of the people, and sinister motives of some men who profess to be doctors, are the hindrances that give boards of health and sanitary workers their greatest annoyance. And if these two elements could be eradicated, there is no doubt but what all the funds necessary for effective work, based on scientific observations for the prevention of these diseases, could be secured.

We have all the machinery necessary for prophylactic work in this State, what we need is our machinery put in running order, and co-operation upon the part of the mass of people. As long as prophylactic measures are regarded as measures only to be used by boards of health and sanitary workers preventable diseases will remain quite common.

A difficult problem confronting health authorities in their endeavor to limit the spread of contagious diseases is the control of those who are in more or less intimate contact with the patient. The measures recommended by writers on hygiene and sanitation and those practiced by boards of health in this connection seem, as a rule, to be based on the supposition that such persons carry the germs on their clothing and on exposed skin surfaces, leaving these carriers with infected throats to roam the country, and infect the universe.

Another source in the prevention of the spread of diphtheria, is the time that a subject should be discharged. Should this be determined by a specified time or by an examination of throat to ascertain the presence or absence of the specific germ.

The length of time that the bacillus remains in the throat, in a virulent form after recovery differs in different cases, and is not regulated by the severity of the case, some throats are clear in a few days, others last for several weeks, but no case should be released until after two negative tests have been made or the clinical history is such as to admit of release.

Persons residing in infected houses should be prohibited from attending school or from working at any employment in which they are brought in contact with other people. Restriction might be suspended in the case of those whose throats are shown to be free from the specific germ, and fomites have

been disinfected, provided they remain free when so examined.

The great draw-back to boards of health, especially those in rural districts for the fight against preventable diseases is the lack of funds to carry the work on with. The wealth of a community depends largely upon the health of same. The work of preventive medicine has to be carried on largely by those who are authorized by law to do said work, at least they must be leaders in this work.

Every county health officer should be paid a salary that will justify him in establishing a laboratory sufficient to make all necessary tests for a scientific campaign against preventable diseases. He should be required to make all necessary tests free of charge to all physicians in that county, he should also prepare and keep on hand test tubes with a culture medium, ready for inoculation, same to be supplied to all physicians for diagnostic purposes.

There should also be a statutory requirement that all suspected cases should be reported to county or city health officer, and they in turn should supply them with these culture tubes, which should be inoculated with the secretions of membrane if present and presented to health officer for confirmatory diagnosis. Tubes should again be sent to him to determine the presence or absence of the bacilli in order for removal from isolation.

With a free laboratory at the expense of county or city whichever it may be for culture work, with a statutory requirement for all suspects to be examined bacteriologically there is no doubt but what the number of cases of this disease can be reduced.

With the above machinery, when a case of diphtheria develops if all who had come in contact when discovered were examined bacteriologically, and those who had the germs in throat were isolated and properly treated, the remainder could go free.

I wish to close this short paper by quoting the conclusions as given by Solis-Cohen for the prevention of the spread of diphtheria.

1st. The prevalence of diphtheria is due to the lack of control over latent cases of diphtheria and over the so-called "carrier" cases.  
2nd. Diphtheria may occur in a latent form without pseudo-membrane and with only slight symptoms.

3rd. Latent cases of diphtheria should be isolated until two successive negative cultures have been obtained.

4th. All suspected cases of sore throat should be reported to the health authorities and should be examined bacteriologically.

5th. Infected contacts should be excluded from school or work and should not be permitted to frequent public places until two successive cultures have proven negative.

5th. All who have been in contact with a diphtheritic patient, whether at home, at school, at work, should be examined bacteriologically.

7th. Disinfection of fomites and terminal disinfection of rooms and their contents is insufficient and reliance thereon treacherous. Animate carriers of infection are more dangerous than inanimate.

### THE TRINITY OF THE UROLOG.\*

BY CARL LEWIS WHEELER, LEXINGTON.

The Urological aspect of the microscope, studying urinary findings in diagnosis of pathological conditions of the uro-genital tract. The range of the ureteral catheter. The value of the cystoscope.

To-day with such advances in urology, there are perhaps no three devices more accurate in the aid of diagnosis of pathological conditions of the uro-genital tract than the microscope, cystoscope and ureteral catheter.

The urine under the microscope is indeed of very great importance, but there must be some knowledge of the features found, in regard to their source, location and under what conditions they are present. A specimen of urine to be studied should be centrifuged for three minutes or preferably allowed to stand for six to twelve hours in a cool place for sedimentation, and after which the urine is decanted and the sediment poured into a clean watch crystal. A small camel's hair brush is used to transfer the drop to the slide, and this drop is covered with a three-fourths or one inch cover glass. Care must be taken that the cover glass completely covers the drop, and otherwise that no excess of urine runs out from under the cover glass, nor the cover glass floats.

After the mount has been carefully prepared, it is then placed on the stage of the microscope under a one-sixth lense; with concave mirror; Abbe condenser out; iris diaphragm almost closed, using a one-inch eye piece.

In order to see and clearly define all the features in any given specimen of urine, the magnifying power must be at least 400 diameters. The ordinary custom of using a two-third inch lense and looking at urine smeared upon a slide without a cover glass is indeed a very poor method and should be condemned, because of the great difficulty of seeing

all the features with a magnifying power of only 100 to 125 diameters, besides you are unable to differentiate a red blood corpuscle from one of the rarer forms of calcium oxalate or a cast at times from mycelia and other fungi; and many other confusing errors far too numerous to mention.

In studying a specimen under the microscope it will many times consume one or two hours and therefore it is best to keep a record of all the features as they are found and noting their comparative numbers.

My eminent teacher, Louis Heitzmann of New York taught me to draw in my record book, every feature, its exact size, every characteristic of that feature and its comparative presence with all the other features. This little book to-day is a treasure, it contains scores of sketched records of fresh specimens studied in that laboratory under his personal care and criticism.

In the study of urine it is necessary to know and be able to readily recognize every element likely to be found in a given specimen—this includes normal, pathological and extraneous matter.

Owing to the time allotted me it will be impossible to go into detail such as taking up normal features with their significance, as occurring in acid and alkaline urine. So I will begin with pathological findings and the first of these will be the pus corpuscle, which is absolutely essential for the diagnosis of an inflammation and is taken as a standard for the comparative sizes of the various epithelia.

Pus corpuscles occurring in urine (even in small amounts) is indicative of an abnormal process somewhere in the uro-genital tract, if scanty it is not necessarily an inflammation, but undoubtedly an irritation; if in moderate numbers, the diagnosis of an inflammation can be made, which is the more pronounced the greater the number of pus corpuscles; when they are very numerous, the diagnosis of an ulceration or suppuration may be made—but not without other features.

Every urine in which pus corpuscles are present in any appreciable numbers contains albumin, no matter from what organ they are derived, and the larger the number of pus corpuscles, the greater the amount of albumin.

Pus corpuscles, also called leukocytes, are emigrated white blood corpuscles, partly derived, not only from the connective tissue, but also from the epithelia themselves, the protoplasm of which, becomes changed by endogenous new - formation to inflammatory corpuscles, which later reach the surface of

\* Read before the Kentucky State Medical Association Louisville, October 15-17, 1907.

the epithelia and are carried along by the urine as pus corpuscles.

They appear as small round granular bodies, in which one or more nuclei may or may not be seen and are about twice the size of a normal red blood corpuscle.

*Blood Corpuscles.*—The presence of blood in the urine (except when it is known to come from the female genital tract) is the most prominent objective symptom in urology. So important it is in its general relation to the surgery of the genito-urinary system, that it demands due consideration, especially because it is symptomatic of so many pathological conditions.

The quantity of blood present may vary from an amount sufficient to render the urine slightly turbid to that of almost pure blood.

*Red blood corpuscles* as seen in urine vary in color and size. In fresh urine they appear as yellowish tinged biconcave discs, but in a few hours lose their haemoglobin and become practically colorless—this is the condition in which they are most frequently seen.

When urine is of a low specific gravity, they frequently swell and become hydropic—in this state they are large, pale double contoured bodies—called “Ghosts.”

Also in active hemorrhage, small sized corpuscles may be seen—about one-half the size of the regular red blood corpuscles, but characteristic. These are in process of formation and are called “hematoblasts.”

In hematuria it is always absolutely essential to the physician to discover the source. This can only be determined by the nature of the epithelia found in the urine. If the hemorrhage is mild or of moderate degree, the epithelia can always be found with little difficulty, but in profuse hematuria where the field is crowded with red blood corpuscles, it is necessary to examine many drops before the source of the hemorrhage is positively determined.

*Epithelia.*—In the uro-genital tract we find three kinds of epithelia, viz: Flat, cuboidal and columnar.

Nevertheless, it is claimed by many that it is impossible to differentiate the source of epithelia, but with careful training and a few general points borne in mind, it is not at all difficult, for it is only an accurate knowledge of their source that we can ascertain the location of a morbid process and such processes found within the uro-genital tract are of an inflammatory nature and marked by the presence of pus corpuscles in the urine and the location is determined by the character of the epithelia found.

The arrangement of the epithelia in the

uro-genital tract is either in single or stratified layers, and when in stratified layers are composed of all the varieties; the flat compose the upper layer; the cuboidal and middle layer and the columnar the deep layer which is nearest the connective tissue.

Normally, the epithelia found in the urine is the flat variety, in small numbers, coming from the bladder, while in the female will be seen flat epithelia from the bladder and vagina. The presence of all other epithelia is indicative of a morbid process.

Flat epithelia are irregular in outline, presenting a broad front surface, cuboidal are round or oval and having about the same diameter in all directions, while the columnar are elongated in one direction or rather cylindrical.

All epithelia are granular, with one or more nuclei which may or may not be seen, or else may have dropped out, leaving a vacuole. The granulation is either coarse or fine, the flat are finely granular, the columnar are coarsely granular and the cuboidal have a degree of granulation which is intermediate between coarse and fine.

Care must be taken not to mistake epidermal scales for epithelia; these come from the prepuce in the male and from the clitoris and labia in the female, also from the fingers while handling the cover glass and slide. They are highly refractive, with a jagged contour and do not contain a nucleus.

Remember that the diagnostic point in differentiating epithelia is absolutely the size.

Epithelia may be classed as follows:

- (1) Those common to both sexes.
- (2) Those found only in male urine.
- (3) Those found only female urine.

The epithelia common to both sexes are those from the bladder and the urethra, pelvis of the kidney, ureters and uriniferous tubules of the kidney.

*Bladder.*—Epithelia in the bladder are stratified and all three varieties are present; the flat compose the upper layer and are normally found in health. The cuboidal compose the middle layer and when found are associated with pus corpuscles—which is indicative of an inflammation.

The columnar compose the deep layer—when found are of course associated with pus corpuscles and indicates a very intense inflammation—in fact an ulcerative process.

All cuboidal and columnar epithelia are subject to secondary developments such as glistening fat granules and globules—this indicates chronicity.

Also there is another change where epithelia are seen to have two, four or five nuclei—called endogenous pus corpuscles or endogen-

ous new formations,—this state of epithelia is indicative of pressure by tumor or some process in the immediate vicinity.

*Urethra.*—Epithelia from urethra vary in size and shape, they are comparatively large and irregular—they are seen as being partly flat, partly cuboidal and partly columnar. Their irregularity and simulating double type epithelia make them easily diagnosed.

*Pelvis of Kidney.*—Epithelia from the renal pelvis are cuboidal and smaller than those from middle layer of bladder—the deeper layers are mostly irregular such as caudate, pear-shaped or lenticular. Pelvic epithelia are rarely found alone, nearly always being associated with epithelia from ureter.

*Ureter.*—Epithelia from the ureter are distinctly smaller than those from the pelvis—they are cuboidal and are never very numerous; their diagnosis is rather easy, because they are always found with epithelia from pelvis.

The columnar variety such as caudate or pear-shaped from the deeper layers are seen in deep-seated processes, viz; ulcerations due to impacted calculi or in tubercular lesions.

One of the most confusing points about epithelia from the ureter is that they resemble in size the epithelia from the prostate, and differentiation without other features is impossible.

*Uriniferous tubules of the Kidney:* These are the most important of all the epithelia found in the urine.

We have a habit of calling them “small round epithelial cells” and not for one moment considering they have any significance, also the urine may show only a trace of albumen, with absence of casts. They are never seen normally in urine, and whenever present are associated with pus corpuscles and means an inflammation.

Epithelia from the convoluted and straight tubules of the kidney are of the cuboidal and columnar variety respectively — distinctly smaller than the epithelia from the ureter—and are *one-third* larger than the pus corpuscle.

*Epithelia found in the male,* are from the prostate, prostatic ducts, seminal vesicles and the ejaculatory ducts.

*Prostate and Prostatic Ducts:* Epithelia from the prostate are cuboidal and exactly the same size as those from the ureter. They are twice the size of the pus corpuscles, and are the epithelia in which we most frequently see the endogenous new formations; always seen in hypertrophy.

The epithelia from the ducts are columnar (caudate) variety and distinctly larger than those from the straight collecting tubules of

the kidney. Remember to diagnose a prostaticitis these epithelia must occur together.

*Seminal Vesicles and Ejaculatory Ducts:* Both these are of the columnar variety, while from the vesicles are about the size of those from the prostatic ducts, but are distinctly more irregular and are non-ciliated. Those from the ejaculatory ducts are ciliated, long and slender resembling those from deep bladder, but distinctly smaller.

*Epithelia found in the female* are from the vagina, cervix and mucosa uteri.

*The epithelia of the vagina* are stratified with all three varieties present, the arrangement is similar to that of the bladder: being distinctly larger and many times containing bacteria, they are readily diagnosed.

*Middle vaginal* are a frequent occurrence in the urine, especially of women who have borne children, there being a slight leucorrhoea more or less always present.

*Deep vaginal* are of the columnar variety, resembling deep bladder—but larger, and are present *only* in deep-seated inflammations such as ulcerations.

*Cervix uteri:* Epithelia from the cervical portion of the uterus are very irregular and considerably smaller than those from the vagina.

*Mucosa uteri:* These epithelia are the columnar ciliated variety and resemble those from the ejaculatory ducts—but distinctly smaller. In freshly voided urine these cilia may be seen in waving motion and are indicative of a catarrhal endometritis.

*Connective Tissue.*—This underlays the epithelia in the entire uro-genital tract and is only seen in the urine associated with the deeper seated or more intense morbid processes.

*Connective tissue shreds* vary in size from those so small that they can scarcely be detected with a power of 400 diameters to those so large that they cover one-half or the entire field.

They are made up of wavy, moderately refractive fibres which compose small bundles. At times these shreds may be granular, or contain formations resembling nuclei, which are known as connective tissue corpuscles.

In an ulcerative process these connective tissue shreds are broad and numerous, with pus corpuscles always present.

Also in freshly voided urine will be seen conglomerations known as zoogla masses which are cocci entangled with mucus surrounding the connective tissue shreds.

*Tubercular ulcerations* are determined by the various staining methods and finding the specific bacilli.

Suppuration of abscess formation can be di-

agnosed when the connective tissue shreds are in large numbers and pus corpuscles are abundant, with presence of the characteristic epithelia determining the locality.

The shreds may vary considerably in size—their presence is indicative of a destructive process hence, the diagnosis is made.

Tumors.—The presence of connective tissue shreds are absolutely essential for the diagnosis of papilloma, sarcoma and cancer.

In papilloma the shreds are very large, with branches assuming the shape of coils or knobs—called protoplasmic out-growths of connective tissue, being coarsely granular and containing numerous inflammatory corpuscles and there are also present regular connective tissue shreds in varying amount.

Sarcoma:—In this process we find the sarcoma corpuscles which are seen as groups of glistening, coarsely granular corpuscles, non-nucleated, at times almost homogeneous smaller than the pus-corpuscles and larger than the red blood corpuscles.

The connective tissue shreds are large and frequently contain inflammatory corpuscles.

Cancer.—In cancer of the bladder, especially the villous type, the connective tissue shreds are very large and irregular, forming the cauliflower excrescences and are seen to contain numerous inflammatory corpuscles.

Shreds may contain cancer epithelia or "cancer nests."

Calculi.—Whenever there is a stone present in the urinary tract it is accompanied by more or less inflammation.

Such concretions are formed in the kidney, pelvis of kidney or bladder. Uric acid compose about 75% of all calculi, the next in frequency are the calcium oxalate, while phosphatic stones are less frequent and more commonly found in the bladder.

There is a certain form of uric acid found in the urine that is indicative of stone. This peculiar uric acid formation is not the lozenge crystal, nor the comb or brush variety; but it is a rosette formation, consisting of needless radiating from center to periphery, also variously sized spicules and needles, stellate masses and irregular plates.

When irregular amorphous masses are present, with peculiar refraction, together with the octahedral formations, we may suspect the composition to be of calcium oxalate.

The above findings linked together with the features of an ulceration usually leads to diagnosis of stone.

Case I.—Mrs. H.—, urinary findings were as follows:—Crystalline and amorphous sediment.—Crystals of Ammonio-magnesium-phosphates. (complete and incomplete) fairly abundant.

Red blood corpuscles.—Scanty.

Pus corpuscles.—Moderate.

Epithelia from bladder.—Upper layer, Scanty.

Middle layer.—Abundant (fatty).

Deep layer.—Moderate (fatty).

Vagina.—Upper layer, moderate.

Middle layer.—Scanty.

Connective tissue shreds.—Broad and abundant.

Other features.—Free fat granules and globules. Connective tissue shreds surrounded by zooglea masses. Bacteria and cocci.

Examination for tubercle bacilli. — Negative.

Diagnosis.—Mild catarrhal vaginitis, with chronic ulcerative cystitis.

Cystoscopy revealed an intense catarrhal cystitis with a solitary ulcer about the size of a dime towards the posterior border of the trigone midway between right ureteric orifice and median line.

The ulcer was covered with grayish white film with eroded edges.

Bladder capacity four ounces. — General anesthesia.

Case II.—Determining the source of a "Symptomless hematuria" (3rd attack in 5 years).

Specimen of urine was that of almost pure blood. In the urine under the microscope the field was so crowded with red blood corpuscles that it was almost impossible to make out any other features.

I managed to find some small shreds of connective tissue and epithelia from the pelvis of kidney. So I concluded that the hemorrhage was of renal origin.

Cystoscopy revealed a normal bladder. At intervals from 20 to 30 seconds the right ureteral os was seen to pump almost pure blood.

Urine from the left ureteral os was clear.

To be sure that the blood was coming from pelvis and not from eroded areas along the ureter—I gently pushed a catheter up the ureter—stopping at every three inches and waiting to see if catheter would drain clear. Blood continued until I reached the renal pelvis when the catheter became clogged with clots. I then pushed the second catheter up this ureter to the pelvis to facilitate my drain. Pelvis was lavaged for ten minutes and catheters withdrawn.

Diagnosis.—Hemorrhage from pelvis of right kidney, probably due to small sized tumor.

Case III. Mrs. V.—, "hematuria with intense bladder symptoms existing ten months."

Urinary findings were as follows:

Crystalline and amorphous sediment. —

Concretions of ammonio-magnesium and calcium phosphates.

Red blood corpuscles.—Very abundant.

Pus corpuscles.—Moderate.

Epithelia from:

Convoluting tubes of kidney.—Scanty.

Pelvis of kidney and ureter. — Moderate (fatty)

Bladder.—Upper layers, moderate.

Middle layers.—Abundant (fatty).

Some with endogenous new formations.

Deep layers.—Moderate (fatty).

Vagina.—Upper layers, moderate.

Connective tissue shreds.—Abundant; some rather broad and some very large.

Other features.—Zooglea masses; free fat granules and globules, microorganisms.

Diagnosis. — Chronic ulcerative cystitis; chronic catarrhal ureter; pyelitis with hyperemia of kidney.

Hemorrhage of vesical origin.

Remarks: The cause of such pronounced vesical irritation was very puzzling, from the fact that some of the epithelia from middle layer of the bladder contained endogenous new formations; this secondary change in epithelia is indicative of pressure probably due to some growth in the immediate locality.

The presence of such large shreds of connective tissue pointed to a vesical neoplasm; while the presence of such concretions of mixed phosphates were suspicious of stone.

Cystoscopy.—First cystoscopy was done at home of patient without anesthesia, owing to intense pain the procedure was rapid. A stone about the size of a large hazelnut was discovered within the trigonal area.

Patient was ordered to hospital for operation.

Second cystoscopy (under general anesthesia). This same stone was discovered, but posterior to the trigonal area, to the left at the median line. There was an ulcerative trachelo-basal cystitis, the anterior, posterior and lateral walls and summit of the bladder were apparently normal.

The direct cystoscope armed with a ureteral bougie was introduced. A thrush at the stone with the ureteral bougie to turn it around and ascertain the size and if it was adherant to bladder wall—smashed the phosphatic cap exposing a villous papilloma.

Case IV.—Mrs. S.—, pain in dorsal-lumbar region—mass over right kidney.

Urinary findings as follows:

Crystalline and amorphous sediment. —

Crystals and concretions of uric acid gravel.

Red blood corpuscles.—Few.

Pus corpuscles.—Abundant. (with fat globules).

Epithelia from:

Convoluting tubules of kidney.—Moderate.

Straight collective tubules of kidney.—Few.

Pelvis of kidney.—Abundant (fatty).

Ureter.—Moderate (fatty).

Bladder.—Upper and middle layers (few).

Connective tissue shreds.—(abundant).

Other features. — Putriferous microorganisms.

Diagnosis.—Intense chronic pyelo-nephritis, with areas of suppuration probably due to concretions—a catarrhal cystitis.

Before a nephrectomy was done the surgeon requested a double catheterization with comparative analysis.

Cystoscopy revealed a somewhat congested bladder wall. Right uterel os was pointing, with irregular puckered outline as described by Fenwick denoting past stage of severe pyelitis.

Left uterel os appeared normal, although slightly congested.

Both ureters were catheterized and the catheters driven well up into the pelvis. Cystoscope was withdrawn, leaving catheters *in situ* for ten minutes to obtain separate urines for comparative analysis, as follows:

RIGHT.	LEFT.
Albumin: About 1-30 of 1%	Albumin: About 1-40 of 1%
Reaction Acid.	Reaction: Acid.
Urea: 4 1-2 gr. to oz.	Urea: 3 gr. to oz.
Epithelia from convoluted tubules	Epithelia from convoluted tubules
Pelvis and ureter (fatty).	Pelvis and ureter (fatty).
Connective tissue shreds (moderate).	Connective tissue shreds (large shreds abundant).
Red blood corpuscles (moderate).	Red blood corpuscles (scanty).
Pus corpuscles (scanty).	Pus corpuscles (abundant).
Uric acid gravel (moderate).	Uric Acid Gravel (Scanty).

The result of the comparative analysis shows similar condition in both kidneys, but the process being far more advanced in the right.

Surgeon declined to operate as left kidney was involved and not capable of carrying on renal function.

In a few weeks patient died of general sepsis. At the autopsy both kidneys were found greatly enlarged (about 8 inches from pole to pole) nodular. Pelves very capacious. In the calyces were multiple abscesses filled with stones.

In conclusion:

1. The ordinary methods employed in the study of urine under the microscope (be-

yond the detection of casts) are faulty and almost worthless.

2. The ureteral catheter means separate urines. It detects stones and strictures, and determines their location. It guides the surgeon in abdominal operations. It medicates the renal pelvis; and a continuous catheterization will provoke the closure of a traumatic ureteral fistula.

3. By the aid of the cystoscope we are able to know the true condition of the bladder.

#### DISCUSSION.

Dr. I. N. Bloom, of Louisville: Mr. President: I regret very much to say that I only heard the last few lines of Dr. Wheeler's paper. I am very sorry, too, that the title of the paper gives no index of what the paper really is.

I want to compliment the essayist on the exceedingly fine differential diagnosis he is able to make between the thirtieth and fortieth per cent. of albumin, because during a practice extending over twenty-two years I have never been able to draw such fine distinctions. For the past eight or ten years I have been using the urethroscope and cystoscope when occasion demanded it, and I think during that time I have acquired some dexterity in their use. - I have quite a large clinic at one of the medical schools here, and have demonstrated, so far as I am able to do so, to students, as well as in my private practice, and I have used the cystoscope probably more frequently than those with less opportunities. But I have never been able to acquire that dexterity in the use of the instrument which was mentioned by the essayist. I thought it was owing to my own technique, if you will permit the use of that word, especially as one of my students, who had adopted the same specialty as I have, would spend a part of his vacations in seeing demonstrations, and would come back and tell me the wonders of the cystoscope in his hands, and would mention catheterization of the ureters as glibly as you and I would mention catheterization of the bladder. I do not hesitate to say, that I fail in catheterizing the ureter quite as often as I succeed, without knowing the cause, and I came to the conclusion it was want of skill on my part. This gentleman was in Louisville five or six weeks ago in connection with a case in which I had been called in consultation. I had made a probable diagnosis with the use of the cystoscope. I suggested that at some future time we might try catheterization of the ureters, inasmuch as my instruments were being overhauled by a Rochester firm. The next day, however, this young man insisted upon catheterizing the ureters. He tried to do so, but after an hour's manipulation failed to find them. The patient was then chloroformed, and he tried

another hour and was unable to pass the catheter, and yet this young man had constantly informed me that it was just as easy to catheterize the ureters as it was to catheterize the bladder. I have catheterized the ureters at times and failed in so doing, and apparently without any reason. Why I should succeed in catheterizing the ureters in one case and fail in another, I do not know. But it is not an easy procedure.

In conclusion I wish to say that the cystoscope has come to stay, and is of the greatest value. It is a valuable aid to diagnosis. I have seen cases, however, in which the use of the instrument has been grossly abused, and have seen positive injury done with the urethroscope, but more with the cystoscope. In using these instruments one should ask himself the question, Is the benefit to be obtained greater than the amount of harm I might do? Of course, in exceptional cases it is of the greatest value; but its abuse is not so well understood, and one must be a specialist to find a number of cases in which this aid is being abused by those who are less expert and who use it without sufficient cause. (Applause.)

Dr. Wheeler (closing the discussion): In reply to the remarks of Dr. Bloom, I know it is difficult to catheterize the ureters. I realized it and worked all the harder in order to do it. I have catheterized the ureters of the male (double) sixty-seven times, and those of the female quite a number of times. I have worked with Dr. L. Harris, who has catheterized the ureters in the male over five thousand times. I have seen him catheterize both ureters within twenty-six minutes after the light was turned on.

#### DIAGNOSIS OF TUMORS OF THE BRAIN.\*

BY W. M. EWING, SMITH'S GROVE.

As a rule the diagnosis of intracranial tumor is not a very difficult matter, but the exact location of it is exceedingly difficult and often impossible. The symptoms are of two groups, general and local: general, which are merely those of increased intracranial pressure and local due to the involvement of centres and tracts. The prominent and fairly constant general symptoms are: Headache, which is as a rule early and severe and may be either constant or paroxysmal, oftener the latter. When the tumor is superficial the headache is apt to correspond to the site of the tumor. Pain is almost always present and may be spontaneous or evoked by pressure or percussion. Vertigo, is a common symptom, but is probably more marked in cerebellar tumors than in cerebral. Vomiting, if cerebral in

\* Read before the Warren County Medical Society, October 30, 1907.

origin is of considerable value. Convulsions usually set in as soon as the tumor is of sufficient size to cause pressure and may resemble true epilepsy or may be Jacksonian in character. The eye symptoms are possibly the greatest help to a diagnosis. Choked disk or papillitis is present in more than 90% of these cases and is usually double, but may be monocular, in which case the tumor is likely to be situated in the opposite hemisphere, but if optic neuritis and choked disk are co-existent in both eyes, the site of the tumor is probably the side on which the least swelling occurs. Inequality of the pupils is of little value in diagnosis as it occurs in most all intracranial diseases. Other eye symptoms are—paralysis or spasm of any muscle or group of muscles, and hemianopsia. The local manifestations are, of course, numerous and I shall only attempt to consider them very superficially: If the tumor is situated in the frontal lobe, the intelligence may be only slightly impaired or not at all; the same statement applies to tumors of the occipital lobe, although hemianopsia may be present, as may also visual amnesia or mind-blindness. In the parietal lobe, muscle sense or vision or speech centres may be affected according to location. Tumors of the cerebellum almost always produce marked disturbance in co-ordination, exhibited by their peculiar staggering gait and in contra-distinction to locomotor ataxia is not affected by closing the eyes. Tumors in the different fossae of the skull often give rise to symptoms dependent upon pressure upon the cranial nerves. In view of the fact that, operations have been undertaken for a tumor supposed to be located at a certain point without finding the tumor and the post-mortem revealing that the tumor existed elsewhere or that there was no tumor whatever, Weir and Seguin have laid down six questions, to which, if possible, we must obtain answers in any suspicious case. 1st. Does a tumor exist? This question is determined by the general symptoms of tumor. 2nd. What is the location of the tumor? To be determined by the local symptoms. 3rd. At what depth does the tumor lie? That is, is it cortical or subcortical? As before stated, a cortical tumor can sometimes be diagnosticated by the tenderness to pressure over the area. 4th. Is the tumor single or multiple. If tubercular it is nearly always multiple. 5th. What is the size of the tumor? This is rarely diagnosticated, but depends somewhat upon the severity and progression of the symptoms. 6th. What is the nature of the tumor? If the patient is suffering with a carcinoma, syphilis or tuberculosis, it is most

likely that the tumor is cancerous, syphilitic or tubercular.

As to differential diagnosis:

Tumors of the brain may be confounded with abscess, meningitis, or mastoid disease. In abscess the growth is usually much more rapid and we often have the history or evidence of distinct injury to the ear or nose. Choked disk is more common in tumor than abscess. Fluctuation in temperature, particularly if it remains subnormal for a prolonged period of time, is indicative of abscess and if the patient is syphilitic he is more apt to have tumor. Meningitis is usually accompanied by high temperature, delirium, photophobia and marked rigidity of the cervical muscles. Mastoid disease will ordinarily be accompanied with swelling, oedema and pain in the mastoid region. The initial symptoms of these diseases may be strikingly similar, but subsequent observation will usually prove the diagnosis to be not very difficult.

If the society will pardon the digression, I would like to relate a case which I have had under observation for about a year, until recently when he was sent to the insane asylum. Patient, male, age 57, color, black; of magnificent physique and a splendid type of antebellum negro. He had always been unusually healthful until about two years ago when he began having severe headaches which would only last a few hours. These gradually increased in severity and duration until possibly about six months ago when a paroxysm would incapacitate him for any kind of work for from 36 to 48 hours and the interval between attacks became correspondingly less. About 4 or 5 months ago or approximately 18 or 20 months after his first symptoms, he had a convulsion and subsequently has had on an average of two or three a week which very closely simulated epilepsy and his mentality also commenced to be impaired and progressively continued with the result as aforesaid, insanity. His co-ordination was greatly disturbed. Patella tendon reflex, diminished. Vertigo and amnesia well marked. Family history negative and he denied ever having syphilis. From a summary of the foregoing I correctly or incorrectly, I cannot say which, diagnosed tumor of the brain and I also believe it was located in the cerebellum.

#### ADDRESS ON SANITATION.

By WM. BAILEY,

Chairman of the Delegation from the Kentucky State Medical Association.

*Mr. President and Gentlemen of the Kentucky State Development Association:*

I deem it a high honor to be permitted to represent the medical profession of the State

of Kentucky, before this honorable body, composed as it is of the best citizens of the State.

Loyalty to the State of Kentucky is a characteristic of all its citizens, yet I may safely claim that none are more loyal than four thousand doctors whom I have the honor to represent. Gladstone claimed that statesmanship had no higher or more important function to perform, than securing and maintaining the public health. The State possesses no more valuable asset than this, and by virtue of citizenship it becomes the guardian and preserver of the public health. On economic grounds alone, it can be easily shown that it is the duty as well as the interest of the State to maintain it.

No class of citizens does so much in this work as the doctors. The work of the doctor in caring for the destitute and sick is purely unselfish, and I am proud that he does it promptly and most willingly; and yet you must realize that it is no more his duty than it is the duty of any other citizen of the State. The work of the doctor is purely altruistic in trying to prevent sickness, for you must know that as sickness is diminished, so likewise is his income lessened. Allow me to assure you that this is not too large at best. No occupation to which is given the same time and expense in preparation, and the same amount of arduous labor, but that will yield more of this world's goods than the profession of medicine.

Yet the entire profession is committed to better preliminary education and more elaborate training in our medical schools, before the young doctor is permitted to assume the responsible duty of caring for the sick.

We are endeavoring to furnish you better doctors, rather than more doctors, and our means of securing this end would be to pay him fees better commensurate with the time and expense of his preparation for his work. The average doctor is rarely able to bear the expense of a post-graduate course, yet this is absolutely necessary if he is to keep up with the procession, for sure it is that the science of medicine has in late years progressed so rapidly, that unless he does this or something like it, he will become a back number and should give up his calling.

Now all this is to show you that we are earnestly engaged in the work of State Development. The science of medicine has progressed in late years with wondrous strides, and is becoming more and more nearly an exact one. Only in the last three decades has become developed the so-called germ theory of disease. This has brought us to a more intimate and perfect knowledge of many

diseases, and hence to a more definite cure, but especially has it enabled sanitarians to prevent many of the contagious and infectious diseases.

Much had been done in the way of prevention before this definite knowledge in regard to causation had been developed as witness the prevention of small-pox by the practice of vaccination, as was shown by Jenner at the very close of the 18th century.

Nothing was afterward developed of great importance until the germ theory was demonstrated. Then by it was shown that many of our common diseases were specific in character, and each one was due to its specific cause. With this definite knowledge, it has been an easier matter to combat these diseases by striking at the root of things by combating the specific cause of them. I mention few of these by way of illustration.

The Great White Plague, consumption, is now known to be curable, communicable and preventible. For centuries it is estimated that about one-sixth of the human family was lost by tuberculosis. Since the discovery of the germ of this disease by Koch, it has been demonstrated that no case exists without it, and that it is propagated by the air we breathe, by the food we eat or the water we drink; that no case is ever developed without relation with a preceding case. Hence, with pure air, food and water, the disease would be blotted from the world with the passing of our generation.

Tuberculosis of the lungs is propagated largely by sputum of our sick with this disease, hence the proper care of this will at once limit its prevalence.

Typhoid fever is specific in character, and is always due to the Eberth bacillus. Its local manifestations are in the small intestines, so its control is gained by pure food and water.

Cholera, which has often devastated many parts of the world is known to be due to a specific germ, and is usually introduced into the system by water, so it is no longer the menace to human life that it was.

Diphtheria, the dread disease that has caused the death of so many children, is due to its own specific germ.

Science has developed the so-called serum therapy, by which the mortality rate has been reduced from about thirty per cent. to about five per cent., so it is no longer so dreaded.

The antitoxin of this disease is developed by incubating the horse or other suitable animal until it becomes immune to the disease; when it is found that the serum of the blood

of the animal becomes both preventive and curative for this malady.

I might mention many other diseases curable and preventable, but time will not permit.

Allow me to mention that fearful disease which has been for centuries the terror of our Southern States, often causing in a few short months thousands of deaths, and the loss of millions of dollars. We have not as yet demonstrated the specific germ of yellow fever, yet it has been definitely determined that it is propagated solely and alone by the bite of one variety of mosquito.

The world is fully compensated for the thousands of lives lost and the millions of dollars expended by the United States Government in the Spanish-American war, for the reason that our occupation of Cuba enables us to make that demonstration.

Havana, previous to our occupation, for one hundred and forty years had passed no month without a case of yellow fever in its limits, but after this discovery it passed four years without a single case developing within its borders, notwithstanding many cases were brought into its hospitals from the outside. It was clearly demonstrated that this disease could not be contracted by personal contact, nor could it be transmitted by clothing and things contaminated by being used by the sick, so there is now and will be more fully shown the necessity of great modification in our quarantine. No longer any need for restriction in commerce, or quarantine of persons, provided this variety of mosquito is not allowed to bite the patient sick with this disease, and after becoming infected to bite any one is immune. So the watchword is death to the mosquito and screening the patient when sick.

The Medical Department of the U. S. Army under Surgeon General Sternberg, made this investigation and demonstration. We were extremely fortunate in having Maj. General Wood in charge in Cuba at that time, for the reason that being a physician himself, and understanding fully the great necessity of solving the yellow fever problem, he gave every aid in his power to the committee sent for the purpose by General Sternberg. Too much praise cannot be given these noble heroes who offered their lives if need be for the good of man.

Drs. Walter Reed, James Carroll, A. Agramonte and Jesse W. Lazar, will be always honored by those who appreciate noble deeds. The last named voluntarily submitted himself to the bite of this mosquito, and gave up his life in seeking truth for the benefit of his race. I have no

doubt but that the benefits of this demonstration will last as long as the world shall endure. It is my hope that this and other pestilential diseases may finally yield to the progress of sanitation and be no longer known among men.

I now call your attention to the necessity for rigid inspection and wise supervision of our public schools. Much may be done for the good of defective children during the school age. Buildings and grounds should be sanitary, properly ventilated and heated and clean. Defects in vision should be corrected, so that the child may not lose standing by its infirmity. Certain physical exercises should be maintained if we would have "a sound mind in a sound body."

So often we see the honor man of the class utterly fail in the battle of life, because the physical part of him has not kept pace with the mental. Educate our children so that they can do things, for this is an age in which the all-round man is needed.

The profession of the State has given its earnest endorsement to "The Food and Drug Act of 1906." We feel that this is a long stride for the benefit of all our people, but especially to the middle and lower classes; for it will enable them to know and realize what vile stuff they often eat and drink. Especially do we hope that it will materially lessen the habit of buying and taking of patent medicines. Taking of what they know nothing of, for something about which they know less. We regard this one of the greatest evils of the present day. It is bad enough to take medicine from an educated physician, who knows something of the physiological action of the drug he gives, and also something of the indications for its use by the symptoms of the disease from which the patient is suffering.

I commend to you The Great American Fraud, as so ably set forth by Samuel Hopkins Adams in Collier's Weekly, and also the work in this line in the Ladies' Home Journal.

You will learn something of benefit to the human race as you have revealed to you the composition and properties of such medicines as Peruna, soothing syrups, many drugs containing opium and cocaine. Headache powders nearly all contain acetanilid, which may lessen headache, but may cause the heart to cease its action, which is at least an undesirable result. People of the United States have expended about 75,000,000 dollars a year for these useless and hurtful patent medicines.

Peruna costs about 15c a bottle and sells to a gullible public at the moderate price of

one dollar per. Loyalty to my native State demands that I say to you it is safer and better to stand or fall by the use of some brand of Old Kentucky Bourbon. It will certainly be less harmful, and will more certainly gratify a cultivated taste, especially if mint is added thereto.

Sanitation cannot be assured unless it has the help of the masses, so the education of our citizens in the matter is of prime necessity.

No money expended by the Government, State or municipality yields such large returns as that given to securing public health, yet how niggardly it is doled out. Thousands of dollars can be secured for the stamping out of Texas fever in cattle, when hundreds cannot be had for the benefit of man.

Kentucky stands toward the lowest among the States in her appropriation for this high purpose. If she keeps pace with her sister States, she must realize that this cannot be done without larger amounts of money. Gentlemen, it is up to you to see that the needful is not wanting. Do not conclude that when sanitarians ask for appropriation or the enactment of some law necessary for the development of the State by improving public health, that doctors are after their own personal gain, for you know it is not so. I will say to you that I have served the State on its Health Board for nearly twenty years, and no single dollar has come to me for time or labor, but my chief reward has been in criticism and misrepresentation. I would not have you understand that this has made me pessimistic as to our State development, for I am highly optimistic, and have always felt that in no other way could I have done for my State and for mankind as much as I have in this work.

Take, I beseech you earnestly, this admonition of mine, and believe me that if I shall ever become convinced of the reincarnation of man, I shall pray that I may be a doctor, and be located in Louisville, in this my own native State, my Old Kentucky Home.

#### VARICOSE VEINS OF THE LOWER EXTREMITY.\*

By J. M. SALMON, ASHLAND.

No pathological condition is more familiar to the physician or more distressing to the patient than varicose veins of the lower extremities.

It must be admitted also that the treatment of this condition has been unsatisfactory; a fact attested by the enormous sale of

elastic hosiery and bandages, which like the hernial truss, are the wearer's delusion and the surgeon's reproach.

The failures of the past, however, have led to a more thorough study of the subject and consequently to the development of improved methods of treatment.

A knowledge of the structure and function of veins is essential to an appreciation of the causes which produce varicosities. It will be remembered that veins, like arteries, have three coats, viz: an internal coat, composed of polygonal endothelial cells; a middle coat composed of circular and longitudinal elastic fibers, capillaries, lymphatics and non-striated muscular fibers; an external coat of fibrous tissue.

In all parts of the venous system, except in the abdominal, thoracic and cerebral cavities, valves are found. These semilunar folds of the intima occur usually in pairs and are situated immediately below the points of entrance of smaller into larger veins, thus effectually preventing the flow of blood in the wrong direction.

In the lower extremity the blood returns to the heart through two sets of veins, the superficial or subcutaneous and the deep or inter-muscular.

The superficial veins are the internal and external saphenous which are formed of a net-work of venous radicles on the dorsum of the foot. The former passes behind the inner malleolus, the posterior border of the tibia and the inner condyle of the femur to the opening in the fascia lata where it empties into the femoral vein. The external or short saphenous vein originates from the same net-work or arch and passes behind the outer malleolus, up the posterior surface of the leg on the gastrocnemius muscle and penetrates the deep fascia to empty into the popliteal vein.

The deep veins of the leg are the venae comites of the peroneal, tibial, popliteal and femoral veins. They are usually double and are plentifully supplied with valves.

A very full communication exists between these two sets of veins. It is not an anastomosis such as obtains in the arterial system, but an arrangement by which the blood can readily find its way back to the heart through many different channels.

The principal forces which determine the flow of blood toward the heart in the veins of the lower extremities are: (a) the *vis a tergo* or arterial pressure propagated through the capillaries, and (b) muscular contraction, by which the veins are intermittently compressed, thus forcing the blood towards the

\* Read by title before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

heart, regurgitation being prevented by the valves.

The chief obstacle to the venous return in these vessels are (a) gravity. The Vena Cava has no valves and in the erect posture a column of blood three or four feet high is supported by the veins of the lower extremities. (b) Increased intra abdominal tension, especially during expiratory effort. (c) Tumors (d) Inflammatory changes in the veins. (e) Disease of the heart, lungs or liver.

Continued obstruction to venous return causes insufficiency of the valves and dilatation of the veins. This occurs first in the superficial vessels, for those of the deep set are supported muscles and fascia. Hydraulic pressure soon causes great distension of the weak vein wall, varicose form and, through free communication with the deep veins, the vicious circle described by Trendelenberg may be formed. In this connection the blood passes from the superficial to the deep vessels, whence it courses through anastomotic branches back again into the superficial veins.

This stagnation of the blood causes impaired nutrition of the vein wall with resulting oedema and sub-cutaneous hemorrhages. Undue tension of the skin causes eczema, phlebitis and thrombosis develop and ultimately ulceration occurs.

Recent statistics by R. T. Miller, Jr., based upon 128 cases treated at Johns Hopkins Hospital, show that two-thirds of all cases of varicose veins develop before the fortieth year and one-third before the thirtieth year. Heredity seems to have some etiological significance. Bottomley thinks the important etiological factor is a congenital one.

Of Miller's cases 73 were male, 55 female, 107 white and 21 colored. A history of phlebitis was obtained in 40 cases. Of these 25 were due to pregnancy, 9 to typhoid fever, 2 to erysipelas; 1 to pneumonia; 2 to enteritis. 1 to surgical operation. In 88 cases no inflammatory factor could be found. Since frequent muscular contraction is essential to proper venous circulation it is evident that those occupations which necessitate the maintenance of the standing position for long periods are conducive to the production of varices. Thus motormen, barbers and laundry women are particularly liable to the disease.

The diagnosis of varicose veins as a rule prevents no difficulty. The dilated, tortuous and knotty veins; the oedema, pigmentation, eczema and ulceration of the skin, constitute a clinical picture familiar to all physicians. Incompetence of the valves of the

internal saphenous vein may be demonstrated by elevation of the limb and emptying the vein by stroking. The thumb is now pressed firmly upon the main trunk just below the saphenous opening and the patient directed to stand. The veins fill slowly and imperfectly until the thumb is removed, when they are immediately distended by the reverse current of blood.

Treatment of varicose veins has for its prime object the extirpation or obliteration of the superficial veins and the establishment of a new system whereby the bulk of the blood shall return through the deep veins.

With this object in view many surgical procedures have been devised, the principal ones being (a) division of the internal saphenous vein between ligaments near the saphenous opening (Trendelenberg); (b) Excision of the vein by several small incisions (Casati); (c) circumcission of the leg down to the muscular aponeurosis at the junction of the middle and upper thirds and division of the superficial veins (Schede).

Division of the vein between ligatures after the methods of Trendelenberg and Schede does not insure permanent occlusion for anastomosis may take place around the points of division or even directly through the scar of the Schede cut.

The subcutaneous removal of the internal saphenous vein as suggested by Casati eliminates the main channel and the deep communicating branches thus minimizing the chance of recurrence. This operation has been greatly improved by the ingenious device of C. H. Mayo whereby the vein is subcutaneously freed from the fascia and from its communicating branches by means of a special instrument shaped like a dull ring eurette. In 184 cases this method was successful in 84% (Goerlich). When the external saphenous vein is varicose it should be divided, preferably by the Schede method as modified by Powell. The modification consists in the substitution of interrupted for continuous circumcission of the leg, the intervening bridges of skin serving to prevent interference with the circulation caused by contraction of the scar.

Large leg ulcers are best treated by excision and closure of the defect by Thiersch skin grafts, from the thigh. This plan shortens the period of convalescence, lessens the danger of infection and obviates the necessity for frequent change of dressing.

The technique of the operation is given in the following case report: G. R., age 23, male, single; railway brakeman; family history negative; patient had typhoid fever 12

years ago and was ill for three months. Phlebitis of the left leg developed as a complication. Since recovery he has had varicose veins with swelling and pain in the limb necessitating the use of elastic bandages. Two years ago as a result of slight abrasion an ulcer developed which was healed with great difficulty. Last May, another slight traumatism caused a second ulcer which still persists.

The patient is a well-nourished young man weighing 185 pounds. Height 5 ft, 10 1-2 inches. The internal saphenous vein and its tributaries are varicose, the greatest dilation being behind the inner condyle of the femur and in the upper third of the leg. The external saphenous vein is in the same condition, but of less degree. There is oedema and cyanosis of the leg and foot and marked distension of all the venous radicles on the dorsum of the foot. The Trendelenberg test shows incompetency of the valves. On the outer surface of the leg midway between knee and ankle is a chronic ulcer 2 1-2 centimeters in diameter.

Operation was performed on July 19, '07 as follows:—After thorough and repeated disinfection of the entire extremity by soap poultices, soap and water scrubbing, bichlorid of mercury and alcohol, the patient was anaesthetized and a Martin bandage was applied from the toes to the junction of the middle and upper thirds of the leg, covering the ulcer.

An oblique incision, 5 centimeters in length was made to intersect a line drawn from the middle of Poupart's ligament to the posterior margin of the inner condyle of the femur at a point, 5 centimeters below Poupart's ligament. This incision exposed the internal saphenous vein just below the opening in the fascia lata. The vein was isolated, doubly ligated with catgut and divided between the ligatures. The distal end was now threaded through the ring of the Mayo vein stripper and seized by hemostatic forceps. As the vein was made tense by traction on the forceps the instrument was pushed down along the vein to a point behind the inner condyle of the femur where it was made to project against the skin. A second incision was made at this point, exposing the vein which was divided. The upper portion of the vein, 30 centimeters long, which had been freed by the instrument, was now drawn out through the second incision.

A Schede incision was now made, circumcising the leg (except the integument over the subcutaneous surface of the tibia) down to the muscular aponeurosis. The external saphenous vein was divided and the distal

end ligated. Other large branches were similarly divided and all incisions closed by interrupted sutures of silk worm gut.

An occlusion dressing of collodion and gauze was now applied and the Martin bandage unwrapped until the ulcer was exposed. The ulcer with its indurated margin and thick basement membrane was excised, leaving a clean wound. All hemorrhage was controlled by hot compressed and by torsion of bleeding points. The defect was then covered by Thiersch grafts taken from the thigh and applied directly to the wound. The dressing consisted of overlapping strips of gutta-percha tissue and dry gauze retained by adhesive strips. The entire extremity was now snugly bandaged from the toes to thigh. Seven days later the incisions were found to be perfectly united and the stitches were removed. The ulcer required a few more dressings and healed without difficulty. Three months later after operation there is no evidence of recurrence and the patient is apparently cured.

The experience of those who have made the most careful study of this subject warrants the following conclusions:

1. Varicose veins of the lower extremities is a disease affecting principally young adults between the ages of 15 and 40.

2. It may be cured by surgical operation in about 84% of the cases.

3. Before attempting any operation it must be demonstrated that no serious obstruction to venous return exists in the deep veins.

4. The operation which gives the best results is that which has for its object the extirpation of the internal saphenous vein and the obliteration of its anastomotic branches.

5. In certain cases the Schede cut is advisable as an additional precaution against recurrence.

6. The danger connected with operation is slight, but it exists and lies in the possibility of infection and embolism.

#### THE VALUE OF LABORATORY METHODS TO THE COUNTRY PRACTITIONER.\*

By J. R. COWAN, DANVILLE.

The numbers of articles in our medical periodicals of the last few years, and especially during the last year, discussing the value of the laboratory seem to me to make a consideration of the value of these methods to the country doctor timely and interesting.

The large majority of such discussions has

\* Read before the Kentucky State Medical Association Louisville, October 15-17, 1907.

dealt with the laboratory in the hands of the pure pathologist, the expert who devotes his whole time to this one thing. We can state as an accepted fact that the influence of the laboratory from the discovery of the microscope has been toward greater accuracy. The laboratory has pulled down the most carefully erected structures whose sole foundation was tradition, empiricism and theory. Its object and aim is to furnish facts—simply facts stripped of all theory and speculation. Its influence on the science of medicine has been far-reaching and of great value.

The whole tendency in medicine is, as a result, an earnest effort to attain the highest possible degree of accuracy. It is evidenced in the desire to discard and to weed out those methods which depend upon empiricism and the mythical, vague and mysterious quality called intuition, sometimes called (or most grossly miscalled) "common sense." There are, of course, many facts which long experience has verified, but which are based upon pure empiricism. Such of these as are proven to be facts are of value and will be accepted, but will remain the subject of continued investigation until they become solved problems. But there are too many conclusions based upon propositions whose sole foundation is tradition—a tradition which has had its origin, in many instances, in the hurried publication of unverified results from the imperfect work of some enthusiast.

There is also much discussion in our medical periodicals of such questions as the relative value of the laboratory and the clinic, and, on account of the laboratory work being more accurate in its results and depending upon actual demonstration rather than deduction, the laboratory investigator shows a tendency to underestimate the value of the clinician's opinion, and vice versa, the clinician often regards the opinion of the pathologist as having too little individuality, too little connection with the case. And each is a little inclined to scoff at the work of the other. So we actually find articles in our periodicals upon such questions as the relative value of the scientist and the practical physician. Such articles seem to originate in the doubt as to whether the physician is, or can be, a scientist. But really it is an expression of the question, "Is the laboratory worker doing more for medicine than the clinician?"

Such questions should not arise, for neither can succeed without the other. There can be no alienation of laboratory from clinical methods. They are so interdependent as to be incapable of separate existence. The lab-

oratory has exploded many fine spun theories of clinical medicine, and the final bedside test has set at naught the work of the laboratory upon which have been founded the highest hopes. Within my own limited time spent inside the medical body I have heard much ridicule cast at the science of bacteriology and laboratory examinations in general.

At this time there can be no excuse for the continuation of such opinions. The medical periodical comes to every man's office, and he can not fail to keep himself in touch with something of the present development of medical science if he reads his periodicals at all. It does not require an intimate knowledge and ability to carry out the technique to be convinced of their value. Even if he knows nothing of the use of the microscope, he is forced to know that its value to medicine can never be calculated.

It is not to be expected that a man can keep so well up in all the many departments of medicine as to be able to take his place as an expert in its every branch, but unless he does read enough to know something of what is being done in these branches he is already so far behind the procession that he will never catch up. There is such a constantly increasing specialization of work in medicine that no one man can do more than keep himself posted upon the more important results of these several branches. In our large cities the matter has so divided itself among numerous men that every man has at his disposal and for his help the skill and peculiar knowledge of some one man working solely in a separate branch. The value of this combination cannot be over-estimated. Even in our smaller cities the division of the work has advanced to quite a degree of helpfulness by developing the efficiency of those men who can devote their whole time to specializing. The more that the work and investigation in the medical sciences is divided up, the more time there will be devoted to individual problems. And each problem will, by this natural selection, be assigned to those men whose acquaintance and experience with it make them peculiarly fitted to deal with its intricacies.

But this does not mean the alienation of the laboratory and the clinic. For without the clinic where would come the problems for solution, or the material for experimentation? In fact, without the clinic there would be no need for any such experiment at all. And where is to be found that supreme test of the correctness of laboratory research and consequent suggestions save at the bedside? But the specialization in medicine means

more than the separation into the abstract investigator and the concrete dealer with individual cases. It means that the laboratory methods must be evolved by one set of men and must be judged of by another set. The clinician will always be the man to have the last say upon medical questions. The true value of any medical discovery is not to be estimated by its scientific accuracy nor by laboratory methods, but always depends upon its value to the clinician at the bedside, in other words, to the ultimate object of our calling—to sick and suffering man.

We, who live in the country, have little time to specialize. It is incumbent upon us all to prepare ourselves to the best of our abilities, and then, not to sit down and let the years pass us by and leave us nothing out of the great accumulation of their knowledge, but to keep on preparing ourselves until the last.

A man comes out of a medical school, provided his opportunities have been good, fairly well equipped to begin to acquire his education. And this education can only be secured by continually keeping up as well as he can. If he lives in a large city he may select a specialty, keep up in his own branch and depend upon others for help in the other branches.

But what of us who live in the country? Simply because the great mass of new matter turned out year by year is too much for any one intellect is no reason why the country doctor should not show in this particular, as he does in all others, evidence of ability to surmount great obstacles.

The city physician is, by reason of his environment, stimulated to mental effort. His surroundings, his contact with thinking men of other professions than his own, but more especially, his close association with the earnest thinking men of his own calling, are constant spurs to bring out all that is best in him.

If we say it is impossible that he should contribute to the advance of scientific medicine, then we must cease to point with pride to all that is meant by the marble shaft in the old Presbyterian Church-yard, in Danville. There must be something inspiring to every local man to think of the great feat of Ephraim McDowell, a country practitioner, in that town, and at a time when the obstacles to advance were relatively far greater than now, he has given to the world one of the greatest achievements of medicine.

The country physician, on the other hand, is isolated; he must meet, single-handed and alone many of the exigencies and unravel many of the problems which are presented to

his more fortunately placed city brothers. He lacks the great advantage of large clinics, which offer the city practitioner such great opportunities, not only for observing a great variety of cases and a great many cases of these varieties, but it gives him the opportunity for putting into practice the many suggestions of which he reads. And yet the real important feature of the large clinic is not in the above enumeration, but, it seems to me, lies in the great opportunity for training, under the very best possible circumstances, the powers of observation; for developing to their highest possible attainments all the faculties.

The association with a body of earnest, hard-working and high-minded colleagues at the same time serves as a stimulus to good work and keeps a man from dropping into routine methods.

The country practitioner lacks the advantages of the clinic; in the more isolated regions he is alone and has no associate with whom he may share responsibilities, or from whom he may derive inspiration. In the towns we do have fraternal relations, which, in the writer's judgment, are capable of producing more valuable results than they do now.

The meetings of the county and district societies show an appalling lack of interest.

We do not meet together and spend pleasant and profitable evenings simply on account of a state of lethargy which has overtaken us. And I am free to say that I believe this chilling lack of interest is due to the feeling that we have nothing of interest to talk about.

We feel that the old story of typhoid fever and appendicitis has been gone over again and again until the subject is thread-bare. We feel that we have said all that we know how to say upon pneumonia, pleurisy and obstetrics, and all of these commonplace topics. It is not that the diseases have changed and modified with the passing of years. They are the same entities as years and years ago, but the change has come from the continued advance putting new interpretations upon them; lending thread-bare topics the keenest of new interest.

And I challenge any member to say that it is impossible to introduce into our county societies the same new features, in kind, if not in degree, as are introduced into the great medical meetings in our large cities. There is not a man among us who does not have a large number of cases every year which, if we would apply to them the discoveries of the newer pathology and methods of investigation, would yield a big return,

not only in the interest of the individual case and cases of its kind, but in every other case; an interest arising from more accurate observation.

It is impossible, from the very nature of the circumstances, that the country practitioner can develop himself into a specialist in every branch of the great domain of medical science. But the limits of his progress and of his improvement are to be determined solely by the amount of earnest, conscientious effort devoted to it. It may be impossible that he should invoke immediately the perfected efficiency secured by the rapidly changing methods of investigation. It may be that he has got to be always a little behind, but just how far he will be behind depends upon himself. If he dismisses the subject of using laboratory methods in their highest development he will never use them at all. But if he will diligently set himself to apply such methods and to adapt them to his changed conditions, conditions modified by his circumstances, and give his whole-souled attention to this adaptation, the degree of proficiency to be attained will be limited by the amount of endeavor. It is perhaps not possible, at least not probable, that he will do much to advance the science of medicine; but it is possible that he can, if he tries, prevent the procession from leaving him behind. And the recompense for such effort is to be found in the endeavor itself.

There is another element—in the use of scientific apparatus to aid us—we are using instruments of precision, which are bound to inspire an admiration for accuracy. Accurate investigation leads to the keeping of records, and as soon as a man begins to put down in writing the results of his investigations of a case, he immediately discards guess work. And many of the most valuable methods employed in the laboratory are open to the country practitioner.

It is quite true that he cannot refer all of his work to the pathologist. Some of it he can send away to some of the city laboratories for an expert opinion, but some of it is of a nature which requires him to be his own bacteriologist or pathologist.

The mere fact that the determination of the tubercle bacillus in the expectoration is a simple and easy procedure withdraws any excuse from the man who fails to apply it. And if the tubercle bacillus, why not others?

There must always be certain portions of laboratory work which will require the attention of the expert, the man who is doing this every day of his life, and who does it to the exclusion of all else. But if the coun-

try practitioner once acquires the laboratory habit all else will come of itself. Even in the case of the simple instance I have mentioned—if a man once reduces an apparently difficult diagnosis in one single case to a practical demonstration—he will never be satisfied again with any other methods. It is likely that from time to time he will be compelled to stop without perfect satisfaction, and it is just this—that he is not satisfied—that makes the difference.

The great ability displayed by some of our country practitioners, their ability to overcome obstacles, is an example worthy of our emulation. The employment of accurate methods not only brings in the individual instance an accurate result, but it begets the habit. It brings us to be unsatisfied with tentative diagnosis and expectant treatment. It leads us, and especially if we make records of our cases, to, as nearly as possible in every instance, draw conclusions which will satisfy all the symptoms. And then to extend our accuracy further than the diagnosis—to think of our case as a pathological entity and not as a symptom complex.

No one will contend that there is not sufficient value attached to urinalysis to make it incumbent upon every man to equip himself to make the commoner urine tests, and to make a microscopical examination of the sediment. These are easily extended, and from the detection of sugar in a case of diabetes to the quantitative estimation is not a long step. And yet this is not only the only means of diagnosis, but practically the only indication of the progress of the case.

The isolated situation of the country doctor imposes upon him the absolute necessity of doing such things, if they are to be done at all. Laboratory methods are of just as much value to the country as to the city practitioner. The only difference is the difference in circumstances of the two, requiring adaptation of city methods to country needs. It is possible for every man to fit up a laboratory with the simpler and more essential apparatus at a small cost. If he has his urinalysis outfit, including his microscope, the expenses are not so great. Very satisfactory culture media can be purchased already prepared, and he may, in this manner, escape the potato-peeling preface to his course in bacteriology. Blood analysis, except the more complicated and unusual processes, is open to the country practitioner. It is not my purpose to attempt to define the lines of limitation for I believe they depend wholly upon the persistence, and conscientious effort of the individual.

Arising from the very necessity of his

relying almost wholly upon himself is the duty of the country practitioner to keep himself prepared for any emergency. I believe in direct proportion to the effort made, so will the benefits of laboratory work accrue to the country practitioner.

There can be no argument as to the great importance of establishing early in every case of acute inflammation of the throat a definite and accurate diagnosis. We also know that such a diagnosis is impossible except from a bacteriological examination of the throat. Such examinations as the detection of the Klebs-Loeffler, the tubercle bacillus, the gonococcus, the pyogenic organism, the plasmodium malaria, the Widal reaction for typhoid, are a few of the examples of the simpler and at the same time most needed bacteriological work, and all open to the country practitioner. For the Klebs-Loeffler he needs culture tubes of the Loeffler serum mixture which are very satisfactorily prepared by the large manufacturing chemists, and an incubator. For the rest he needs only the simple analine dyes, his microscope and oil immersion lens. For the Widal reaction, it is possible to get from one of the large laboratories a pure culture of the typhoid bacillus, which he can keep alive indefinitely by transplanting; for this he only needs the high power of his ordinary objective, No. 7, Lentz.

As I have said before, the more recently perfected stains recent in the last few years, make it possible for the country doctor to do good work in the examination of the blood. The stain called Leishman's is not easily made, and is best secured from some of the large laboratories. A blood film stained with this solution will tell the careful observer almost, if not quite, all that is to be learned from the blood.

The examination of the stomach contents has been so simplified as to be within the reach of the general practitioner. I believe, however, that in case the country practitioner gets "rusty" on any of these matters he can almost take a post-graduate course in his own laboratory by sending to some of the city laboratories and securing mounted specimens. A careful resume of any subject with such specimens before him is of immense value.

There are, I believe, many things in the laboratory which must always be done by the laboratory expert, the man who devotes his whole time to this subject, who is doing the same thing day after day and perforce becomes unusually proficient in it. To him, I think, must belong many investigations in pathological histology. I do not think that the average country practitioner can have

sufficient material to keep him up in this branch. The examination of uterine scrapings, of the stomach contents for cancer cells, is more difficult than the bacteriological examinations, but again, these depend entirely upon the persistent effort of the individual, and this makes the only limitation.

The value of the laboratory to the country doctor is, then, to be summed up in the following conclusions:

(1) Its value in dollars and cents.

Any agency which will increase a business along profitable lines is a valuable asset. In the country community more than elsewhere the results of the physician are discussed by the laity. His successes and his failures are considered and compared with those of his competitors. The intelligent layman can and will distinguish the difference between the authoritative and forcible statements made by the physician who has applied to the cause under investigation accurate, scientific methods and the hesitating, ambiguous expressions of the man who has jumped to conclusions. The right sort of self-confidence, arising from accurate knowledge, begets a confidence in the patient which is the physician's most valuable asset. Such confidence is bound to increase the amount of his business and improve the character of his clientele.

(2) Its value to his patients.

Anything, which increases his efficiency and contributes to his professional attainments, must redound to the good of his patients. The patients of the country doctor are as much isolated as he, and must depend wholly upon him: he is, therefore, in duty bound to give them a compensation for this absolute dependence. But a consideration of the value to the patient implies a doubt of its value in general, which has been settled beyond discussion.

(3) Its value to himself.

And here is to be found a value peculiar to the country doctor. He must find within himself his inspiration to good work. As has already been said, he feels his isolation deeply, and envies his city brother his constant association with earnest, thinking men of his own calling. It seems to me that the laboratory offers to us who live in the country our only means of keeping up with the times and our only stimulant to persistent effort toward self-improvement. The country physician, after a long, cold drive, is too often prone to rush through his investigation of a case, jump to a tentative diagnosis, and apply expectant treatment, blindly depending upon the powers of nature. It may be urged that the country physician cannot systematize his time, and, therefore, lacks opportunity for

laboratory work. This may be answered by saying that there is no class of men doing more work for which they receive no return, either in money or gratitude, than the country physician. And if he will do less work of a certain sort in order that he do a smaller amount of work of a better sort he will be more worthy of compensation. There can be no question that patients are willing to pay a physician, in some measure, in proportion to his ability. If, therefore, he increases his ability by the use of the laboratory he can make his time so spent pay him a return in his greater ability, represented by an improvement in the size of his fees.

The country physician is, too often, an empiricist. He, perhaps more often than any one else, fails to distinguish between *post hoc* and *propter hoc*. This propensity is evidenced in the testimonial "literature" circulated by the proprietary nostrum. This literature often forms the major part of his reading, and is, not infrequently, his whole library so far, at any rate, as his therapeutics is concerned. The desire for accuracy, born of the laboratory, prompts him to discard such sources of information and tends to stimulate him to more profitable reading.

If he is engaged in the application of laboratory methods he is very apt to keep himself posted and keep in touch with his profession.

The chief value in this regard, as in all others requiring mental and intellectual effort, comes in the improvement of the man himself; and, as was said before, the compensation for such endeavor is in the effort itself.

---

### MEDICINE'S SACRIFICE.

[Philadelphia Public Ledger.]

Medical science makes temperately a claim upon the gratitude of the race. In London, New York and Chicago the profession announces that recent progress in the cure and prevention of disease has gone far enough to diminish distinctly the incomes of practicing physicians. If this be true it is a magnificent message of service to humanity.

Without asking for further proof it may be accepted as true. Sanitation, the conquest of infant disease, the lowering of typhoid percentages, aseptic surgery, the acquaintance with food values, the development of scientific nursing and the control of germ enemies are achievements known to everybody. Medical practice has simplified itself at its own pecuniary cost, while it has never faltered in promoting the investigations

which result in the diminution of its earnings.

To medical science and practice we can bow with respect and gratefulness. Their labor has been incessant, their intelligence lavishly applied, and the collective reward is a reduction of income. Their title to the name of benefactors should at least have hearty recognition.

---

### CORRESPONDENCE.

I don't know whose duty it is to attend to the McDowell Park in Danville, and I am not aware of any provision made for that purpose, but I want to call the attention of the profession of Kentucky to the matter. Being in Danville a few days ago, I strolled out toward my alma mater, Centre College, and on the way walked through the park to see the Ephraim McDowell monument erected by the Kentucky State Association in 1879. The condition of the little cemetery is a disgrace to our profession. The falling leaves had been burned and at least one-fourth of the grass was destroyed, even to within a few feet of the McDowell monument. There was a broad pathway running diagonally from the corner of the "old First Church" to a point near the college campus, which path is being washed out by rains; there is a gap cut in the barbed-wire fence and stock have free access to the grounds; dead weeds keep silent vigil over the dear departed of a former generation.

It is a shame, a disgrace, to the community where the remains of the "father of ovariotomy" rest. Something should be done either by the profession of Kentucky, or the city of Danville for the proper care and maintenance of that sacred spot.

Very fraternally yours,

J. B. KINNAIRD.

---

### IMPORTANT TO COUNTY

#### BOARDS OF HEALTH.

All members of county boards of health will be continued in office under the commissions they now hold until January 1, 1909. This action is taken after careful consideration under the provision of the law which continues these officials in office "until their successors are elected or appointed."

J. N. McCORMACK, M. D.

Secretary State Board of Health.

January 1, 1908.

## COUNTY SOCIETY REPORTS.

**Adair.** — To the Adair County Medical Society. Gentlemen:—As our program committee has not published a program for the meeting to-day, I have concluded to give you a short account of my attendance at the State Medical Association which met at Louisville in October. I went as a delegate from this society, and you have a right to ask of me a report of my trip, and an account of my stewardship. I had been notified that the president had appointed me chairman of the committee on public health and sanitation, and that was somewhat embarrassing to me, for I had not the remotest idea of what would be expected of me. The house of delegates were to meet at the Galt House on the night of October 14th and that was another stunner to me. The Galt House I had often heard of it. I had several times seen the outside of it, but had never expected to be called to be chairman of a committee to meet on the inside of that wonderful building. But the night came, and I made my way to the appointed place. I was on time. I wish more of our county society would make it a point to be on time, I found the place of meeting, and several members had preceded me. I knew nobody. Fortunately A. T. McCormack, the secretary of the State Medical Association knew me. He had me to write my name on a card, and pinned on the lapel of my coat a red cross pin that he said cost about six dollars. Then I felt like I was a full-fledged delegate. In a little while the house of delegates met. The roll was called, and as the name was called the delegate was to stand up and make a short report from his county society. I wondered if they would call by counties. I knew I was from Adair County, and that it stood at the head of the list. That was the first time that I had ever been sorry that I belonged to Adair County. At that time I wished that I belonged to Woodford or Webster, or even Whitley, but I had not long to wait. The secretary said he would call by counties, and Adair was called. I rose up. I always rise when my time comes. I made a very short report. I said a few good things about our county society, and a few bad ones. I never expected to hear from that report again. But it came out in the next State Journal, just as I said it. But I was pleased to find quite a number of other delegates that knew as little about what was expected of them as I did. The end finally came, and I rested easy, and that night I slept well. On the morrow the society proper met, I felt more at home, for I met with quite a lot of doctors with whom I was acquainted. The first thing on the program was an address of welcome by His Honor, R. W. Bingham, Mayor of the city. I was wondering

all the time while he was speaking, how so young a man, how so little a man, could make such a big speech. The speech was a grand one, and the large audience enjoyed it. The response by Dr. Aud was fully up to the occasion. The meeting was now fully opened, and ready for business. The president of the State Medical Association, Dr. Griffith, now made the annual address, which was very fine, and very well received. I was pleased to see that he was president in fact, as well as in name. After this the regular business was taken up, I cannot begin to report the proceedings, all the essayists were limited a to time, and the presiding officer would not allow them to go over it. There were a few questions discussed that interested me. One on obstetrics that caused me to wonder greatly, wonder how it was that before germs were invented, before sanitation was ever thought of. Before the causes of septic troubles were known, that women were ever delivered of babies and lived, I know from a long experience that they did—I, myself have been practicing obstetrics for nearly fifty years, and practicing back in the hilly country where modern methods were unknown, among black and white, among the high and the low; among squalor and filth; among cleanliness and dirt, I was never noted specially for tidiness; frequently an arrival to be hurried to the scene by the blowing of trumpets, and ram's horn, giving me no time to even wash my hands; yet I have never had a woman to die on my hands; I attributed this, not to science on my part, but to good luck, and to the saying of the Apostle Paul who said in his letter to 1st Timothy speaking of the suffering of women, nevertheless she shall be sound in child-bearing. And while I am not practicing obstetrics much now, yet I am sometimes called in consultation with an old granny, who had been working with a woman in labor for two or three days, using all the teas known to the catalogue, flying in the face of all sanitation, and yet these women get well just the same as if all modern science had been applied. I am not writing in opposition to modern theories, but to show that it has been overworked, overstated, and exaggerated. I was pleased with the female Dr. Gross' lecture, she seemed to understand her business, and had no meek modesty about her: I really thought, however, that to carry out her suggestions in a case of obstetrics, one would have to be called to a case about two days before the labor sets in. Then we had an address from a name-sake of mine, Dr. Taylor, of Greensburg, on how to treat pregnant women. It was a very able address, but if his suggestions were carried out in every case, there would not be doctors enough to go round, as one doctor could not take care of more than three women at the same time, and each husband would have

to be very rich to afford it, as each bill for the nine months would not be less than five hundred dollars, still it was a fine address, but impracticable in a country practice. I regretted that I was called home before the session closed; I did not hear the address of Dr. Simmons, the Secretary of the American Medical Association. There were several things of interest that I did not hear, but I heard enough to make me want to attend the next, and all the meetings of the State Medical Association.

U. L. TAYLOR.

**Allen.** — The Allen County Medical Society met in the office of A. L. Wagoner, and House, on the morning of December 5th, 1907, and the following officers were elected for the year 1908:—M. Whitney, of Gainesville, president; W. E. Meredith, of Scottsville, vice-president; A. L. Wagoner, secretary and treasurer. H. M. Meredith was re-elected delegate. At the completion of election of officers H. M. Meredith read a paper dealing with the excuses that are often given for doctors failing to attend their county medical society and their prescribing patent and proprietary medicines, which was discussed by all members present, and led to the introduction by the secretary of a resolution same as one sent out by State Secretary to all county societies and insists on their passage; resolution was discussed by all, and the society finally passed it, going on record as disproving the patent medicine business and was going to quit prescribing the stuff.

At this meeting we had with us E. Rau, councilor for the district and Lillian South, assistant editor to the Journal. While our number was small, we all enjoyed their visit in the highest degree. We have known Dr. Rau for several years, and we are always glad to see him; he is so popular here that he even has dogs named after him.

We have always read the State Journal with a great deal of pleasure as well as the profit we gain therefrom. And while we admire the editor very much, yet we are constrained to believe that the assistant editor put the spice in it, and we all like spice. By the way, if the editor makes a date with you and sends his assistant, receive her, for she will fill his place, except in space. Dr. Rau and Dr. South, we welcome you with us. Come again.

A. L. WAGONER, Secretary.

**Anderson.** — The Anderson County Medical Society met at the office of J. L. Toll at 2 o'clock December 2nd, 1907, with the following members present: — C. W. Kavanaugh, Paynter; Toll, Lillard, Gilbert, Allbright, Pindar, Johnson, and Murdock.

G. D. Lillard gave an interesting lecture on

the treatment of la grippe in its many manifestations, his ideas being, in brief, as follows:—Isolate in all cases, especially from cases of tuberculosis, as la grippe is especially severe in this class of patients and all means should be used for protecting them. Use quinine, salicylate, salophen, antipyrine, but most of the treatment is symptomatic

**G. H. Allbright:** Each and every case is, as a rule, a case unto itself. Gastric derangement and some biliousness present in nearly all cases. Give calomel in small doses. Dover's powders and phenacetin to relieve aching and muscle soreness. Treat other symptoms as they arise.

**J. L. Toll** called attention to the depression that accompanies la grippe, and therefore we should be doubly careful in the administration of coal-tar products. It being best to give some stimulant, whiskey preferred, along with them. Some form of opium is often preferred to the coal-tar products, but they have the advantage of not locking up the secretions. Quinine is indicated often.

**J. R. Johnson** indorsed G. H. Allbright's treatment; also believed in free use of whiskey. He also called attention to the unusual sequella of la grippe, insanity being one of them.

**C. W. Kavanaugh:** La grippe, like malaria, has lots of things charged up to it, but we have no specific as yet for la grippe. Opium and its preparations preferred to relieve the pain, morphine being used where there is no idiosyncrasy. Salicylates and coal-tar products, using whiskey along with coal-tar products. Don't use salol. It is a powerful irritant to the kidneys.

**J. R. Murdock:** Use lots of whiskey. Cap-hernin an excellent remedy in 5 gr. doses. It relieves all pain and does not close up secretions.

**C. M. Paynter:** Difficult of treatment on account of various kinds. Do not have much faith in coal-tar products. Use hot whiskey, hot lemonades. Treat complications as they arise.

**G. D. Lillard** closed the discussion, and said that like C. W. Kavanaugh he had ceased almost entirely the use of violent purgatives, using something mild, like castor oil. His favorite prescription for la grippe is:

Salol

Phenacetine ʒʒ gr. iss

Salicylate Quinine gr. iv

Repeat as often as necessary.

**J. R. Murdock** reported a case to the society which he had operated on for gall-stones, assisted by Dr. Lillard. They found extensive adhesions, and a cancerous condition. The adhesions were broken up and he reports the patient doing nicely, all the jaundice having disappear-

ed, evidently having been caused indirectly by adhesion.

Drs. Shoemaker and Duff were elected to membership in the society. The following officers were elected for next year:—J. R. Murdock, president; G. H. Allbright, vice-president; J. W. Gilbert, secretary; C. W. Kavanaugh, delegate; G. D. Lillard was elected to board of censors, and was appointed chairman of committee to wait on our representative-elect and interest him in such legislation as was favored by the medical profession. Adjourned to meet with C. W. Kavanaugh, Jan. 6th.

J. W. GILBERT, Secretary.

**Barren.** — The Barren County Medical Society met December 10, 1907, C. W. Froedge in the chair. Owing to the inclement weather, the attendance was small. R. S. Plumlee reported a case of multiple neuritis following a "diphtheroid" sore throat. The paralysis involved lungs and diaphragm. Treated with strychnia arsenate, massage, and salt baths. Patient improving.

**J. C. McCreary** reported a case as follows:—Man, 40 years old, left home at 9 A. M. Family became uneasy. Found him about 2 P. M. near the railroad unconscious. Gave strychnine and saline enema. No change at 9 P. M. At 1:30 A. M., said bowels wanted to act; arose, called for shoes, put on gown, went across the yard to closet, had a good evacuation of bowels and kidneys, and came back to house feeling as usual.

The opinion of the society is that the man had hysteria.

Officers were elected at the afternoon session as follows:—J. M. Taylor, president; A. T. Botts, vice-president; R. S. Plumlee, secretary; S. T. Botts, censor; R. S. Plumlee, delegate.

The society then took some time discussing means to increase its membership.

We have twenty members in good standing, one of which does not belong to the State Society. We have in the county, after discharging our colored doctor, homeopath (who advertises his special school of practice), and two old doctors who can not well attend, and the doctors who are druggists and do not propose to practice at all, twelve doctors who might be considered available for membership. Five of the number are non-graduates, and seem to prefer the home rather than mix up in medicine and politics. They seem to think doctors and politicians are bad men. Will tell you later about the nostrum business.

R. S. PLUMLEE, Secretary.

**Ballard.** — The Ballard County Medical Society met at Lacerter December 10, 1897, at 9 o'clock A. M. Secretary being absent, for the

first hour the minutes of previous meeting were not read. First order of business was to elect new officers. The following were elected for 1908: W. F. Stevens, president; S. M. Dorris, vice-president; H. V. Usher, re-elected secretary and treasurer; Jno. R. Baker, censor; W. A. Ashbrooks, delegate. Applications for membership were two:—B. F. Morris, of Lovelaceville; C. E. Harkey, of Lovelaceville. Committee of Investigation appointed and reported favorable on both applications, so they paid their dues for 1908 and became members of our society in good standing.

First on programme—W. A. Ashbrooks, subject, LaGrippe; the paper was an excellent one and well discussed by several members.

**C. E. Purcell**, of Paducah read a paper on Hypertrophy of Tonsils. He advises removal in most every case reported. Several cases he had operated on with real good results. He has abandoned the use of the regular tonsillitome and only uses the curved scissors and forceps; says the former will not get a thorough removal of the tonsil. Also had specimen of an enucleated tonsil, showing very plain the capsule; says he had never had but very little hemorrhage from this operation. Discussion by J. C. Boone, W. F. Stevens, J. B. Payne, and J. W. Meshaw.

**J. C. Boone** reports case in 16-year-old girl who died from hemorrhage in removing the tonsil, which was an extremely rare case. He also read a paper on Tuberculosis, giving chiefly the causes and prophylactic treatment. Paper was discussed by J. B. Payne, J. D. Rallings, W. F. Stevens, T. M. Baker and J. W. Meshaw.

**J. W. Meshew** met the admiration of a good many in his talk by very bitterly opposing the kissing habit and more especially babes.

As it was growing late the program was dismissed for another business.

A vote was taken on the repeal of the exemption law, or the law you have just referred me to in your letter of December 9th. The vote was unanimous in favor of same and a committee was appointed to petition to our representative in our behalf to vote for said bill, at the next legislative meeting.

You will find enclosed \$22.00 for dues of the following members for 1908: — J. W. Meshew, Barlow; W. A. Page, Barlow; T. M. Baker, Lacerter; W. F. Stevens, Lacerter; C. N. Merriwether, Lacerter; J. C. Boone, Wickliffe; N. L. Rogers, Wickliffe; W. A. Ashbrooks, Lacerter; R. F. D. No. 2; J. E. Martin, Lacerter; C. E. Harkey, Lovelaceville.

B. F. Morris, Lovelaceville, who is from Mayfield, and wishes to have his Journal sent to Lovelaceville. The following places were selected to meet at during 1908:—Second Tuesday in March, Wickliffe; second Tuesday in June,

Blandville; second Tuesday in September, Barlow; second Tuesday in December, Lacenter.

Yours very respectfully,

H. V. USHER, Secretary.

**Carlisle.** — The Carlisle County Medical Society report is as follows:

Dear Doctor:

I enclose you a sketch composed by myself of our last county society meeting. We meet again at Bardwell, December 3d. W. E. Gholson, of Kirbytown, is our efficient secretary.

We have an excellent county society, one of the best, we think, in the State. All in attendance, and in addition to these G. A. Thomas, J. R. Owen, F. N. Simpson, T. D. Bugg are excellent members, contributing by their presence, papers, and activity in discussion, their share to the interest and profit of our meeting.

There are just sixteen doctors in the county.

All the active practitioners of our county are members of the society except T. L. Lanikin, who was until recently one of our best. He quit on account of a matter between our county board of health and himself. We hope to win him back. O. R. Kidd is a member, but he has gone to Paducah. Reports of our meeting show that we have an attendance of from seventy-five to eighty per cent., and have reached ninety-four. We usually have from four to five papers; often we have had to carry over one until next meeting for lack of time.

We get along pleasantly, more so than the profession in any other county where I am well acquainted.

There has been no malpractice suit in our county for about fifteen years; in fact one the doctor easily won out, but it cost him about \$3.00. That is the only suit of the kind since I began the practice, Sept. 11, 1868. I feel quite sure.

I greatly regretted that I could not attend the State meeting. We appreciate the honor conferred upon one of our members and through him our County Society.

ROBERT T. HOCKER.

**Carter.** — The Carter County Medical Society met in regular session at the office of J. P. Huff, president, in Olive Hill November 12th, 1907, and with eleven members present had a most interesting session. Dr. Gilbert read an able paper on tissue elements; typhoid was aired and had much light thrown upon it by several present.

Some frowns, but more smiles were noticed when the resolutions were read condemning nostrums and proprietary medicines not found up to the standard and also condemning religions and medical journals and other papers from such source. After discussion said resolutions

were adopted and signed by all present, whose names appear beneath the resolutions as follow:

Office of Carter County Medical Society, Grayson, Ky., Nov. 12, 1907.—My Dear Doctor:

No question has ever been presented to our profession of anything like the importance of the nostrum and proprietary medicine fraud. State and County societies are taking action all over the county, but Kentuckians desire to take the same effective and concerted action that has made our profession so successful in all of its undertakings. In opposition to us is the American Proprietary Association and some of the low-grade drug organizations, but with a solid medical profession, and the support of the better element of the druggists, we need have no fear of the result.

If all the profession were members of our county society, or a similar one (and we trust they soon will be) and attended the meetings, so as to take part in its deliberations and actions, it would settle such matters. Of course, you will see the importance of the widest possible adoption of these resolutions, and to that end we are sending a copy to all reputable physicians. I ask you to vote for them and sign your name at the bottom of the next sheet, which is a pledge on your part that, when adopted by our profession, you will loyally stand for the faithful carrying out of the resolutions.

The Council on Pharmacy and Chemistry is employed by the medical profession and is working for them. Arrangements have been made so the Kentucky Medical Journal, can supply you with a copy of the abridged U. S. P. and N. F., together with the latest revision of the "New and Non-Official Remedies," all for 50 cents. Either send the money direct to the Journal at Bowling Green, or to me and I will send in the order for your county together.

It is now up to the individual doctors of the country as to whether they shall make effective the work and views of our representatives who have given the matter special study. Are you not willing to stand by them?

The result of this referendum will be published in the Journal of the American Medical Association. Please sign your name to the enclosed resolutions and mail them to me in the enclosed envelope so I can get them by next mail.

This will be a harder fight on our part than the insurance fight, but it means a thousand times more to our profession when it is won.

Be sure to send me your ballot by next mail. "United we stand, divided we fall."

Very respectfully,

A. T. McCORMACK, Secretary.

Whereas, through the cupidity and avarice of drug manufacturers many nostrums and so-called proprietary medicines have been put on the

market, and used by doctors in the treatment of sick people, and,

Whereas, the majority of the physicians of the United States, acting in their organized capacity through the American Medical Association, which is composed of the county and State medical societies of the country, have established a Council on Pharmacy and Chemistry whose sole purpose is to examine new preparations not in the United States Pharmacopoeia or National Formulary for their chemical and pharmaceutical purity, and,

Whereas, the said Council has examined many hundreds of such preparations and have found the large majority of them to be fraudulent or worthless, or both, and has published a list of those which it has approved: Now, therefore, be it

Resolved, That the Carter County Medical Society, and the medical profession in sympathy with them, in session assembled, hereby expresses its confidence in the Council on Pharmacy and Chemistry of the American Medical Association, and, in order to make its work of force and effect among the physicians of this community and their sick and afflicted patrons, be it further

Resolved, That in so far as may be practicable, we, and each of us, will confine our prescription writing and use of drugs to those preparations contained in the United States Pharmacopoeia and National Formulary, which have been established as the law of the land by the National Pure Food and Drug Law, and that we will not use, or permit to be used, any proprietary preparation until it has received the approval of the Council on Pharmacy and Chemistry of Council on Pharmacy and Chemistry of the American Medical Association; and, be it further

Resolved, That we condemn the acceptance of advertisements of fraudulent nostrums and proprietaries by the medical and religious press, and that we, and each of us, decline to receive any copy of any medical or drug journal, whether owned and controlled by a medical society, laymen, druggists or doctors, which advertises such preparations after January 1, 1908.

We, the undersigned, and each of us, hereby pledge ourselves to abide by the above resolutions and to use no medical preparations which are not contained in the official United States Pharmacopoeia or National Formulary, or in the list of new and non-official remedies approved by the Council on Pharmacy and Chemistry of the American Medical Association, and that we will subscribe for no medical or religious journal, nor will we receive such a journal from the post office, which advertises fraudulent or worthless nostrums and proprietary medicines after January 1, 1908.

That these resolutions be forwarded to the

Kentucky Medical Journal and the Journal of the American Medical Association for publication in order to show to the profession of the country that the physicians of Kentucky propose to free themselves of this curse and danger to themselves and their patients.

P. J. HUFF, President.  
D. B. WILCOX, Sec.  
HARDIN GILBERT,  
J. Q. STOVALL,  
J. WATTS STOVALL,  
C. B. O'ROARK.  
G. H. BURK,  
CHAS. McCLEESE,  
M. W. ARMSTRONG,  
W. D. WILLIAMS,  
W. M. HOWARD,  
CECIL S. HUDGINS,  
W. A. HORTON,  
J. W. STROTHER.

Dr. Strother, Dr. J. Watts Stovall, and Dr. Horton signed at their homes, making 14 who have signed. Every member would have signed if they had been present.

Owing to train run we had no time to see how many will take the book which separates the wheat from the tares, but will try to attend to it at next meeting. Dr. John C. Wilcox, of Willard, Ky., joined, and I send check for \$2.00.

Very respectfully,  
D. B. WILCOX, Secretary.

**Crittenden.** — According to previous arrangements by the local Board of Health, a public meeting was held in the Methodist church, in Marion, Dec. 11, 1907, for the purpose of discussing the subject of tuberculosis, and educating the people along the line of personal and public sanitation.

Dr. W. T. Daughtry, president of the local Board of Health, presided over the meeting. Dr. Daughtry called the meeting to order at 7:15 P. M., and in a few well chosen words stated the object of the meeting, after which Dr. T. A. Frazer delivered an address on the subject of tuberculosis. Dr. Frazer's address was followed by short talks by Hon. John W. Blue, Attorney C. S. Nunn, Rev. J. W. Adams, Dr. G. C. Moreland, and Rev. Benjamin Andres.

This meeting was well attended by representative citizens of Crittenden County, and every one present showed intense interest in the subject of Preventive Medicine. The speakers were enthusiastic over the prospects of work being done to prevent the great white plague, and the lay speakers paid high tribute to the medical profession, and the physicians of Crittenden County in their efforts to stamp out tuberculosis.

The following delegate were elected to attend the State Anti-Tuberculosis Association in the

city of Louisville early next year. C. S. Nunn, T. H. Cochran, Geo. M. Crider, Rev. Benjamin Andres, of Marion, and Vernon Fox, of Crayne.

State Senator P. S. Maxwell, of this district, was present at this meeting, indorsed the plan, and said he would do what his people wanted him to do.

T. ATCHLISON FRAZER, Secretary.

**Carroll.** — The Carroll County Medical Society held a called meeting Nov. 12, 1907 in the council-room of the city hall in Carrollton, J. P. Wheeler, the president, in the chair.

There was an informal discussion on what could be done for the betterment of our society, with interesting talks by S. E. Hampton, L. G. Carter, B. L. Holmes, and J. P. Wheeler.

**J. P. Wheeler** suggested a plan of building a county sanitarium for the treatment of charity patients. The plan was heartily endorsed by all present, it being decided to invite the county and city officials, the boards of the several churches, and the public generally to our next meeting, January 13, 1908 and get them interested in the plan, and ask their financial aid. S. E. Hampton, Holmes, and Gaines were appointed as a committee to work up an interest in the enterprise, and advertise it in the local papers.

Resolutions were passed endorsing the Council on Pharmacy and Chemistry for their actions in regard to the nostrums and so-called proprietaries, and also against journals and periodicals accepting advertisements of nostrums and proprietary medicines.

F. M. GAINES, Secretary.

**Fulton.** — The Fulton County Medical Society met at Cayce, November 29, 1907, being entertained by John Naylor, who gave us a nice dinner. Dr. J. M. Alexander in the chair. Also had W. W. Richmond, our district councillor with us and as usual he gave us a nice talk and entertained the society very nicely. The society by an unanimous vote extended their thanks to have him with the society also by the same vote to John Naylor and wife for their kindness. Roll call as follows:

John Naylor, Lon Naylor, C. A. Wright, Sam Luten, L. P. Baltzer, Hugh Prather, Ed Prather, J. M. Hubbard, J. W. Phelps, S. Cohn, J. M. Alexander, J. C. Yates, Geo. L. Majors, Horace Luten, W. W. Richmond, councillor.

Clinical cases reported as follows:

**Geo. L. Majors:** A case of full-term child; cord wrapped three times around neck, constricting and preventing the development of the head, the head was like a foetus of three months and the neck size of little finger, mother felt no movements for a week before her delivery.

**J. H. Hubbard's** case was a monstrosity with two tumors on back part of the head; thinks it was a meningocele.

There was quite a good deal of discussion on both papers. Then the chair saw we were running out of material for work and he made it a quiz class.

The question was "What do you get out of ergot, and when do you use ergot in obstetric practice?"

It was very lengthily discussed and answered by the society as a whole; some found no effect from it and others couldn't practice without it. Most of them used it after the third stage of labor.

By an unanimous vote the society agreed to make Cayce the permanent meeting point on account of it being midway between Fulton and Hickman.

Next meeting to be some time in January, the secretary to set the date.

Election of officers.—Although it was not the time, but thinking we had as many in attendance, if not more than we would in January the following officers were elected: — Sam Luten, Hickman, president; Lewis P. Balzer, vice-president; S. Cohn, Hickman, secretary-treasurer; J. C. Yates, Fulton, delegate.

One new member taken in, C. A. Wright, Cayce.

The society also approved the resolutions of the State Society in regard to the nostrum practice and you will find inclosed the resolution, signed by the secretary.

S. COHN, Secretary.

**Harrison.** — The regular quarterly meeting of the Harrison County Medical Society was held at the hospital in Cynthiaana, December 2nd, 1907. C. A. L. Reed and H. H. Heppe, of Cincinnati, were present. The application for membership of John Bate was read and handed to the censors.

This being the last meeting of the year the officers were elected for the ensuing year. They are:—J. M. Rees, president; W. B. Moore, vice-president; M. McDowell, secretary; B. B. Pety, treasurer; L. T. Eckler, censor, to fill the vacancy caused by the retiring censor, W. F. Phillips. The delegate, L. S. Givens was elected last year for two years.

The president's address by W. H. Carr was well received. He spoke of the post-graduate work that the society has been doing for the past two years, and advised those that had been absent frequently to make an effort to attend more regularly; that they needed the society as well as the society needed them; he urged the society to take up the post-graduate course as recommended by J. H. Blackburn.

**J. E. Wells** read a paper entitled "The duty

of the physician to himself, to his patient and his fellow practitioner." The essayist showed that by organization the medical profession had become more efficient in doing good and that the profession by thus being organized enables each of its members to feel more keenly their duty to self, patient and brother physician. He dwelt especially upon the cheap man, and said that he was not only a detriment to his profession, but one that should be avoided by the laity as one not being able to render the same amount of skill as his fellow practitioner, who, by charging legitimate fees is enabled to obtain the best medical literature and to do post-graduate work.

**C. A. L. Reed**, after emphasizing the importance of bringing before the society such papers as read by Drs. Carr and Wells, gave us a talk on "Movable Kidney." In the course of his talk he mentioned some new ideas in the anatomy of the structures supporting the kidney.

**Dr. Heppe** read a paper on "Brain Tumors" and exhibited many specimens taken from the cases that had come under his observation. The various phases of paralysis developing in these cases was thoroughly brought out. After the program was concluded the society was entertained at lunch by Drs. Givens, Wells, and Moore.

We now have thirty members in our society. This includes all the eligible physicians in our county that are in active practice.

J. M. REES, Secretary.

**Hart.** — The Hart County Medical Society met at Munfordsville, on Tuesday, December 3, 1907. Nine members were present; all alive and enthusiastic. After several interesting discussions the following officers were elected: — H. C. Bruner, Hardyville, president; M. V. Edwards, Horse Cave, vice-president; C. B. Creech, Munfordsville, secretary. J. F. Gaddie, Rowletts, was chosen delegate to the State meeting. J. H. Hester, Munfordsville, alternate. W. T. Pace, Monroe, was chosen censor.

C. B. CREECH, Secretary.

**Jefferson.** — The New York Academy of Medicine being desirous of having its file of the Proceedings of the Kentucky State Medical Association, complete, is endeavoring to secure the Proceedings of the Third, Fourth, Sixth to Twelfth, and Fifteenth to Thirty-fifth inclusive. Any one being able to spare any of these numbers, and will kindly forward them to the Jefferson County Medical Library, they will be forwarded to the New York Academy of Medicine. We bespeak the Academy's thanks for the reception of any or all of these numbers.

**McLean.** — The McLean County Medical Society met in regular session at Calhoun, November 11, 1907. The following members were present: — Drs. Harrison, Ford, Thorp, Haynes, Gates, Miller, Bondy, and Ayer.

By motion Sam Crow, of Beech Grove was elected a member of the society.

After carrying out the regular program, a motion was made that the society fix the time of meeting for 1908, on the second Mondays in January, March, May, July, September and November.

On motion the chair appointed J. H. Harrison, and Thorp to arrange the program for the January meeting.

Committee submitted the following:

Sam Crow—La Grippe and Treatment.

A quiz on Eruptive Diseases will be conducted by Dr. Ayer from 10 to 12 A. M.

The following resolutions were adopted:

Whereas, H. W. Gates, who has been practicing medicine in this, McLean County, for about twenty-five years, has, on account of his health, removed from our midst to the South-West, it is

Resolved, By the McLean County Medical Society that it has lost one of its brightest members, and that we, as physicians, do sincerely regret to part with him a brother practitioner, and furthermore, the board of health loses him as its health officer, and the people in general sustain a loss on account of his valued services as a physician.

We most heartily commend him to the people of any community in which he may locate as an earnest, efficient and honest physician, and as an upright and pure gentleman in every respect, and we bespeak for him the success that he so well deserves.

W. P. MILLER,

W. L. HAYNES,

J. H. HARRISON.

J. H. HARRISON, Secretary.

**Mercer.** — The resolutions regarding nostrums and proprietary medicines were adopted in full by our county society in the annual business session to-day, and were spread upon the minutes of the society. The only amendment made was one to cut out the words "religious journals" from the phrase "we will subscribe for no medical or religious journal," etc.

Very truly,

C. B. VANARSDALL, Secretary

**Nelson.** — The Nelson County Medical Society held its regular quarterly meeting to-day, with a small attendance. Two excellent papers were read and freely discussed by all of the members present. The first paper was by John R. Wathen, of Louisville, on "Gall Bladder Diseases," which was an interesting and exhaustive

paper, for which the secretary extends thanks.

**J. M. Crenshaw**, of Mt. Washington, next read a fine and very practical paper on "Post-inflammatory Adhesion of the Peritoneal Cavity." The society also thanks J. M. Crenshaw.

Owing to the small attendance no action was taken on the resolutions sent out by the State Secretary, but the secretary of the county society will forward the resolutions to every doctor in the county and get them signed. As there were so few present the election of officers was deferred until the March meeting, so the secretary is unwillingly forced to hold over till then. Oh, Lord! If some means could be devised to get doctors to take more interest in the county society meetings, how much more easy it would be for county secretaries to do their work satisfactorily. Can't you, Mr. Editor, suggest some means to draw doctors to county meetings? I thought that I had a fine program for to-day's meeting, but it failed to be a drawing card. While I acknowledge that I am a little discouraged I am not going to give up yet. I am going to have a good program and a good dinner for the March meeting.

HUGH D. RODMAN, Secretary.

**Owen.** — The Owen County Medical Society, with three-fourths of its membership present, met at Owenton December 5th for the purpose of electing officers and for the good of the society. In the regular order of business the following officers were elected to officiate during the ensuing year: J. H. Chrisman, Owenton, president; S. C. Davis, Gratz, vice-president; George Purdy, New Liberty, secretary; W. B. Salin, treasurer; D. T. Lusby, Hallam, delegate, and S. H. Veal, Cleveland, censor.

Under "Good of the Society" able talks were made by the retiring president, D. P. Curry, Wheatley; J. A. Estes, Owenton, and all of the officers-elect. Under this head arrangements were made for an informal luncheon to be given by the society at its next regular meeting, June 2, 1908, to which every physician in the county, whether a member or not, is to be cordially invited.

At present prospects look more favorable for our society. More interest has lately been manifested. Strenuous efforts will be made during the coming year to increase the membership and attendance and to promote more direct and systematic instruction along modern medical lines.

GEORGE PURDY, Secretary.

**Pike.** — The Pike County Medical Society met at the Pike Hotel, on the second day of December, 1907, and was called to order by President Booth. The following members were present:— J. E. Grady, Stallard, Walters, Bond, Thomp-

son, and Pinson. Visiting doctors, E. P. Walters, and Evans.

It being regular election time, we proceeded to elect officers for the ensuing year. The following were elected:—R. C. Booth, president; V. B. Pinson, vice-president; W. J. Walters, secretary; C. F. Bond, treasurer; W. A. Campbell, censor. For delegates, Drs. Pinson, Bond and B. R. Gibson. We had a nice talk from E. D. Evans, formerly of West Virginia.

The above-named officers were all elected by acclamation. There being no other business, the society adjourned until the next regular meeting.

Respectfully,

W. J. WALTERS, Secretary.

**Scott.** — The Scott County Medical Society held its regular meeting December 5th, 1907, at the city hall. Those present were A. B. Coons, W. G. Moore, Harry Caseldine, D. B. Knox, W. D. Scott, W. S. Allphin, and C. T. Coleman.

**W. G. Moore** read a short and concise paper on Pleuritis, giving mainly his own views as to the best management and treatment of the disease.

**W. D. Scott** favored the society with a paper on Influenza. Both papers were discussed at some length by A. B. Coons and Knox.

**D. B. Knox** suggested that further time be granted P. H. Crutehfield for the preparation of his paper on Acute Articular Rheumatism, as up to this meeting he has only had 12 months.

There are other members who fail to prepare papers, and take extension without leave of any kind.

Harry Caseldine, Georgetown, and C. T. Coleman, Delaplane, were admitted to membership.

The election of officers resulted as follows:— Jno. A. Lewis, Georgetown, president; W. S. Allphin, Biddle, vice-president; Jno. E. Paek, Georgetown, secretary-treasurer; Wan. A. Coffman, Georgetown, referee; Jno. E. Paek, delegate; L. F. Heath, alternate; W. H. Coffman, W. S. Allphin, L. F. Heath, censors.

Program for next meeting:

A. S. Allphin, Baird, and Barlow, subjects to be assigned later.

There being no further business, the society adjourned to meet first Thursday in March.

JNO. E. PACK, Secretary.

**Simpson.** — The Simpson County Medical Society met in regular session on Dec. 3, 1907. It being the last meeting in the year the election of officers was the business of the hour. W. A. Guthrie was elected president; W. H. Williams, vice-president; M. M. Moss, secretary-treasurer, and J. C. Douglas, censor for three years. We have brighter prospects for the next year and hope to make it the banner year of this so-

ciety. We are more united than ever before, and for this reason hope for better things. Our State representative made a good report which encouraged us greatly, and will no doubt stimulate us to greater activity and effort. It will be the pleasure of the secretary of this society to report to the Journal each and every meeting and the proceedings during the year. I will promise to leave no stone unturned to make of this society one of the best in the State if it is one of the smallest. Hoping this will find a place in our State Journal,

M. M. MOSS, Secretary.

**Shelby.** — The regular monthly meeting of the Shelby County Medical Society was held in Shelbyville November 21, 1907, at 10 A. M.

There was a very much better attendance than usual. The Shelby County doctors are getting together again; we had fine meetings until a few months ago, but it seems in the last three or four months all the efforts of the secretary to get them together were in vain, but the secretary is happy to report a good meeting in November. There were twelve present and all took part in the discussions of a paper read by the secretary on the "Management of Normal Labor." After the scientific part of the program the members partook of a three-course dinner at Hollenback's Cafe. There were several after-dinner speeches made along the lines of society work and aroused quite a little enthusiasm in the society, all promising to do better in the future.

Those present were:—Curtis, Austin, Morris, Eggen, Ray, Hawkins, Buckner, F. M. and S. L. Beard, Lawrence, Pratt, Smith, Yager.

Program for December meeting:

1. Mechanism of Abnormal Labor—Lawrence.
2. Accidents of Labor—E. Hawkins.
3. Quiz on the Anatomy of Female Pelvis.

S. L. BEARD, Secretary.

**Warren.** — The regular meeting of the Warren County Medical Society was held in the doctors' club-room Wednesday, November 27, 1907, at 1 P. M. The following doctors were present:—J. H. Blackburn, Simmons, McCormack, Rau, Ewing, Stone, McCracken, Freeman, Lewis, Rodgers, Rutherford, and South.

The Board of Censors admitted E. L. Adington to membership.

Moved and seconded that the next meeting be held Jan. 8, 1908.

Moved that a reporter for each month give a review of current literature on the subjects discussed in the post-graduate course; the following were appointed:

W. M. Ewing to report on diseases of lungs; J. H. Blackburn, on fractures; W. H. McCracken, blood and ductless glands.

W. H. McCracken opened the meeting with a

paper on Bacteriology of Acute Articular Rheumatism.

T. W. Stone spoke on the Therapeutics of the Salicylates.

The salicylates are derived from winter green and, by synthetic processes; the various preparations were described and the efficacy of each dwelt upon.

It is quickly excreted by the urine as was demonstrated by testing the urine in specimens passed every fifteen minutes after taking salicylate; traces of the drug can be detected from 10 to 12 hours after taking a dose.

The subject was ably discussed by Rau, McCormack, Blackburn, Simmons.

L. H. SOUTH, Secretary.

**Woodford.** — The Woodford County Medical Society met in regular session on Tuesday, the 12th of November, in Versailles. Present, W. E. Sleet, Parrish, Crawford, Anderson, Morgan, Blackburn, Arnold, Phelps, Stedman, Worthington, Crenshaw.

The minutes of the October meeting were read and approved.

By motion J. H. Arnold was appointed to make collection for the printing and framing of 14 "Schedules of Charges."

S. M. Stedman, being the only one of the essayists present, proceeded to read a paper on "The Doctor, His Business Side and His Relations to His Fellow Doctors." (the paper is thought to be worthy of publication and is forwarded in its entirety to the State Secretary).

Committee on subjects for next meeting reported:

J. H. Arnold, "How to Keep Our Patients at Home."

S. J. Anderson, (a subject of his own selection).

The society passed resolutions of regret at the prospective loss of C. L. Crawford by removal.

J. W. CRENSHAW, Secretary.

## BOOK REVIEWS.

**Diseases of the Stomach**, by Dr. I. Boaz, Specialist in Gastro-enteric diseases in Berlin and Albert Bernheim, M. D., of Philadelphia, Assistant to the late Dr. D. D. Stewart at the Polyclinic Hospital and Post-graduate School, as Instructor in the Department of Diseases of the Stomach and Intestines; Privileged Physician to the Jewish Hospital of Philadelphia; Examining Physician to the Free Hospital for Poor Consumptives; Philadelphia White Haven; Consulting Physician to the Nazarene Home for the Aged, Ex-president of the Northern Medical Association of Philadelphia.

Illustrated with Five Full-Page Plates and sixty-five engravings in the text. F. A. Davis &

Co. Publishers, 1907.

Dr. Boas's book is as Dr. Boas himself says, particularly a book for the general practitioner, but also for the specialist and for the student. Dr. Boas and Bernheim's long and varied experience render them peculiarly fitted to write a book on diseases of the stomach. The work is well balanced, and gives the reader not only the benefit of the author's extensive knowledge of the varied pathological condition, but also describes the details of diagnosis and treatment in a manner born of ripe experience.

The manner in which these authors handle such subjects as Balneotherapy, Technique of Gastric Lavage, the employment of Acids and Alkalies in the stomach, the artificial ferments, show that the book is well up to date and worthy of a place in any medical library.

A. L. W.

**Practical Fever Nursing.** By Edward C. Register, M. D., Professor of the Practice of Medicine in the North Carolina Medical College. Octavo volume of 352 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1907. Cloth \$2.50 net. W. B. Saunders Company, Philadelphia and London.

**A Manual of the Practice of Medicine.** New (8th) Edition, Thoroughly Revised. A manual of the practice of medicine, by A. A. Stevens, A.M., M.D., Professor of Therapeutics and Clinical Medicine in the Woman's Medical College of Pennsylvania. Eighth Edition, Revised. 12mo of 558 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1907. Flexible Leather, \$2.50 net. W. B. Saunders Company, Philadelphia and London.

**Diseases of the Skin.** For the use of advanced students and practitioners. By Henry W. Stelwagon, M.D., Ph.D., Professor of Dermatology, Jefferson Medical College, Philadelphia. Fifth Edition, Revised. Handsome octavo of 1150 pages, with 267 text-illustrations, and 34 full-page colored and half-tone plates. Philadelphia and London: W. B. Saunders Company, 1907. Cloth, \$6.00 net; Half Morocco, \$7.50 net. W. B. Saunders Company, Philadelphia and London.

**Progressive Medicine,** Vol. ix, No. 4; a quarterly digest of advances, discoveries and improvements in the medical and surgical sciences; edited by Hobart A. Hare, Professor of Therapeutics and *Materia Medica* in Jefferson College, Philadelphia; assisted by H. R. M. Landis, of Jefferson Medical College. Lea Brothers & Company, Philadelphia and New York, \$6.00 per annum.

List of contributors and contents:

Diseases of the Digestive Tract and Allied Organs, the Liver and Pancreas, by J. Dutton Steele.

Diseases of the Kidneys, by John R. Bradford.

Surgery of Extremities, Fracture, Dislocation, Tumors, Surgery of Joints, Shock, Anesthesia and Infections, by Joseph Bloodgood.

Genito Urinary Diseases, by W. T. Belfield.

Practical Therapeutics Referendum, by H. R. M. Landis.

**Osler's Modern Medicine.** Modern Medicine. Its Theory and Practice. In Original Contributions by American and Foreign Authors. Edited by William Osler, M.D., Regius Professor of Medicine in Oxford University, England; formerly Professor of Medicine in Johns Hopkins University, Baltimore; in the University of Pennsylvania, Philadelphia, and in McGill University, Montreal. Assisted by Thomas McCrea, M.D., Associate Professor of Medicine and Clinical Therapeutics in Johns Hopkins University, Baltimore. In seven octavo volumes of about 1,000 pages each; illustrated. Volume iii just ready. Price per volume, cloth, \$6.00 net; leather, \$7.00, net; half morocco, \$7.50 net. Lea Brothers & Co., Publishers, Philadelphia and New York, 1907-1908.

The following list of some of the contributors to the third volume of the series of Modern Medicine will give the reader an idea of the great value of these new books:

J. M. Anders, Hobart A. Hare, William Osler, Edward R. Baldwin, and many others.

This volume finishes Infectious Diseases, begun in the second series, and begins The Diseases of the Respiratory Tract. Five chapters are devoted to Tuberculosis, the etiology and history is written by E. B. Baldwin, of the Saranac Laboratory; the remaining topics are written by men who make a specialty of that phase of Tuberculosis.

The contributors have realized in this volume that exhaustive theories aid the practitioner but little, and a book to be of value must not only give remedies, but must give directions how to follow out methods they devise.

Osler has contributed a monograph on Syphilis in this volume which adds greatly to its value and interest.

**A Text-Book of Physiology.** For Medical Students and Physicians. By William H. Howell, Ph.D., M.D., LL.D., Professor of physiology, Johns Hopkins University, Baltimore. Second Edition, thoroughly revised. Philadelphia and London: W. B. Saunders Company, 1907. Cloth \$4.00 net; Half Morocco, \$5.50 net. W. B. Saunders Company, Philadelphia and London.

The author says in the preface that he has endeavored to keep in mind two principles: first, the importance of simplicity and lucidity in the presentation of facts and theories; second, the

need of judicious limitation of material selected. The fundamental facts of physiology is not difficult to understand if writers would select only the fundamental facts which are desirable for students to know, and state them clearly and concisely, which the author has carefully done in the volume.

The book is especially recommended to those societies following the post-graduate scheme in preparing subjects on physiology.

The chapter on Enzymes is novel and interesting; he says an enzyme is the key that unlocks the molecule of food stuffs, the most interesting feature of its activity is that it is a specific, there is a separate enzyme for each food.

Opothrapy or internal secretion has a chapter devoted to the explanation of this peculiar phenomena of the secretions of the various organs, namely the thymus, adrenalin, etc.

As a whole the book is especially designed for medical students and practitioners, it has been thoroughly revised and a good physiology that is essential to every physician's library.

**Osler's Modern Medicine.** Modern Medicine. Its Theory and Practice. In Original Contributions by American and Foreign Authors. Edited by William Osler, M.D., Regius Professor of Medicine in Oxford University, England; formerly Professor of Medicine in Johns Hopkins University, Baltimore; in the University of Pennsylvania, Philadelphia, and in McGill University, Montreal. Assisted by Thomas McCrea, M. D., Associate Professor of Medicine and Clinical Therapeutics in Johns Hopkins University, Baltimore. In seven octavo volumes of about 1,000 pages each; illustrated. Volume ii just ready. Price per volume, cloth, \$6.00 net; leather, \$7.00 net; half morocco, \$7.50 net. Lea Brothers & Co., Publishers, Philadelphia and New York, 1907-1908.

The first chapter of this volume, on Infectious Diseases, is devoted to an "introduction to the study of infectious diseases." In this chapter Hecktoen gives a very clear statement of the most modern teaching regarding infections and immunity, taking up the sources, means and routes of infection, the different forms of toxins and autotoxins, immunity and serum therapy. Oposonins, precipitins and agglutinins are treated in a concise manner.

Each of the infectious diseases is treated by one who has given special attention to it, as for instance, McRea on Typhoid Fever, Councilman and Doek on Small-pox and Vaccination, Ruhräh and McCollom on certain of the exanthemata, Anders on Erysipelas, Musser on Pneumonia, Carroll on Yellow Fever. Among the foreign contributors may be mentioned Poynton on Rheumatic Fever and Shiga on Bacillary Dysentery.

Since each of the subjects has been contributed by a specialist, each chapter is a complete monograph on that subject. In the Treatment on each subject, which is fairly complete, considerable attention has been given serum therapy.

Altogether this volume sustains the purpose for which the system was issued, to give a complete presentation of the science and practice of medicine in their most advanced development.

**Treatment of Diseases of Children.** By Charles Gilmore Kerley, M. D., Professor of Diseases of Children, New York Polyclinic Medical School and Hospital, etc. Octavo volume of 597 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1907. Cloth, \$5.00 net; Half Morocco, \$6.50 net. W. B. Saunders Company, Philadelphia and London.

This work has been prepared for those engaged in active general practice in order to give them the modern methods of management and treatment in greater details than is commonly given in the works on pediatrics.

After briefly describing a disease minute instructions are given as to plan of treatment, methods of using colon tube, stomach pump, etc., after prescriptions are given.

Artificial foods, home modification of milk, the *bete noir* of the country doctor is explained so as to be comprehended. Infections, gastroenteric diseases are duly discussed.

An interesting chapter on Cretinism is illustrated with photographs taken before and after the use of the thyroid extract.

The book is valuable because it tells us how to do things in details.

**Diseases of the Genito-Urinary Organs and the Kidney.** By Robert T. Greene, M.D., Professor of Genito-Urinary Surgery at the Fordham University, New York; and Harlow Brooks, M.D., Assistant Professor of Pathology, University and Bellevue Hospital Medical School. Octavo of 536 pages, profusely illustrated. Philadelphia and London: W. B. Saunders Company, 1907. Cloth, \$5.00 net; Half Morocco, \$6.50 net. W. B. Saunders Company, Philadelphia and London.

This book embraces the more important disease conditions of the uro-genital tract, taken from the standpoint of the general practitioner and surgeon. The opening chapter is devoted to the discussion of various methods of examining patients and different positions are illustrated.

In instrumental examinations a cut of all instruments are given with directions as to their use.

The writers have attempted to devote the greatest amount of space and the fullest de-

## COUNCIL OF PHARMACY.

### SAL ETHYL.

Ethyl salicylate,  $C_2H_5(C_6H_4.OH.CO O) = C_9H_{10}O_3$ , is the salicylic acid ester of ethyl alcohol and is analogous to methyl salicylate (oil of wintergreen).

Actions and Uses.—Sal ethyl has the same action as the salicylates, but is said to be less toxic. Dosage.—3 to 6 c.c. (5 to 10 minims), 3 or 4 times a day in the form of gelatin globules. Manufactured by Parke Davis & Co., Detroit, Mich.

### SALIFORMIN.

Saliformin  $(CH_2)_6 N_4.C_6H_4.OH.CO OH$ , is salicylate of hexamethylenamine.

Actions and Uses.—Saliformin is a genitourinary antiseptic and is recommended as a uric-acid solvent. Its action does not differ materially from that of a mixture of hexamethylenamine and salicylic acid, for it is largely hydrolysed into its constituents in the presence of water. It has been recommended in cystitis, lithiasis and bacterial affections of the urinary passages, also in gout, etc. Dosage.—0.3 to 2 Gm. (5 to 30 grains) in tablets of elixir. Manufactured by E. Merck, Darmstadt (Merck & Co., New York).

### SALIT.

Salit consists chiefly of the salicylic acid ester of borneol,  $C_6H_4.OH.CO (C_{10}H_{17}O) = C_{17}H_{22}O_3$ .

Actions and Uses.—Salit is absorbed by the skin after inunction and is decomposed in the body, liberating salicylic acid in the tissues. It appears to be liable to produce some local irritation and eczema of a mild type. It is antiseptic. It is recommended in gout, articular and muscular rheumatism, neuralgia, erysipelas, pleurisy, etc. Dosage.—It is used only externally, undiluted, by penciling, or preferably by inunction with 5 to 10 Gms. (75 to 150 minims) of a mixture of equal parts of salit and olive oil. Manufactured by The Heyden Chemical Works, New York.

### SALOPHEN.

Salophen,  $(C_6H_4.OH.CO O). C_6H_4.NH. (C_2H_5CO)$ , is the salicylic ester of 1.4-acetaminophenol,  $C_6H_4(NHCH_3CO)(OH)$ .

Actions and Uses.—The actions of salophen resemble those of phenyl salicylate (salol). It is not changed in the stomach, but is broken up in the intestine, liberating salicylic acid and acetylparamidophenol, which is not toxic, like phenol. It acts as an antirheumatic, antipyretic, antiseptic and analgesic. It has been recommended in rheum-

atism, gout, typhoid fever, and as an intestinal antiseptic, in diarrhoea and dysentery. Externally it has been applied in psoriasis and other itching skin diseases. Dosage—0.3 to 1 Gm. (5 to 15 grains), in powder, wafers or capsules. Externally in 10 per cent. ointment. Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York).

### SALOQUININE.

Saloquinine,  $C_6H_4.OH.CO O (C_{27}H_{23}N_2O) = C_{27}H_{23}O_4N_2$ , is the salicylic ester of quinine, containing 73.1 per cent. of quinine.

Actions and Uses.—It is a tasteless substitute for quinine and salicylic acid. Dosage.—0.5 to 2 Gm. (8 to 30 grains). Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Merck & Co., New York).

### SALOQUININE SALICYLATE.

Saloquinine salicylate,  $C_6H_4.OH.CO O (C_{20}H_{23}N_2O) + C_6H_4.OH.CO OH = C_{31}H_{23}N_2O_3$ , is the salicylate of the salicylic ester of quinine.

Actions and Uses.—It is recommended in acute rheumatism, neuralgia, tabes, gonorrhoeal inflammations, etc. Dosage.—1 Gm. (15 grains). Manufactured by E. Merck, Darmstadt (Merck & Co., New York).

### SEXTONOL.

A mixture of tonols in tablets of 0.3 Gm. (5 grains), each tablet being said to contain lime tonol, 0.13 Gm. (2 grains); sodium tonol, 0.13 Gm. (2 grains); iron tonol, 0.03 Gm. (1-2 grain); manganese tonol, 0.015 Gm. (1-4 grain); and strychnine tonol, 0.00033 Gm. (1-200 grain).

Actions, Uses and Dosage.—See Glycero-phosphates. Manufactured by Chemische Fabrik auf Actien, vorm E. Schering, Berlin (Schering & Glatz, New York).

### SIDONAL.

Sidonal  $\begin{matrix} \diagup CH_2CH_2 \diagdown \\ NH_2C_6H_7(OH)_4(CO \\ \diagdown CH_2CH_2 \diagup \end{matrix}$

$OH) = C_{18}H_{24}N_2O_{12}$ , is the normal salt of piperazine and quinine acid.

Actions and Uses.—Sidonal is recommended as a uric acid solvent in gout, neurasthenic, etc. Dosage.—1 to 1.3 Gm. (15 to 20 grains) 5 or 6 times a day, dissolved in water. Manufactured by Vereinigte Chemische Werke Actiengesellschaft, Charlottenburg (Victor Koechl & Co., New York).

### SODIUM CACODYLATE.

Sodium cacodylate,  $(CH_3)_2AsO.ONa + 3 H_2O$ , is the sodium compound of cacodylic

acid  $(\text{CH}_3)_2\text{AsO.OH}$ , a dimethyl derivative of arsenic acid,  $\text{AsO}(\text{OH})_3$ .

**Actions and Uses.**—The action of sodium cacodylate is similar to other arsenic compounds, but it is much less toxic than the ordinary preparations of arsenic and is also less apt to cause undesirable side effects. This superiority is due to the slow liberation of the arsenic ion in the body. The cacodylate is particularly recommended in obstinate psoriasis, pseudoleukemia, diabetes, anemia, chlorosis, tuberculosis, malarial cachexia, etc. **Dosage.**—0.025 to 12 Gm. (1-2 to 2 grains) in pills, hypodermically or by enema.

#### SODIUM CINNAMATE.

Sodium cinnamate,  $\text{C}_6\text{H}_5\text{CH}:\text{COONa} = \text{NaC}_9\text{H}_7\text{O}_2$ , is the sodium sale of *B*-phenylacrylic (benzene-propenoic) acid,  $\text{C}_6\text{H}_5\text{CH}:\text{CH.COOH}$ .

**Actions and Uses.**—Balsam of Peru, cinnamic acid and sodium cinnamate are recommended by Landerer for the treatment of phthisis, the drugs being injected intravenously under strict aseptic precautions. The effect is referred by him to an inflammatory reaction, localized about the tuberculous foci and leading to cicatrizations. He records very favorable results in well-selected cases, and other clinicians have also reported some successes, although the treatment fails very often. The synthetic cinnamate is preferred on account of its purity. **Dosage.**—0.001 Gm. (1-60 grain), gradually increased to 0.02 Gm. (1-3 grain), in 1 to 5 per cent. solution, injected intravenously thrice weekly for long periods (3 to 18 months).

#### SODIUM ICHTHYOL.

A derivative of ichthyol containing sodium instead of ammonium.

**Actions, Uses and Dosage.**—These are the same as those of ichthyol. Its firmer consistence makes it more suitable for pills. Manufactured by the Ichthyol Co., Hamburg (Merck & Co., New York).

#### STOVAINE.

Stovaine,  $\text{CH}_3\text{C}(\text{C}_2\text{H}_5)_2(\text{O.CO.C}_6\text{H}_5)\text{CH}_2\text{N}(\text{CH}_3)_2\text{HCl} = \text{C}_{14}\text{H}_{22}\text{O}_2\text{NCl}$ , is the hydrochloride of 1-dimethylamino-2-ethyl-2-propanol benzoyl ester.

**Actions and Uses.**—Stovaine acts as a local anesthetic of about the same power as cocaine, but dilates the blood vessels, whereas cocaine contracts them and exerts a tonic action on the heart. It is only 1-3 to 1-2 as toxic as cocaine. It is used as a local anesthetic; while most reports are favorable, one case of gangrene has been reported following the use of a 10 per cent. solution. **Dosage.**—Internally, 0.002 Gm. (1-30 grain), as pill. Lo-

cally it may be used in the eye in 4 per cent. solution and applied to other mucous membranes, as in laryngology, in from 5 to 10 per cent. solution. For hypodermic injections for local anesthesia it can be used in 0.75 to 1 per cent. solution. Manufactured by the Poulenc Freres Company, Paris (Walter F. Sykes, New York).

#### STYPTICIN.

Stypticin,  $\text{C}_{12}\text{H}_{13}\text{O}_3\text{N.HCl}$ , is the hydrochloride of cotarnine an oxidation product of narcotine, similar to hydrastinine.

**Actions and Uses.**—Stypticin is a hemostatic, analgesic and uterine sedative. The mechanism of its action is obscure. It has been recommended particularly in functional dysmenorrhea and menorrhagia of puberty and of the climacteric; in subinvolution of the uterus after parturition and abortion, as well as in all profuse uterine hemorrhages; in bleeding from the bladder, from the nose, after extraction of teeth, etc. **Dosage.**—Internally, 0.05 Gm. (3-4 grain) four to five times daily, in sugar-coated tablets or gelatin capsules; or by hypodermic injection (in urgent cases) 2 Cc. of a 10 per cent. solution; externally, as a styptic, pure or in strong solution. Manufactured by E. Merck, Darmstadt (Merck & Co., New York).

#### STYPTOL.

Styptol,  $(\text{C}_{12}\text{H}_{13}\text{O}_3\text{N})_2\text{C}_6\text{H}_4(\text{COOH})_2$ , is the normal phthalate of cotarnine, an oxidation product of narcotine, similar to hydrastinine.

**Actions and Uses.**—Its action resembles that of stypticin. Compounds with phthalic acid are said to have especial hemostatic properties. Styptol has been recommended in uterine hemorrhages. **Dosage.**—0.065 Gm. (1 grain) in sugar-coated tablets, 3 to 5 times daily. Manufactured by Knoll & Co., Ludwigshafen a. Rh. and New York.

#### STYRACOL.

Styracol,  $\text{C}_6\text{H}_5\text{CH}:\text{CH.COO}(\text{C}_6\text{H}_5\text{OCH}_2)_2 = \text{C}_{16}\text{H}_{14}\text{O}_2$ , is the cinnamic acid ester of guaiacol.

**Actions and Uses.**—Styracol is an intestinal antiseptic and is claimed to combine the antituberculous actions of guaiacol and cinnamic acid. It is said to liberate in the intestinal canal a larger proportion of its guaiacol (up to 85 per cent.) than other synthetic preparations of that substance. It is recommended for the initial stage of phthisis, chronic enteritis and intestinal disturbances in general, catarrh of the bladder, etc. **Dosage.**—1 Gm. (15 grains) in powder or tablets. Manufactured by Knoll & Co., Ludwigshafen a. R. and New York.

## SUBLAMINE.

Submaline  $3\text{HgSo}_4 \cdot 8\text{C}_2\text{H}_4(\text{NH}_2)_2$  is a compound of three molecules of mercuric sulphate with eight molecules of ethylenediamine (which see).

**Actions and Uses.**—Sublamine is a disinfectant similar to mercuric chloride, over which it has the advantage of being non-irritating, more penetrating and readily soluble. **Dosage.**—It is used in 1:1,000 solution for skin disinfection and in 1:5,000 to 1:10,000 solutions for irrigations of the bladder, etc. It may be used in syphilis by injection into the gluteal muscles of a 3 or 4 per cent. solution. Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin (Schering & Glatz, New York).

## SULPHONAL.

A name applied to Sulphonmethanum, U. S. P. Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Company, New York).

## SUPRARENAL ALKALOID.

The active alkaloid of the suprarenal (epinephrine) glands.

**Actions and Uses.**—Suprarenal alkaloid acts peripherally on a variety of structures, probably by stimulating the sympathetic nerve endings. Its most important therapeutic actions consist in a constriction of the blood vessels, with consequent high rise of blood pressure; a stimulation of the vagus center with slowing of the heart, and a direct stimulant to digitalis. Large doses also cause glycosuria; continued administration of large doses leads to atheroma. The effect of a single dose is very fleeting. It is not irritant. The effects are seen on local application and intravenous and intramuscular injection. When given to animals, by mouth or hypodermically, moderate doses have almost no action. Dilute water solutions rapidly lose their strength, the deterioration being accompanied by a reddish or brownish discoloration. The alkaloid is used mainly locally for its vasoconstrictor action, in hemorrhage, and in catarrhal and congestive conditions. It is said to cut short the asthmatic paroxysm (being used by spraying the larynx and by hypodermic injections). Intravenous injections are effective in shock and anesthesia accidents (care being taken not to give an overdose). It has also been recommended in heart disease, Addison's disease, etc., but opinions as divided as to the benefits to be expected from oral administration.

## TANNIGEN.

Tannigen,  $\text{C}_{14}\text{H}_8(\text{C}_2\text{H}_3\text{O})_2\text{O}_9 = \text{C}_{18}\text{H}_{14}\text{O}_{11}$ , is the acetic acid ester of tannin.

**Actions and Uses.**—Tannigen passes unchanged into the intestine, where it becomes effective as an astringent in contact with the alkaline juice. It is said to be free from irritant action. It is recommended in acute diarrhoeal affections, such as acute intestinal catarrhs, cholera morbus, cholera infantum and dysentery; it has also been used with reported success for the diarrhoea of typhoid fever and intestinal tuberculosis. **Dosage.**—0.2 to 0.7 Gm. (3 to 10 grains) four times per day, dry on the tongue followed by a swallow of water; or mixed with food, avoiding warm or alkaline liquids. Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York).

## TANNALBIN.

Tannalbin is a compound of tannic acid and albumin thoroughly exsiccated.

**Actions and Uses.**—Tannalbin is astringent. Being insoluble in the gastric juice, it becomes effective when it reaches the intestines, where it slowly splits off tannic acid. It does not produce gastric disturbance. It is commended in diarrhoea, especially in that of children, and in phthisis. **Dosage.**—1 to 4 Gm. (50 to 60 grains) in powder (or tablets) followed by water; infant doses, 0.3 to 0.5 Gm. (5 to 8 grs.) in gruel or other mucilaginous liquid. Manufactured by Knoll & Co., Ludwigshafen a. R. and New York.

## TANNOFORM.

Tannoforn,  $\text{CH}_2(\text{C}_{14}\text{H}_9\text{O}_9)_2 = \text{C}_{29}\text{H}_{20}\text{O}_{18}$ , is a condensation product of formaldehyde with gallo-tannic acid.

**Actions and Uses.**—Tannoforn is astringent and antiseptic. It is recommended on account of these properties in chronic intestinal catarrh and externally in hyperdrosis, bromidrosis, weeping eczema, ozena, etc. **Dosage.**—0.25 to 0.5 Gm. (4 to 8 grains); externally, pure or in 25 to 50 per cent. triturations (with tale) as dusting powder, or as 10 per cent. ointment or soap. Manufactured by E. Merck, Darmstadt (Merck & Co., New York).

## TANNOPIN.

Tannopin,  $(\text{C}_{14}\text{H}_{10}\text{O}_9)_2 \cdot (\text{CH}_2)_6\text{N}_4$ , is a condensation product of tannin with hexamethylenamine.

**Actions and Uses.**—Tannopin is an intestinal astringent and antiseptic; it passes unchanged through the stomach, but, being gradually decomposed by alkalies, it becomes effective in the intestinal tract, exerting the action of its two components. **Dosage.**—0.3 to 0.5 Gm. (5 to 8 grains) for infants and children; 1 Gm. (15 grains) for adults, dry on the tongue, followed by a swallow of wat-

er, or sprinkled on food four times a day. Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York).

#### THEOBROMINE.

Theobromine,  $\left| \begin{array}{c} \text{CO} \text{-----} \text{NII.C} = \text{N} \setminus \text{CO} = \\ \text{C}_7\text{H}_8\text{O}_2\text{N}_4 \end{array} \right.$ , is a base occurring in *Theobroma cacao*, *Kola acuminata*, etc., and also made synthetically.

Actions and Uses.—Its uses are similar to caffeine but it has relatively greater diuretic, cardiac and muscular activity. It does not act so powerfully on the central nervous system. It is recommended as a diuretic. The great obstacle to its use has been its insolubility and the consequent uncertainty of the degree of its absorption. It is liable to produce gastric disturbances. Dosage.—0.35 to 0.5 Gm. (5 to 8 grains).

#### THEOBROMINE SODIUM SALICYLATE.

Theobromine sodium salicylate,  $\text{NaC}_7\text{H}_7\text{N}_4\text{O}_2 + \text{NaC}_7\text{H}_5\text{O}_3$ , is a double salt of theobromine-sodium and sodium salicylate.

Actions and Uses.—Its effects are the same as those of theobromine (which see), over which it has the advantage of greater solubility. Dosage.—1 Gm. (15 grains) five or six times a day. Its tendency to produce gastric irritation may be prevented by giving it in well-diluted solution, or, if preferred, in capsules or wafers, followed by water.

#### THEOCIN.

A name applied to synthetic theophyllin (see Theophyllin). Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York).

#### THEOPHYLLIN.

Theophyllin,  $\left| \begin{array}{c} \text{CH} = \text{C}_7\text{H}_8\text{C}_2\text{N}_4 \\ \text{CO.N}(CII_3).C.N \end{array} \right.$

is an organic base isomeric with theobromine; it is found in small amounts in tea and is also made synthetically.

Actions and Uses.—Theophyllin is a powerful diuretic, claimed to surpass all other remedies of this kind, increasing not only the amount of liquid, but the solids in the urine as well, the secretion of urine being sometimes very copious. The diuretic effect, however, is not prolonged and its administration is, therefore, advantageously followed by one of the theobromine derivatives having a weaker, but more persistent, action. It occasionally produces gastric disturbances and renal irri-

tation has also been reported. It is claimed that these may be obviated by the use of acet-theocin-sodium (which see) instead. It is recommended in cardiac affections, nephritis, dropsy, etc. Dosage.—0.2 to 0.35 Gm. (3 to 5 grains) in warm tea.

#### THERMODIN.

Thermodin,  $\text{C}_6\text{H}_4(\text{OC}_2\text{H}_5).(\text{N}(\text{COOC}_2\text{H}_5)(\text{CII}_3\text{CO})) = \text{C}_{13}\text{H}_{17}\text{O}_4\text{N}$ , is a compound of acetphenetidin (phenacetin) and ethyl carbanate (urethane).

Actions and Uses.—Thermodin is an analgesic, antipyretic and antiseptic. It is recommended as a mild and reliable antipyretic in typhoid fever, pneumonia, influenza, tuberculosis and febrile conditions in general, and is said to be free from unpleasant by-effects. Dosage.—0.3 to 0.6 Gm. (5 to 10 grains) as an antipyretic; 1 to 1.3 Gm. (15 to 20 grains) as an analgesic. Manufactured by E. Merck, Darmstadt (Merck & Co., New York).

#### THIOCOL.

Thioeol,  $\text{C}_6\text{H}_4(\text{OH})(\text{OCH}_3)(\text{KSO}_3) 1:2:6 = \text{C}_7\text{H}_7\text{O}_5\text{KS}$ , is the potassium salt of ortho-naïacol sulphonic acid.

Actions and Uses.—Thioeol is said to be non-irritating to the mucous membranes of the digestive tract, readily absorbed and is claimed to promote appetite and improve nutrition. It is recommended in pulmonary tuberculosis, acute and chronic bronchitis, pneumonia, whooping cough, emphysema of the lungs, etc., as a means of relieving expectoration, diminishing night sweats and improving nutrition. Dosage.—0.3 to 1.3 Gm. (5 to 20 grains), in solution with orange syrup or in tablets. Manufactured by F. Hoffmann-LaRoche & Cie, Basel, Switzerland (The Hoffmann-LaRoche Chemical Works, New York).

#### TONOLS.

Tonol is a name applied by E. Schering to identify the glycerophosphates of his manufacture.

Actions. Uses and Dosage.—These are described under glycerophosphates (which see). Manufactured by Chemische Fabrik an f Aktien, vorm. E. Schering, Berlin (Schering & Glatz, New York).

#### THIOSINAMINE.

Thiosinamine,  $(\text{NH}_2).CS.NHCII_3.CH:CH_2 = \text{C}_4\text{H}_8\text{N}_2\text{S}$ , is a condensation product of allyl thiocyanate and ammonia.

Actions and Uses.—Thiosinamine appears to cause or quicken the absorption of exudates, lymphatic swellings, scar tissue, etc., the action being unexplained. The opinions as to value are contradictory. It is recommended for use by hypodermic injection in lupus,

chronic glandular tumors, cicatrices, etc. By the mouth in stricture, corneal opacity, chronic deafness. Dosage.—0.03 to 0.1 Gm. (1-2 to 1 1-2 grains) in capsules or tablet triturates; in subcutaneous injections, 0.05 to 0.2 Gm. (1 to 5 grains) in 15 per cent. alcoholic or 10 per cent. glycerinated water solution.

## TRIFERRIN.

Triferrin is ferrie paramaleinate; a compound of caseinparamaleic acid with iron, containing 22 per cent. of iron, 9 per cent. of nitrogen and 2.5 per cent. of phosphorus in natural (organic) combination.

Actions and Uses.—In addition to its hematinic action derived from the iron, it is claimed to act like lecithin by reason of the phosphorus in organic combination which it contains. It is said to agree with the most sensitive stomach, since it passes the stomach unchanged, but is freely absorbed in the intestines. It is recommended in anemia, chlorosis, neurasthenia, rachitis and general debility. Dosage.—0.3 Gm. (5 grains) in powder, taken during meals. Manufactured by Knoll & Co., Ludwigshafen a. Rh. and New York.

## TRIFERROL.

Triferrol is an elixir of triferrin, containing 0.06 Gm. (1 grain) triferrin and about 1 Cc. (15 minims) of alcohol in 4 Cc. (1 fluidram).

Actions and Uses.—It is introduced as a convenient substitute for triferrin. Dosage. 16 Cc. (4 fluidrams) corresponding to 0.24 Gm. (4 grains) of the powder. Manufactured by Knoll & Co., Ludwigshafen a. Rh. and New York.

## TRIKRESOL.

A liquid said to consist of 35 per cent. orthocresol, 40 per cent. metacresol and 25 per cent. paraeresol. It closely corresponds to Cresol, U. S. P. Manufactured by the Chemische Fabrik auf Actien, vorm. E. Elberfeld, Germany (Continental Color and Chemical Co., New York).

## TRIONAL.

A name applied to Sulphonethylmethanum, U. S. P. Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Continental Color & Chemical Co., New York).

## TRIOXYMETHYLENE.

Trioxymethylene,  $(\text{CH}_2\text{O})_x$ , is a polymeric condensation of formaldehyde.

Actions and Uses.—Antiseptic and escharotic. It is recommended internally for diarrhoea. Externally it is used chiefly to generate formaldehyde by heating, for disinfection, for inhalations in phthisis and eryzema. It is also recommended for warts. Dosage.—

Internally, 0.3 to 1 Gm. (5 to 15 grains); externally (for warts) in 10 per cent. suspension in collodion. Manufactured by E. Merck, Darmstadt (Merck & Co., New York).

## TRITIPALM.

A fluid extract, each 4 Cc. (one fluidram) of which is said to represent: Fresh saw palmetto 2 Gm. (30 grains) and tritium repens 4 Gm. (60 grains) in a menstruum containing 20 per cent. of alcohol. Dosage.—4 to 8 Cc. (1 to 2 fluidrams) four times a day, preferably with water. Prepared by F. Stearns & Co., Detroit, Mich.

## TRIPHENIN.

Triphenin  $\text{C}_6\text{H}_4(\text{OC}_2\text{H}_5)_2\text{NH}(\text{CH}_3\text{CH}_2\text{CO}) = \text{C}_{11}\text{H}_{16}\text{NO}_2$ , is a derivative of parphenetidim, differing from acetphenetidim (phenacetin),  $\text{C}_6\text{H}_4(\text{OC}_2\text{H}_5)_2\text{NH}(\text{CH}_3\text{CO})$ , in that the acetic acid residue,  $\text{CH}_3\text{CO}$ , has been replaced by the propanoic residue,  $(\text{CH}_3\text{CH}_2\text{CO})$ .

Actions and Uses.—Triphenin is antipyretic, analgesic and hypnotic; its action is slower and milder than that of phenacetin, because it is less soluble, and it is said to be free from by- or after-effects. Dosage.—As an antipyretic, 0.25 to 0.6 Gm. (4 to 10 grains); as an antineuralgic, 1 to 1.3 Gm. (15 to 20 grains), preferably in wafers. Manufactured by E. Merck, Darmstadt (Merck & Co., New York).

## TROPACOCAINE HYDROCHLORIDE.

Tropacocaine hydrochloride,  $\text{C}_8\text{H}_{14}\text{NO}(\text{C}_7\text{H}_7\text{O})\text{HCl} = \text{C}_{15}\text{H}_{21}\text{NO}_2\text{HCl}$ , is the hydrochloride of synthetic tropacocaine.

Actions and Uses.—Tropacocaine hydrochloride is a local anesthetic, resembling cocaine very closely in its general action, but only half as poisonous. It is reported that anesthesia sets in more rapidly and lasts longer than with cocaine. It produces less dilatation of the pupil, sometimes none at all. It is recommended as a local anesthetic. Dosage.—It is applied in 3 to 10 per cent. aqueous solutions containing 0.6 per cent. sodium chloride. Manufactured by E. Merck, Darmstadt (Merck & Co., New York).

## TUMENOL.

Tumenol is a crude mixture of tumenol sulphone and tumenol sulphonic acid derived from bituminous shale.

Actions and Uses.—It is said to be a non-toxic and non-irritant protective and palliative to the skin. Dosage.—As 5 to 20 per cent. ointment or 10 per cent. solution in water or glycerin and in the form of soap plaster (with salicylic acid). Manufactured by Farbwerke, vorm. Meister Lucius & Bruning, Hoechst a. M. (Victor Koechl & Co., New York).

FEBRUARY, 1908.

\$2.00 YEARLY.

## A PRACTICAL OBJECT LESSON FOR OUR DOCTORS AND PEOPLE.

For the information of our readers we present here the amount of the annual appropriation for various departments of the State Government, some of the greatest importance, but others involving hundreds of thousands of dollars, made as a matter of routine, and endured because the people have carried the burdens so long that they have acquired the habit.

For the same purpose we publish the amount of the annual appropriation given the state boards of health in some of the other states, for which the information could be promptly obtained.

Contrast in Appropriation in Kentucky for other purposes and for the protection of health and life. Auditor's Report for 1905.

1. Public Schools . . . . .	\$2,234,509
2. Charitable Institutions . . . . .	661,047
3. Juries . . . . .	342,409
4. Criminal Prosecutions . . . . .	282,665
5. Penitentiaries . . . . .	257,374
6. Idiots . . . . .	163,341
7. Commissions to county officers . . . . .	147,966
8. Judicial Salaries—Appellate and Circuit . . . . .	146,000
9. Assessors . . . . .	119,720
10. Militia . . . . .	64,855
Protection of Health and Life . . . . .	5,000

Contrasts in Annual Appropriations for Protection of Health and Life in various States for the year 1907:

1. Pennsylvania . . . . .	\$1,000,000
2. Massachusetts . . . . .	138,500
3. New York . . . . .	129,179
4. Illinois . . . . .	119,000
5. Florida . . . . .	70,000
6. Ohio . . . . .	69,000
7. California . . . . .	56,000
8. Texas . . . . .	54,660

9. Indiana . . . . .	43,500
10. Minnesota . . . . .	34,500
11. New Jersey . . . . .	34,620
12. Michigan . . . . .	24,000
13. Kansas . . . . .	21,320
14. Vermont . . . . .	12,200
15. Missouri . . . . .	15,000
16. Maine . . . . .	14,500
17. Maryland . . . . .	14,300
18. Wisconsin . . . . .	14,200
19. Colorado . . . . .	13,950
20. Washington . . . . .	11,500
21. New Hampshire . . . . .	11,450
22. Rhode Island . . . . .	10,520
23. North Carolina . . . . .	9,000
24. Utah . . . . .	8,250
Kentucky . . . . .	5,000

In justice to our legislators it should be said that our state board of health has been so busy heretofore in perfecting and enforcing our health and medical laws, and has been so successful with the latter especially, that it has never asked for an increase in the appropriation. A stage of the work has now been reached when this must be done or the interests of the people must suffer. The pressing needs are:

1. To establish and equip a State Laboratory for the free examination, for any board of health, physician or citizen, of the products of typhoid fever, tuberculosis, diphtheria and other communicable diseases, with the view to their prevention.

2. To employ a skilled State Bacteriologist and such assistants as may be necessary for the proper conduct of this work.

3. To make a sanitary survey of the rivers, creeks, water-sheds and other matters relating to the sources and character of the water supply in all sections of the State, including the ground water wells and springs, with the view to the protection and purification of the same for the benefit of the present and all future generations.

4. To provide for the systematic collection of births and deaths and the facts as to the location and cause of every case of sickness, not only for the protection of the public health but the inheritance and other legal rights of individuals, as is done in all other civilized countries. The bill will provide ample compensation to physicians for every report of a birth or death, as is done with the most ignorant county and other officials for all similar work.

5. To provide for an annual conference, or school of instruction at some central point for all county and city health officers, the expense of such officials to be paid as is now done in some of the other states.

We believe that the time has come for the people to know that a properly equipped board of health in any county or city is as important to their interests as any court could be, that a health officer, so paid that he can devote his time to the discharge of his duties, is as important as both the circuit and county judges, and that sanitary inspectors are as important as sheriffs, policemen and clerks, all combined. We have been ignored and treated with disdain for so long by small officials in most sections that it will at first surprise them when we demand fair treatment, but we are now sufficiently organized to begin to make ourselves felt.

If you agree with us, we ask you to write both your Senator and Representative at Frankfort by the next mail urging the importance of these matters and asking for a proper consideration of them.

---

#### YOUR DUES.

It is our pleasure to notify our fellow members that that period of the year has again rolled around when it is the privilege of each of us to again contribute our dues to our county society, which in turn supports and helps to form the State Association. Look at it what way you will, the paying of such dues is a privilege and a pleasure as well as a duty.

As an investment, the dues are, under our Constitution, paid as a subscription to this JOURNAL. Last year it cost more to publish it than all the subscriptions received, the balance being made up by our advertising income. Each member, therefore, receives for his dues a larger return each year than the cost.

Again, as a result of the work of this Association last year in the insurance fee matter the physicians of Kentucky will receive more money in actual cash this year and each year hereafter than they would have re-

ceived without such organized work than all the physicians of Kentucky have expended for medical society work since the first medical organization in the State over fifty years ago.

This year, as a direct result of our crusade, the physicians of the State will save more money in actual cash out of their own pockets than our work will cost in five years, by cutting out the expensive and useless nostrums and proprietaries of unknown or doubtful composition, and substituting therefor the known and reliable preparations of the United States Pharmacopoeia and National Formulary. This is not taking into consideration the ten times greater amount of money saved our patients and our reliable druggists.

Besides these things in the county societies, their members are studying medicine together, and are learning as well about new methods as how to improve and keep the valuable old ones.

Through their co-operation with the State Board of Health, they are elevating the standard of entrance and graduating requirements of medical colleges. This means that the future graduates will be better prepared when they leave college, and will help to exclude the unfit and unprepared.

They are co-operating with the American Medical Association, through its Council on Pharmacy, in investigating the various pharmaceutical preparations that are being offered to the physicians of the United States.

They are co-ordinating the force and influence of the medical profession through their Legislative Committees, and through co-operation with the National Legislative Council, so that its influence may be felt in national as well as State affairs.

They are publishing this JOURNAL which will come to you once each month. It belongs to the doctors of the State and every cent paid to it for subscriptions or advertisements is spent in making it larger and better. It tells what the profession is doing in every other county and gives the news about doctors. It also tells about the practical scientific advances in medical practice.

They are trying to bring about a better state of affairs socially among the members of the profession all over the country.

They are helping to abolish contract practice, and to relieve the profession from poverty and incompetence in every possible way. If you want to help, see or write the secretary of your county medical society *to-day*, sending him your county and State dues, and pledge him your active support in all the work he can arrange for the year 1908.

### THE ETHICS OF IT.

Article I, Section 8, of the Principles of Ethics of the American Medical Association, promulgated as a suggestive and advisory document by that great body, and formally adopted by the Kentucky State Medical Association and all of its component county societies, is as follows:

#### PATENTS AND SECRET NOSTRUMS.

It is equally derogatory to professional character for physicians to hold patents for any surgical instruments or medicines; to accept rebates on prescriptions or surgical appliances; to assist unqualified persons to evade legal restrictions governing the practice of medicine; or to dispense, or promote the use of, secret medicines, for if such nostrums are of real efficacy, any concealment regarding them is inconsistent with beneficence and professional liberality, and if mystery alone gives them public notoriety, such craft implies either disgraceful ignorance or fraudulent avarice. It is highly reprehensible for physicians to give certificates attesting the efficacy of secret medicines, or other substances used therapeutically.

If every sentence in this section could be read, then understood, and, finally, *acted upon*, the use of secret medicines would be relegated, as it should be, to the discarded history of the healing art along with sorcery and witchcraft. Speed the day!

Another interesting section of this great document is Section 5, of Chapter III. It reads:

#### RELATIONS TO PHARMACISTS.

It is the duty of physicians to recognize and by legitimate patronage to promote the profession of pharmacy, on the skill and proficiency of which depends the reliability of remedies, but any pharmacist who, although educated in his own profession, is not a qualified physician, and who assumes to prescribe for the sick, ought not to receive such countenance and support. Any druggist or pharmacist who dispenses deteriorated or sophisticated drugs or who substitutes one remedy for another designated in a prescription ought thereby to forfeit the recognition and influence of the physicians.

#### NOSTRUMS AND PROPRIETARIES.

The Century Directory says that the word, nostrum, is from the Latin, *noster*, ours. "The name is supposed to refer to the habit of quacks and other advertisers [italics ours] of claiming special virtue for their wares as 'our own make.'" The same authority defines a nostrum as "a medicine the ingredients of which, and the methods of compounding them, are kept secret, for the purpose of

restricting the profits of sale to the inventor or proprietor; especially a quack medicine."

A proprietary medicine is defined as "a medicine the manufacture or sale of which is restricted through patent of the drug or combination of drugs, of the label, or of the name or otherwise, or a medicine concerning which the person making it claims a private formula."

Remembering that all nostrums are bad, and that many proprietaries are nostrums, how would you classify the following, which are taken from the advertising pages of a journal whose publishers write that it is "owned and controlled by physicians and published by them without profit for the good of the profession."

Glycothymoline, Bovinine, Uriseptin, Angier's Petroleum Emulsion, California Fig Syrup, Peacock's Bromides, Chionia, Seng, Cactina Pellets, Tongaline, Fellow's Hypophosphites, Papayans (Bell), Cystogen, McArthur's Syrup, Pond's Extract, Wheeler's Tissue Phosphates, Sammetto, Hydroleine, Hayden's Viburnum Compound, Bromidia and Sulpho-Naphthol.

We would like to know what the physicians of Kentucky would do with such a journal if an attempt were made to put it in circulation in this State. *But the Journal above referred to is published in Boston! Massachusetts!* and its publisher writes that it does not accept nostrum advertisements. It is hardly necessary to remind our readers that Rip Van Winkle lived in the same neighborhood.

---

#### AN IMPORTANT CHANGE.

It is well to remember that the official list of members of county societies will be made up on April 1, this year, for transmission to the American Medical Association, under the instructions of the House of Delegates at Louisville. The American Medical Directory will be revised this year and if you wish your name to appear in it so as to establish your right to reciprocity with other States, you should pay your dues at once.

---

#### OUR INDEX.

Last month we published the index for 1907 volume of the JOURNAL. It will be noted that a large number of the members of our Association were contributors to that volume, and we trust still more of them will assist in the editing of this one.

Many articles are published about which professional opinions differ. The Council desires this year to open a Department of Correspondence, which shall be denominated—

“The Forum,” which will be open to all of our members. If you disagree with any author, write to us about it. If you wish to ask questions, write them in and we will ask all of our readers to reply. If you have some favorite prescription which is giving you good service, write it out for us. It is the ambition of this JOURNAL to reflect all the views—both orthodox and heterodox—of all of its members. No clique, ring or “bunch” control, or can by any means control it, because it is the property of all the physicians in Kentucky, all of whom own and edit it. During 1908, will you not do your share?

#### SOME CORRESPONDENCE.

The following correspondence is self-explanatory and will be of interest to our members:

##### OUR LETTER.

KENTUCKY STATE MEDICAL ASSOCIATION.

*Office of the Secretary,*

Bowling Green, Ky., Dec. 11, 1907.

*Messrs. D. C. Heath & Co., Publishers Boston Medical and Surgical Journal, Boston, Mass.*

MY DEAR SIR.—The enclosed resolutions are self explanatory. If passed by a few cranks or faddists they would be of small value, but they were unanimously adopted by the 641 members of this Association who attended our recent Louisville session, and have already been endorsed by 91% of the 3,600 physicians in Kentucky on referendum vote. Medical societies in other States are acting rapidly, and we need only the practical co-operation of the medical press to make this movement a complete success. We realize fully the difficulty of convincing a firm which has been conducting a successful medical journal for many years at a considerable profit that a portion of their dealings with their subscribers have been at least unwise, and often misleading; but if you, my dear sir, were ill, yourself, would you want one of our fraternity, after diagnosing your case, more or less well, to treat you with some pharmaceutical preparation in regard to the chemical combination and therapeutic indication of which he had absolutely no knowledge, except the advertising statement of laymen, who could not even understand that they were often committing a blunder, frequently a crime in delaying reasonable treatment. The temporary pecuniary sacrifice from such a course would be great, of course. The KENTUCKY MEDICAL JOURNAL, the organ of this Association, rejected more than four thousand dollars in advertising last year, and the Council has cut out fourteen hundred dollars

more under the terms of these resolutions. But, in the long run, is not such a policy, leaving out the question of common honesty involved, sure to be successful? Our profession is already awakened to this evil that has gradually grown upon it as well as upon the medical journalist. Without its patronage and confidence our advertisers will all soon quit us.

May we not ask your thoughtful consideration of this matter, and, after consultation with your editor, such expression of your views regarding it as will indicate that our profession may expect your co-operation.

Very truly yours,

KENTUCKY STATE MEDICAL ASSOCIATION,  
By A. T. McCormack, Secretary.

##### THE REPLY.

THE BOSTON MEDICAL AND SURGICAL JOURNAL.

Boston, Mass., Dec. 18, 1907.

*Dr. A. T. McCormack, Bowling Green, Ky.*

DEAR SIR.—Your letter of December 11 addressed to the publishers of this Journal is at hand.

We do not advertise nostrums. We refuse much nostrum advertising, and we discourage probably more than we refuse.

In the Journal of March 1, 1906, nearly two years ago, Dr. Shattuck published an editorial upon this question, which to our mind settled the matter effectively; at least in all the discussion since then the Journal has not found it necessary to change its position or say any more.

This Journal is owned and controlled by physicians and published by them without profit for the good of the medical profession. The editor-in-chief is Dr. George B. Shattuck, a very honorable, intelligent and respected member of the medical profession, of this city, who has, as he deserves, the confidence of a very wide acquaintance, personally and editorially.

He does not find it necessary to urge our subscribers not to use nostrums. Physicians who care for this Journal are men of average intelligence, and do not so prescribe.

We are at a loss to understand how the physicians of Kentucky can be as stated in your letter and resolutions. It seems to us a terrible indictment, and we may well wish that it is too severe.

Yours truly,

D. C. HEATH & CO.,  
Per W. M. LEONARD.

##### OUR ANSWER.

KENTUCKY STATE MEDICAL JOURNAL,  
*Office of the Secretary,*

Bowling Green, Ky., Jan. 6, 1908.

*Messrs. D. C. Heath & Co., Publishers The*

*Boston Medical and Surgical Journal,*  
*Boston, Mass.*

GENTLEMEN.—I was at first pleased to receive your letter of the 18th ult., in which you make the plain statement, "we do not advertise nostrums. We refuse much nostrum advertising, and we discourage probably more than we refuse." Again you say, "The Journal is owned and controlled by physicians and published by them without profit for the good of the medical profession. The editor-in-chief is Dr. George B. Shattuck, a very honorable, intelligent and respected member of the medical profession, and of this city, who has, as he deserves, the confidence of a very wide acquaintance, personally and editorially. And again, "He does not find it necessary to urge our subscribers not to use nostrums. Physicians who care for this Journal are men of average intelligence, and do not so prescribe." And still again, "we are at a loss to understand how the physicians of Kentucky can be as stated in your letter and resolutions. It seems to us a terrible indictment, and we may well wish that it is too severe."

Taking it for granted that your evident faith in the superiority both of your publication and your profession is caused by local pride and patriotism rather than an apparent superciliousness; and that your lack of knowledge in regard to nostrums is more due to the fact that you are laymen, than to a wilful ignoring of the world-wide campaign against such preparations, which has been quite as active in England and Germany as in all of this country except such isolated sections as are supplied by such medical publications as yours, to which the words of the psalmist might well be applied: "Their idols are silver and gold. Eyes they have, but they see not; they have ears, but they hear not. \* \* They that make them are like unto them: so is every one that trusteth in them." I shall take the liberty of submitting for your consideration something about the present status of these matters.

In your advertising pages I find, among other things:

Glycothymoline. Bovine. Angler's Petroleum Emulsion, California Fig Syrup, Peacock's Bromides, Chionia Pillets, Tongaline, Fellows' Hypophosphites, Papayans (Bell), Cystogen, McArthur's Syrup, Pond's Extract, Wheeler's Tissue Phosphates, Sanmetto, Hydroleine, Havden's Viburnum Compound, Bromidia, Sulpho Naphthol, etc.

Do you, or does Dr. Shattuck, or does any one of those who "care for" your Journal to the extent of subscribing for it know any more of the composition of any one of these

preparations than they have been told by their interested—usually venal—manufacturers; or do any one of you know anything of their indications or uses not written by these same lay manufacturers either in such medical journals as yours or in the still more blatant literature—God save the mark! — with which they wrap the original packages of their stuff? This being true, and it is, are not each of such preparations nostrums, and therefore unfit for acceptance in a Journal which is "published without profit for the good of the medical profession."

Your distinguished editor is held in esteem and honor in the West as in the East, and yet it is entirely inconceivable that a physician of his learning and eminence should use or commend for the use of others medical preparations of whose formulae and indications he knows nothing, or, what is worse, *thinks he knows and yet does not*. It is far easier and more profitable to assume that Dr. Shattuck has exercised no supervision over the advertising columns of your Journal, and more charitable to assume that an honorable lay firm, such as yours, not realizing the danger of these stuffs to sick people, has been imposed upon by the manufacturers whose wares you advertise rather than that you have been the accomplices of such people in foisting products of unknown composition through your medical readers on their ill, and therefore helpless patients. I feel that I understate the character of your advertisements in suggesting that most pages should be headed, "These preparations should be condemned and avoided."

If it could be true, as you state, that your editor does not find it necessary to urge your subscribers not to use nostrums, as the men who care for your Journal are men of average intelligence and do not so prescribe, no criticism of your course, beyond a mere moral one, would be possible. Your advertisers are astute business men and it is hardly possible that they would continue to pay you for publishing advertisements of their wares if they were not used to a profitable extent by your readers. In the greatest centre of medical teaching in this country—Philadelphia—recent careful investigation has shown that 47% of the prescriptions filled are for such nostrums as you advertise, and worse. Even with the wonderful intelligence and vast learning of the magnificent profession of your great city and State, we are compelled to feel that at least a portion of it, like your firm, has not kept pace with the trend of modern, impartial investigation along these lines, and that the difference between your profession and your medical publications and

this Association and our JOURNAL is that we have seriously erred in the past because of the same ignorance which is still guiding you, and that we are now endeavoring with all our might and main to correct serious evils that crept upon us, as upon you, unawares, of which you have not yet taken cognizance.

The physicians of Kentucky realize fully the high character of your firm as publishers, and the splendid attainments and traditions of the great medical profession of New England. It is with a full realization of all this, and of the wonderful possibilities open to your Journal as their representative, that I write these suggestions perhaps too bluntly and frankly, and with no desire for carping criticism or in any "holier than thou" attitude. In the shadow of Harvard and Tufts, with the Massachusetts General and the Boston City hospitals as your clinics, with the greatest sanitary force in the Union back of your State Board of Health, with the glorious city of Boston as your cradle and New England and the East as your field of operation and influence, "owned and controlled by physicians and published by them without profit for the good of the medical profession," and with one of the most honorable, intelligent and respected members of the medical profession as your editor-in-chief, our profession appeals to you in all sincerity to investigate this whole question coldly and dispassionately, and we hope to have your cooperation in removing this blot and disgrace from American medicine, and this danger even more insidious than disease, from our sick people. It is unnecessary for me to add that all this is written with no other personal feeling than one of admiration for your profession, and from one as jealous of the reputation of your Journal as of all things pertaining to the welfare and probity of our profession.

Very truly yours,

A. T. McCORMACK,

Of a different character is an attack on medical organization and a defense of the worst class of nostrums is an editorial in the Southern Practitioner. Inspired by an evident venality, this rather well written screed is worthy of the type of medical journal to which it belongs. Most of its editorials are inspired reading notices of the well known commendatory type of the worst class of nostrums. Even its so-called original articles are interspersed with advertisements of products which every intelligent physician knows to be pure fakes—from anasarca to antikamnia.

Unfavorable comment from such a source is a compliment.

## SCIENTIFIC EDITORIALS.

### CATHARTICS.

It has been said of quinine that it is one of the most used and most abused drugs, but this is probably more true of cathartics. During the first lecture that the writer ever listened to in a medical college he heard this statement: "When you don't know what else to do, give a purgative," and he has heard it many times since. Must the patient's intestinal canal be made the scapegoat pending the making of a diagnosis? Will American physicians never attain that degree of independence or enjoy that confidence of their patients that will enable them to resist the temptation to make observation-diagnosis and to frankly say: "I do not now know what the exact nature of your trouble is, and shall be obliged to study it more closely by further observation." It is further true that after the physician has definitely determined that a cathartic is indicated, he many times manifests an indifference as to a choice of agents at his command by generalizing to the patient or the nurse in his instructions: "The bowel must be 'cleaned out'; give him something this morning."

"What shall it be, doctor?"

"O, anything convenient—calomel, salts or oil." or worse still he instructs that they send for Leech & Company's Packer & Moore pills, and take *two or three*. No definiteness as to dosage, time or frequency of administration. Quite a different attitude do we assume when we desire to give a cardiac stimulant. No vague instructions now; no suggestions to "get strychnine or caffeine or digitalis or something of that sort and take it occasionally—and if you don't do well let me know." Instead, we rise to the dignity of our profession, write a prescription or dispense ourselves exactly *what* we want, *how much* we want and order it given *when* we want. There is no good reason why a prescription should not be written for a purgative, or why the same careful determination as to the patient's needs in selection of agent, dosage, etc., as would be given to diuretics.

### NECESSITY FOR CLOSER STUDY.

If the above be conceded to be true, even in part, a familiarity with the mechanism of purgation and manner of action of those agents used for this purpose becomes imperative. A class of drugs with so many numbers and presenting widely differing activities through which a more or less common end is obtained must, of necessity, present

varied phenomena. One acts on one portion of the intestine, for instance, while another extends its influence on a part many feet removed; a familiarity with the *locality* of a purgative's activity will be of material assistance to the physician when prescribing, as he may thus avoid giving two drugs whose combined effect in the colon, for example, would produce undue irritation at that point without securing any more thorough emptying of the entire canal. On the other hand by combining such agents as affect different anatomical portions of the gut the entire tube may be thus induced to empty itself more completely; to illustrate: if podophyllum, which acts in the upper part of the small intestine, colocynth, which affects the colon chiefly and aloes, which exerts its influence in the lower part of the large intestine, be combined in their administration, the sum total of their respective activities would be represented by a most thorough discharge from the entire intestinal canal from the pylorus to the anus. It sometimes happens, also, that there exists a need for a certain portion of the intestine to be influenced—the small bowel may be doing its work, while the large one is not, and *vice-versa*.—and if a drug is given as a laxative, or purgative merely because it is a laxative or purgative and with no regard to the field of its operations it need scarcely be said that the patient would not receive proper relief.

Again, a knowledge of *how* a cathartic acts is important. All such drugs do not act alike any more than all men put on their clothes alike. The doctor's function is to relieve, not to aggravate, and if the mucous membrane of the canal is already much irritated from whatsoever cause, it would be poor therapy to give a drug that would increase the condition merely because, forsooth, the physician determined the "bowels must move." How much greater relief with just as satisfactory a stool if castor oil had been administered, securing a two-fold effect—a fecal discharge and a soothing, protective and healing effect on distressed cells? Or, to further illustrate, if the object of the purgative be to extract fluid from the tissues of an edematous patient, how little good would be had from epsom salts in ounce doses given in a *pint* of water as compared with the rapid, safe and satisfactory depletion which ensues from its administration in *two ounces* of water.

To carry the reader a little further in the effort to impress him at the outset of the importance of a more intimate familiarity with the actions of the drugs he uses for the purpose of catharsis as in any other instance,

it will be assumed that a nursing mother is in need of a purgative, the baby healthy and in no such need; should a drug be given that is eliminated by the mammary glands the child will, through the milk, be unnecessarily drugged and the physician branded with incompetency. It is equally as important to know the length of time it takes a given drug to cause purgation. Some of these agents act in a few minutes, others require hours. It would be absolutely useless to administer podophyllum with elaterium since the former requires 10-12 hours to act, while the latter's time action is so short that by this combination it would cause the bowel to be emptied of its contents—including the may-apple—long before that drug had had time to establish physiological action.

#### OUTLINE FOR STUDY.

In order to make the study of cathartics both comprehensive and less difficult the writer has used in his college work the following outline:

1. Name of agent.
2. Origin.
3. Preparations and Dosage.
4. Mode of action.
5. Effect on the liver.
6. Effect on the mammary gland.
7. Portion of intestine affected.
8. Media (alkaline or acid).
9. Character of stools.
10. Number of stools.
11. Pain.
12. Time action.
13. Method of administration.
14. Time of administration.

The idea and the scheme are original and after six years' trial he is convinced that it is of material benefit to students. He is further convinced that if good for students, it would also be good for practitioners, who after all are, or should be, students. By studying the various drugs in this class from these viewpoints it is believed that not only can a more intelligent grasp be had, but it will also serve to facilitate remembrance.

V. E. SIMPSON.

(To Be Continued.)

#### RICKETS.

Rickets is a disease of nutrition appearing in young children and infants. Its main features are very familiar to all practitioners but far more so to those who are located in the larger cities, and most of all in the great crowded districts of the largest cities. It affects particularly the poorest classes and the foreign population. With the local profession it is seen in its most typical forms in the negro race.

The earliest symptoms are very characteristic and obvious. Sweating of the head and oftentimes of the neck also, poor sleeping, restlessness at night, delayed dentition, beading of the ribs, nodes upon the wrist and ankle joints, open fontanel, all these and many others need no repetition for they are fresh in the memories of all. There are certain more recondite and less patent symptoms which are sometimes overlooked and yet they have a far more vital relation to the future health of the child than any of those which have been mentioned.

One of the most important of these is the effect of the Rickets on the muscular system both voluntary and involuntary. In this disease there occurs a relaxation of the muscular fibres and also of the ligamentous tissues. The hollow viscera suffer from this relaxation as shown by the enlargement of the stomach and the distention of the bowels. Holt has shown very graphically the great extent to which the stomach is dilated in many of these cases and one can easily deduce some of the gastric conditions which are almost bound to arise.

The more recent studies of the physiology of digestion have shown how the food lies almost dormant in the stomach for quite a time after it has been swallowed but then rhythmical movements begin in the fundus of the stomach and the food is projected against the pyloric extremity and is again thrown back into the greater curvature thus churning the food and mixing it thoroughly with the gastric juice and insuring perfect preparation for the intestinal secretions. One can readily understand that with the greatly softened muscular wall that the mixing of the food and secretions would be seriously interfered with; the mass of food remaining in the stomach longer than it should would undergo fermentation with its resulting acid formation. This fermenting and highly acid chyme has not been prepared for intestinal digestion and so the vicious condition is transferred to the intestines.

It is small wonder that potbelly is so common in these children. We fail to remember at times that this dilated condition of the stomach not only seriously handicaps digestion but it is also a menace to the proper growth and development of the stomach. It is very certain that the relaxed condition of the intestinal tract is the cause of the accumulation of gas in the bowels and of constipation which alternates with diarrhoea which in the summer time is quite an etiologic factor in the production of summer complaint.

Another phase of the malign influence of this disease is seen in its action on the nervous system. There is a marked tendency in this

disease for the blood to overfill the capillaries of the brain. Some believe that this fluxion of blood to the head explains the poor sleeping of these children. They sleep high in Rickets. Often the only way to get these children to sleep is to carry them over the shoulder so that the head will be high. The enlargement of the cranial bosses, the increase in size of the whole head, the head sweating, etc., all show the derangement of the blood supply to the head. The nervous system is in a state of unstable equilibrium and convulsions are prone to occur with slight if any cause. Chvostek's symptoms and also Trousseau's will give very valuable information as to the likelihood of the child's developing convulsions. Most of these children have a convulsion at the beginning of any serious illness. The mother soon learns to know that the child has convulsions very readily and she is apt to feel like minimizing the danger of the convulsive seizure but right here lies the danger of the child's initiating the epileptic habit, a catastrophe which should be guarded against with all our skill.

In the matter of treatment there is a consensus of opinion that fat should be administered in whatever form the child can best take it. Cod liver oil is probably the best of the means by which fat can be administered but it has been supplanted by the numerous so-called tasteless cod liver oils. A tasteless cod liver oil may be good for some things but it is not indicated in Rickets for here the fat is what is really needed to supply the deficiencies which may have arisen from various sources. One does not have to limit himself to this disagreeable oil but may administer almost any oil which will suit the taste of the child. Good butter, or olive oil will answer the purpose practically as well.

Along with the fat, lime salts and phosphorus should be given. Phosphorus is a dangerous drug to use for any length of time as it is one of the most toxic and insidious drugs in the Pharmacopoeia. It is especially indicated in the nervous and convulsive cases. The combination of lime with phosphorus in the form of the hypophosphites will exert practically all the beneficial influence of the phosphorus without the danger that inheres in the original element. Lime in itself is indicated and is beneficial in whatever form it may be given.

PHILIP F. BARBOUR, M. D.

## THE FORUM.

---

### TRAINING IN MEDICAL ORGANIZATION.

MR. EDITOR.—The students of the Universi-

ty of Pennsylvania Medical School have formed an organization, the purpose of which is to acquaint the undergraduates with the workings of the American Medical Association, after which it is very closely modeled. The various student societies take the place of the State organizations and elect members to a House of Delegates which transacts all the business of the association. An annual meeting is held at which papers are read by chosen members, thus encouraging original research and a scientific spirit. The organization is named The Undergraduate Medical Association of the University of Pennsylvania and already has over two hundred and fifty members.

*Mr. Editor:*

At the recent Annual Meeting of the American Pharmaceutical Association the undersigned was directed to send you a copy of the following resolutions:

WHEREAS: The American Medical Association, the American Pharmaceutical Association and the National Association of Retail Druggists together with many State and local organizations and journals in both professions have been for some years endeavoring to bring about a return to the practice of medicine based on the Pharmacopoeia, and

WHEREAS: The medical colleges are represented on the Committee of Revision of the U. S. Pharmacopoeia, and

WHEREAS: It is manifest to the thoughtful men both in medicine and pharmacy that a very large number of medical men might be better informed regarding the Pharmacopoeia as a book of reference and standards. Be it therefore

*Resolved:* That it is the sense of the American Pharmaceutical Association in convention assembled, that a great advance in the ethical practice of medicine and pharmacy will be made when the medical colleges make the Pharmacopoeia a prescribed textbook or book of reference and require a familiarity with it in their examinations.

*Resolved:* That we request the governing authorities of all medical colleges in the United States to put into force such a ruling in their respective institutions as will insure in future classes a well-grounded knowledge of materia medica and Pharmacognosy, as set forth in the Pharmacopoeia.

*Resolved:* That the General Secretary be directed to transmit a copy of these resolutions to each medical college in the United States and to the medical and pharmaceutic-

al press.

Yours very truly,  
CHAS. CASPARI, JR.,  
General Secretary.

*Mr. Editor:*

I notice in the issue of your Journal that I have just received, an editorial on the subject of establishing an Epileptic Colony in this State. In that article you state that there has never been any action with regard to this matter. I write to disabuse your mind. During Governor Beckham's first reign, the Louisville Clinical Society appointed a committee of which I was chairman to present to the legislature a bill for the establishing of a colony. I went to Frankfort and met the committees, it was referred to and they recommended the bill unanimously and it passed one branch of the legislature without hardly a dissenting vote and for lack of time or rather neglect in superintending the matter it was not introduced in time for its passage before adjournment.

I have a bill drawn up and have put it into the hands of Mr. T. D. Osborne, who is noted for his philanthropic life, and I want your Journal to urge the medical men to assist its passage. The Clinical Society will be represented when needed in Frankfort and I hope you will be there also.

Yours truly,  
T. P. SATTERWHITE.

## ORIGINAL ARTICLES.

### THE PRESENT STATUS OF GASTRIC SURGERY WITH ILLUSTRATIVE CASE.\*

BY J. GARLAND SHERRILL, A. M., M. D.,  
LOUISVILLE.

It is but little more than 25 years since the first gastroenterostomy was performed. Since that time, after many modifications and the employment of numerous methods of suture and a variety of mechanical aids to anastomosis, this operation has found a permanent place in the treatment of stomach disorders. The persistent regurgitation and vomiting of food, bile and intestinal secretion, which occurred so frequently after this operation as first performed, are now comparatively rare. This result has been reached only through the failure of many suggested procedures for the prevention of the vicious circle.

It seems strange that so many and such complicated operations should have been tried and yet the desired result obtained with such slight change from the original posteri-

\*Read before the Southern Surgical and Gynecological Society, New Orleans, Thursday, December 17, 1907.

or gastroenterostomy (Van Haacker), consisting in making the anastomosis a little nearer the cardiac end of the stomach than had been customary. As a result of the operation having gone through this experimental stage, as it were, the technic has been so simplified and its annoyances and difficulties so guarded against that those who follow the pioneers in this field find their task greatly lessened.

It is quite true that the operation of gastroenterostomy is not ideal and that it is in many cases purely a mechanical palliative measure in that it provides an escape for the contents of the stomach into the intestine, thus preventing overdistension of the organ in cases of stenosis, and in cases of ulcer or cancer at the pyloric extremity relieving the part from the irritation of food, etc. The fact that gastro-enterostomy is only a palliative measure accounts in part for much of the opposition to the employment of surgical treatment in cases of ulcer. We have a proceeding as yet little employed which seems likely to revolutionize the treatment of gastric ulcer and that is excision of the ulcer bearing area—not only will it prove absolutely curative, but it will tend to prevent the recurrence of the ulcer because of the diminution of the secretory portion of the gastric mucosa, and it may cure an incipient case of malignant disease. Many cases, it is true, will not demand this radical procedure, nor will it be possible to employ it in all, but in suitable cases it should prove most satisfactory and its mortality in skilled hands should not greatly, if at all, exceed that of gastroenterostomy. It seems to us that the questions now of paramount importance in the consideration of this subject are accurate diagnosis and the determination of the cases best suited for surgical interference. Because we believe that surgical technic has so greatly simplified that method of treatment we must not conclude that every patient suffering from dyspepsia must be subjected to surgical interference. On the other hand we must urge that cases of ulcer, suspected carcinoma, or of stenosis must not be neglected until even surgery will prove of little avail for their relief. Ulcer of the stomach and duodenum must be considered as both a medical and surgical ailment and the best results will obtain when the physician and surgeon study the case in unison. Many cases of acute ulcer are relieved at least temporarily by proper medical supervision, some of them recur either because the patient becomes careless and indifferent as soon as the symptoms subside or in spite of any care on his part. When such a recurrence is noted and response to medical treatment is not prompt, resort should be made to surgical advice.

Again when hemorrhages are occurring in acute ulcer very frequently, or where they are profuse, operative means should be employed before the patient is bordering upon dissolution. Chronic ulcer which has resisted time should be subjected to excision, or, if this is not feasible, gastroenterostomy. In this kind of a case the danger of malignancy is sufficient to demand excision—aside from all other reasons.

Where rupture of an ulcer is imminent either in the acute or chronic type *operate*. *Perforation* makes operation imperative at the earliest possible moment. The mortality increases directly in proportion to delay.

Dilatation due to high situation of the pylorus causing food stasis and pyloric obstruction from cicatricial contraction or bands of adhesion are more satisfactorily treated by gastroenterostomy than by either the Heineke-Mieuiliez or the Finney operation.

Gastroptosis, atony, and duodenal ulcer when excision is not feasible, are indications for the performance of gastroenterostomy. The indications for excision are chronic ulcer with induration, with hemorrhage, or where the danger of rupture is imminent.

In carcinoma and cicatricial hour-glass contraction from multiple ulcers excision is employed when possible, and gastroenterostomy when excision cannot be performed safely. Even in extreme cases the palliative benefits of gastroenterostomy justify this procedure.

Gastroenterostomy has some disadvantages which must be considered when arriving at an opinion in a given case:

1. Vicious circle.
2. Vomiting.
3. Regurgitation.
4. Contraction of opening.
5. Jejunal ulcer.
6. Recurrence of ulcer and failure to cure or relieve symptoms (hemorrhage, etc).
7. Ileus.

The first four are practically negligible, as they occur but infrequently with our present methods.

The formation of jejunal ulcer may occur, although not frequently. It seems the best way to prevent it is to place the opening nearer the cardiac than was formerly done, and after the operation to give proper attention to diet, as for the treatment of the original ulcer. Very little can be done to make a cure certain or to prevent relapse beyond what the operation does in the way of drainage. The patient is placed in the best condition to be benefited by medical treatment, which should be continued.

The disadvantages of resection lie in its higher mortality, in the sacrifice of a considerable portion of the secretory function of

the stomach, and in the fact that it will prove inapplicable to all cases. Its advantages are the removal of the probability of a recurrence and of the development of carcinoma, and the diminution of the acid secretion from the smaller sized stomach which remains. The cure of a carcinoma is possible in exceptional cases, or at least an ulcer which is a potential carcinoma may be cured.

It is beyond the scope of this paper to enter into a description of the many operations offered to prevent the reflux of food, bile and pancreatic fluid into the stomach which are rather fully described by the late Dr. Fowler in Vol. xxxvi—1902—Annals of Surgery. The number of methods and their intricacy would seem to show that the pioneers in this field considered this so-called vicious circle a real difficulty, and an objection to the operation. It has been learned more recently that the best means of overcoming this difficulty is by the employment of a posterior gastroenterostomy at the lowest point of the stomach and within a few inches of the point of emergence from the ligament of Treitz, without a loop. This is the simplest and best form of anastomosis, is least likely to be followed by ileus (a real danger in many methods), and accomplishes the desired result of doing away with the vicious circle. (Peterson of Heidelberg, Mienliez, Moynihan, Czerny, Mayo and Mayo-Robson have popularized the plan. To properly appreciate the "no-loop" method see November 1905 Annals—Mayo).

The incision of Moynihan seems to me to meet all the requirements, although the rectus muscle can be split instead of pushed to the patient's right. A three and a half or four inch incision is made about half an inch to the right of the median line in the epigastric region—down to and through anterior sheath of rectus; this muscle is pushed to the right and the posterior layer of the sheath is cut directly behind the anterior incision. Upon opening the peritoneum a rapid, but careful examination is made of the gall bladder and passages, duodenum, pancreas, pylorus and stomach. If the conditions justify completion of the operation, the colon and its omentum are lifted up and the jejunum brought into view. The transverse mesocolon is separated and the lowest point of the stomach drawn through the rent. In some cases this cannot be accomplished, a condition which was present in one of the cases reported herewith, where I completed the anastomosis by opening the greater omentum near the stomach, drew a loop of the intestine through the opening in the mesocolon, and both it and posterior wall of the stomach through the opening of the gastro-epic omentum. After com-

pleting the anastomosis, with clamps holding the structures meanwhile, the points of anastomosis were drawn back, the mesocolon sutured about it, and then the opening in the omentum was closed. This modification of the technic was necessitated by the presence of a cancerous infiltration which involved a large part of the lesser curvature and so much of the stomach walls as to force us far to the left to obtain a good point for anastomosis. The later history of the case shows the value of going far to the left, since when distended the low point lies farther to left. This patient had practically no trouble from regurgitation, although she had a hemorrhage from the cancerous ulcer. After the stomach wall has been brought through the opening in the mesocolon its posterior wall is caught in clamps in an oblique direction (from below up and from right to left); the jejunum is made taut and clamped. Each organ should be placed in the clamps so that an incision from two to two and a half inches can readily be made. Gauze pads are placed to protect the field. The two strictures are then united by a chromic catgut suture embracing the peritoneum and muscularis by Cushing's or a continuous Lembert suture. We have found it well to place a knot at each end of this stitch to prevent any puckering of the opening. The wall of the stomach and that of the intestine are then incised for the desired distance, if thought advisable the redundant mucosa can be cut away before this is done. The posterior layers are sutured together preferably with celluloid yarn by a running stitch closely applied, or by a buttonhole stitch. This suture should be inserted with a view to the prevention of hemorrhage from the cut edges as well as to approximate the walls, and should be continued around the anterior edges so as to close the opening. The clamps are then removed and any hemorrhage checked. Then the serous surfaces are approximated by continuing the suturing with the catgut which has been left long with the needle attached. When the first knot is reached the two ends are tied and the structures can be replaced in the abdomen after making sure that the line of suturing is perfectly closed and the opening of sufficient size. Before doing this it is well to wash off the field of suture with a sponge wet with saline solution. The line of the anastomosis is attached to the mesocolon by suture to prevent the intestine being dragged into the opening in this structure and strangulated when the stomach is distended. The operation is best done with clamps, and in some cases can only be accomplished with their aid, while in others it can be readily done with a competent assistant holding the stomach and

intestine in position. This operation is done in feeble individuals, and time is quite a factor, hence the operation should be performed with all the speed consistent with accurate approximation. After the anastomosis is completed the abdominal wall is closed in layers with catgut; one or two silkwormgut sutures can be placed for safety if desired. Before leaving the consideration of the operation it is worth while to mention the mechanical aids to anastomosis, such as Murphy's button, Senn's plates, Robson's bobbin, McGraw's ligature and Moynihan's clamps. The latter may be said to be the only one which is standing the test, and it certainly facilitates the operation. Of Murphy's button we have always been doubtful as to the propriety of the use of a body which may or may not be expelled; and which has in many cases caused sloughing, resulting in the death of the patient, and we can see no real indication for McGraw's ligature for it saves nothing in operative time, does not enable us to feed the patient any sooner, is not by any means certain to cut through and the resulting opening is no better than the one made by proper suture methods. The late Dr. Fowler, speaking of it, says, "I confess, however, to a feeling respecting the elastic ligature akin to that expressed by Codivilla, who, speaking of the use of the Murphy button in gastroenterostomy, said, 'Its good function is always in God's hands.'"

The diagnosis of gastric ulcer and carcinoma is of special importance in the study of the surgery of this organ. The nearer we can arrive at a correct differentiation of the condition presenting in a given case the better equipped are we to properly handle the case upon the operating table. We therefore urge upon the profession the necessity for the most careful study of every case presenting symptoms of persistent dyspepsia or indigestion. Many such cases find the seat of their distress in the gall bladder region, and others in the morbid process in the stomach. Many of them can be relieved by proper medical or surgical means or a combination of the two, but linger, suffer, and finally die because the attendant does not go into a case carefully, but writes for a tonic or a digestive agent and dismisses the patient from his mind. The most important conditions which are present in this connection are,—ulcer of the stomach and duodenum, carcinoma of the stomach, and gall stone disease. We will therefore only consider the diagnosis of these three conditions since the entire subject would carry us beyond the scope of this article.

Ulcer occurs at any age, usually under forty, may be acute or chronic, and usually

is painful. This pain is of gnawing or burning character over a small localized area, relieved sometimes by eating. It comes on soon after meals, the time of occurrence depending on the distance of the site of the ulcer from the cardia; if after three or four hours the ulcer is probably situated in the duodenum. The pain is relieved by vomiting soon to recur, nearly always at the same spot. In addition to the painful point anteriorly, there is another in the back near the tenth or eleventh spine on the left side to which attention has been called by Boas. Pressure over the stomach increases the pain and tenderness is elicited. The muscles of the abdomen make an effort to protect the stomach by contraction, hence rigidity is present in some cases. Change in posture may relieve the pain, as for instance if the ulcer is on the anterior wall of the stomach relief is obtained by dorsal decubitus, while if the posterior wall is affected the prone position is assumed to obtain relief. The symptoms may disappear for some months under treatment or from simple abstinence from food for a short time, to recur later.

The mistake has been made to consider haematemesis as necessary for diagnosis, since it occurs in macroscopic amount in a minority of the cases. Much stress is laid upon the detection of occult blood in the stools, especially by the German observers. Certainly hemorrhage from hemorrhoidal tumors must be excluded in order to make the observation accurate. This occult blood is present so frequently that Boas uses its absence as a guide in the determination of the certainty of a cure.

The secretion in ulcer is often increased in amount, is highly acid, and contains an increased amount of free hydrochloric acid. The motor power may be increased or diminished and the dilatation with spasm of the pylorus may cause retention of the stomach contents for an abnormal period of time.

If this condition is present evidence of it will be found in the stomach washings. Blood is at times found in the gastric contents, but not so frequently as in carcinoma. The value of gastric lavage as a diagnostic measure cannot be overestimated, yet a word of caution must be offered against its indiscriminate use, since in many cases the wall of the stomach is sufficiently attenuated to make the possibility of rupture a serious danger. In order to determine the location of an ulcer bismuth has been exhibited and a skiograph taken, but with only fair success. The use of the gastrodiphane has the disadvantages of the stomach tube and yet may prove of value in some instances.

In order to differentiate between ulcer and gall stone diseases Murdoch has recommended the use of fifteen grain doses of orthoform, claiming that this will relieve the pain of ulcer, but not of gall stone. Hemmeter and others concur in this opinion. In my hands orthoform has proven of value for its analgesic effect, but has not proven to be a very efficient diagnostic means.

Carcinoma presents usually a history of digestive troubles, having been present for a long period, or perhaps gives the typical history of ulcer, with or without a period of relief from symptoms. In other instances it presents very suddenly with distressing symptoms referable to the stomach, such as pain, anorexia, epigastric distress, nausea and vomiting, perhaps even vomiting of blood. While the duration of ulcer may be prolonged, that of malignant disease is never more than one or two years. Most cases of carcinoma occur after fifty years of age, making this a very valuable point in the diagnosis. Pain, if present, is usually persistent, accompanied by tenderness, not so acute, nor so circumscribed, is neither so much increased by the ingestion of food, nor so fully relieved by vomiting as is the pain of ulcer. Loss of flesh and strength is a well-known characteristic of carcinoma in any locality, but more especially does it accompany that attacking the stomach. Any serious stomach disorder, however, will cause a loss of flesh and sometimes in ulcer it is quite rapid. Anemia is present in catarrhal gastritis, ulcer, and in cancer, and may be extreme in some forms of ulcer, especially the acute type, yet it never gives quite the same hue to the skin that malignancy imparts. In some cases of indurated ulcer it so closely resembles malignant cachexia that one should refrain from drawing conclusions upon the complexion alone.

Hemorrhage occurs less frequently in ulcer than in cancer, but is more often profuse and more likely to be intermittent. It may occur early when the general health is not greatly impaired, while hemorrhage from carcinoma occurs late and is persistent though slight in amount, yet may be profuse in some cases. Cancer progresses surely, but steadily toward a fatal issue, while ulcer shows periods of improvement lasting often for some years.

Tumor is observed in a large percentage of cases of carcinoma if they are seen late, but if much benefit is to be obtained operation must be done before a tumor can be readily palpated. I do not mean to say, however, that every case where a palpable tumor is present is inoperable, on the contrary many cases of ulcer show sufficient induration, adhesion to surrounding structures, and

even lymphatic enlargements, to be palpated through the abdominal wall, still do not present either the clinical or histological picture of malignancy.

Glandular enlargements are more likely to be noted in carcinoma than in ulcer and this enlargement may be noted some times in the supraclavicular glands. A routine examination of this region is well worth while. Some cases of ulcer show well marked lymphatic infiltration in the glands of the lesser curvature.

The size of the stomach is not of major importance in the diagnosis of these conditions, for we may find a dilated stomach without ulcer or cancer present, or, again, we may find a normal capacity and these conditions present or absent, or, yet again, a contracted empty stomach may be found; in ulcer, because of spasm causing rapid emptying of the viscus—in cancer because of the infiltration of the walls and the discomfort on eating makes the patient refrain from taking anything into the stomach. Vomiting may occur in either, and in many other conditions. Usually the vomited material in ulcer is of large amount and very acid, containing free hydrochloric acid in excess, oftentimes even when fasting, while the vomitus in cases of malignant disease is found to contain sarcinae, lactic acid, the Boas-Oppler bacillus, and at times fragments of the growth. The latter is rare, however. Again, while I deem the careful analysis of the stomach contents of great value in the diagnosis of these conditions, it is well to know that ulcer may occur without the hyperacidity and cancer even in the presence of free hydrochloric acid, yet this takes place with such rarity that if taken with the usual symptom complex one need not censure himself if a mistake be made.

Examination of the blood is of some value, but it teaches us less perhaps here than any of the aids to diagnosis which are in use. It is of more worth as a basis for prognosis, or to determine for or against operation. Examination should be made for occult blood in the stools. The final means for diagnosis is an operative exposure of the stomach, when one can in most cases determine the condition, but in rare instances the microscopic examination is needed to confirm the opinion.

Some of the conditions with which ulcer and carcinoma of the stomach might be confused are—gastric catarrh, gastroparesis, atony, dilatation (a frequent occurrence in both conditions), gall stones, diseases of the pancreas, malignant disease of the bile ducts, liver or pancreas, and ulcer of duodenum. It is beyond the scope of this essay to enter fully into the discussion of the diagnostic

symptoms of these conditions, yet it is worth while to consider the most frequent source of confusion—gall stone disease.

*Gall stones* usually cause trouble for years—attacks of colic accompanied by vomiting occur often in the night, following several days of over-feeding;—relief of nausea often occurring as soon as the stomach is empty, the pain ceasing at same time. These attacks are frequently accompanied by fever and followed by tenderness over the gall bladder region for some days. Jaundice may be present (one-third of cases), and the pain is usually greatest over the gall bladder—radiating toward navel and up toward right shoulder.

The conditions referable to the stomach are in many cases not clearly determined until the time of operation, yet any case of troublesome interference with stomachic function, which has not responded to a well applied medical treatment based upon a diagnosis made after careful inquiry with the aid of the known methods of precision, is one for exploration. Many of these unfortunate sufferers can obtain a cure, and even the incurable may obtain great relief, therefore I would urge the profession to awaken from its position of ultra conservatism and give to these so-called dyspeptics the benefits that follow well applied surgical means for their relief. As an evidence of what may be done for them I am adding the reports of three cases which are illustrative of three distinct conditions that are met in this connection.

Case No. 1: J. T. D., age 35; laborer; native of Southern Indiana. Came to us from Dr. E. N. Flynn on October 4, 1905, presenting the following history:

Family history shows one maternal aunt to have died of cancer of the breast, and his sister is now under our care for carcinoma of the parotid gland. There is no history of tuberculosis in the family.

His present trouble dates back ten years, since which time he has had a chronic bronchitis, which has caused him less inconvenience during the last few years. Ten years ago he began to have stomach trouble following a period of hard drinking. The symptoms presented were abnormal appetite, gaseous distention, general malaise, constipation, and furred tongue. This condition continued with very little improvement and five years ago he began to have vomiting after meals, appearing immediately after leaving the table. He complained of considerable pain and discomfort, which was relieved for a few minutes after eating, but reappeared in a short time. He also stated that there was a sore spot about the size of a dollar over

the stomach which caused him much inconvenience, and now and then he has noted pain in the back. He has never vomited blood, but upon one occasion expectorated a small amount and once found some in the stomach washings. He washes out his stomach twice daily, and states that this is the only way in which he can obtain a fair degree of comfort.

*Physical Examination:* I found the abdomen rather flat and covered with minute pustules from croton oil, which he had been recommended to use as a counter-irritant. The area of stomach resonance was about normal; slight resistance was felt near the pylorus, and tenderness was not marked.

On October 7, 1905, Dr. Lucas saw him and drew off 24 ounces of contents from the stomach two hours after breakfast. The distended stomach showed a marked increase in size, lower margin reaching below the level of the umbilicus; 125 Cc. of greenish fluid were removed from the fasting stomach, the total acidity of which was 46 and free hydrochloric acid 26.

*Diagnosis* of pyloric obstruction with dilatation of the stomach was made and he was subjected to operation October 17, 1905. On opening the abdomen the pylorus was found to be placed very high; the gall bladder was normal, and the stomach markedly dilated, but with the wall of normal thickness. No ulcer was discovered. A posterior gastroenterostomy was done, silk being used for the outer row of stitches, and chromic gut for the mucous surfaces. The operation was completed in twenty minutes, and the patient left the table with pulse of 60 which later dropped to 44, with a very full volume and quite regular. The pulse rate increased slowly, and on October 23rd was 60 beats per minute. Considerable regurgitation occurred, at first of blood stained fluid, later of greenish mucus. Buttermilk was given him on the third day and broth on the fifth day after the operation. He regurgitated at least half the quantity of broth given, but none of the buttermilk. He was placed in the semi-sitting posture, which seemed to prove beneficial, and later he complained of regurgitation at intervals until he left the hospital on November 7, 1905. On November 10th he came to my office and showed considerable improvement, but had had trouble with gas and eructations at times since. His condition in August, 1907, is fine—complains of no pain, has no trouble at all and has abandoned the use of the stomach tube.

A most interesting feature in this case was the marked slowing of the pulse rate, which we have observed in other cases appears to be

due to a reflex sympathetic nerve action.

Case No. 2. J. E., white, age 50 years; referred to me October 15, 1906 by Dr. Robt. Wallace. His father died from a tumor in the chest which was diagnosed cancer of oesophagus. His mother died of softening of the brain; a young brother had two or three small tumors on his head, probably sebaceous.

*Personal History:* He has always been a great eater. Had scarlet fever when four years of age; light attack of typhoid fever sixteen years ago; thirty years ago he had a local sore with suppurative adenitis, but no secondary symptoms; has always been constipated. Years ago he drank whisky and beer pretty liberally, but for the last sixteen years has not been drinking any liquors.

Four or five years ago he had a watery, bloody stool which he thought due to piles. His present trouble began three and a half years ago, at which time he was working in a tannery wheeling bark. It began with a diarrhoea, and a few days later, after drinking a cup of very hot coffee, he began to have pain and burning in the stomach like a red hot poker. This pain was eased by taking baking soda. Subsequently the pain began from two to three hours after eating. It appeared more slowly when meat and solids were taken; earlier when fluids were taken. Water made the pain worse, causing a sour belching which did not follow the ingestion of beer. The ingestion of apples excited the pain. At first he had a feeling of weight in the stomach like a flat iron lying there. The pain was increased by walking about, but was present in almost every position of the body. It relieved the pain for an hour or more and for a longer time if he lay on his back. Lying on his abdomen sometimes eased it also, and the same was true at times of eating. The pain, which was of a gnawing or cutting character, seated above and to left of umbilicus, radiated to the left, sometimes downward and sometimes upward, and he also had some pain in the back. It was often easier in the morning. He noticed a rumbling of gas, and relief followed as soon as the gas passed a certain point. He often suffered from belching, sour eructations, slight nausea, but did not vomit and has had no further passages of blood by the stool. Stools are brown usually, now and then slate colored—on one occasion black. He has lost 30 pounds in the last year—now weighs 131 pounds.

*Examination:* Man of sallow complexion, thin, but muscular, in only fair nourishment. He has a number of multiple lipomas over the body, mostly on the right arm—some over the abdomen. His abdomen is irregular, ap-

parently from muscular development. By palpation the liver was found two and one-half inches below the normal position; by pressure on the right side of the abdomen a slight bulging appeared upon the left side. When the stomach was distended with air a palpable mass was found at the pyloric region. The lower border of the stomach was found two finger breadths below the umbilicus, and the upper border of the line of tympany was but little lower than normal. Twelve (12) ounces of very acid material was taken six hours after a light breakfast that showed a total acidity of 130 with a free hydrochloric acid value of 54. The following morning four (4) ounces were removed from the fasting stomach, with a total acidity of 80 and with a free hydrochloric acid value of 32. Splashing sound was distinctly audible. No laetic acid; no Boas-Oppler bacilli.

Urine 1020, no albumen, no sugar, no casts.

*Diagnosis:* Ulcer of the stomach with imperfect drain.

Operation was performed on October 24, 1906. Upon opening the abdomen the stomach wall was found thickened and indurated over an area of about three inches in diameter, involving the anterior surface, a large portion of the lesser curvature and extending on to the posterior surface of the stomach. The glands in the gastrohepatic omentum were enlarged and readily palpable. The pylorus was not involved, but was spasmodically contracted.

The induration and the glandular enlargement, taken in connection with the age of the patient, made the suspicion of carcinoma quite strong, and we decided to remove the mass: a resection of more than one-third of the stomach was made, the line of incision reaching as near toward the cardiac end of the stomach as was deemed feasible. The greater portion of the lesser curvature was removed and about four and a half or five inches of the greater curvature, the second incision passing through the stomach near the pylorus. Both incisions were closed and a posterior gastrojejunostomy made with the stump of the stomach.

On the morning of October 25th his temperature was normal and pulse 82. Later his pulse dropped to 66 beats, and at 5:00 P. M., was 54. Had a slight amount of regurgitation of blood stained fluid at intervals during the day.

On October 26th temperature 99, pulse 48—full and strong, bloody fluid still being regurgitated in small quantity. The administration of ice and small doses of adrenalin chloride relieved it. In the afternoon of the 26th regurgitation fluid contained no blood,

The ulcer shown in this illustration was removed from Case No. 2. In size it was about one-half an inch in diameter, with smooth sharpened edges and a rounded cup-shaped base. About the ulcer the wall of the stomach was indurated for a space covered by the radius of one-half inches.

but was slightly greenish in color. He received saline nutrient enemata (one pint) three times a day after the first twelve hours. Was placed in a sitting posture on the second day. He made a favorable convalescence and his pulse rate gradually increased to 60 beats per minute. On the fourth day he had liquid food and on the fifth day began to take solids. At intervals some regurgitation would occur, but this was very small in amount and finally ceased entirely. In the course of six or eight weeks he showed a prompt gain in flesh. Upon examination of the excised tissue a small round ulcer was found in the center of the indurated mass just large enough to receive the tip of the index finger and fit snugly over the same. The edges were sharply cut and it resembled the shape of the inner surface of a hemisphere. The edges showed no tendency to granulation whatever, and were rather firm. The tissue about the ulcer was quite firm—the wall very much thickened, but without any nodulation.

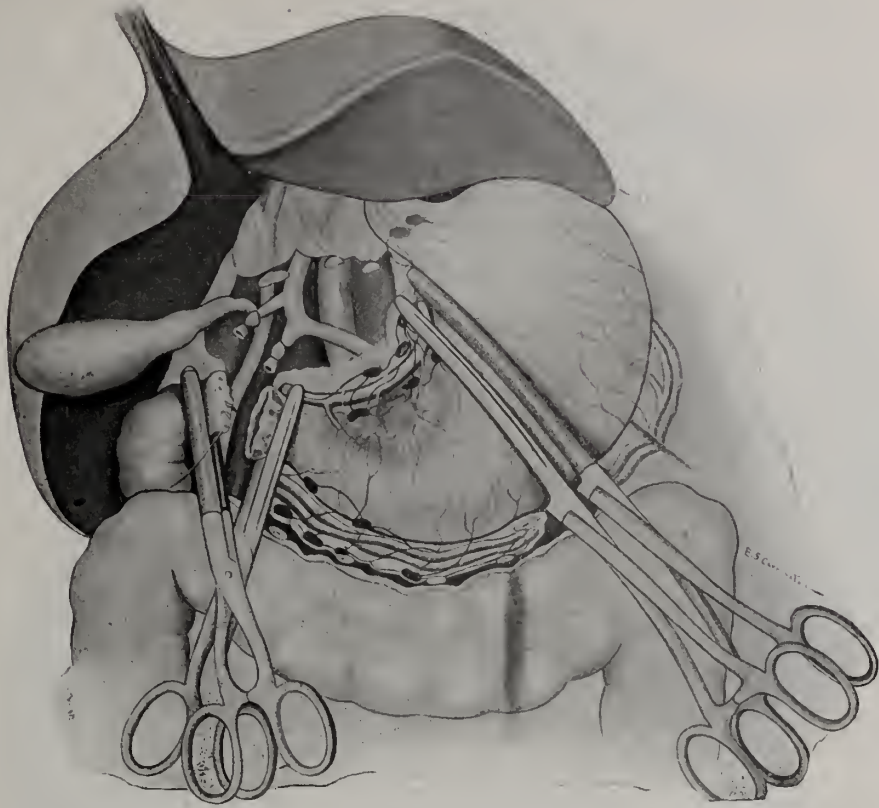

The pathological report showed the condition to be ulcer with simple inflammatory thickening. The enlarged glands showed no evidence of malignancy and were evidently the result of an inflammatory process.

The result in this case has been most gratifying, the patient at no time being in a dangerous condition, and has for many months been able to follow his daily occupation.

Case No. 3: Mrs. J. W., white; 55 years of age; was referred to me by Dr. Robt. Wallace on October 23, 1907. The family history shows that no one in her family has ever suffered from any tumors, benign or malignant. About six years ago she had an attack of trouble with her stomach in which hematemesis was present a number of times in considerable amount. Following this for some time she was fairly comfortable, but during the past two years she has been growing steadily worse, with pain in the epigastrium increased by food. This pain is dull, aching in character—felt most over the center and left portion of the epigastrium, and also to some extent posteriorly. It is accompanied with considerable tenderness on pressure.

She has also suffered from regurgitation of ingesta, the fluid being salty, rarely bitter, but never sour. Her appetite has been capricious and she has lost some flesh, although the amount is not marked, the patient never having been very fleshy. On one occasion several years ago she was jaundiced, but the

Illustrates the steps taken for the excision of the ulcer-bearing area of the stomach.

jaundice soon disappeared. She has not been able to eat with any degree of comfort for some months, now everything, even water, taken into the stomach causes distress. Her complexion has a hue very suspicious of malignant disease.

Examination shows the epigastrium to be somewhat distended and full. The muscles over it are quite rigid. She is very tender on pressure. Her bowels are either constipated or loose; her stomach is small. Her urine is normal, although she had edema of the ankles some years ago.

*Diagnosis:* Ulcer of the stomach with contracture, probably beginning malignant change.

On October 26, 1907, gastroenterostomy was done. A hard nodular mass was found involving the lesser curvature of the stomach for three-fourths of its length and the central portion of the stomach, both anterior and posterior surfaces for several inches, and the left lobe of the liver, which was closely bound by the growth to the stomach. The infiltration was so extensive that excision was impossible. We could with difficulty get far enough to the left to obtain sufficient stomach tissue to make an anastomosis. An opening was made in the mesocolon, but we were still unable to complete the anastomosis and found it necessary

to open through the gastrocolic omentum and to bring the posterior wall of the stomach and intestine through this opening to make the anastomosis. We used Moynihan's clamps, suturing the peritoneum with celluloid yarn and also a through and through suture through the coats of the intestine with the same. The patient left the table in good condition, pulse 112. Had a very quiet convalescence up to third day, when she vomited, which the nurse thought to be the result of an eighth of a grain of morphia given during the previous night. She took water and egg albumen after twenty-four hours, then had panopeptone, tea, coffee, etc. She had no bad symptoms until November 1st, when, after feeling splendidly in the morning she suddenly felt faint and shortly vomited a pint of bright red blood. This I think was undoubtedly due to a disturbance of the ulcer from food distention and not to any suture defect. The usual remedies were exhibited to control the hemorrhage and no further bleeding occurred. The patient's recovery was prompt and she had no further vomiting. Healing of the wound was complete on the eighth day. The amount of nourishment was increased so that on November 13th she stated that she had taken more food and had remained more comfortable than she had

Shows the appearance after the operation was completed.

for many months. She left the infirmary for home on November 13, 1907.

On November 18, 1907, she was in good condition except for edema of the legs, which threatened to become very serious. The urine failed to reveal, however, any evidence of Bright's, although we suspected this to be the cause of the condition. Since that time the edema has somewhat subsided. Her stomach condition is very much improved and the induration in the epigastrium is less; she has absolutely no tenderness and suffers no inconvenience after taking food.

#### MANAGEMENT OF A PRIMIPARA DURING PREGNANCY AND LABOR.\*

BY LILLIAN H. SOUTH, BOWLING GREEN.

In presenting this subject for your consideration, I have no idea that I shall offer any-

thing new, still yet anything with which you are not already familiar. My object chiefly is to direct your attention to certain conditions and complications that arise during pregnancy that can be prevented, and to other subjects which we should always carefully consider in managing a primipara.

Pregnancy represents the highest functions of the female productive system and labor should be a natural process, but long inheritance of civilization has made the border line between normal and abnormal conditions so slight, that the woman during this period should be constantly under the care and guidance of a physician. We should endeavor to teach the patient to report any symptoms, however trivial, and, what is more important for us to give them our conscientious attention and find the cause for every complaint. I deem the following subject important to every physician who assumes the responsibility of managing a primipara.

*Exercise.*—The patient should be encouraged to take exercise, and seek pleasant di-

\*Read before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

versions. Too vigorous exercise should be desisted from toward the later months, as it will prevent the physiological relaxation of the pelvic ligaments which occurs during pregnancy.

*Diet.*—The diet should be limited to plain, nutritious food, easily digested. Cereals and vegetables should be substituted for meat if there is a tendency to nephritis. That restriction of the diet will influence the size of the child was first demonstrated by Prochownik, who had considerable success by withdrawing the carbo-hydrates and liquids during the last six weeks of pregnancy in a case of contracted pelvis. Bokelman carried out a diet for twelve weeks in an elderly primipara and found even the labor pains were less severe. In my own experience two cases of previously difficult labors on a diet free from carbo-hydrates there was an uneventful termination of labor. If there is any tendency to contraction of pelvis, the diet should be given a trial.

*Bowels.*—Constipation is very common during pregnancy, due to sedentary habits, carelessness on part of patient, interference with peristaltic movement of the bowels from the enlarged uterus. When the bowels are regular, there is less strain on the kidneys, elimination is more active, the patient is less liable to complications, due to toxemia. Oil or magnesium sulphate is the best cathartics to be administered. Pills containing aloin should be used cautiously. I recall one case that aborted at the fourth month from the use of these pills.

*Urine.*—The urine should be carefully examined for albumen and casts at regular intervals, once a month during the first period of gestation, and every week during the last month. Eclampsia is probably due to the circulation in the blood of syncytio-toxines, a sufficient amount to cause convulsions circulating in system will give rise to some renal complications which can be recognized in a complete examination of the urine, before onset of severe symptoms. The mortality from the disease is very high, and I can safely say the treatment will always be along the line of prevention by early recognition of the renal changes, which do exist sometimes only as a trace of albumen. Remember that a woman, however strong and healthy at other times, is always a ready prey to toxemia during pregnancy, careful attention to the details of urinalysis, followed by appropriate eliminative treatment will prevent eclampsia. Impress upon the patient the importance of reporting persistent headaches, dizziness, swelling of the feet, decrease in the flow of urine. Hot baths, saline

purges, milk diet and Basham's mixture in the line of eliminative treatment suggested. Urea is of little value unless carried out as follows:

Put the patient to bed, give milk diet, examine twenty-four hour specimen, if there is a continual decrease in the excretion of urea and other symptoms of faulty metabolism exist, after active eliminative treatment, termination of gestation should be considered. Vomiting of pregnancy is one of the forms of toxemia, due to the circulation in the blood of products of fetal metabolism not properly eliminated by the mother. If the condition does not respond to treatment and urea continues to decrease premature labor should be accomplished before the strength of the patient is exhausted. I have seen fatal cases due to procrastination. It is better to err too early than too late.

*Preliminary Examination.*—An obstetrician should be thoroughly familiar with external palpation and learn to depend upon this method of diagnosis. A careful examination should be made from four to six weeks prior to delivery, before this time the position changes. The knowledge gained from such an examination reveals presentation, position and variety. The existence and extent of any abnormal condition can be recognized, a plan of procedure decided upon in advance. It is well to be able to rely upon this method because little information can be gained at the onset of labor by vaginal examination, except the presenting part as the "bag of waters" or the caput obscures the landmarks. You can hardly dare expose women to the dangers of sepsis for the mere knowledge of the amount of dilatation. Pelvic measurement is essential in preliminary examination, although it does not give accurate information regarding the internal conjugate we can form some idea of the character of the pelvis. If the spines, crests and Bandeloque diameters are normal you can reasonably suppose the internal measurements correspond. If the external conjugate is below eighteen, if the abdomen is pendulous, the head not engaged in the last week of gestation, internal measurement should be taken. I consider Caesarian section an operation only of selection, depending upon the accurate internal pelvimetry to decide.

*Vaginal Examination.*—With normal measurements, vertex presentation, head deeply engaged, vaginal examinations at the onset of labor are not necessary and do positive harm. Williams has demonstrated that pathogenic organism inhabit the inner surface of the labia and margin of the hymen in

60% of pregnant women, each examination exposes the patient to sepsis. Even with the most careful preparation of the hands the organisms are carried in with the mere introduction of the finger.

*Armamentarium.*—In justice to yourself and patient you should carry equipment sufficient to meet any obstetrical emergency that may arise. The patient is never safe from complications until an hour after delivery. All instruments should be kept sterilized and ready for use, in a large size bag devoted to that purpose only. I shall not take your time in enumerating the articles required, but refer you to Edgar's *Obstetrics* and Dr. Spiedel's article in the March issue of the *JOURNAL*.

*Preparation of the Patient.*—In regard to the preparation of the patient a few directions from the physician are necessary. At the onset of labor the patient should have a high rectal enema, it prevents contamination of the parts with feces, allows more room at the perineum for the passage of the fetal head. I strongly advocate clipping hairs at the lower portion of the labia, this is very necessary in a primipara, for, in a majority of cases, one stitch is required in the perineum for support to the tissues. Parts can more readily be sterilized, and kept more antiseptically after parturition. In forceps shave the parts. As long as the maternal and fetal pulse is good, head well engaged, vaginal examination is unnecessary. During this stage keep the woman walking, give her encouragement, but let her alone. It has taken obstetricians many decades of time to realize that nature has so delicately and accurately adapted the fetus to the parturient canal the slightest interference is harmful. The beginning of the second stage is usually indicated by the rupture of the membrane and the onset of bearing down pains, and terminates with the delivery of the child. At this stage the patient should be put to bed and preparations made for delivery. The accoucheur should wear rubber gloves and a gown. In a primipara, if labor is progressing normally and by previous preliminary examination, you know the position and presentation, no vaginal examination is necessary, even in this stage. After the rupture of the membrane the danger of sepsis increases in proportion to number of vaginal examinations made. During this stage most septic cases receive the initial dose. Records of the Health Department of Chicago show that 13% of all women dying between the ages of twenty and fifty died of puerperal sepsis, and this in spite of the era of asepsis. Various methods have been

devised to protect the perineum and they still tear. As soon as there is bulging of the parts, chloroform should be administered with each pain, this regulates the progress of the delivery, allows slow dilatation, prevents a sudden expulsion of the head, parts are more relaxed, the patient under control. When maximum distention of the vulva occurs, give chloroform sufficient to render the patient unconscious and deliver between the pains. Any manipulation through the rectum should be avoided. Depend upon slow dilatation rather than rectal or perineal manipulation for the prevention of lacerations. After delivery of the child before expulsion of the placenta, make a careful inspection for lacerations. The man who says he has delivered hundreds of women without a tear is a dangerous man, for he is either making erroneous statements or, worse, has not the ability to recognize the damage that has been done, consequently will not repair it. Rupture of the perineum occurs under the most skillful treatment, there is never an excuse for a complete rupture. Use silk worm gut for external tears, going well behind the laceration with a broad sweep, using a large curved needle, avoid pockets. The sutures are clamped but not tied until after delivery of placenta. This procedure saves time. The parts are not sensitive, patient still under chloroform, the temptation to pull on the cord is lessened if you are otherwise engaged. If the placenta is not expelled within half an hour after delivery, little is gained by waiting longer, and Crede's method can be employed to an advantage. Thoroughly examine the placenta for retained lobules, if there is sepsis you can be assured it is not due to retention of the secundus. If the membranes have adhered rhythmic pressure just above the pubes with slight traction will release them, if not, it is better to let them be discharged in the lochia. After delivery of the placenta the parts are irrigated and the sutures tied. In a primipara one stitch in the perineum will give support to the tissues.

*Puerperium.*—Immediately after delivery, a binder may be applied for twenty-four hours, more to give support to the bowel that have been suddenly relieved of the pressure of the enlarged uterus. After that time it favors retroversion and subinvolution. The breast binder is of service during the entire puerperium in supporting the breasts and securing a sterilized dressing placed over the nipple. Fissures are best treated by using nipple shields and a bland ointment. The use of ergot is a disputed question, for we are loathe to part with this pet. Happily its

popularity is declining, and it is always contra-indicated until the uterus is entirely empty. In the treatment of post-partum hemorrhage it acts too slowly to be of service. This accident can always be avoided if we carefully control the fundus. It may be given to promote involution, although strychnia and hot douches are more serviceable. I oppose the administration of any drug as a routine practice. Medicine should only be given when there are therapeutic indications. Its early administration after delivery gives you a false sense of security in believing that you will be free from post-partum bleeding. The bladder should be emptied a few hours after delivery. It often becomes distended and prevents contraction. I prefer to put the patient on a commode than to resort to the catheter.

Before dismissing the case, thoroughly examine the woman in regard to perineal and cervical lacerations and adnexa. The child should be examined immediately after delivery for abnormalities. It will avoid future embarrassment.

[CONTINUED ON PAGE 105]

#### THE SURGERY OF INGUINAL HERNIA WITH REPORT OF FIFTY-TWO OPERATIONS UPON FORTY- EIGHT SUBJECTS.\*

BY AUGUST SCHLACHNER, LOUISVILLE.

The operative cure of inguinal hernia dates back about a quarter of a century, when Bassini devised the basal principles underlying the surgery of this common affliction.

Since then, the various structures concerned in the production, as well as the cure of hernia, have been variously dealt with by various operators, but the basal principles advanced by Bassini, have always remained intact, and about these principles, the operation has definitely crystallized.

Prior to the introduction of these principles, there was no procedure that offered sufficient certainty to make it worthy of the name of radical cure. That we now have a practical certainty in our operative measures, is attested by the results as follows:

Coley, *Journal American Medical Association*, Vol. 49, No. 12, p. 1018, reported a thousand one hundred and eighty-five cases of Inguinal Hernia in the male with nine relapses or seven-tenths of one per cent. using the typical Bassini operation, and the same author in the *Annals of Surgery* vol. 38, p. 86, reports a mortality in a thousand and

seventy-five cases, two deaths or less than one-fifth of one percent. At Carle's Clinic in Rome, there were two deaths in fourteen hundred operations on 1285 patients.

While it is admitted that these results represent the work of operators of unusual experience, there is no reason why the results of operators of less experience should widely differ, provided the principles are carried out with aseptic precautions.

It is also apparent that the risks and inconveniences that would attend a given number of subjects exposed to a radical cure, would be a great deal less than the mortality, inconveniences and the exclusion from certain occupations which would in the long run attend the same number of subjects not operated upon but sent through life trussed: even though the trussing is ever so carefully carried out.

To-day, trussing should be restricted to the very young, children under four years of age for whom, if carefully employed, there is a chance of cure, to the very old, provided they can be securely trussed, and to those afflicted with such diseases that would place them beyond the pale of surgery.

According to Leekwood, the mesentery of a child is longest before the second year, and decreases in length after the second year of life, an anatomical fact that aids in the explanation of the cures that are affected in early life, as it is well known that a long mesentery, or a large omentum are prominent anatomical factors in the production of hernias.

In the development of the operation, Bassini took his cue from nature, in that the inguinal canal, or more properly speaking, the inguinal cleft is necessarily present to permit the passage of the cord or ligament according to the sex. This cleft, although existing only in a potential sense, in those not afflicted with hernia, comes into actual existence by its widening through the introduction of a second body in the form of the hernial sac, or we might say, that between the inguinal canal in the herniated subject and the cleft in the unherniated subject there exists a difference in degree only.

The investigations of Turk have shown that the internal oblique rises from the outer four-fifths of Poupart's ligament in the female, whereas it occupies the outer two-thirds in the male.

From this it is not unreasonable to suppose that in the absence of either of the cord or ligament, nature would have the internal oblique and transversalis arising practically from the entire length of Poupart's ligament

\* Read before the Kentucky State Medical Association  
Louisville, October 15-17, 1907.

cord, has also abandoned this.

The Mayos have practiced the twisting of the sac before its ligation as a simple and effective means of more perfectly obliterating the peritoneal fossa.

Most operators have considered the method of Halstead by over-correcting and suturing the peritoneum as in an ordinary laparotomy as unnecessary, and have contented themselves either with a high ligation or the use of purse-string suture applied high up on the inner aspect of the neck of the sac.

The cord has also been variously cared for, Halstead hoping to reduce the size of the opening of exit, has resected most of the veins. This has not been considered necessary, and since its performance has been attended in certain cases with atrophy of the testicle, it has deservedly become obsolete.

There are to-day many operators who believe that the transplantation of the cord is not only unnecessary, but undesirable.

According to Cornell, Woelfler in 1892 was the first to suggest the cure of hernia in an operative way, without the transplantation of the cord. Since then, many promin-

ent operators have utilized this suggestion and the statistics are more favorable as to re-currence where the cord is not transplanted, but brought out at the external ring than they are where the cord is transplanted as in the typical Bassini operation. This practical fact proves that the point of emergence must also be the point of resistance, and all things being equal, the intestine would be more likely to force an exit at a point corresponding to the internal ring than it would at a point corresponding to the external ring.

When recurrences take place at the external ring, they take the form of a direct hernia.

In cases of undescended testicle, there is a distinct advantage in not transplanting the cord as by this observance a distance of one-half to three-quarters of an inch is gained.

Ferguson, who does not favor the transplantation of cord in ordinary cases practices the transplantation where there is a defective conjoined tendon.

This operation also suggests the use of the procedure of Halstead and Bloodgood to use either the sheath or the rec-

tus muscle itself to reinforce the weak spot in Hesselbaek's triangle where the conjoined tendon is defective and does not permit a secure closure in the region of the external ring.

The closure of the inguinal canal or cleft has been modified by bringing all three muscles down to Poupart's ligament as practiced by Andrews, and then overlapping this line of sutures by the lower flap of the external oblique in the form of an imbrication with, or without, transplantation of the cord.

This overlapping was, perhaps, first practiced by Lucas-Champonniere and then popularized in this country by Noble in his abdominal work and more lately by Andrews in hernial surgery.

Although the unmodified Bassini operation has been highly satisfactory as attested by the results of Coley, there can be little doubt that the modifications of Andrews of bringing all three muscles down to Poupart's ligament on the one hand and the overlapping of the lower flap on the other, substituting thereby a "lap" for a "butt" joint, are not without their advantages.

In cases where appendicular disturbances complicated the hernia, the appendix can in most instances be easily removed through the hernial opening in right sided hernias. In exceptional instances, it may be necessary to extend the separation of the fibres of the external aponeurosis upward and outward and then elevating the upper half, thereby exposing the internal oblique, permitting the separation of its fibres as in the McBurney grid-iron operation.

*Case 1.*—Mr. T., white, age 27. Left oblique inguinal hernia. Operated upon by the Bassini method. Recovery.

*Case 2.*—Mr. R., white, age 32, right oblique inguinal hernia. Incomplete. Bassini operation with successful result.

*Case 3.*—Mr. B., white, age 40, right oblique hernia. Bassini operation, result successful.

*Case 4.*—Mrs. P., colored, age 43, oblique inguinal hernia. Bassini operation; result successful.

*Case 5.*—Mr. A., white, age 36, direct hernia, right side, Bassini operation; successful.

*Case 6.*—Mr. W., white, age 19. Oblique inguinal hernia, operation, Bassini method; successful result.

*Case 7.*—Mr. L., age 23, white, oblique inguinal hernia, removal of portion of omentum. Bassini method, result successful.

*Case 8.*—Mr. K., white, age 28, right inguinal hernia, Bassini method with successful results.

*Case 9.*—Mr. J., white, farmer, left inguinal hernia, Bassini method with successful result.

*Case 10.*—Mr. C., colored, age 41, general work, strong muscular subject, large hernia, Bassini method, result successful.

*Case 11.*—Mr. T., white, 29 years, oblique inguinal hernia, left side, Bassini method, result successful.

*Case 12.*—Mr. G., white, age 44, right inguinal hernia, oblique, which proved to be of the sliding variety the cecum coming down occupied the sac in addition to small intestines. On the third day intestinal paresis, death on fourth day.

*Case 13.*—Mrs. S., colored, age 29, right oblique inguinal hernia, Bassini method result successful.

*Case 14.*—Mr. F., oblique inguinal hernia, Bassini operation, result successful.

*Case 15.*—Mr. S., white, age 35, book-keeper, right inguinal hernia, Bassini method, successful.

*Case 16.*—Mr. R., Frenchman, age 23, general work, right inguinal hernia, Bassini method, result successful.

*Case 17.*—Mrs. W., colored, 29 years, right inguinal hernia, oblique, Bassini method, result successful.

*Case 18.*—Mr. H., German, age 37, grocery keeper, sarcoma of the testicle the size of a foetal head, complicated the hernia, orchidectomy and herniotomy by the Bassini method, recovery uneventful, both tumor and hernia were right sided.

*Case 19.*—Mrs. T., German, age 45, right oblique hernia into the canal of Nuck. Referred to me for what seemed to be a cyst of the labia majora. Owing to the obese condition swelling of the hernial region was not apparent. An incision over the labia disclosed the true condition. This was carried upward and a mass of omentum more than the size of a fist, removed. Bassini method, recovery uneventful. The hernia was upon the right side.

*Case 20.*—Mr. B., age 27, white, left oblique inguinal hernia. Bassini operation with successful result.

*Case 21.*—Mr. W., age 30, white, right oblique inguinal hernia, Bassini operation, result successful.

*Case 22.*—Miss L., age 4, white, right oblique inguinal hernia. Bassini operation, partial recurrence due largely to the delicate condition of the child, and which manifested itself soon after the operation. Second operation successful.

*Case 23.*—Mr. M., white, dentist, age 39, double inguinal hernia, Bassini operation,

successful.

*Case 24.*—Miss S., white, trained nurse, age 26, right oblique inguinal hernia, Bassini operation, employing spinal analgesia, recovery successful.

*Case 25.*—Mr. P., white, oblique inguinal hernia, Bassini-Andrews operation, result successful.

*Case 26.*—Mr. L., white, left oblique inguinal hernia, Bassini-Andrews operation, result successful.

*Case 27.*—Mr. M., colored, age 72, peritoneal prostatectomy and Bassini operation for right oblique inguinal hernia of good size. Both operations at same sitting under spinal analgesia. Recovery uneventful, and results successful.

*Case 28.*—Mr. W., oblique inguinal hernia, Bassini-Andrews operation, results successful.

*Case 29.*—Mr. A., colored, age 44, right oblique inguinal hernia. Bassini-Andrews operation. At the same operation the appendix was removed through the hernial incision and four months prior he had the Gasserion Ganglion removed by the Hartley-Krause method, result successful.

*Case 30.*—Mr. P., Irish, age 79, right side oblique hernia which was operated by the Bassini-Andrews method. At the same sitting, the second division of the fifth nerve was resected at the foramen rotundum for tri-facial neuralgia by the Lieke-Braun-Looson method. His recovery from both was uneventful. At the end of a year the hernia remained cured, but some return of pain in the second division. He was driven to surgery by his neuralgic pains.

*Case 31.*—Master B., age 6 years, Hebrew, right inguinal hernia, operated upon by the Bassini-Andrews method with successful result. About a week thereafter a double osteotomy was performed for genuvalgum, result successful in both instances.

*Case 32.*—Mr. N. white, age 35, book-keeper, double inguinal hernia, both sides operated at the sametime by the Bassini-Andrews method, result successful.

*Case 33.*—Miss H., white, 34 years, right inguinal hernia, operated upon by the Bassini-Andrews method. During the operation the right half of pelvis explored and right cystic ovary that had become adherent, removed, result successful.

*Case 34.*—Mr. S. C., German, age 55, right oblique hernia, operated upon by the Bassini-Andrews methods. 6 months previous he had had an excision of the rectum by the Kraski method, recovery.

*Case 35.*—Mr. S., Hebrew, age 19, right ob-

lique inguinal hernia, Bassini-Andrews methods, result successful.

*Case 36.*—Mr. S., white, age 39, commercial traveler, right oblique inguinal hernia, patient having had attacks of appendicitis, appendectomy and herniotomy by the Andrew Bassini operation at the same time. Result successful.

*Case 37.*—Mr. W., age 43, oblique inguinal hernia operation by Andrews-Bassini method. Result successful.

*Case 38.*—Master K., age 9, left oblique inguinal hernia operation Andrews-Bassini method, recovery successful.

*Case 39.*—Mr. E., Irish, age 44, groceryman, double oblique inguinal hernia, Andrews-Bassini operation, left side sigmoid adherent, result successful.

*Case 40.*—Mr. W., age 32, farmer, Bassini operation for right oblique hernia, result successful.

*Case 41.*—Mr. N., age 34, white, right oblique inguinal hernia, strangulation, intestine and omentum occupying hernial sac. A portion of the latter was removed, Bassini operation, result successful.

*Case 42.*—Mr. M., Hebrew, age 30, strangulated left oblique inguinal hernia, operation for the relief of strangulation without any effort being made for radical cure, recovery.

*Case 43.*—Mr. B., 40 years, hotel-keeper, having taken a bath and applied the truss, in playfully kicking, the hernia descended beneath the truss, and became strangulated. Bassini operation, sac contained omentum, a part of which equal to the size of fist removed. In ligating the omentum, silk was employed. Stitch abscess, which continued to discharge for almost three months, at which time the sinus closed and the result satisfactory so far as the hernial cure was concerned. Slight atrophy of the testicle.

*Case 44.*—Mr. K., age 44, white, cigarmaker, strangulated hernia, operated upon by the Bassini method. The sac was occupied by several loops of intestine, all of which were more or less adherent to one another from an old peritonitis. About half of these were separated, the other being so firmly adherent that separation was deemed inadvisable, result successful.

*Case 45.*—Mr. C., white, age 20 years, salesman, congenital oblique inguinal hernia right side with undescended testicle on the left. Strangulation occurred at a pleasure resort and was occasioned by swinging on a line. Operation by Bassini-Andrews method removing a portion of the strangulated omentum, recovery successful.

*Case 46.*—Mr. B., Canadian, 48 years, left oblique inguinal Hernia with undescended

testicle, orchidectomy and herniotomy, the latter by the Andrews-Bassini method, recovery successful.

*Case 47.*—Mr. W., age 49, had been operated upon at the Alexian Brothers Hospital in Chicago some time previous, owing to a profuse suppuration described by the patient, there was recurrence, operated upon in Louisville by the Bassini method, result successful.

*Case 48.*—Mr. S., age 43, double inguinal hernia, patient having had attacks of appendicitis, the appendix was removed and both sides operated upon by the Bassini-Andrews method, result successful.

*Summary.* — 52 operations upon 48 subjects; of these 41 were males, 7 females; incomplete, 1; direct, 1; double, 4; strangulated, 5; recurrence, 1; death, 1; 3 had appendectomy in addition to herniotomy; 2 had orchidectomy of which one was for sarcoma of testicle and one for undescended testicle; one had prostatectomy; one had the resection of the fifth nerve, second division at foramen rotundum, one had double osteotomy, supracondyloid, a week following the herniotomy; one had an oophorectomy at the same operations in most cases the nitrous oxide and ether anesthesia was employed; in two cases, spinal analgesia; the youngest 4 years, the oldest 79 years; one case was operated upon for the relief of strangulation without an attempt at cure.

#### PERINEO-VAGINAL RESTORATION.\*

By D. C. BOWEN, ELIZABETHTOWN, KY.

It is the purpose of the essayist in presenting under the above title a paper in which are briefly considered some of the frequent injuries to the perineum and lower segment of the vagina in childbirth, and a surgical procedure for restoring them to an approximately normal condition.

Plastic operations for Perineo-Vaginal restoration are required when primary sutures has failed or been omitted.

It is not the purpose of your essayist to discuss perineal laceration or the necessity for repair in detail.

It is well known to every careful observer that extensive lacerations of the perineum and vaginal walls occurs in childbirth from which no bad results follow. On the other hand, it is equally well known that many discomforts and reflex symptoms often ensue from laceration at the time of occurrence seemed too insignificant to require an after thought or even a single suture.

\*Read before the Muldraugh Hill Medical Society at its December meeting, 1907.

You see from what has already been said, that immediate or primary operation will not be discussed.

It is to the consideration of secondary operations that your attention is called. Operations are not necessary because of the laceration per se, but when there are unmistakable discomforts plainly traced to them, and that health and comfort is recovered by the restoration of the lacerated parts to their normal relations. The perineal body is a triangular space or wedge bounded at base by the skin, anterior by the posterior wall of vagina, posterior by the anterior wall of rectum.

The following table presents the subject in an elementary way:

Perineal body, how composed:—The most important are, Skin and Muscles. Transverse Perinei. Levator Ani and Sphincter Ani.

Supports:—Bladder, Rectum, Uterus and Intestines.

Degrees of Rupture:—Concealed. To Sphincter Ani. Through Sphincter Ani. and Recto-Vaginal Septum.

Symptoms—Prolapsus of Vagina and Uterus. Rectum, Bladder. Incontinence of Feces and gas. Dragging down feeling and a nervous state.

Pathology:—Raw surface, supplied by lymph and blood vessels. Complicated by—Rectocele, Cystocele, Neuralgia of denudation.

Prognosis:—Gravity according to degree of laceration, or cause, viz: constitutional feebleness, prolonged overdistention, senile atrophy and subinvolution.

Treatment—Operative—Immediate or Primary—Place first suture at commissure to close off the secretions. Delayed or Secondary—Place the first suture at the anus. Medicinal or Constitutional.

In a general sense there are four important ends to be attained in perineorrhaphy: (1) To restore the loss of power to rectum and vagina; (2) to restore the normal sustaining quality to vaginal walls and to the bladder; (3) to provide the usual support to the uterus; (4) to cure the many nervous accompaniments. The writer has seen cases operated upon that to all external appearances seemed to be a perfect result with a rectocele above the operated field, which formed a pocket for the retention of the uterine and vaginal secretions in which the cervix uteri was constantly macerating.

Any surgical procedure which does not obtain relief in a degree, falls short of accomplishing the desired results.

If above the line of denudation there remains a redundancy of the vaginal walls, or the restoration is not sufficient to support the anterior vaginal wall, the operation is only a partial success. This is true whether the uterus is supported in its original and normal position or not. To accomplish the best permanent results it is essential that the denudation extend as high up within the recto-vaginal septum as there are redundant tissue in the posterior wall. After operations for restoration of the ruptured perineum, if you will pass your finger into the vagina and as it passes over the restored perineal body, if the examining finger is firmly pressed against the upper vaginal wall and upon the withdrawal of the finger the separated walls are observed to come in contact at once by the rising of the posterior vaginal wall you may be assured that the object of the operation has been attained.

We are taught in text books, that, plastic operations for the restoration of the perineal body should not be undertaken until from six to twelve months after the original injury. Dr. Kunde places the time not less than eight weeks.

I can see no reason for such delay, provided you have a patient that is not debilitated. I have operated a number of times in three and four weeks after confinement, but in every case the injury was sustained at a previous labor. In three of these cases my patient had third degree ruptures and suffered from incontinence of feces and gas. It is essential in all cases that the bowels should have been thoroughly cleared out by laxatives and the descending colon finally washed out by copious enemata, before the operation, and it might be well to use an opium suppository in rectum. The vagina and vulva should be repeatedly douches for several days previous, and the field shaved and scrubbed immediately before the operation.

The operative mode of procedure that has served me best is modification of Tate's operation, and is as follows: I first nick with scissors each labium to mark either anterior margin of flap, and then I make an incision through the skin along the labium, beginning at nick, extending around the margin of healthy skin and encircling rupture at anus, extending the incision up the labium to the nick opposite the point of beginning, and then having introduced one or two fingers of the left hand into the rectum, a tenaculum or volsellum is hooked into the center of incision near the median line, as assistant making the parts taut, and at the same time making slight traction on hook.

I dissect up the flap with scissors slightly curved, and with rounded points, the blades

completely overlapping each other; I have found this form of scissors less liable to puncture the rectum than the ordinary sharp pointed blades.

With the fingers in the rectum as a guide and a retractor, we are enabled to dissect a flap from a very thin recto-vaginal septum up as high as any redundancy of the walls can be observed; continuing the dissection up the sides of labiae, as high as the incision extends and dipping deep into the tissue where there are much scar tissue or atrophy. In the event of arteries being severed compression with hot sponges or torsion will usually suffice, but ligation is required, catgut is preferable, if the ligature is buried. If the injury be one of the third degree we now proceed to freshen up the edges of tear in the rectum.

This leaves a triangular space with base at anus, the sides of which are to be subsequently united. This brings us to the next important step, that of placing the sutures. If the injury be of the third or fourth degree, the sutures for rectal tear are preferably of silk and should be placed from left to right, which is carried by slightly curved needle, guarded by the fingers in the rectum and inserted along the margin of the freshened sides of triangular space to be closed, two or three like ligatures will be sufficient.

In completing the operation I use silkworm gut which possesses the principle advantage of the silver wire and is not so unyielding and if this is not at hand I use the silk throughout. The assistant lifts up the flap by means of the tenaculum hooked in the edges at the center, with the two fingers of left hand in rectum to guard against wounding it, I start the needle from one-third to one-half inch back from the denuded surface turning the point well towards the left buttock, I push it deeply into the tissue of the anterior ischio-rectal space, then upwards and inward along the recto-vaginal wall until it has been carried above the highest point of denudation, in the center at which location the needle point is brought out.

The needle is then reintroduced and brought out at corresponding point on the opposite side. The second suture is placed in like manner about one-third of an inch above the first. The third suture is placed about the same distance from the second and penetrates the flap and is carried out at corresponding point, this stitch can sometimes be introduced at one continuous circuit. The fourth stitch is placed as the third burrowing across the flap as before. The fifth stitch is buried under the denuded surface as far up as the junction of the septum and flap where it passes under the flap without penetrating it, to the opposite side. The sixth

stitch is placed at upper part of denuded surface and through the sides of the flap, when tied draws flap up like a purse string. If there is a redundancy of flap tissue it may be cut away, bearing in mind the gradual retraction of flap and absorption of tissue being as great here as in hair-lip operation. The flap treated in the manner above indicated, serves as a hood for the vaginal portion of perineum and shuts off all uterine and vaginal secretions from above, thereby lessening the source of infection, as well as giving strength to the newly created perineum, which lessens the chances of subsequent laceration. As there are no exposed raw surfaces either externally or internally, but little dressing of any kind is used and few vaginal donches, are required. The external parts, require about the same attention, as in other perineal operations.

Morning and night, and each time after urinating, the soft parts contiguous to the line of union and also the buttocks should be carefully separated and the wound and adjacent parts gently irrigated with sterile water or a carbolic solution. The patient is instructed to turn on her face to avoid the urine.

The bowels are moved by laxatives, salines or enemas about the fourth or fifth day, and the sutures removed about the tenth day. The patient should be kept in bed for two or three weeks.

In conclusion I will say that there is no operation in the domain of surgery that gives more prompt and permanent relief to so many pathological conditions than the successful Perineo-Vaginal Restoration, as indicated by the symptoms of prolapsus of uterus, vaginal wall, rectocele, cystocele and the subsiding of the nervous state, last but not least the cure of the incontinence of feces and gas.

#### THE THERAPEUTIC USE OF X-RAYS.\*

BY J. J. RODMAN, OWENSBORO.

In the use of the X-ray in medicine art is far in advance of science, or to speak more to the point, we have learned more from practice than we can explain by theory.

After Roentgen's discovery of the X-ray light in 1895, its limitations seemed boundless. Wonderful cures were reported by those whose enthusiasm ran riot with their judgment. Coils and static machines were purchased all over the country. As the static machine besides doing good therapeutic work,

would excite the X-ray tube, it became the favorite. Manufacturers were kept busy making and lauding their machines. They issued catalogues, telling in glowing terms the cures that had been wrought, giving detailed information to enable you to do likewise.

Doctors with no knowledge of physics or electricity, bought machines and Crook's tubes expecting to do good work. As in everything one extreme leads to another, there was no exception here.

Any agent that is powerful for good, will, in hands of the ignorant, work evil at times. X-ray burns became too numerous. Where so many were being treated and so many people dying, some necessarily died shortly after being treated by the X-ray. The "posthoo" argument was resorted to, and some deaths were reported as due to the X-ray. A great many became discouraged, and as a result a large number of static machines are now standing idle all over the country. Here as elsewhere evil reports have the swiftest wings. As in the beginning we knew not the power or therapeutic limitation of the X-rays, it was used indiscriminately in many cases, failures necessarily follow in a large percent. of these cases, and sometimes a bad burn. One burn would turn away an hundred prospective patients, and ten successes would not compensate for one failure. Hence progress with the new agent has been slow. Those who have not qualified themselves by study and the purchase of the necessary paraphernalia, exense themselves for not employing this very valuable agent by saying "it is a very dangerous remedy."

It is generally conceded that the X-ray contracts tumors, such as boils, carbuncles, enlarged glands, etc., enmass. It probably does this by contracting the large blood vessels forcing onward the stagnated blood, at the same time it sterilizes the field rendering the bacteria inert, it forces out the infiltration by contracting the tissues restoring normal activity, and function to the parts.

CASE I. Referred by Dr. S. S. Watkins. The patient was a middle-aged lady and quite heavy. She had an ulcer on the back of the leg about the junction of the middle and lower third, which had not healed for two years. The ulcer was circular in shape, about one to one and a half inches in diameter and perhaps one half inch deep. The walls were clear cut with the integument slightly overlapping. The surrounding tissue for from two to four inches were swollen, indurated, very hard and discolored a purplish-blue next the ulcer gradually fading towards the circumference which was a dull red. On August 28th, 1906, I exposed the ulcer and

\*Read before the Daviess County Medical Society, November 12, 1907.

surrounding parts to the X-rays for seven minutes, using a moderately high vacuum tube, with the anti-cathode ten inches distant. On the 31st same treatment except distance was nine inches and time of exposure ten minutes. Sept. 3rd, same as last. Sept. 5th, same with distance ten inches. On 7th same as last, but double exposure, one to either side of leg, making a twenty minutes treatment. On the 10th one exposure for ten minutes directly over the ulcer. At this sitting also used static brush discharge.

On the 14th same exposure, but as there was some fetor, time was limited to five minutes followed by a brush discharge.

That fetor was a red flag signal. The rays had completed the death of those tissues, next the ulcers that never could be revived, but were receiving sufficient nourishment to prevent their early decay. But the parts possessing more vitality had been sterilized and the circulation stimulated, and if left alone could work out their own salvation. Hence the last rays were limited to five minutes.

Sloughing began and the patient was forced to take her bed. A line of demarkation was formed, the dead tissues thrown off and the ulcer proceeded to heal, which was accomplished in a reasonable length of time.

Let me quote from Wm. B. Snow: "The stimulating or tonic effect of the Roentgen ray induced by short exposures or with a high vacuum tube at distances of sixteen to twenty inches from the anti-cathode is probably due to the disposition of the vibratory influences of the rays to first overcome local stasis, restoring tone to the muscular coats of the arterioles, and at the same time inducing a more active local metabolism."

CASE II. Referred by Dr. W. R. Stephens: A lady about thirty-five years old with a neglected mastitis of about five months standing. The doctor had seen her for the first time about one month previous. Had tried the usual remedies but could not get the breast to heal. There were two or three external openings, and a great many sinuses. On May 11th, 1904, I exposed the whole gland to the rays of a medium vacuum Crook's tube for ten minutes the anticathode being ten inches distant. Four more such treatments were given, the last one on May 23rd, with a perfect cure.

CASE III. A middle-aged, stout, healthy man referred by Dr. O. W. Rash. The left inguinal glands were very large and indurated, forming a tumor nearly or quite as large as a goose egg, following a bubo. On August 23rd, 1906, I gave a treatment as above. Same on the 25th and 27th, each followed by a static spray. On the 28th gave brush discharge. Sept. 1st, exposed rays for

thirteen minutes, followed by brush discharge. On the 3rd, same treatment lasting ten minutes. On the 5th, same for thirteen minutes. Six X-ray treatments were given, and as many static sprays or brush discharges. In a short time the adventitious material had all disappeared and complete involution of the glands had taken place.

CASE IV. A middle-aged man with an intractable neuralgia, referred by Dr. W. F. Stirman, who said he had tried every thing in his line including the actual cautery. Patient had suffered for six months, was pushed by business affairs, that with great energy kept him going. I treated him for some time with the static wave current, which had never failed me in such cases. It looked like my first failure had come. About this time I read an article written by Wm. B. Snow in which he stated that the X-ray was "invaluable in the treatment of chronic sciatica." I at once began the treatment, using a high vacuum tube, the anticathode being ten inches from the lumbo-sacral region, using no shield. Gave seven such treatments on an average of one a week. Have heard no further complaint.

I use a Waite and Bartlett static machine with ten revolving plates of thirty-two inches diameter.

#### COMPLETE TURBINECTOMY.\*

BY DUDLEY S. REYNOLDS, LOUISVILLE.

Complete turbinectomy is no longer an experimental operation. There can be no question of the importance of removing the entire bone in preference to a mere section of it. Removal of the inferior turbinate is much more frequently demanded for the reason that gravity naturally carries all fluids downward, and where there is much swelling in the soft parts covering the superior and middle turbinates, drainage would be impossible by the presence of an obstructing inferior turbinate. The posterior end of the inferior turbinate body frequently projects so far into the pharynx as to cause in the presence of an ordinary rhinitis, either partial or complete stenosis of the faucil orifice of the Eustachian tube. There are many cases of deviations of the septum narium which cause contact between a septal ridge and the inferior turbinate body. Complete removal of the inferior turbinate in such cases does away with the necessity of any operative interference with the septal ridge. In many cases, septal spurs on the osseous portion cease to be obstructive when either the inferior or middle turbinates have been

\*Read before the Jefferson County Medical Society

removed. Operations on the septum are therefore much less frequently necessary than was formerly considered. The radical measures introduced by Dr. Asch some years ago, are now seldom imitated.

So far as I am aware, complete turbinectomy as a rational and frequently required surgical procedure, was first brought to the notice of the profession in an article on Nasal Polypus, which appeared in the Cincinnati Lancet Clinic, Jan. 30th, 1904; and, subsequently, in an article entitled, Turbinectomy, read to the American Academy of Ophthalmology and Oto-Laryngology, Aug. 25th, 1904. The paper on Nasal Polypus was read to the Marion County Medical Society, Dec. 15th, 1903, and provoked no unfavorable comment, although it was pretty generally discussed by a number of competent surgeons. The second paper brought forth a general discussion in which sixteen members of the American Academy took part. On the whole, the discussion was of an unfavorable character. It was claimed by some of the gentlemen, all of whom were eminent specialists, that the operation would lead to the development of permanent dryness and discomfort of the naso-pharynx. One gentleman said it would cause chronic pharyngitis and laryngitis, on account of the unrestrained admission of cold air. Another gentleman thought a tendency to hypertrophy in the lining of the vault of the pharynx would ensue, etc. One of the gentlemen who denounced the practice as most pernicious and unwarranted, has become a convert. Now, the operation is being done pretty extensively over the country, and, when it is skillfully and well done, it fulfills a requirement not to be met otherwise. In my experience, which now numbers more than five hundred cases, I have had one death; and troublesome hemorrhage in two cases only. In every other instance my patients have been pleased; in fact, the results have been all that we could have wished. Persons who have pharyngeal adenoids are often relieved permanently by inferior turbinectomy alone. It must, of course, be understood that complete turbinectomy should in all cases, be done where partial turbinectomy seems indicated; because the most annoying situation for an obstruction in the nasal passages is the posterior region. I frequently operate on persons who have no obstruction in the anterior and middle portions of the passages and who have been subjected to partial turbinectomy. Recently, a lady aged twenty-nine, who had been subjected to partial turbinectomy at the hands of three different operators, came to me and submit-

ted to the removal of the posterior extremities of both inferior turbinates. In less than a month after the operation, she wrote me of the delightful change in her voice as well as in her comfort, and the astonishing improvement in her capacity to sing.

Another notable instance is that of a Professor of vocal music in an academy for young ladies. She was annoyed with a posterior nasal catarrh which had resisted all sorts of treatment. Noticing the lack of resonance in her voice, I passed my finger behind the soft palate, and found a considerable narrowing of the space. Complete inferior turbinectomy was done on both sides. She not only experienced complete and permanent relief, but enjoys a greatly improved vocal capacity in singing. A considerable percentage of the cases in which I have done inferior turbinectomy, were annoyed by tinnitus, many of them suffering with impaired hearing. I do not recall an instance of this kind in which improvement was not decidedly marked within a week after the operation. I have here a few specimens, illustrating some of the conditions of the turbinates which necessitated their removal. Some of them, although altered by the preserving fluid, show the marks of pressure of contiguous structures, whilst the posterior extremities of nearly all of them present the strawberry appearance, indicative of pharyngeal adenoids.

As to the after treatment, I wish to say I have abandoned the use of the pack in any form. I use the adrenalin spray before operating, almost immediately afterwards, and again a half hour later. In a few rare cases, secondary hemorrhages of very slight and unimportant character have followed the operation, six to eight hours later.

On the occurrence of secondary hemorrhage, the Adrenalin spray undiluted, 1 to 1000, has proven promptly efficient. In the two cases where I had troublesome hemorrhage, I had used the pack and was obliged to remove it. Adrenalin, hypodermically injected as well as in the form of spray for the nose, controlled one of the cases. The other, proving more intractable, yielded finally to five grain doses of Gallic Acid. In one case, a gentleman thirty-seven years of age, left the office at 11 A. M., going into the business part of the city where he transacted considerable business, and returned to St. Joseph's Infirmary at 4 P. M. Half an hour later, he was seized with a chill, attended by increasing coldness and nervous depression followed at midnight by delirium. He perished at 11 A. M., the next day, with acute general muscular cramps, without

ever having reacted from the chill, which set in the evening before. Whether the turbinectomy had any relation to the chill it was impossible to determine. Prof. H. A. Cottell saw the patient a few hours after the beginning of the attack, and attended him to the end. In view of the large number of cases upon whom I have operated, I consider myself extremely fortunate to have had so few accidents. In the performance of the operation, I rely chiefly upon the saw, rarely employing any other instrument excepting the forceps with which the bone is removed. It is sometimes necessary to cut a small tag of the soft tissues which remains undivided at the anterior-superior extremity. This I do with scissors. The best saws for the purpose are those made for me by the DeVilbiss Manufacturing Co., of Toledo, Ohio, specimens of which I am pleased to exhibit. They have twenty-four teeth to the inch, cut in strips of steel one-eighth inch wide and a twenty-fourth of an inch thick, the teeth being cut so that every third tooth is longer than the two intervening ones, arranged so that the saw cuts by pushing alone, and not at all in the movement of withdrawal. In some cases it is necessary to saw in a semi-circular direction. These saws readily bend, adapting themselves to such curves.

### COUNTY SOCIETY REPORTS.

**Adair.**—The Adair County Medical Society met in W. F. Cartwright's office on Jan. 9, 1908, with the following members present:—J. H. Grady, W. R. Grissom, W. L. Grissom, C. M. Russell, R. Y. Hindman, W. F. Cartwright and U. L. Taylor. This being the day for the election of officers, the following were named:—President, John H. Grady; vice-president, C. M. Russell; secretary-treasurer, U. L. Taylor. Committee on Program—W. F. Cartwright, W. R. Grissom, and R. Y. Hindman. W. R. Grissom was elected delegate to the State Association. All the physicians of the county had been invited to take dinner with W. R. Grissom to-day, and all that were present went. I cannot undertake to give an account of the dinner; I am much better at sampling a dinner than in describing it; suffice it to say it was round after round of good things. The first round consisted of a 25-pound turkey, with all the appurtenances thereto belonging. The other courses were considered better, but to me this was the crowning glory of the whole outfit. The strange thing about the matter was that not a single country doctor was present. The hostess had invited them all alike, but they did not come. Perhaps they did not know, or were afraid they did not know how to eat a big din-

ner in town. I don't think this is the cause, but it will be hard for them to give a satisfactory explanation as to the cause of their absence.

After dinner we had two or three papers read and discussed, but after such gastronomic possibilities the performances were stale and unprofitable. The society then adjourned to meet again on the second Thursday in March.

U. L. TAYLOR, Secretary.

**Anderson.**—The Anderson County Medical Society met with C. W. Kavanaugh on Monday, January 6th, the following members were present: C. W. Kavanaugh, Murdock, Payton, Lillard, Witherspoon, Toll, Albright, Simpson and Gilbert.

C. W. Kavanaugh read a paper on "Fractures of Base of Skull." His ideas as to diagnosis and treatment being generally agreed to by all present.

There was some discussion as to what constituted the line of division between the vault and the base; the consensus of opinion being, "A line drawn from the outer canthus, passing just above the ear, and below the occipital protuberance.

O. L. Pindar was on the program, but was unable to be present.

Dr. Gibbs, of Fox Creek, was admitted to the society as a member.

After a lengthy discussion Dr. Toll's motion to take up the post-graduate course of study, after consulting with Dr. Blackburn, of Bowling Green, was carried.

C. W. Kavanaugh was again requested to write a piece to be published in the Anderson News, to interest the public in the building of a hospital.

J. R. Murdock reported the case on which he and Dr. Lillard operated, had entirely recovered.

The society adjourned to meet with Dr. Witherspoon on Monday, February 3rd.

J. W. GILBERT, Secretary.

**Barren.**—Dr. J. B. Honeycutt, one of our leading physicians and surgeons died here Dec. 14, of Meningitis. Dr. Honeycutt was born in Barren County December 25th, 1857. He had lived all his life in the county except five years, spent in Texas. The profession loses one of its best doctors, and the community a good citizen. He leaves a wife, son and 11 children.

R. S. PLUMLEE, Secretary.

**Bourbon.**—By the hand of an all-wise Providence who "moves in a mysterious way His wonders to perform," our friend and co-laborer Dr. Robert T. Wood was called to his eternal resting place, January 26th, 1907.

The subject of this sketch was born near Mt. Olivet, Ky., July 25th, 1851. He received his

preliminary education in the common schools. Choosing the practice of medicine as his life work, he secured his degree from the Ohio Medical College at Cincinnati, O., in January, 1879. Returning to his native heath, he practiced there about four years, whence he came to Paris, Ky., where he practiced until he received his summons from the "Great Physician."

Dr. Wood always filled with conscientious fidelity every duty imposed upon him by his medical society upon which he was a faithful attendant. His medical career was an honorable and creditable one and as a citizen he was upright, was held in high esteem and was always regarded as a man of the strictest integrity. In his untimely death and sudden taking off we are again reminded of our mortality, that "in the midst of life we are in death."

"Angels of life and death alike are His;

Without His leave they pass no threshold o'er;  
Who then, would wish or dare, believing this,

Against His messengers would shut the door?"

F. L. LAPSLEY, Chairman.

**Boyle.**—At the December meeting of the Boyle County Medical Society the following officers were elected:—President, George Cowan; vice-president, H. M. Pittman; secretary-treasurer, W. H. Smith.

I have turned over to Dr. Smith your letter and papers enclosed, and requested him to report to you.

F. H. MONTGOMERY.

**Bullitt.**—The Bullitt County Medical Society met at Shepherdsville, December 19; members present—J. R. Holtsclaw, S. W. Bates, J. H. Shafer, J. G. Dodds, A. C. Carroll, S. H. Ridgway, and R. L. Hackworth. The following officers were elected:—President, J. G. Dodds; vice-president, S. H. Ridgway; secretary, R. L. Hackworth. C. J. Cook and J. M. Crenshaw were admitted as members of the society. S. H. Ridgway read an interesting paper on pneumonia. Paper discussed by S. W. Bates, Holtsclaw, Overall, Cook, and Dodds. A committee was appointed to prepare and arrange for a post-graduate course. The committee on schedule of prices made their report; the report was adopted.

R. L. HACKWORTH, Secretary.

**Boone.** — The Boone County Medical Society met in Burlington, Wednesday, the 18th, and elected the following officers for 1908: — President, Y. F. Hopkins, Rabbit Hash; vice-president, R. C. Tilley, Petersburg; secretary and treasurer, F. L. Peddicord, Burlington; delegates to State Convention, W. O. Rouse, Burlington. Our next meeting will be held at Burlington, February 19, 1908.

F. L. PEDDICORD, Secretary.

**Bourbon.** — The Bourbon County Medical Society held one of the most enthusiastic meetings since its existence at the office of Drs. Fithian & Daugherty, Thursday, December 19th, 1907, being the annual meet and occasion for election of officers for the ensuing year.

The removal of one, expiration of term of another and the election of another to office required the election of a complete board of censors. The election resulted as follows:—President, Frank M. Faires; 1st vice-president, J. S. Wallingford; 2nd vice-president, J. T. Brown; secretary-treasurer, C. G. Daugherty; assistant secretary-treasurer, F. L. Lapsley; historian, F. L. Lapsley; censor, one year, Wm. Kenney; censor, two years, E. A. Cram, Centerville; censor three years, Jno. A. Gilkey, North Middleton.

The location of the hospital was discussed at length, the proposed location not being thought the best that could be had. The society voted to discontinue the use of separate club rooms and the proposed bi-monthly meetings and to meet as the society has done so successfully in the past, the third Thursday in the month. The scope of work for 1908 was discussed, but the program left to the committee appointed by the incoming president, F. M. Faires.

I. A. Shirley, of Winchester, councilor for his district was present, as was Julius M. Purnell, assistant surgeon of U.S.A., of Manila, P.I. Dr. Shirley is very sanguine as to the meeting of the State Society in his town next year, as he says in "The city second in size and first in enterprise in Kentucky." May his shadow never grow less.

At the conclusion of the formal meeting the society partook of a "buffet" supper as guests of the hosts of the evening.

C. G. DAUGHERTY, Secretary.

**Calloway.**—The Calloway County Medical Society was called to order by the president, Newton Evans, at 1:30 P. M., with a full attendance, sixteen being present. J. V. Stark, Kirksey, and E. B. Houston, Cherry, were elected to membership.

The action of the Kentucky Medical Association relative to the use of "Patent and Proprietary" medicines and medical journals advertising same was discussed at length. All but one doctor present signed pledge to discontinue the use of such medicines, and discontinue receiving all medical journals advertising same.

W. H. Groves and C. N. Crawford were chosen to represent the society at the Kentucky Anti-Tuberculosis Association's display in Louisville early in 1908, and Senator Conn Linn, and Representative J. B. Swan, and Superintendent L. A. L. Langston were chosen to represent the county at large.

A committee of three was appointed by the chair to draft resolutions from the society signed by its members and the doctors in the county and present same to our Senator and Representative requesting them to support the measure to come up before the next Legislature relative to the collection of debts.

The officers elected for the ensuing year are as follows:

President, C. O. Gingles, Kirksey; 1st vice-president, J. T. Wall, Murray; 2nd vice-president, T. B. Houston, Cherry; secretary-treasurer, P. A. Hart.

The society also elected G. H. Covington, J. G. Hart and C. N. Crawford to be recommended to the Kentucky State Board of Health for appointment on the county board of health at the expiration of the present board's term of office.

Program.—P. A. Hart, Clinical Examination of Blood to the Practitioner; Newton Evans, Uric Acid as Cause of Disease; W. M. Mason, Arterial Hypertension.

W. H. GRAVES, Secretary.

**Carlisle.**—The Carlisle County Medical Society held its annual meeting at Bardwell, December 3, 1907. This was a profitable meeting, with all the interest manifested, which usually characterizes our meetings. The society was called to order at 10 o'clock by the president, and after prayer the official program was taken up.

In the morning session, one paper only was disposed of, that being a treatise on rheumatism by T. D. Bugg, which elicited much discussion and was generally good for the profession.

When the afternoon session had been called to order at 1:30 P. M. and the minutes of the last meeting had been read and approved, Dr. Crouch, chairman of Committee on Finance made a report for the committee and submitted a revised fee list, and articles of agreement (copy of which I enclose for publication), all of which were adopted by the society and signed by the following members:—H. T. Crouch, J. M. Peek, R. T. Hoeker, G. A. Thomas, Geo. W. Payne, F. N. Simpson, Jno. R. Owen, W. L. Mosby, Wm. Graves, T. D. Bugg, W. Z. Jackson, Wm. E. Gholson, C. D. Shelburn, and R. C. Burrow.

W. L. Mosby next read a paper on "The Differential diagnosis of Diphtheria and Membranous Croup" which was well discussed by W. W. Richmond, Crouch, Peek, Payne, Hoeker, and others, and was very interesting. There was a difference of opinion as to the existence of the two conditions, but one thing upon which all were agreed, was to administer Antitoxine early and in large doses and to all cases.

Passed resolutions concerning "Nostrum and Quack Medical Journals," and endorsing the

work of the Council on Pharmacy and Chemistry of the A. M. A.

The election of officers for 1908 resulted in the election of:—President, W. E. Gholson; vice-president, G. A. Thomas; secretary, H. T. Crouch, Bardwell; treasurer, Wm. L. Mosby.

The next meeting will be held at Arlington on the first Tuesday in March. Next meeting, Milburn, June 1st Tuesday, and the third quarterly meeting at Kirbyton first Tuesday in September.

W. E. GHOLSON, Secretary.

#### Articles of Agreement.

Agreement made between the Carlisle County Medical Society and the members thereof, as follows:

We, the undersigned members of the Carlisle County Medical Society, of Carlisle County, Kentucky, hereby agree and bind ourselves, subject to the penalties named herein:

First: Each member shall submit to the Secretary of this society the names of persons who have persistently refused or neglected to settle their accounts for medical services rendered within a reasonable period, and such other names from time to time as each member may think to their interest.

Second: The names submitted as per section first shall be arranged alphabetically, to be known as the "Information List," and each member of this society shall be assigned a number by which he shall be known in the list.

Third: Every member of this society shall be furnished a copy of the "Information List." All names reported by the secretary shall be added or removed as reported.

Fourth: It shall be the duty of each member of this society to inform any person whose name appears in the "Information List" apply to them for medical services, that they owe an account to the physician or physicians reporting their names. Exceptions to this rule may be made as follows: In case of emergency the physician applied to may render immediate medical aid to the extent of one visit to such person, providing the physician rendering the service demands and receives cash payment for the service; but shall refuse further services except for cash or a written voucher signed by some legally responsible person for the payment of same.

Fifth: The person so reported may make application to the physician or physicians reporting his name, pay the amount due, or make satisfactory arrangements for the payment thereof. Then it shall be the duty of the physician reporting said person to issue a certificate on the form prescribed by this society, certifying that he had paid the account or made other satisfactory arrangements for the payment of the same. In this event, it shall be the privilege of any physician to whom said person shall apply

and present said certificate, to render medical services.

Sixth: In the event of a person receiving a certificate of satisfactory arrangements for settlement of his account failing to comply with his agreement made in order to receive said certificate, the name shall again be placed on the "Information List," and each and every member of the society shall refuse absolutely to render further medical services until the terms of said agreement have been complied with or a new certificate issued.

Seventh: The following form of certificate shall be used for the purpose set forth in section sixth:

This certifies that Mr. .... has this day agreed to settle his account of \$..... by making payment on the ... day of each and every ..... until said account is settled in full. Date ..... 19 ..... Signed

..... M. D.

Eighth: It shall be the duty of each and every member of this society to render statements to his patrons quarterly on the first day of January, April, July and October of each year. Privilege is hereby granted to render monthly statements.

Ninth: It shall be compulsory upon each and every member of this society to comply with the conditions of this agreement, also to abide by the minimum fees as set forth in the fee bill adopted, also the code of ethics; and upon trial and conviction before the Censors of the Carlisle County Medical Society pay a fine of from \$5 to \$10; or expulsion from the society shall be imposed upon any member who wilfully or negligently refuses to comply with the conditions herein set forth. (Signed)

MEMBERS.

**Carter.**—The Carter County Medical Society met in regular session on the 10th inst., and elected its present officers for the year 1908, and also fixed its dues at \$3.50 per member for said year, so as to be better equipped for whatever emergencies that may arise.

**G. B. O'Roark** read an interesting paper on "Ptomain Poisoning," and also exhibited a knotted funis which was somewhat remarkable on account of it being so closely drawn and yet not obstructed as to function.

D. B. WILCOX, Secretary.

**Christian.**—The Christian County Medical Society met on December 16th, 1907, and elected the following officers:—President, F. M. Stites; vice-president, B. A. Caultle; secretary, J. Paul Keith; delegate to State Society for two years, R. L. Woodward; alternate, J. E. Stone; board of censors, J. W. Harned, T. W. Blakey and A. H.

Edwards. The date of meeting was changed from third Monday to third Tuesday in each month. Next meeting Jan. 21, 1908.

Respectfully yours,

J. PAUL KEITH, Secretary.

**Crittenden.**—The Crittenden County Medical Society met in Marion, December 11, 1907. It being the annual meeting the following officers were elected:—President, E. E. Newcom, of Repton; vice-president, C. G. Moreland, of Ford's Ferry; secretary, W. T. Travis, of Marion; delegate, Jas. E. Fox.

W. T. Travis, of Marion, and J. R. Perry, of Tribune, were elected members of this society.

W. T. TRAVIS, Secretary.

**Cumberland.**—The Cumberland County Medical Society met in the office of H. L. Cartwright, on Wednesday, Dec. 25th, and elected the following officers for the year 1908. — President, H. L. Cartwright; vice-president, W. F. Owsley; secretary, Osear Keen.

**Dr. Cartwright** reported two cases of pneumonia which were freely discussed by all the members present.

The society adjourned to meet again Wednesday, Jan. 8th, at which time the annual dues will be collected.

OSCAR KEEN, Secretary.

**Clinton.**—The Clinton County Medical Society met on the twenty-third of December and elected their officers:—President, Alvis P. Ryan; vice-president, M. B. Flowers; Secretary, F. W. Huddleston; treasurer, S. F. Stephenson.

The board of censors was composed of Drs. Cook, Flowers, and Huddleston.

The following members were enrolled for the coming year:—J. A. Sloan, A. P. Ryan, M. B. Flowers, S. F. Stephenson, D. L. Cook, W. H. Norris and F. W. Huddleston.

Our society is progressing very nicely and each member seems enthusiastic in the work.

We expect much good from our society this year.

Enclosed find check for twelve dollars, which is fee from all members except Norris.

F. W. HUDDLESTON, Secretary.

**Casey.**—The Casey County Medical Society met in J. S. Wesley's office on December 26, 1907, with but five members present. In the absence of the president and vice-president, the society was called to order by the secretary, and J. M. Haney was elected president, pro tem. In the absence of a program J. T. Wesley gave an interesting talk on the nostrum evil. Prof. J. S. Lowhorn gave us a good talk on the edu-

## MANAGEMENT OF A PRIMIPARA DURING PREGNANCY AND LABOR.

[CONTINUED FROM PAGE 91]

### DISCUSSION.

**John G. Cecil**, of Louisville: Mr. President. It is with no little trepidation that I undertake to open the discussion on this paper. I appreciate, however, the privilege of discussing it. Dr. South has presented a paper which, to my mind, represents practically all that is best and up-to-date in the management of primipara. While I disagree with her in a few things, yet in the main I can accept her management of a case and be perfectly satisfied with it. All that she has said with reference to preliminary preparations leading up to labor I heartily endorse. I think outdoor exercise, normal living, and careful watching of the patient are very essential. There is no situation in life to me that is more pathetic than to see a young woman, a young wife, taken to the grave yard as a result of an effort on her part to reproduce her kind. It is the saddest of all deaths to me.

In regard to the urine, she has touched on it in a very pertinent way. I believe it would be a good plan if every physician in a community, wherever he may be, declined to accept obstetrical cases, ordinarily speaking, unless he is employed long enough before the labor to give him ample time to study the case and to prepare for the frightful emergencies which so often occur. It has been my unfortunate practice to have met with many cases of puerperal eclampsia, and I do not know of any condition where I felt more helpless. Some of these cases get well possibly by the grace of God, but a great many of them do not. The time to treat puerperal eclampsia is before it occurs. You should begin a long time in advance if you know that you are going to treat the case. If you do not, and permit the woman to go to labor without having prepared for this emergency, if anything should happen, you are criminally negligent.

As to the value of urea, I do not know what is the cause of eclampsia. I wish I did. It is a routine practice of mine in every case of labor I expect to attend to have the urine examined carefully and frequently, not only with reference to albumin, but with regard to the quantity of urea, and I have been surprised to find how often the quantity of urea has diminished. It has given me no little uneasiness; yet I have seen some of these cases get through very well.

Another point I wish to speak of is the vomiting of pregnancy. Of course, we all recognize what we may call physiological vomiting, which occurs in the first six weeks, or second six weeks of pregnancy. You can treat these

women any way you please, and you will probably have the same results. You have all had such experiences. When vomiting persists, or when it comes on late, and is accompanied by nervous symptoms, sleeplessness, blurred vision, you may expect the storms that occur during labor in the shape of convulsions; then, I believe, they are due mainly to the effort on the part of the stomach to eliminate the poisons which should have been eliminated by the kidneys, or by the bowels, or by both. That type of vomiting of pregnancy puzzles me more than any other.

With reference to the examination of the patient and the treatment, the doctor stated that after an effort has been made to deliver the woman with forceps, Cesarean section is not to be thought of. I beg leave to differ with her in that respect, because sometimes after we have tried patiently and faithfully to deliver with forceps we have failed, and then our only recourse is Cesarean section, version, or craniotomy.

**D. G. Simmons**, of Adairville: I wish to endorse this paper in its entirety, so far as I am able to judge of its merits. Dr. South has handled the subject so exhaustively that, it seems to me, very little has been left to be said by those who are called upon to discuss it. I, however, would like to call your attention to one or two features in her paper and to emphasize them. First, with reference to nausea and sour stomach, or heart burn. Perhaps there is not a symptom from which the majority of these women suffer more acutely and more generally than from heart burn, an excess of acid in the stomach. It is absolutely necessary for the comfort of the patient, to say nothing of anything else, to overcome that. After an observation extending over a number of years I have found nothing whatever that would compare with the use of carbonate of magnesia for that condition. It is an old remedy. I have no doubt you have all used it, and those of you who have used it have been satisfied with it. It subserves two very important purposes. First, it neutralizes the acid, and relieves the pain and discomfort incident to its presence; but still more important, it subserves or forms, by the union with the acids in the stomach, a chemical purgative salt which acts most admirably in keeping the patient's bowels open, where there is a tendency to constipation, which there most frequently is. Sometimes there is no tendency to constipation. There may be a little diarrhoea: but if it is only a little, I would still use it because of the tendency toward kidney trouble.

**I. A. Shirley**, of Winchester: I cannot let this opportunity go by without saying a few words on this interesting paper by the lady doc-

tor. She has discussed the subject in a very able way, and while she has said many things with which I agree, still there are others with which I disagree. In the first place, with reference to making examinations. She has told us that we should keep our hands off and examine pregnant women who are approaching labor as little as possible. I think the matter of urging the practitioner to keep his hands off in these cases and not make these examinations has been emphasized too much. It has been given too much prominence. An examination, properly conducted with a clean hand and a clean patient, is attended with little or no danger.

Again, I do not think it is really necessary to shave the labia in every case.

What the doctor said with regard to the use of forceps and of shaving the parts before that instrument is employed is rather unique, and I want to say, if that practice prevailed in my section of the country I fear it would not be tolerated.

As to the use of ergot, I usually carry the fluid extract of ergot in my grip, and on it I rely to bring about contractions of the uterus. In the practice of obstetrics, the man who has not clean hands should not undertake this work.

Again, I do not think every lacerated perineum needs repairing. It is natural for a primipara to have a torn perineum, but when it is slight, nature will take care of it and do much better than a bungling operator who attempts to sew it up.

**B. L. Holmes**, of Carrollton: I desire to commend this excellent paper. In a great many cases of normal labor the physician will be able to determine all that is necessary with regard to the position and presentation of the child. Besides, this can be obtained by abdominal palpation. I think the rule will apply here, that the fewer digital examinations are made the fewer cases of puerperal infection we will have. This is certainly a point the physician should endeavor to carry out and observe. He should make as few vaginal examinations as possible.

In regard to tears of the perineal body, the doctor did not dwell extensively on the means which may be used to prevent them. There is one thing I would like to mention to those who have had considerable experience along this line, namely, episiotomy, which consists in making an incision on each side of the labia majora just at the time the parts are greatly stretched. I believe in that way many tears of the perineal body may be prevented. These little incisions can be sewn up without much trouble.

There is another point I wish she had dwelt on more, and that is the treatment of that troublesome constipation we meet with accompanying pregnancy. I would like to have the experience of members of the Association in regard to the

use of high rectal enemata in the treatment, given daily, and requiring the patient to remain in bed for hours after they have been given.

**William H. Wathen**, of Louisville: The question of the treatment of the nausea of pregnancy is one that comes to every doctor, and unfortunately there is not one of us who has a clear idea of this condition so that we can treat it intelligently. There are, however, two causes apparently distinct which operate differently. One may be said to be a neurosis, reflex or otherwise, which never causes death if the patients are properly treated. The other is the absorption into the system of chemical poisons generated in the chorionic structures, either in the syncytial tissue or in Langhan's layer. This will often go on to the death of the woman unless labor is terminated promptly; but this is such an infrequent condition that we may go a lifetime without meeting with it. In this condition, after the death of some of these patients, apparently we will find syncytial structures in the liver; and we will find a liver that is in practically a malignant condition.

I do not agree with Dr. Cecil that all cases that continue long are necessarily fatal, or will not yield to treatment. I have had many cases in my earlier experience where I have found that vomiting for six or seven months yielded promptly to appropriate treatment. In the ordinary nausea of pregnancy, where there are no chorionic products absorbed in the blood, the patients will get well if you feed them properly. Give them food per rectum, and keep the stomach empty, giving them nothing by the stomach except 1-8 to 1-4 gr. of cocaine, one drop of carbolic acid, if you wish to keep the stomach absolutely empty.

**T. A. Frazier**: I want to endorse this paper in the main. I think it is excellent. We can all appreciate it.

I differ with the essayist in regard to irrigation. I believe that when we irrigate the vagina before labor is completed, or whenever we irrigate it after labor is completed, and after the placenta has been delivered, we increase the chances of puerperal infection. (Applause).

One of the most important things in conducting any case of labor is to prevent infection. We know by experience, we know from authorities, that ninety-five per cent. of women will deliver a baby unaided and unattended. While we can assist them oftentimes and save them from much suffering, we know it is a fact that this percentage of them will give birth to babies without assistance. We know that this is a fact, that nature in her wisdom has provided for secretions in the vagina which are supposed to lubricate and assist in delivery. Nature has supplied the amniotic fluid which is aseptic.

**F. H. Clark**: I wish to commend this paper in a general way, particularly with regard to the

examination of the patient before she goes to labor. But the essayist goes too far, I think, when she attributes all cases of puerperal eclampsia to the kidneys. I believe that the toxemia of eclampsia is not well or clearly understood, and that the kidney is only one of the organs at fault in the generation or manufacture of the poison.

**J. T. Green:** I wish to add a word or two to one point brought out by the essayist, and that is, that all cases of eclampsia are caused by poison being in the blood. I believe in the great majority of cases that is true. However, I don't believe that all cases are called eclampsia. There is no doubt that the poison circulating in the blood is a remote cause; but the most direct cause in my experience is that mentioned by Dr. Wathen, namely, a neurosis, a nervous condition, in which the sympathetic nervous system has become very irritable, and on that account we have a vaso-motor constriction. The arterial tension is usually greatly increased; on account of this irritation, we have in my judgment a toxin. This has been borne out where an examination of the urine has been made, and the proper waste has been found to be eliminated from the kidneys. When these examinations have been made and we find the waste is sufficient, my experience and my practice is to give a hypodermic injection of morphia and atropine in these conditions, with which I can control the convulsions, and the woman has no further trouble. I believe the convulsions in many of these cases are purely from nervous irritation.

**T. J. Shoemaker,** of Morganfield: I want to endorse in the main all that has been said by the lady physician in her paper, and I am glad to see that woman physicians are coming to the front in the practice of obstetrics. In my judgment, they ought always to have been the obstetricians. Women do not want men physicians fooling around them when they are about to be confined, and I believe a woman physician can examine a woman better than a man can. I want to say, however, that it devolves on women to contrive some kind of an instrument to prevent tearing of the perineum in cases of primipara. Men never seem to have genius enough to contrive anything for that purpose, but until that is done these women will continue to have lacerations of the perineum.

**James W. Kincaid,** of Catlettsburg: In reference to that part of the paper in which the essayist spoke of the repair of a laceration of the perineum and the time it should be done, in my judgment the proper time is after the birth of the child, and before the expulsion of the placenta. Any temptation to pull on the cord should be removed, and I simply want to say that a cord-puller should not repair the perineum. In order to remove that temptation, the work had

better be left to somebody else.

**C. Z. Aud, of Cecilian:** My experience is that sepsis sometimes occurs in obstetrics from pus tubes or some other infection may have been conveyed from the father and mother of the child, and in such cases the profession should not be held responsible for the infection.

I am sure the essayist is just as well informed as I am with regard to preventive measures in obstetric work. I rose particularly to answer my good friend, Dr. Shoemaker, who said women do not like men to be fooling with them. Gentlemen, this is no foolish business. It is a serious business. I have daughters to be attended, and I expect doctors to attend them as carefully and with as little immoral thoughts in their minds as if they were women. It is a serious business to practice obstetrics, and I do not believe there are half a dozen physicians within my hearing who think of anything except their serious duties when they attend women in confinement.

**S. J. Harris,** of Philpot: I endorse the paper of the essayist, and am glad to say, I believe nearly everything she says. But I am not prepared to say that I use gloves and a gown. I practice medicine in the country, and I fear that women would hardly have me wait on them if I arrayed myself in a gown.

I do not agree with Dr. Shoemaker, that women do not like to have men "fooling around" when they are about to be confined. I take the position of my friend, Dr. Aud, that it is the greatest compliment a woman can pay a doctor when she calls on him at such times as this to render her that service which her dear husband cannot, and I think every practitioner ought to be prepared to render that service in the very best, up-to-date manner.

I do not believe in flushing or washing, as we were formerly taught to do. Those of us who have practiced medicine for thirty-five or forty years have passed through a number of teachings along this line. When we used to flush and were taught to flush, I had more trouble in those days than I have now, when I seldom ever touch my patients until the time comes for me to do so, and I find I have better results when I have thoroughly disinfected her, which I always do, and do it as soon as I am called in. I may disinfect the woman a number of times, washing possibly the individual, flushing the vagina with antiseptics, or with any other agents I may see fit to use.

I am glad to have heard the paper and the discussion on it.

**L. H. South** (closing): In regard to Cesarean section, I said it was an operation of selection only. Dr. Cecil says, you have to apply forceps, but even after applying forceps it may be necessary to resort to Cesarean section. Before applying forceps you let the woman go through the allotted time of labor, you recognize that there is

some dystocia; you make an examination to see if the membranes have ruptured or not; you may call in a consultant and think of performing Cesarean section. He also makes an examination, and in so doing you have run the risk of subjecting that woman to sepsis. You have an unknown quantity; the child's life may be imperiled, and, of course, in applying forceps you use force; you cannot deliver a child without applying more or less force in extracting it.

In regard to Dr. Shirley's criticism of shaving the vulva, I do not shave the vulva, but shave portions of the labia when I apply forceps, as the woman is under chloroform anesthesia, and this can be done very readily. I find it necessary to do this in order to sterilize the parts. In obstetrics, it seems to me, we have to consider sepsis more than in abdominal operations.

With regard to what was said about the use of gloves, the gentleman who says he does not use them forgets his bacteriology. According to the bacteriologist, there is no such thing as clean hands, and it is impossible to render the hands completely aseptic. Bacteriologists have tried time and again to get absolutely negative cultures from hands, regardless of how long the hands were scrubbed, and have been unable to do so; consequently, the use of the gloves is necessary.

With reference to the repair of a lacerated perineum, I will say that a bungler should not attempt to repair a laceration of the perineum.

As to whether convulsions occur from enlargement of the uterus, I will say that they are due to a toxemia or to a toxin circulating in the blood. We must learn that it is a poison and treat it as such.

In regard to the protection of the perineum, one of the speakers (Dr. Holmes) recommended episiotomy. That operation has been relegated to the past years ago, and there is very little one can do to protect the perineum except by controlling slow dilatation of the vulva. He also asks about the vomiting of pregnancy. That is due to a toxemia and should be treated accordingly, whatever may be the real cause. It is a poison circulating in the blood, and must be treated as you would treat any other poison.

Dr. Frazier spoke about irrigating the vagina. I do not give douches in obstetric work; I irrigate the stitches. How can you bind a wound as large as the palm of the hand full of blood clots? You have to irrigate it, but not irrigate the vagina.

As to eclampsia being preventable, the kidney is one of the many organs that suffers from the toxemia circulating in the system. There will never be sufficient poison circulating in the system without producing irritation of the kidneys to some extent, and this irritation may be slight, but you should try to find it. If you do not, you are not capable of retaining the care of that patient. Dr. Green said that some cases of vomit-

ing are due to irrigation of the nerve centers. What is going to irrigate the nerve centers but a certain amount of poison circulating in the blood? Vomiting of pregnancy, eclampsia, and acute yellow atrophy are all various grades of toxemia and should be treated accordingly.

## COUNTY SOCIETY REPORTS.

[CONTINUED FROM PAGE 104.]

education of the people as to the use of narcotics, especially the cigarette habit, stating that in his experience as a teacher that he could soon see a difference in the ability of one addicted to the habit.

Chester B. Creech, formerly of Munfordsville, Hart County, but now of Middleburg, Casey County, presented an application for membership in the Casey County Medical Society. The same was accepted and he was elected to membership. We are glad to welcome him to our county and society. The election of officers was called for by the president and the following officers were elected for the ensuing year:—President, J. M. Haney; vice-president, D. S. Floyd; secretary and treasurer, L. F. Hammonds. The following program was arranged for the next meeting:

Lagrippe, J. M. Haney; own selection, D. S. Floyd; A Course in Bacteriology, C. B. Creech. The society then adjourned to meet in Liberty, Ky., on the 27th day of February, 1908.

L. F. HAMMONDS, Secretary.

**Cumberland.**—The regular monthly meeting of the Cumberland County Medical Society met January 8th, 1908, in the office of W. C. and Oscar Keen, at Burkesville. The house was called to order by the President, H. L. Cartwright. No papers were read, but each doctor reported cases which were freely discussed by all the members present.

A collection for the annual dues for 1908 was made, those paying their dues were H. L. Cartwright, W. C. Keen, A. W. Sharp, Oscar Keen, and J. G. Talbot.

We do not have a very good attendance at our County Society during the winter months owing to the fact that several of our doctors live a considerable distance from Burkesville, and the bad roads and high water keep them away, though we usually have good attendance through the summer and fall.

We are going to make a strong effort this year to have every physician in the county become a member of our society.

OSCAR KEEN, Secretary.

**Greenup.**—The Greenup County Medical Society met in regular session December 12th, 1907

at Greenup, in the home of H. T. Morris.

**A. S. Brady** reported several cases of gun shot wounds of the head which were discussed by all members present.

**E. E. Raïke** reported a case of gun shot wound of the head in a boy 9 years old which was discussed at some length.

**E. T. Raïke**, **R. C. Biggs**, and **O. P. Clarke** were appointed on Public Health and Legislation Committee.

It was decided to hold the next meeting in Greenup January 9th, 1908. The same officers were re-elected for the ensuing year. A motion to adjourn was carried.

**Greenup.**—The Greenup County Medical Society met in regular session at the home of H. T. Morris, Greenup, January 9, 1908, at 2 P. M. We had with us **J. W. Kincaid**, of Catlettsburg. The members present were **H. T. Morris**, **A. S. Brady**, **R. C. Biggs**, **E. E. Raïke**, **E. R. Fitch** and **A. D. DeBeard** came in as a new member.

**J. W. Kincaid** was given most of the time to explain the post-graduate work, which he did very ably. He gave some very good ideas on the mode of study for which we are truly thankful to him.

The next meeting will be held in Greenup on February 13, 1908, at 2 P. M.

We adjourned at 5 P. M. and were served at the Kowns House to an elegant supper at 5:30, with the ministers of the town as our guests.

**E. R. FITCH**, Secretary.

**Davies.**—The Davies County Medical Society met at the city hall, Owensboro, December 17th, 1907, with 38 physicians present.

The secretary-treasurer reported \$58.25 in the treasury. He was instructed to order a copy each of "Physicians' Manual of the U. S. Pharmacopeia and National Formulary," "New and Non-Official Remedies," and "The Propaganda for Reform in Proprietary Medicines" for the members of the society. As a few members previously purchased them, the secretary ordered sixty-six copies only of each. He has them on his desk, and members will please call and get them. The following officers were elected:—President, **W. F. Stirman**, Owensboro; vice-president, **Ed Barr**, Rome; secretary-treasurer, **J. J. Rodman**, Owensboro; delegate, **M. A. McDonald**, Whitesville; censor, **C. H. Todd**.

A committee consisting of **S. J. Harris**, **C. H. Todd**, and **D. M. Griffith** was appointed to revise the by-laws.

The society took dinner with the ladies of the Methodist Memorial Church, as guests of the city physicians.

**J. J. RODMAN**, Secretary.

**Gallatin.**—At a meeting of the Gallatin Coun-

ty Medical Society, held at the office of **S. B. Robinson** in Warsaw, Tuesday, November 26th, 1907, there were present **Jas. S. Brown**, chairman; **S. B. Robinson**, **Jno. T. Robinson**; **C. A. Menefee**, being a quorum. The secretary, **Dr. Stallard** being absent, **Dr. Menefee** was made secretary pro tem.

On motion, duly seconded it was resolved that the society heartily endorse the action of the Kentucky Medical Association in its efforts to rid the profession of all nostrums and unprofessional methods, and that we will confine ourselves in all particulars to the rules and methods enjoined by the resolutions of said society.

**C. A. MENEFE**E, Sec. pro tem.

**JAS. S. BROWN**,

**S. B. ROBINSON**,

**JNO. T. ROBINSON**,

**C. H. DUVAL**L,

**A. M. SHUPERT**,

**Ohio.**—At the meeting of the Ohio County Medical Society January 1, 1908, the following officers were elected:—President, **S. D. Taylor**; vice-president, **S. J. Wedding**; secretary-treasurer, **J. W. Taylor**; censor, **A. F. Stanley**; delegate, **J. S. Smith**.

We will continue to meet first Wednesday of each month at Hartford.

Respectfully,

**E. W. FORD**.

**Hardin.**—The Hardin County Medical Society held its regular monthly meeting at Elizabethtown in the city hall Thursday, January 9, 1908, with the following members present:—**Riggs**, **Flanigan**, **Mobley**, **Bowen**, **O'Conner**, **Hubbs**, **Rodgers**, **Nusz**, **Strickler**, and **English**.

The monthly post-graduate work for third month was taken up, **Dr. Nusz** was assigned a lecture on Bacteriology of Acute Articular Rheumatism; **Dr. O'Conner**, Dietetics in Rheumatism and Gout; **Dr. Howell**, Therapeutic Action of Salicylates. All that was said by **Drs. Nusz** and **O'Conner** was very good, and to the point. **Dr. Howell** being absent, his subject was taken up by all present. The afternoon was used for report of cases. Some interesting cases were reported and thoroughly discussed.

The Hardin County Board of Health met with the society in the afternoon, and offered a resolution that all the laity be invited to attend the Tuberculosis Exhibit in Louisville and try to educate themselves so that they could be able to co-operate with the medical fraternity and try to blot out the great white plague. Every member of our society seems to be delighted with the post-graduate work and we are getting along very nicely indeed with it.

**J. W. ENGLISH**, Secretary.

**Hopkins.** — The Hopkins County Medical Society met in the County Court-room, December 12th, 1908. There was a good attendance and we had an interesting meeting. It is pleasing to see the physicians of this county, stimulated by the achievements of the State Medical Society, taking more interest in the county society. And the prospects are flattering for a grand old revival in Hopkins. New officers for the year 1908 were elected as follows:—President, C. N. Ferguson; vice-president, I. J. Townes; secretary-treasurer, A. O. Sisk.

A. O. SISK, Secretary.

**Hopkins.** — The Hopkins County Medical Society met in the offices of Drs. Bane and McNary on Jan. 16th, 1908, with the following members present:—R. L. Hardy, W. T. McNary, W. F. Kell, R. W. Long, W. P. Ross, A. L. Thompson, A. W. Davis, Roy F. Robinson, and A. O. Sisk.

There being no papers to read the meeting resolved itself into an experience meeting. Several interesting cases were reported. Several helpful points were brought out in the discussions.

A. O. SISK, Secretary.

**Henry—Death of Dr. W. T. Coblin.**—The death of Dr. W. T. Coblin, occurred at his home in Campbellsburg, on last Friday, December 13, at 5 o'clock, P.M., after an illness of about a month of softening of the brain. He

W. T. COBLIN.

had been dangerously ill, however, only two weeks. His many friends in the community

were prepared for the worst, for they kept informed as to his condition, but his death will be a shock and a surprise to many who are farther away—for he was an exceedingly popular man, having friends everywhere.

The funeral occurred Sunday morning, religious services being held at the Methodist church in Campbellsburg, of which Dr. Coblin was an honored member.

Dr. W. T. Coblin was graduated from Miami Medical College, Cincinnati, in 1872, and from that date till the close of life he practiced medicine in Henry county—at Franklinton, Turners Station and Campbellsburg successively, and he was ever regarded as a competent and progressive physician, by both the laity and his fellow physicians.

He had served as President of the Henry County Medical Society and had represented the county as a delegate to the State Medical Association. Indeed, he had a large measure of the professional spirit; he was a student; he sought the latest and best thought bearing on his life's work; he was a conscientious practitioner; he carried professional ethics into all his practice.

Dr. Coblin was united in marriage October 28, 1869 with Miss Jennie Carr, a resident of this county, who survives, with two children—Miss Ella, of her own household, and Dr. Reuben M. Coblin, a prominent young physician, of Frankfort. They lost one child, a six year old girl, a number of years ago.

Verily the community and county will miss Dr. Coblin and feel keenly the loss of his services.

Requiescat in pace.

**Jefferson.**—Report of Proceedings of Jefferson County Medical Society meeting at the Galt House, Dec. 23, 1907. According to its constitution and by-laws, no scientific program was presented at this the last meeting of the year. Miscellaneous business, reports of committees, election of officers for the ensuing year and the annual banquet occupied the attention of the society.

J. G. Sherrill, chairman of the committee appointed at previous meeting to draft a new constitution and by-laws, reported the result of his committee's deliberations which, after some minor changes, were adopted. The most important changes are: requiring that an applicant shall be **elected to membership by a majority of members present after recommendation by a majority of the Judicial Council**: creating the offices of **2 Vice Presidents**: making the tenure of office of **Secretary two year**: providing that no officer is eligible to serve **two terms consecutively**:—percent of the society's membership may after prescribed notice, transact any business of

the society, and — per cent may transact routine business and engage in scientific work: providing for **bi-monthly meetings**, to be held on the second and fourth Monday evenings; meetings to be called to order at 7:45 o'clock.

The following were elected officers for 1908: B. F. Zimmerman, President; Chas. W. Hibbitt, J. Rowan Morrison, Vice Presidents; Jno. J. Moren, Treasurer; Virgil E. Simpson, Secretary; J. Morrison Ray, J. Garland Sherrill, Judicial Council; Sidney J. Meyers, Chairman, Chas. G. Lucas, Geo. A. Hendon, Executive Committee.

A vote of thanks was tendered the retiring officers which was spoken to in a most happy summation of the year's work by the retiring President, S. J. Meyers, on behalf of himself and the other retiring officers.

The report of the milk commission showed most commendable, conscientious work on the part of its members. This report is deemed of such importance as to quote at length: The first dairy was certified Sept. 1, 1906, furnishing 30 gallons of milk per day; 3 dairies are now certified furnishing 130 gallons of milk and 10 gallons of cream per day, and two more are about to be put in commission. The society financed the project at the beginning but for the past year it has been self-sustaining. The commission is a member of the American Association of Medical Milk Commissions organized last June and one of its members is a member of the Judicial Council. Twenty-one Commissions were represented at the initial meeting at Atlantic City in June, 1907. The use of the term "certified milk" has been limited by the State Pure Food Commission to the Jefferson County Milk Commission. The present State legislature will be asked to make this a State law. An "Inspected Milk" is also on the market here under the supervision of the commission. It is produced by tuberculin-tested cows, is cared for under the same strict precautions as "certified milk," is distributed in original two-gallon cans or bottled by the city distributing plant and is intended for family consumption.

The year 1907 was one of the most satisfactory in many ways in the society's history. It closed with a membership of 232; it saw, through its committee, its recommendations as to necessary changes in the City Hospital accepted and put in effect; it saw, through its milk committee, certified milk placed on the market; it saw the foundation laid for the Jefferson County Medical Library; it had as its guest the Kentucky State Medical Association in the best meeting that Association has ever had; and last though far from least, it saw a most significant enthusiasm and cooperation among its members which augurs well for its increased influences during the present year.

The following program was had at the meeting on January 13th.

VIRGIL E. SIMPSON, Secretary.

**Jefferson.** — At the regular meeting of the Jefferson County Society last night, the following officers were elected: — President, B. F. Zimmerman; vice-presidents, C. W. Hibbitt and J. Rowan Morrison; secretary (for two years), Virgil E. Simpson; treasurer, John J. Moren; executive committee, S. J. Meyers, chairman; Chas. G. Lucas, and G. A. Hendon; judicial council (for three years), J. M. Ray and J. G. Sherrill.

The enclosed report of the Milk Commission was read and it was voted that copies be sent to the daily and medical press with a request that it be published.

HENRY ENOS TULEY.

#### REPORT OF MILK COMMISSION.

Mr. President and Members of the Jefferson County Medical Society:

It is now eighteen months since your Milk Commission was appointed. The first dairy was certified September 1st, 1906, with the modest beginning of thirty gallons. The Commission now certifies to the product of three dairies with an output of 130 gallons of certified milk and ten gallons of certified cream. Financial aid was had from the society for operating expenses at the start, but for a year it has been self-sustaining, though for a short while it felt the burden of debt. The commission now owns sufficient paraphernalia for its present needs, though there is a constant expenditure for chemical reagents, culture media, postage, stationery, and for inspection of dairies, etc.

It has been most gratifying to the Commission that there have been so few complaints in regard to the milk, and that the demand has grown and is growing so constantly, and this, too, in spite of the fact that the price of certified milk has been raised twice in the last six months. Because of the increased demand two more dairies are about ready to begin supplying Certified Milk and a third will be ready in a short while.

We wish to call attention to a milk produced under our supervision which is called Inspected Milk. This milk is produced from tuberculin tested cows and under the same strict precautions as Certified Milk, but it is shipped to the distributor in two-gallon cans, and either delivered to the consumer in the original can or it is bottled at the city distributing plant and delivered in bottles. The advantage of this milk for institution consumption is manifest.

The Jefferson County Milk Commission is a member of the American Association of Medical Milk Commissions, which was formally org-

anized last June at Atlantic City, and one of its members was elected a member of the Judicial Council for a term of four years. The dues of the Jefferson County Commission have been paid by its individual members personally. The next meeting of the National body will be held at Chicago in June, 1908. At the Atlantic City meeting there were twenty-one commissions represented, showing the recognition given Certified Milk from Boston to Los Angeles.

The State Pure Food Commission has effectually limited the use of the term Certified Milk to the Jefferson County Milk Commission. This was done through a suit in a magistrate's court to stop the sale of a milk bearing these words, which had been certified to by interested parties. The House of Delegates of the last State Medical Association passed a resolution memorializing the Legislature to make it a State law limiting the use of the term Certified Milk to Medical Milk Commission appointed by a regularly organized county medical society. This law is in force in New York State and we believe it will be in Kentucky.

We ask your attention to the exhibit of Certified and Inspected milk, photographs of the dairies, shipping boxes, plated milk for bacterial content, etc., and to consume the milk at the banquet generously donated by our distributor.

#### REPORT OF LIBRARY COMMITTEE OF JEFFERSON COUNTY MEDICAL SOCIETY.

We wish to state in this preface that the object of this report is to review the movement from its inception to the present time—to explain its present status and to venture a forecast of its possibilities. In addition we hope through its liberal publication in the medical press to aid the popularization of the movement.

The committee was appointed during the presidency of Dr. Wm. Cheatham—more than two years ago, and consisted originally of Drs. Bullitt, Pfingst, and Schachner. Dr. Bullitt, after much valuable work temporarily left the city. This occasioned the appointment of Dr. T. H. Baker.

The original purpose of the committee was to create a department of current medical literature in the Louisville Free Public Library. In this the committee was not successful and those who are interested in this part of the history of the movement we would refer to the **Kentucky Medical Journal**, April, 1906, page 789, which records some of the reasons explaining our failure in securing a footing in the Public Library, as well as other features that occurred at this time. Following this failure the committee prepared to establish its own library. About this time another committee from this society was endeavoring to establish a club or academy

of medicine. Both committees being entirely friendly in their purpose, the library committee, in deference to the other committee retired to await the outcome of its labors. After the failure of the other committee, which entailed a loss of about a year's time to the library committee, we began the second step in the evolution of the movement, namely, the establishment of an independent medical library. As soon as the Atherton building, in which the library is situated was completed, we were ready to receive books. The library is located in Room 515 and is open to the entire profession between 10 A. M. and 9 P. M., excepting the hours of 12 to 1 and 6 to 7.

The first contribution was the David Wendall Yandell Memorial Library, consisting of 1,000 volumes. This occurred about October 1st, 1907.

About the middle of October the library was ready with the above number of volumes, and 50 current medical journals, foreign and American.

To-day about two months after the opening, the library has 1965 bound volumes and 23 unbound volumes, making a total of 1988 volumes, not including 76 duplicate volumes, and some incomplete volumes of journals, making over 2,000 volumes.

In addition, there are more than 50 different journals, the latter representing the best current literature.

From the foregoing, a partial evolution of the movement is plain, and it is also apparent that its development in the future must be in keeping with the existing external conditions upon which it is dependent, and which it is intended to serve.

Heretofore one had to rely upon his own library which at best was inadequate, and while the present library is still in its infancy, it is today sufficiently complete to aid any member in the preparation of a paper or the investigation of any problem, and with time this value increases.

It is needless to say that every one who possessed a private library, concedes through the possession of a library the value of a public medical library as a powerful supplement to his own collection.

Right here it is entirely in order for us to remind the medical profession of the fact that for years the legal profession has had its own library through its own efforts and one that has grown extremely valuable. The clergy has several libraries, one of which, occupies a good sized building centrally located. Even the engineers have their club and library. But the medical profession, in which changes more rapid, radical, varied and important, has up to this time, been without any collection of books what-

ever. Here is food for thought and if the medical profession has been unconscious of this omission, we can testify that the outside world has not. For in our efforts to establish ourselves in the Louisville Free Public Library we were plainly asked, why we did not do for ourselves that others had done for themselves. And, it is needless to say we were obliged to admit the truth of their statement.

As we have mentioned on a former occasion that if we had been without books in the past, we would not be where we are to-day, and unless we can have access to books as we proceed, we will soon cease to advance, and to stand still will mean to recede.

The stimulating influence which is necessary to keep men from becoming machines and practicing their profession in a mechanical way, can only be secured by keeping in close touch with questions still unsettled, and therefore, a library supplied with the best current literature, represents the most urgent demand.

The committee has always endeavored to make the current literature the chief feature of the library. It is not clear to every doctor that the current literature represents the best part of every medical library. Some favor text books until the difference between standard text books and current literature is made clear. It must be remembered that the text book contains only the essence of what has appeared at one time in one or more medical journals, and therefore if any one desires a full knowledge of any subject it can not be obtained from any standard work and is only obtained from the medical journal in which it originally appeared. Therefore we have labored to make this part of the library as complete as possible, and it should be the policy to direct the best efforts towards this end. Keeping a fair list of journals will supply knowledge upon all subjects still unsettled and will in time grow to be an invaluable reference library.

The library is fortunate in having an almost complete set of the Index catalogue of the Surgeon General's Library. The missing numbers we expect to supply in the near future. Through this catalogue a complete bibliography of any subject can be obtained, which makes it invaluable to any investigator.

There are in almost every private library, some books of an uncertain value that are consulted at occasional intervals. Many of these books are lost in one way or another and which will not be lost if there exists a library which will be a common center to which these books will gravitate. To a public library they would have a far greater value than they had in the private library, because they would serve to complete the library and instead of being consulted

but once a year by the original owner, would be consulted many times a year by different members of a large profession.

We wish to call attention to the importance of making free use of this library in order that the profession will be able to see for themselves its advantages.

Important as the library is, it is still a new venture and the history of all innovations is, that, however valuable, they must be pushed until their value is felt and only then is their permanency established.

Many of these questions that will arise in the coming year, are about settled. Nearly all of the medical societies have been addressed and we are glad to say that all that have been seen, favor the movement. We feel, however, that steps should be taken now for the future control of the library.

We have found from experience the necessity of frequently modifying our plans to conform with the existing conditions. Therefore, it is difficult to outline precise details as to future management.

We would venture the following as an entirely feasible arrangement:

**FIRST:** That a board of trustees be created at once by selecting one representative from each society contributing to the library fund, provided this society's membership be less than one hundred. Should the reverse be the case, then the society, having a membership of more than 100 be entitled to one trustee for every 100 members, or a major fraction thereof. This arrangement to be based on the society's membership at the end of the past year.

**SECOND:** An organization that is to cluster about this Board of Trustees and known as the Library Association which is to consist of every member of each society. In other words, that entrance into any society carries with it membership and its obligations in the Library Association, in this way adding another purpose to that which medical societies are accomplishing.

We would suggest that the appointment of the trustees be made annually, but that the old trustees hold over one year in order that the work be not jeopardized by a complete change of boards. This, of course, would give each society the choice of a trustee annually with the holdovers doubling the number.

In the appointment of a trustee, we urge in behalf of the movement, that it be made only after it is determined that the prospective trustee is really in sympathy with the work, as only such a member can be of any service since the trusteeship carries with it a certain amount of labor and interest.

The committee wishes to acknowledge with

thanks, subscriptions from the following:

Hon. Swager Sher-	ne).
ley,	

Other important aids from Mr. Peter Lee Atherton:

Home Telephone Company — Mr. Wm. Y. Yust, Dr. B. J. Lammers, and Miss Rademacker, the librarian, for faithful and efficient services.

In conclusion we would again urge the entire profession to utilize the library especially this year, that they may become familiar with the movement. The library is situated in the Atherton building, Fourth and Chestnut streets, room 515. Hours—10 A. M. to 9 P. M., ex-

cepting from 12 to 1 and 6 to 7.

AUGUST SCHACHNER, Chairman.  
 ADOLPH O. PFINGST,  
 T. H. BAKER.

**Knox.** — The Knox County Medical Society met in the office of the secretary on November 25th, 1907, at 10 o'clock A. M. The meeting was an exceptionally interesting one. The paper of the day was read by W. Burnside, and discussed by each member present. We have arranged a strong and interesting program for the December meeting and as that is the last meeting in the year we hope to make it the best for the year. The society adopted unanimously the "Nostrum Resolutions" and we join with you in urging every county society to adopt them and each individual to be sure that he is guided by them in his prescribing. I return to you a copy of the resolution which you sent, approved and signed.

J. S. LOCK, Secretary.

**Laurel.**—At the regular meeting of the Laurel County Medical Society, December 18, 1907, the following officers were elected for the coming year: — President, G. S. Brock, Bush; vice-president, J. W. Sams, East Bernstadt; secretary-treasurer, J. B. Mason, London.

H. V. Pennington, London; Wm. Johnson, Brock; J. G. Owsley, Lilly, were elected board of censors.  
 J. B. MASON, Secretary.

**Lincoln.** — The Lincoln County Medical Society convened in the parlor of the St. Asoph Hotel in Stanford, Tuesday, December 10th, 1907, at 10 A. M., Birdie Carpenter, president; E. J. Brown, secretary pro tem, with the following members present, viz:—Joshua T. Wesley, the most worthy councilor from Middleburg; Edward Alcom, Carpenter, and Barker, of Hustonville; Lee Pepes, of Moreland; T. H. Singleton, McKinsey; Wm. J. Edmonson, W. Phillips, of Craborchard; L. B. Cook, W. Bohannon, G. W. Perry, J. F. Peyton, E. J. Brown, H. Reed, and J. G. Carpenter, of Stanford; J. D. Morris, of Maywood; W. F. Hinkle, of Hubble. All of the doctors of the county who are doing practice were present except five.

**Edward Alcom** read a most entertaining paper on Ante-Post Partem Hemorrhages, the Causes and Treatment, and it was discussed by all members present, which was both practical and interesting.

Resolutions of respect from the Madison County Medical Society on the removal of G. W. Perry to Stanford were read by the secretary. It was moved and seconded to have them placed upon the minutes of our society.

Dr. Perry was immediately elected unanimously a member of the Lincoln County Med-

ical Society.

**Birdie Carpenter**, the retiring president read the valedictory, subject—"United we stand; divided we fall."

Mrs. Patsy Brown, Superintendent of the new Joseph Price Infirmary extended an invitation to the society to visit this institution located on Logan avenue, Stanford, and also to the physicians of the adjoining counties. Mrs. Brown is the widow of the lamented and skillful physician, Joseph Brown, of Mt. Vernon, Rockcastle county, who also stood high as a gentleman and Mason.

**J. T. Wesley** presented a case of placenta previa, its pathology and treatment.

**L. B. Cook** read an interesting paper on two cases of membranous croup in same family; intubation was successfully practiced on both, and ended in recovery.

A resolution was read by **J. G. Carpenter** and unanimously adopted by the society, asking Congress to repeal the Bankrupt Law.

Another resolution was offered by **Dr. Carpenter** and unanimously passed to co-operate with the Merchants' Protective Retail Association, Louisville, in having an act passed by the next Legislature making salaries, crop, and rents liable under the law for groceries, dry goods, family supplies, drugs, physicians, surgeons and dentists' bills, and do away with the Homestead Law.

**Drs. Reny, Brown and Carpenter** were appointed a committee to draft resolutions on the departure of **Dr. Steele Bailey** to the State of Utah, and report at the next meeting, the second Tuesday in February, 1908, at Stanford.

**G. W. Remy** was appointed essayist for next meeting, subject, Bronchitis.

**J. G. Carpenter** was selected to discourse on the pathology, diagnosis, and treatment of Hemorrhoids.

The following officers were elected:—President, **Wm. J. Edmunson**; vice-president, **G. W. Perry**; secretary-treasurer, **W. F. Hickle**.

The members were entertained by the Stanford physicians at the St. Asoph Hotel. Each person was filled full of good things that tickled the palate and the pledge of the local physicians was fulfilled. **W. B. O'Bannon** was elected county referee. **J. T. Wesley**, the greatest and best of councilors, added to the interest of the meeting in his speech, and shed light and wisdom in every sentence he uttered.

This day's meeting was truly a "Post-Graduate Course" and every one was loath to leave, but testified he was highly benefited and edified.

**J. G. CARPENTER**, Secretary.

**Livingston.** — The Livingston County Medical Society met at the court house in Smithland December 11th, 1907. We have nineteen physie-

ians in the county; twelve of that number are members of the society. We have been in bad shape for the past three years, but judging from the interest that was taken in our last meeting, I think we will come to the front.

**F. G. LaRue** read a paper on so-called "slow fever," which was discussed by all present.

**J. E. Chipps** reported a very interesting case of abortion, which was discussed by all present, every member being benefited by being present.

After the regular order of business the society adjourned to meet at Smithland the second Wednesday in March, 1908.

As the Cumberland River divides our county we think we could not meet successfully oftener than quarterly.

**EDWARD DAVENPORT**, Secretary.

**Muldraugh Hill.**—The Muldraugh Hill Society convened in the City Hall at Elizabethtown, Thursday, Dec. 12th, and was called to order by President **B. M. Taylor** at 10 o'clock. On motion of the Secretary and second the minutes of December meeting were accepted as they appeared in the August Journal.

There were thirty members present.

**Essays.**—**D. C. Bowen** read a paper entitled, "Perineovaginal Restoration." Discussions by **A. D. Willmoth**, **R. C. McChord**, **E. S. Smith**, **Louis Frank**, **Henry E. Tuley** and by **Dr. Bowen** in closing.

**Irwin Abell** presented a paper on "Diagnosis and Indications for Treatment of Lesions of the Gall-bladder and Bile-ducts." Discussed by **R. C. McChord**, **N. A. Ligon**, **Louis Frank**, **E. S. Smith**, **A. D. Willmoth** and by **Dr. Abell** closing. Adjourned for Dinner.

Afternoon session called to order at 1 o'clock.

**E. S. Smith** read a paper entitled "Abscess of the Liver." Discussion by **Irwin Abell**, **Louis Frank**, **W. H. Strother**, and by **Dr. Smith** closing.

**Henry E. Tuley** read a paper on "Hemorrhages in the New Born; Report of a Case of Melena."

**H. R. NUSZ**, Secretary.

**Marshall.** — The Marshall County Medical Society met in Benton to-day in the office of **Stilley & Jones**, with the following members present:—**T. C. Coleman**, **W. T. Little**, **E. G. Thomas**, **V. A. Stilley**, **J. M. Woodall**, **J. E. Jones**, **Bob Overby**, and **A. J. Bean**.

The society was called to order and immediately went into the election of officers for 1908. The following were elected:—President, **Bob Overby**; vice-president, **W. T. Little**; secretary, **A. J. Bean** (re-elected); delegate to State Association, **E. G. Thomas**; alternate, **V. A. Stilley**. The following members compose the board of censors:—**E. G. Thomas**, 1 year; **V. A. Stil-**

ley, 2 years; J. M. Woodall, 3 years.

There was only one subject disposed of at this meeting, and that was a quiz on Abortion, by Dr. Thomas, which was very instructive and enjoyed by all present.

Owing to the winter weather and bad roads there will not be many meetings in January and February, but will meet the second Wednesday in March, 1908.

A. J. BEAN, Secretary.

**Owen.** — The Owen County Medical Society met at Owenton, its regular meeting place, at 10 A. M., Tuesday, Jan. 2, 1908, with all but two of its members, and with two physicians who were not members, present. Members present:—J. H. Chrisman, J. E. Estes, S. C. Davis, M. S. Veal, W. B. Salin, W. E. Foster, D. E. Lusby, D. P. Curry, J. W. Botts, J. C. B. Foster, and G. Purdy. Members absent:—W. G. Birchett and K. S. McBee. Non-members present:—T. G. Connell, and E. Estes.

The applications for membership of T. G. Connell, New Liberty, and Elmer Estes, Owenton, were received and referred to board of censors.

**D. P. Curry** reported a case, ligature operation for hemorrhoids. He prefers the clamp and cautery method because recovery is more prompt.

**J. W. Botts** reported a case of injection treatment of hemorrhoids with constitutional poisoning resulting—hence a warning in practicing this method.

**J. H. Chrisman** read a paper on "Modern Ideas in Dealing with Small-Pox Epidemics." Among other things he said there is no difficulty in diagnosing modern small-pox due to the mildness of the disease. It is often mistaken for chicken-pox, impetigo contagiosa, and Dermatitis. It is harder for the older physicians who have had to deal with small-pox in its more severe forms to realize that this mild eruption is really small-pox. Many patients with small-pox, in his experience, are able to go about their usual vocations, thus causing a wide-spread of the disease. The symptomatology of the prevalent mild form of small-pox resembles that of small-pox modified by vaccination. The mildness of any epidemic disease must be regarded as due either to an attenuation in the virulence of the exciting cause, to a lessened susceptibility of the individuals affected or to a combination of both these factors. He believes the present mildness is due to vaccination and revaccination, and that the only way to prevent small-pox epidemics is by rigid enforcement of vaccination, isolation and disinfection. There is no specific in the treatment of individual cases. Complications must be treated as they arise.

The discussion was opened by J. W. Botts, and W. B. Salin, and further discussed by D. E. Lusby, D. P. Curry, and G. Purdy. The paper was of especial interest at this time because there is, and has been for several winters, small-pox at different points in the county and as the essayist is secretary of the county board of health, the paper coming from him had additional interest.

Promptly at one o'clock the society adjourned for refreshments. Every physician present was entertained by the society at an informal luncheon, which was served very acceptably. Flashes of wit and the good feeling of the participants were very evident for the hour. Several laymen were present, by especial invitation, and added to the joy of the occasion. At 2 o'clock the regular work was again taken up.

**D. P. Curry** read an interesting paper, the subject of which was "Exophthalmic Goitre; Its Symptomatology; Early Diagnosis, and Treatment." He said:

"The disease should be studied in contradistinction to myxoedema. The exciting cause is unknown, but it has been known to follow severe mental strain, fright, worry or grief. The first manifestations are probably due to changes in the vascular system. Tachycardia, dizziness, vertigo, faintness, and, secondarily, enlargement of the heart are present. Heart sounds are accentuated, arterial pressure exaggerated and nervous and capillary pulsations present. Exophthalmos may or may not be present in both eyes. Enlargement of the thyroid occurs early, but does not reach the extreme condition of simple goitre. In the form under discussion more tension is found and pulsations and arterial bruit are marked. The fine tremor may lead to an early diagnosis. Acute cases usually run fever. Medical treatment has had varying success, but is now limited to a treatment of symptoms. Iodine locally or internally stimulates the gland to further activity. The danger of digitalis, when pushed to combat tachycardia is a myocarditis, but he has heard it very favorably recommended so late as his own school days. Prefers aconitine to aconite, but difference is immaterial. For nervous symptoms he gives bromides and valerian. Opium must be used cautiously. Electricity and the X-ray should soon be discontinued if no improvement is noted. The surgical treatment is gaining rapidly on account of our increased knowledge of the gland and its anatomic surroundings. Relief may be had by removal of all or part of the thyroid gland or by excision of the cervical sympathetic ganglia. The discovery of the parathyroid bodies has awakened a great interest and we may hope for some light on the function of the thyroid as well as the treatment of its ailments. The paper was

commended and discussed by J. A. Estes and later by several members.

On account of the absence from the afternoon session of W. E. Foster, who had been assigned "The Nostrum Evil; Its Remedy," no paper on this subject was read, but S. C. Davis opened the discussion, which was followed by other interesting talks to the point. It was the unanimous opinion that this important subject should have more time of the society at some future meetings.

The sense of the society concerning the movement on foot to secure uniformity in the State laws regulating the practice of medicine and to secure reciprocity in the licensing of physicians was called for, resulting in a unanimous vote favoring such a movement.

The treasurer reported the society in good financial condition.

The society, through an efficient committee has secured the I.O.O.F. lodge-rooms, which is very commodious and comfortable, for its regular meeting quarters during the ensuing year.

The program for the next meeting is as follows:

"The early diagnosis and curative treatment of pulmonary tuberculosis." Paper, M. S. Veal; discussion, K. S. McBee. "Our individual responsibility in regard to the fight being waged against patent and unethical proprietary medicines." Paper, J. C. B. Foster; discussion, W. E. Foster. "Infection of the gall-bladder, cystic and common ducts." Paper, D. E. Lusby; discussion, W. B. Salin.

The meeting adjourned in order until 10 A. M., Thursday, February 6th, 1908, with the best of fellowship and a general desire to promote the welfare of the Owen County Medical Society and to advance the profession in Owen County.

GEORGE PURDY, Secretary.

**Pulaski.**—The December meeting of Pulaski County Medical Society was the annual business meeting. The society was called to order at 10 A. M., December 12th, 1907, in the assembly room of the public library, Dr. Allen being in the chair and the following members present: G. M. Reddish, Owens, J. W. F. Parker, Griffin, Taylor, Murphy, Bryant, Stigall, Price, Jasper, Warren, Cundiff, Hart, and S. F. Parker, J. T. Wesley, district councilor was present, and made quite an entertaining talk, dwelling upon the good work done by the doctors of the State the past year and urging active co-operation in the coming struggle relative to "Pure Food and Drug Laws." Dr. Wesley is full of hustle and we are proud to own him. The flame of enthusiasm is always rekindled in our society by his presence and encouragement and he certainly does his part to keep it bright, even when at home, and despite the duties and hardships of a justly large practice. Sometimes we blush with

modesty and some sense of unworthiness when he tells us what a "good society we are."

Election of officers was made, after which the society adjourned until January.

S. F. PARKER, Secretary.

**Pulaski.**—The regular monthly session of the Pulaski County Medical Society was held January 9th, at 10 A. M. in the assembly room of the public library. The following officers, elected in December last, were installed for the ensuing year:—President, G. M. Reddish, Somerset; first vice-president, N. D. Stegall, Burnside; second vice-president, I. S. Warren, Somerset; secretary-treasurer, S. F. Parker, Somerset; censor, J. M. Owens, Somerset; delegate, A. W. Cain, Somerset.

**G. M. Reddish** in opening the meeting made a short talk to the society. Among other things he mentioned the achievement gained by union in the fight against the reduction of insurance fees. He spoke of the work laid out for us this year and of special legislative bills to come up in the General Assembly and urged all the doctors to be present and active in the preparation of papers and the discussion of subjects presented.

Upon call for clinical cases Dr. Price reported a deep stab wound across right side of back. Immediate closure with deep sutures without drainage and without irrigation. Case discussed by G. M. Reddish, Cain, J. W. Parker, and Murphy.

Upon call for regular program it was found that the essayists were unable to be present.

Upon suggestion, it was found to be the will of the society that a general discussion should be indulged in.

**A. W. Cain** opened the discussion upon "Preparation of Patient for Operation," and made quite an interesting and instructive talk. Dr. Cain's talk was followed by timely thoughts along the same line, from J. W. F. Parker, Murphy, and Reddish.

The society then by motion unanimously adopted the resolutions relative to the "drug" fight, and instructed the society to obtain the signatures of all the doctors possible to a suitable paper in support of such resolutions.

"The State Tuberculosis Sanitarium" was discussed and the move approved by the society.

Motion carried that the society adopt the public library (assembly room) as permanent meeting-place and extend their thanks and appreciation to Board of Directors for use of the same. No further business. Motion to adjourn met with approval of members present.

S. F. PARKER, Secretary.

**Warren.**—The annual meeting of the Warren County Medical Society was held in the doctors' club-room Wednesday, January 15,

1908, at 10 A. M., for the purpose of electing officers.

Drs. Cecil and McMurtry, of Louisville, were invited guests, but these luminaries failed to shine at the appointed hour. The secretary, however, combatted the anger and disappointment of the assembled doctors by announcing that an elegant dinner would be served at the Mansard at 1:30 P. M.

The president, W. C. Simmons being delayed, T. W. Stone, the vice-president called the meeting to order.

A. L. Wagner, of Scottsville, and Dr. Douglas, of Franklin were introduced to the society and were given a cordial welcome.

The secretary's report was given, and again gloom fell over the society, when it was found that the panic had visited even our treasury, the total amount collected and begged from the doctors of the county amounted to \$169.96.

The amount expended was \$199.48, leaving an indebtedness of \$29.75.

A cruel bank failure first took all the funds, then the ambition to have a home-like club-room with varnished floors and lace curtains, the gift of the society of Dr. Arnold's library cost nearly \$53.00 for buying a book-case and paying freight; three years ago twenty-five beautiful chairs were bought, but the society failed to pay for them until this year. The secretary, after passing tearfully over the financial situation, spoke of the excellent work the post-graduate club was doing, the meeting being well attended.

The monthly meetings were better than they have been for years, as the country doctors always come, some driving twenty miles in order to be present. Many town doctors still have the same old chestnut of being too busy, but the secretary has investigated several cases and found the busy man enjoying the solitude of his office.

There are fifty-one active members and nine non-members who are beyond all redemption.

Eleven proceedings of the society and five papers were published in our Journal.

The Secretary of the State Association, the originator of the Post-Graduate, the Chairman of the Councillors, and the Chairman of Organization of the American Medical Association are members of this society.

A. T. McCormack moved that a vote of thanks be spread upon the minutes to the secretary for her efficient services.

The secretary modestly recorded it.

E. Rau, Chairman of the Councilors, gave an address, telling the work required of all the councilors, their unselfish devotion to the organization, and the great good they had accomplished. He spoke of the patent medicine evil, and said since the Journal had taken up the fight the societies all over the State had adopted the resolutions against nostrums.

J. O. Carson said the dues of the society should be fixed so as to cover the expenses and every doctor should be taxed equally, the subject was discussed by the members.

W. C. Keen made a motion that a committee be appointed to confer with the secretary and the dues be raised to meet the running expenses of the society.

The president appointed W. C. Keen, T. W. Stone, and the secretary.

The committee reported that an increase of one dollar from each member would relieve the society of its indebtedness and cover the running expenses.

W. C. Simmons, the president, then gave a brilliant address, which will be published in full in the Journal; it was delivered without notes, in an earnest style, and enthusiastically received.

W. C. Kerr reported a case of scarlet fever

G. E. Huddle reported a case of scarlet fever in which the glands were swollen; he considered scarlet fever an extreme manifestation of blood poisoning, being due to the same bacillus.

The following officers were elected:

T. W. Stone, unanimously elected president.

W. C. Keen, vice-president.

W. H. McCracken, censor for 3 years.

E. N. Hall, delegate for 2 years.

Lillian South, secretary-treasurer.

The society adjourned to meet at the Mansard Hotel at 1:30 P. M.

J. H. Blackburn opened the afternoon meeting with a history of the post-graduate work, telling us that 32 States and 53 county societies had adopted the course, and 136 counties have written for literature.

F. D. Reardon then gave a demonstration in physical diagnosis.

Dinner was served with W. H. McCracken as toast master.

The following toasts were responded to:

The Journal—A. T. McCormack.

Country Practice—E. N. Hall.

The Telephone—J. H. Blackburn.

Woman—E. Rau.

Poem—L. H. South.

The Association—A. L. Wagner.

The Old Man—J. O. Carson.

The society adjourned to meet the last Wednesday in February.

L. H. SOUTH, Secretary.

Dr. Granville S. Hanes has returned to his home in Louisville after a sojourn of three months in Europe. He spent most of the time in London, where he was engaged in special clinical studies upon diseases of the intestines and rectal surgery. Dr. Hanes is associated with Dr. J. M. Mathews in the practice of his specialty.

## OUR NEW PURE FOOD AND DRUG LAW.

It is with peculiar pride and pleasure that we chronicle the passage of the Pure Food and Drug Bill by both houses of our General Assembly by a practically unanimous vote. This is one of the best measures that has ever been put on the statute books of any State. Primarily its perfection is due to Prof. Scovell, the Chief of the Agricultural Experiment Station, and his able and indefatigable assistant, Hon. R. M. Allen, the Head of the Pure Food and Drug Division. Mr. Allen is an honorary member of this association and one of the editors of the JOURNAL. He is a pure bred Kentuckian of the highest and best type, and deserves, as he has, the active and moral support of every thoughtful physician in the State in his work.

The unanimity with which this bill was passed was due not only to its intrinsic merit but to the fact that through every possible agency the people and their representatives at Frankfort had been brought to a firm conviction of its necessity. Mr. Allen's enforcement of the present law has been along educational and persuasive lines as far as possible, and he expresses much gratitude to the members of this Association who have been especially interested in this subject since the Louisville meeting and the general letters sent out to the profession of the State in December. In like manner the State Board of Health, the State Federation of Woman's Clubs, the State Pharmaceutical Association, the State Board of Pharmacy, and every other agency that has realized the necessity for legislation along these lines, has not only been aroused, but aroused with a unanimity so complete that opposition has nowhere found a weak point.

The law is simple and complete. To sum it up, it provides that the contents of every

package of food or drugs shall be true to the accompanying label or literature, which shall contain no false statements. The profession of the State will be especially pleased that "certified milk" is a term which may hereafter be used only upon the authorization of a regularly constituted medical society. This is a splendid recognition of the work of Drs. Tuley, Thompson and Frazier in Louisville, and will, we trust, lead to the formation of milk commissions by our societies in Daviess, Fayette, Kenton-Campbell, Mason, McCracken and other counties along the valuable and practical lines laid down by the Jefferson County Society.

It is further provided that any sample of food or drug suspected of impurity may be sent to the Pure Food and Drug Division, State Agricultural Experiment Station, Lexington, for analysis by any county or city board of health in the State. This is a valuable privilege, and puts upon these boards a reciprocal obligation to assist at all times and upon all occasions in the enforcement of the law.

A most important provision is one that no prescription may be refilled except for the person for whom it was written. This is one of the most valuable provisions for the protection of the public health. A person who has been relieved by the use of some prescription, feels a natural confidence in its curative powers, and so, without the slightest diagnostic ability, passes it on to the next sick friend he meets, ignorant of its power to do good or harm. This puts the layman, through ignorance on the same plane as a doctor who will prescribe any medicament of doubtful or unknown composition or indication.

The Rules and Regulations under which the law will be administered will be formulated by a representative of this Association, one from the State Pharmaceutical Association and the Director of the Department.

Especial thanks and gratitude are due not only Messrs. Seovell and Allen, but also Dr. Gayle, representing the pharmacists; Miss Breed, of Louisville, who is chairman of the Pure Food Committee, of the State Federation of Women's Clubs, and to the representatives of this Association and our State Board in Frankfort, but to the rank and file of the profession of the State.

Like intelligent action on the part of every physician will result in the defeat of two vicious bills now before the Legislature, and the passage of the meritorious measures prepared and endorsed by our Legislative Committee. If *you* have not already done your part in the campaign for these bills, and against the two bad ones, will you not *to-day* communicate with your Senator and Representative about them?

The essential parts of the Bulletin on Pending Legislation are published herewith:

### BULLETIN.

FOR THE PROFESSION AND PEOPLE OF KENTUCKY  
ABOUT PENDING HEALTH AND MEDICAL LEGISLATION.

#### BILLS WHICH OUGHT TO BE DEFEATED.

House Bill 130, ostensibly intended to lower the entrance requirements for students into medical schools, does very much more than this. It should be entitled "An Act to debauch the Medical Profession, Destroy Reciprocity and Ruin the Medical Schools of this Commonwealth," as this is what it would do. After years of patient labor the State Board of Health has at last secured the privilege of reciprocity with 28 States, and the list is gradually being extended for all of our physicians of every school of practice. This bill would take away this privilege in a day and all who go to other States on account of failing health in themselves or families or for other reasons would be forced to take an examination. The present law works no hardships on any worthy student, requiring only such preliminary education as is necessary to understand lectures, and there has been no complaint against it from either students or schools. That a man should be able to understand lectures and know how to study before entering a medical college, is a requirement solely for the benefit of the people.

Senate Bill 176, H. B. 243, the same bill, is intended to make the State Board of Health a purely political body. At present each State association nominates its members, qualifications and fitness to represent the entire profession being alone considered. This bill gives the nomination to the governor, a

politician, whether he be a democrat or republican, with the idea that politicians know better what we need than our own societies. Whether intended or not, it is an insult to the organized profession of every school or system of practice. It is also in direct opposition to the platform and teaching of the present administration and there is no reason to believe that the bill has its approval.

#### BILLS WHICH SHOULD BE PASSED.

House Bill 102, provides for a complete system of vital statistics with proper compensation for physicians reporting births and deaths. The need for a proper law upon this subject is so fully recognized that no argument need be made to physicians in its favor.

House Bill 98, provides for an annual school for county and city health officials to last not less than three days for a practical study of the best method of performing their duties. It involves no appropriation except that actual traveling expenses are paid by the local fiscal authorities. This plan is in successful operation in other States and is greatly needed.

House Bill 148 provides an annual appropriation of \$25,000 for a State Laboratory, to employ a State Bacteriologist who can examine specimens suspected of tuberculosis, diphtheria, etc., and analyze water for you without cost, to make a survey of the rivers and water sheds and an examination of the water supply of every section of the State and for other purposes fully set forth on the first editorial page of the State JOURNAL for February. It will be seen there that Pennsylvania appropriates \$1,000,000 annually for these purposes. Massachusetts \$138,500; New York, \$129,179; Illinois, \$119,000 and so on with Kentucky at the foot of the list of the States reporting with only \$5,000. By reference to the same page it will be seen that money is poured out like water in our State for other purposes far less meritorious. Dr. McCormack has furnished the State Board of Health an office, fuel, lights and janitor for 25 years free of cost and now pays two-fifths of the salary of its stenographer. Much good has been done in spite of all this, Kentucky being the only State in the Union which has been freed from open quackery, but the time has come when more money must be appropriated as in other States, or the best interests of the profession and people must suffer.

Committee on Legislation.

## BOARD OF CONTROL.

No more important institution exists in Kentucky than the State Board of Control of Charitable Institutions. The physicians of the State are especially interested in it as its duties are one fourth administration and three-fourths medical. Our asylums appeal with peculiar force to the medical profession. Realizing, as laymen cannot, the helplessness and dependence of the poor unfortunates maintained in them as public charges, it is of the utmost importance that a physician be a member of this Board at all times. Governor Wilson has pledged himself wisely and voluntarily to the principle of nonpartisanship. We are confident that it will as readily appeal to him to make at least one of his selections from our profession, which, in all public matters has always been non-partisan.

It is all very well to talk about business men being the only ones competent to run the affairs of our State institutions, but business men would be utterly helpless in the matter of selecting superintendents and other physicians, for consultations with medical officers about sanitary and medical matters, as to recovery of patients, and a hundred other things which no one but an experienced business doctor as distinguished from a business layman would be qualified to pass on.

Those who are acquainted with the recent history of our eleemosynary institutions know that Dr. Board, who has but recently retired as a Vice President of this Association, is responsible for nine tenths of the improvement in them. No one knows better than Dr. Board and no one else has insisted with more cogency, how much more can be accomplished by entirely divorcing them from political influences. In choosing the successor of such a man on the Board of Control, in the name not only of the medical profession of Kentucky, but of the unfortunates in the asylums whom it is our peculiar province as a profession to represent, we appeal to our Governor to select an active physician of the best type to assist in this work. The names of such men as Joseph M. Mathews, W. W. Richmond, Arch Dixon, David Barrow, men of large business experience, of great executive ability, born leaders of men, all of them naturally suggest themselves to physicians as types of the class from which we trust the Governor will select his appointee regardless of their politics, regardless only of their conscientiousness and their resourcefulness. Every member of this Association should exert all his influence to help bring this about.

## ANTISEPTICS.

At this season of the year when the grippe, measles, scarlet fever and diphtheria are all unusually prevalent, it is well to remember the importance of prescribing an antiseptic solution as a spray or gargle in every case of sore throat, however mild it may be. Peroxid of hydrogen, U. S. P. or the Liquor Antisepticus Alkalinus, N. F. are either useful for the purpose. They should be used undiluted, and repeated at frequent intervals. Such a simple procedure would have terminated at its inception many an epidemic of scarlet fever or diphtheria which started with one of the cases said to be too mild to be recognized.

## SCIENTIFIC EDITORIALS.

## UTERINE FIBRO-MYOMATA AND PREGNANCY.

Pregnancy is not of frequent occurrence in fibro-myomatous uteri, but when present and recognized is a source of anxiety both to the mother and her attending physician. That it is not always recognized is amply demonstrated by the reports of hysteromyomectomies in which the foetus was found in the tumor either in the course of, or after removal, in patients who did not before the operation present the usual signs of pregnancy. The increased vascularity of the uterus means increased nutrition of the tumor with oftentimes subsequent growth of more or less rapid degree; and equally true is it that during involution the tumor materially decreases in size oftentimes, while instances have been reported in which the tumor has completely disappeared. Such a fortunate outcome, however, is not to be expected in every instance, yet in selected cases, and these embrace the majority, the presence of such tumor or tumors does not materially alter the course of the pregnancy or delivery. In the advent of a recognized pregnancy in a fibromyomatous uterus the location and character of tumor or tumors are to be carefully studied and the treatment based on findings. Many cases abort in the early months and some writers have advised the induction of abortion as a routine treatment of such pregnancies. The writer believes this advice to be unsound since the dangers of hemorrhage and sepsis are present in an increased degree, the growth at times interfering with uterine contraction and retraction before or after separation of the placenta, so that alarming or fatal hemorrhage occurs, or placental retention with conditions favoring infection is presented; the distortion of the uterine body renders its emptying difficult and at times impossible without surgical aid of varying magnitude; and granted that the abortion is suc-

essfully done, the patient still retains her myomatous growth which must needs be removed at some subsequent date. If the tumor be situated in the upper segment of the uterus so that it can not mechanically interfere with the passage of the child through the birth canal, and not of sufficient size to prevent full development of the uterus, pregnancy will in practically all such instances pursue an uninterrupted course and terminate in the delivery of a living child. The tumors that give us greatest concern are those situated in the lower segment of the uterus; these are potent sources of harm, both during pregnancy and delivery. In some instances they either become softened or changed in position during pregnancy or labor so that they rise above the pelvic brim and permit of delivery; in others they either so fill the pelvis that the uterus can not rise into the abdomen and permit of foetal development resulting in abortion, or, if the uterus does rise into abdomen, they, from their size and location obstruct and prevent passage of child through canal. Following miscarriage in the first type of cases, hysterectomy is not only the procedure of choice, but of necessity, while in the latter, two courses of action are open to us; if the tumor is in an accessible region of the uterus it seems to the writer that myomectomy in the early months of pregnancy offers the best chance for both mother and child; the uterus tolerates well the removal of such tumors under such circumstances and many cases are on record where after such operations patients have favorably progressed through an otherwise normal pregnancy. If either from choice or necessity on account of location of tumor, pregnancy is permitted to reach the point of viability or full term, a Caesarian section is oftentimes necessary to effect the delivery of a living child, a procedure more hazardous than myomectomy in selected cases. In those cases in which the size and location of the tumor plainly indicate the impossibility of delivery by natural means the operation should be undertaken before the onset of labor, thus conserving the strength of the patient and lessening the risk of infection, while in those in which there is a possibility of ascent of tumor into abdomen, the onset of labor should be allowed to demonstrate the impossibility of delivery before operative measures are carried out. In either instance the Porro is the operation indicated. McMurtry, in an able paper presented to the Southern Surgical Society, reviews this subject at length and concludes that "while indiscriminate operation in uterine fibro-myomata associated with pregnancy is not to be advised,

the mortality of this condition when unaided is so great as to justify an extension of the field of operative treatment, both myomectomy and hysteromyomectomy; and every case should receive individual consideration so that a judicious selection of cases for operation may be observed."

IRVIN ABELL.

#### SIMPLE ANEMIA IN CHILDREN.

Simple anemia is far more common in infancy and early childhood than is usually accepted. It is frequently overlooked and when it is found the gravity of its course is often not fully appreciated.

At birth nature endows the new-born child with an abundance of red blood cells, averaging over five million and the hemoglobin content often reaches as high as 120. We believe that this richness of the blood is a wise forethought on the part of nature to protect and guard the child against a subsequent loss of blood which is almost necessitated by the various conditions and diseases through which the child must pass.

As a rule the anemia from which children and infants suffer is of the secondary type. Among the causes which tend to produce this are in the first place the insufficient production of blood by reason of difficulty in securing proper nutrition in the child, and secondly, very great demand from the tissues, the exhaustion so to speak of the blood by reason of the rapid growth of the child. It is fully appreciated by every one that the feeding of the infant is one of the most complicated problems with which the general practitioner has to contend.

Even when the child is fed upon breast milk, there is danger of the development of anemia from the too prolonged nursing of the child. Milk with all its good qualities is deficient in iron. When a child has been nursing at the breast for 12 months or longer anemia is bound to develop. If, in addition to this, the milk for any reason is not thoroughly suited to the child's digestion and nutrition, there is an added drain upon the bloodmaking organs.

It is a matter of common experience that the infant when it has reached the age of 6 months or more begins to insist upon food supplementary to the milk feeding. It is a natural instinct of the child which thus finds expression. We can at this age begin to feed the child such food as contains iron in an assimilable form and long experience has demonstrated that the administration of eggs particularly and of other forms of proteid containing iron such as beef juice, becomes absolutely essential to the child at this time.

Whatever may be the views of physiologic chemists and therapists as to the value of inorganic iron, there can be no doubt of the ready absorption of the organic iron that comes in the form of the yolk of the egg and the expressed juice of beef. These should form a part of the diet of the child before it has completed its first 12 months.

Coupled with this lack of formation of iron and of the hemoglobin is the destruction of the blood, resulting in a great part from the contagious and other diseases to which the flesh of childhood is heir. Diphtheria, scarlet fever, and other forms of contagious diseases leave a very distinct impression upon the blood.

There are many other forms of diseases which tend to the production of anemia. It will be sufficient to mention the various forms of bowel diseases such as enteritis or the intestinal protozoa, and nephritis. To these must be added those great constitutional disorders, malaria, rheumatism, tuberculosis, and syphilis.

The diagnosis of anemia is not difficult, but it is often overlooked and the child fails to receive the needed medicine. The far-reaching influence of anemia will appeal to every physician and frequently it will be found to be the connecting link in a vicious circle. Under such circumstances it will be necessary for the practitioner to use all his therapeutic skill to reach the fundamental trouble.

The treatment of anemia calls for more than the mere administration of iron or arsenic as the case may be. It will be necessary also to secure an abundance of fresh air at all times, and the utmost attention should be paid to the general and personal hygiene. Food must naturally be of the most nutritious and easily assimilable character and designed to furnish as much iron as possible. Exercise must be in moderation for the blood is not able to carry the oxygen that the tissues need for exertion. For the same reason the child should have very warm clothing so that the maintenance of the animal heat will not use up the oxygen which could be utilized for other purposes.

PHILIP F. BARBOUR.

#### PREMATURE EXPULSION OF THE OVUM, ABORTION, MISCARRIAGE AND PREMATURE LABOR.

Premature expulsions of the ovum are classified according to the time of occurrence. The distinction being made by some authors between an interruption of a pregnancy be-

fore the 16th week, between the 16th and 28th and between the 28th and 36th week. A simpler arrangement is the one, that fixes the interruption of gestation in the first three months, as an abortion, in the second three months as a miscarriage and in the last three months as a premature labor. The same author also divides abortion into early or late, dependent upon whether they occur in the first month or in the second or third. The distinction in all instances, is based upon the anatomical differences in the product discharged from the uterus. In the early abortions, the intact ovum is generally expelled and the decidua vera remains in the uterus and is transformed into normal endometrium, in the late abortions, the ovum with the decidua vera must pass away, the latter either being cast off entire or coming away in shreds. In miscarriages, the ovum and the placenta and membranes must come away, early in the period, manual removal often being necessary, in the latter part of this period, Crede expression generally being effective in bringing it about.

After the 6th month in premature labors, the process closely resembles labor at term. Various authors give the 28th week or the end of the 7th month as the period at which the fetus is viable, but with the modern improved incubator, infants have been kept alive at much earlier periods.

The terms spontaneous and induced abortion are self explanatory. A division is made of induced abortion into therapeutic or medical and criminal. Therapeutic or medical abortion, is induced by the physician for clearly indicated reasons, to save the mother's life. Criminal abortion, is the interruption of a pregnancy by unlawful means and simply for the purpose of relieving the mother of an unwelcome pregnancy.

At the time of its occurrence, abortions are spoken of as threatened or inevitable, complete or incomplete and of missed abortion. An abortion is threatened when the patient shows all signs of an impending abortion and by the institution of proper therapeutic measures, the condition becomes quiescent and the pregnancy continues. An abortion is said to be inevitable, if the lower pole of the ovum can be felt or if the cervix allows the passage of more than one finger.

A complete abortion is one in which the ovum and decidua are discharged, an incomplete abortion, one in which part of the product generally the decidua is retained.

In a missed abortion, there is a retention of an ovum which died early in pregnancy and is not discharged until the normal termination of the pregnancy. When an abortion follows a slight accident, there is always attendant, some pathological condition, gener-

ally chronic endometritis as a predisposing factor.

Of the chronic diseases, syphilis and Bright's disease are the most common factors and if a woman aborts habitually it is generally safe to suspect a specific condition regardless of a history to the contrary. Retro displacements, adhesions and overdistention of the uterus, uterine, ovarian and abdominal tumors are causative factors.

In married women under normal circumstances, the diagnosis is easy. A woman with regular menstruation, subjected to the possibility of conception, misses one or more periods, there is a bloody discharge from the uterus attended with colicky pains. Even in such cases, a differentiation must always be made with a possible ectopic pregnancy. In the latter case, the mass is more to the side of the uterus, it is more sensitive to pressure, the hemorrhage is less and more irregular and the pains are more severe.

In the unmarried, the condition is often overlooked because the patient intentionally misleads the physician. If the product of conception has not been expelled, then colicky pains recurring at regular intervals will greatly assist in making a diagnosis and justify him in making a vaginal examination even in the best of families. In medico legal cases, in the absence of an ovum, an absolute diagnosis is only safe if chorionic villi can be found microscopically. It must be remembered that in membranous dysmenorrhoea, the discharge and the symptoms closely simulate an abortion.

An abortion is followed by a number of pathological conditions that may seriously impair the patient's health. The hemorrhage may induce profound anemia, an improper evacuation of the uterus or lack of care after the occurrence may lead to subinvolution. The virulent septic infection following most criminal abortions, often ends in chronic invalidism or death.

The treatment must be considered under three subdivisions, prophylactic, the treatment of threatened and of inevitable abortion. A successful prophylactic treatment is dependent upon the removal of the cause. In those instances, however, in which no definite cause can be established, the empirical use of iodide of potassium with iron often leads to success and should be continued throughout the pregnancy. The same therapy is applicable in undoubted cases of syphilis and renal diseases. In habitual abortion in addition, prolonged rest in bed and especially at recurring menstrual periods has the desired result.

In retrodisplacements the patient should be watched especially in the 3rd and 4th

months, the uterus being replaced and supported by a pessary. After the 4th month the uterus has become an abdominal tumor and will take care of itself. All exertions must be avoided and sexual relations discontinued.

In the treatment of threatened abortion, the patient must be put to bed, the bed-pan used, the diet should be cool and bland and must be taken without assuming an elevated position. No cathartics are used, when necessary the bowels are moved by low enema. If pains are very severe, then a hypodermic of morphine gr. 1-4 should be given at once. Thereafter, suppositories of 1 gr. Aqueous Extract of Opium inserted into the rectum at intervals of 4 to 6 hours will give the best results. If the hemorrhage is profuse, cold applications may be made to the vulva and the foot of the bed elevated. It is useless to give medicines by the mouth, nearly all authors agreeing that the administration of Vi-the more unfavorable for good results.

To be on the safe side the patient should be kept in bed for one week after all symptoms have subsided.

There is a great diversity of opinion as regards the treatment of inevitable abortion, whether it should be expectant or operative. In support of the active treatment Edgar says:

"The latest observations tend to show that in abortions, contrary to the generally received opinion, the separation of the decidua vera from the uterine wall takes place from above downward and that consequently the complete removal of the decidua by the finger seldom if ever takes place. The removal of small fragments of decidua, is easily accomplished by the curette, whilst it is difficult, if not impossible by the finger. Other advantages are less dilatation of the cervix is necessary, the operation is less painful, anesthesia is not always required."

A combination of the two probably is most favorable for the patient and can be best carried out by the general practitioner. The expulsion of the ovum should be favored by tamponing the uterus and the vagina. If the cervix is not patulous, then a vaginal tampon should be used; if this is not effective, then upon its removal, the lower segment of the uterus should be packed through the cervix, which has generally dilated as a result of the vaginal tampon and then the vagina should be packed again. The vagina is first douched with 1-2 gallon 1% Lysol solution. For the vaginal tampon, lambs' wool is saturated with Boroglyceride and packed around and in front of the cervix, the vagina is then well packed with sterile gauze wrung out of 1% Lysol Solution and a T bandage placed over the vulva. After 24 hours the tampon is re-

moved and if the ovum has not been expelled, then the cervix which has dilated under the influence of the tampons, is caught with a double volsellum and the lower segment of the uterus packed with sterile one inch gauze bandage wrung out of 1% Lysol solution. The lambs' wool Boroglyceride tampon is again packed around the cervix and the vagina filled with 1% Lysol gauze as before. In most instances, upon the removal of the tampons after another twenty - four hours, the ovum should be found on top of the dressings, if not, then the patient should be anesthetized and the uterus emptied with the fingers and a sharp curette, the whole procedure being supplemented with a large hot intra uterine irrigation with normal saline solution. Some authors advocate immediate dilatation of the cervix and curettage under anesthesia.

By the above method nature effects a gradual dilatation of the cervix and in many instances expels the ovum whilst by the active interference, tears in the cervix may result from the instrumental dilatation. A careless operator might even perforate the uterus with the curette.

In case of doubt as to whether the abortion has been complete or not when the physician is called late in the case, then the patient should be kept under observation for 48 hours and if the hemorrhage does not diminish in that time, the uterus must be curetted, provided there is no infection. In the interval, if the hemorrhage is at all profuse, it must be controlled by vaginal tampons.

In miscarriages especially of the 4th month the placenta and membranes are often retained for a long time after the expulsion of the fetus and at any moment the patient is liable to a furious post-partem hemorrhage. Under such circumstances, it is safest in private practice at least, to tampon the vagina firmly with 1% Lysol gauze, removing it after 12 hours, when the placenta as a general thing will come away with it.

In miscarriages of the 5th and 6th month it is more often possible to express the placenta by the Crede method, as in full-term labor. The treatment of the criminal abortion demands especial consideration.

When called to such a case, if the patient shows signs of infection, then it is safest to call a consultant at once for ones own protection. Neglect of this precaution has brought a number of physicians into serious trouble after the death of such a patient.

The treatment must be active, the patient anesthetized as soon as possible, the cervix dilated and the uterus emptied with the finger assisted if need be by the placental forceps.

The sharp curette should not be used for this purpose, it removes the granulation zone that has been formed as an effective barrier to a spread of the infection and besides, it is a well known fact that the sharp curette will often pass over large placental masses without removing them.

The after treatment is conducted as in puerperal infection, strychnine and stimulants being the mainstay.

EDWARD SPEIDEL.

### OSTEOMYELITIS.\*

BY J. G. CARPENTER, STANFORD.

Osteomyelitis may be (1) acute; (2) chronic.

The suppurative inflammation of the marrow of the bone is an exceedingly frequent affection with children and young adults and may be due to infection without, viz., traumatism following compound fractures, gunshot injuries or amputation. The so-called spontaneous variety occurs without direct exposure of the medulla to infective micro-organism from without.

The bacteriological and experimental researches of Kocher, Rosenback, Passet, Krause and Kraske have established the fact that non-traumatic osteomyelitis, like the traumatic form, is a suppurative inflammation of the medullary tissue caused invariably by infection with pus microbes.

Primary suppuration in bone begins in the medullary tissue as an osteo-myelitis, not as an ostitis. Primary suppurative periostitis is an exceedingly rare affection, consequently osteomyelitis must be considered as the most frequent of all inflammatory diseases of bone. Rhinne states that the indirect cause of suppurative osteomyelitis are changes brought about in the medullary tissue by the microbes and their ptomaines of general febrile diseases, such as typhoid, scarlatina, diphtheria, etc., which prepare the soil for the action of the pus microbes or the disease is produced by the direct extension from a localized suppurative lesion as a furuncle through the lymphatic vessels or long vessel or nerve sheaths to the medullary tissue. Kraske asserts that recurring attacks should not always be looked upon as the result of former infection, but as a consequence of a new infection of the old site. "Infection in most instances takes place by pus-microbes, which have found their way into the circulation from a sup-

\* Read before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

purating wound or through the respiratory or intestinal mucous membrane, and which localize in the medullary tissue prepared for their reception by anatomical peculiarities of the capillary vessels, or by a *locus minoris resistentiae*, created by an injury or some antecedent pathological condition. A number of well authenticated cases have been reported where a subcutaneous fracture became the starting point of an attack of osteomyelitis in patients who suffered at the same time from a suppurating wound in a part distant from the fracture. In such cases it is reasonable and logical to assume that pus-microbes enter the circulation and are conveyed by the blood-current to the seat of fracture, where they are arrested and find a favorable soil for their re-

production and the exercise of their pathogenic properties. Such cases are simply the counterpart of what has been accomplished by experimentation. Clinical experience and experimental research have shown that pus-microbes localize in preference near the epiphyseal line of the bones. During the growth of bone this region is supplied with new, growing, and imperfectly developed capillary vessels, a condition which cannot fail in favoring localization of floating micro-organisms in this locality. Neumann has also called attention to a peculiarity of the capillary vessels in the medullary tissue, their calibre being four times that of arterial branches that supply them, another important anatomical condition which predisposes to localization of

microbes in this tissue. Histological investigation has also shown that the small blood-vessels in the medullary tissue are devoid of a proper vessel-wall, and appear more like channels or excavations than blood-vessels, another condition which must yield a potent influence in determining congestion in these vessels and mural implantation of infected leucocytes under the action of an exciting cause of action. As Lneeke has shown, and as Rhinne again asserts, the medullary tissue is prepared for the action of pus-microbes by the causes which precipitate an attack of some acute febrile affection, as variola, typhoid fever, scarlatina, rubeola, and diphtheria. Children and young adults who have passed through an attack of any one of these infectious diseases are strongly predisposed to an attack of acute suppurative osteomyelitis. Excluding all such influences, there is still left a large number of cases where osteomyelitis attacks persons otherwise apparently in perfect health. My own observations induce me to attribute to exposure to cold an important role as an exciting cause. I do not wish to be understood that exposure to cold alone could ever result in an attack of acute suppuration of the medullary tissue. Pus-microbes inhabit persons in perfect health, and they do not cause disease as long as the circulation remains normal, as localization does not take place in the absence of a proper soil. If, however, in such a person the circulation in the medullary tissue is disturbed suddenly, in consequence of a sudden or prolonged chilling of the surface of the body congestion, mural implantation and localization of the floating pus-microbes occur in a locality which offers the least resistance in such an emergency, and a suppurative inflammation is established in the medullary tissue. I have repeatedly observed cases of osteomyelitis in boys who, after active exercise, suddenly became chilled, by bathing in cold water, or who, after an exciting game of base ball, stretched themselves out on the cold ground to rest. A disturbance of the equilibrium of the circulation from any cause is an important factor not only in precipitating an attack of acute osteomyelitis but many other local infective processes in persons already infected with the essential cause.

Symptoms of osteomyelitis are—chill, rapid pulse and respiration and high temperature, indicative of the commencement of an acute suppurative affection. In some cases the general symptoms are out of proportion to the local lesion presenting a clinical picture of intense septic intoxication. Dr. Senn states in several cases of multiple osteomyelitis the patients passed into typhoid condition, muttering delirium, dry tongue, diarrhoea, and a

continued form of fever with high temperature and rapid pulse, who died within a week, before the local disease had made any considerable progress.

In one case a lady 18 years of age, the disease affected both tibiae, 1 femur, both humeri, 1 clavicle and several ribs from the very beginning and the disease proved fatal on the 6th day. A bronchial catarrh would indicate an infection through the respiratory organs, while an infection through the gastro-intestinal canal would give rise to a diarrhoea as a premonitory symptom.

Local symptoms are pain which may be absent in multiple osteomyelitis, where the patient passes into a condition of stupor almost from the beginning.

The pain is excruciating, of a boring, tearing or throbbing character not confined to the area involved, but becomes diffused over a large portion of the shaft or to an adjacent joint.

Pain is caused by the great tension resulting from pressure of the compact bone and increases as the exudate becomes greater and lessens or subsides with the escape of the inflammatory exudate from the interior of the bone into the surrounding soft tissues.

Sudden subsidence of pain indicates perforation of bone has occurred or that pus has escaped into the paraperiosteal tissues. In osteomyelitis the symptom of pain alone will show the number and location of bones affected.

Pain in a new locality is an indication that another bone has become affected.

#### TENDERNESS.

Pain may be diffuse and not appear in the primary focus of the disease, but pain on pressure will enable the surgeon to locate the primary focus within the bones with accuracy even before external swelling has appeared. "During the first few days the area of tenderness will correspond to the extent of the disease in the interior of the bone, and the centre of this area will correspond to the primary focus of the inflammation. Tenderness is most acute where the disease has approached nearest the surface of the bone, and by this means the surgeon locates the site for early operation. Tenderness is caused by the secondary periostitis. In osteomyelitis of the long bones, this symptom appears first near one of the epiphyses and extends later toward the shaft of the bone as the periostitis ascends or descends in that direction."

#### SWELLING.

The swelling may be absent the first few days of an attack of acute osteomyelitis; viz, until

the information has extended to the periosteum and soft tissues.

With the secondary periostitis tumefaction occurs, a hard induration followed by oedema and deep seated fluctuation.

"The rapid local diffusion of the process is largely due to the unyielding nature of the tissues around the primary focus, and to the fact that the blood-vessels are directly concerned in the extension of the process by becoming the channels for the diffusion of the septic infection, their contents forming a nutrient medium for the pus-microbes. Thrombo-phlebitis is a constant and early condition in every case of acute osteomyelitis. The oedema of the soft parts is caused, in part at least, by the deep-seated venous obstruction. The external swelling seldom appears before the end of the first week, but when it once shows itself it increases very rapidly. The secondary suppurative periostitis results in extensive denudation of the bone of this membrane, a large portion of the shaft being surrounded by pus. As soon as the suppurative inflammation extends to the soft tissues, diffuse burrowing of pus takes place between the bone and the periosteum and among the muscles. Within a few days an immense abscess or, a very extensive purulent infiltration, develops in this manner.

#### REDNESS.

The skin over the diseased bone may be normal or pale at first; but when pus reaches the subcutaneous tissue it becomes a red or brownish red color.

The superficial veins are dilated and turgid, indicative of a deep-seated thrombo-phlebitis.

#### SYNOVITIS.

Joints near the osteomyelitis as a rule become inflamed. Catarrhal synovitis is apt to occur the first two or three weeks later in the disease a suppurative synovitis often occurs as a complication of acute suppurative osteomyelitis.

A serous synovitis is not the result of infection with pus-microbes, but due to vascular disturbances outside of inflamed and infected area. The synovitis occurs quickly and the serous effusion causes pain, swelling, impaired motion, tenderness and contraction of the joint, which disappears after pus has been evacuated. Suppurative synovitis results from infection of the joint with the same microbes that produced the acute infective osteomyelitis. The infection extending through the lymphatics, blood-vessels or diseased epiphyses to the tissues of the proximal joint. Suppurative synovitis is much more serious than serous synovitis and increases the general symptoms very much and

is attended with more serious local manifestations than when the effusion is aseptic or non-microbial. An exploratory puncture will decide the diagnosis between non-septic and septic effusion within the joint.

#### EPIPHYSEOLYSIS.

Is the separation of an epiphysis from the diaphysis or shaft in the epiphyseal line and is a frequent accident in cases of osteomyelitis of the long bones. Epiphyseolysis is a pathological fracture and due to necrosis, inflammatory, osteoporosis or molecular disintegration of bone in the epiphyseal line and causes false motion at the point of fracture and displacements of the fractured ends of bone. Epiphyseolysis occurs about the fourth or sixth week from the commencement of the attack.

*Loss of Function.*—In a limb affected with acute osteomyelitis there is partial or complete loss of function; the patient being unable to raise the limb or move the nearest joint.

The characteristic symptoms of acute osteomyelitis are, (1) pain, (2) tenderness, (3) swelling, (4) redness, (5) synovitis non-septic, (6) suppurative synovitis, (7) a pathological fracture, separation of the epiphysis from the diaphysis at the epiphyseal line or epiphyseolysis, (8) impaired motion of the limb, (9) loss of function.

#### DIAGNOSIS.

Osteomyelitis has been diagnosed and treated for periostitis, inflammation of joints, ostitis, rheumatism, typhoid fever, erysipelas and phlegmanous inflammation of the soft parts, ostitis, periostitis, synovitis and cellulitis or secondary diseases, sequels or complications of osteomyelitis, yet do occur often independent of the latter.

The fever attending osteomyelitis resembles typhoid fever. During the first week or days, there is an absence of external swelling; though the general symptoms be severe; second, the rapid diffusion of the swelling after it has made its appearance.

In periostitis and phlegmanous inflammation of the connective tissue swelling is one of the earliest symptoms.

In osteomyelitis the swelling first is oedematous symmetrically around the entire bone and gradually diminishes at a point where the morbid process in the interior of the bone has become arrested.

In acute cases fluctuation appears from about 7th to the 14th day. A consecutive synovitis will supervene from about the 7th to the 28th day.

The high pulse, temperature, rapid respiration, tympanitis, dry tongue, enlargement of liver, spleen, bronchitis, a gastro-intestinal ailment with diarrhoea and delirium may simulate typhoid fever until the characteristic, severe, deep-seated, constant, boring, tearing or throbbing pain attended with tenderness, redness, appear at the inflamed focus or foci on or near the epiphyseal line. After the chill and fever, the first so-called symptom indicative of osteomyelitis is pain and severe pain in one or more epiphyseal areas or foci of infection.

The limb or bone has the feeling of being broken; impaired mobility and aggravation of the severe pain on being moved.

In phlegmanous inflammation of the connective tissue fluctuation is at first circumscribed, but is diffused from its commencement in osteomyelitis.

The differential diagnosis between rheumatism, gonorrhoeal arthritis, and osteomyelitis is not difficult, in the former the synovitis occurs as the primary disease, while in osteomyelitis the joint affections occur as complications of sequelae.

The differential diagnosis between rheumatism, gonorrhoeal arthritis, and osteomyelitis is not difficult, in the former the synovitis occurs as the primary disease, while in osteomyelitis the joint affections occur as complications of sequelae.

#### PROGNOSIS.

Multiple osteomyelitis with grave symptoms of septicaemia from the beginning almost without exception proves fatal in less than two weeks. Death being due to progressive sepsis caused by the entrance of large quantities of pus microbes into the circulation.

The first source of danger to life in osteomyelitis is acute septicaemia, secondly, thrombo-phlebitis.

One or more thrombi may soften and disintegrate and fragments enter the general circulation and the infected emboli produce new

centres of suppuration in kidneys, lungs, liver, etc., attended with recurrent chills and intermittent form of fever, soon followed by death from sepsis and exhaustion.

Fat embolism is another fatal accident, the medullary tissue becomes liquefied by the suppurative inflammation; some of the fat globules are forced into the general circulation by intra-osseous pressure and death is preceded by rapid shallow breathing, cyanosis, small rapid pulse and symptoms which point to the existence of an obstruction to the passage of blood from the right to the left side of the heart. Extensive destruction of medullary tissue is always followed by marked anemia. Schede has seen in cases of acute osteomyelitis, the proportion of white to the red-blood corpuscles increased 1:100. The clinical thermometer is an important prognostic aid; the morning and evening temperature remain continuously high during the first week between 103 and 105 degrees. The more the case simulates typhoid fever the graver the prognosis. The occurrence of decubitus is always an unfavorable sign. After an attack of acute osteomyelitis, necrosis of the bone to a greater or less extent follows. "The extent of periosteal detachment during the acute stage is no indication of the area of subsequent sequestration, as the greater part of the denuded bone may receive an adequate blood supply from the vessels within the bone, and soon becomes covered with granulations, and later unites with the periosteum or the paraperiosteal tissue." Disease of the joints and separation of one or more epiphyses are often complications.

A catarrhal effusion may be and is most often removed by absorption as the acute inflammation subsides. If the effusion of the joint is sero-purulent and the articular cartilages remain intact, aspiration, with subsequent washing out of the joint with an antiseptic solution may be sufficient to remove the effusion and restore the usefulness of the limb. Stiffness of the joint and malposition of the articular surfaces of the bone can not always be avoided even by the most skillful and attentive treatment. If the articular surfaces are destroyed by suppurative arthritis, the best result that can be hoped for is a useful, but ankylosed joint. Pathological fractures through the shaft of a bone or epiphyseolysis are complications which greatly tax the duties of the attending surgeon; but from which the patients frequently recover with a useful limb.

#### PATHOLOGICAL ANATOMY.

The long bones are more readily attacked by acute osteomyelitis; but the scapula, clavicle, ribs and ilium are often affected. The femur

is more apt to be involved in the lower epiphyseal region, the tibia in the upper epiphyseal end. As acute osteomyelitis, without direct exposure of the marrow is caused by infection with pus-microbes, which reach the tissue through the circulation, the inflammatory process must commence in the capillaries from mural implantation of microbes or leucocytes containing them.

The cause of the inflammation is primarily endo-vascular, and reaches the medullary tissue with the leucocytes. Intense alteration of the capillary wall is always present in these cases, giving rise to rhexis. Pus from acute osteomyelitis almost always presents a reddish appearance, which is owing to the presence of extravasated blood. The inflammation extends rapidly to the larger veins, which become blocked by the formation of a thrombus. If pus microbes enter the thrombosed veins in sufficient quantity to cause liquefaction of the coagulated blood, pyemia results from transportation of fragments of such infected thrombi to the distant circulation. Extensive thrombo-phlebitis results in arrest of circulation in portions of the bone, or perhaps of the entire shaft, which is followed by the usual consequence of such a condition, necrosis. Necrosis is undoubtedly also caused by the tissues and the pressure resulting from the presence of the inflammatory exudate in a tissue not capable of distention."

Following the acute osteomyelitis there are the following pathological sequelae, viz., phlebitis, thrombi, often embolism, suppuration in the central medullary canal transforming it into an abscess cavity, or multiple abscess cavities, then periostitis and paraperiosteal inflammation with suppuration, then cloaca forms in the new bone. With subsidence of the acute periostitis there is new bone formed by the periosteum around the necrosed bone, viz., the involucrum, and with the formation of fistulous openings between the surface of the skin and necrosed bone in the involucrum.

The fistulous openings in the skin are often quite a distance from the cloaca and it will be difficult or impossible to detect the necrosed bone or sequestrum by probing.

The necrosed bone or sequestrum may form at one or several points and will be included in the involucrum. The sequestrum or sequestra are separated by suppuration or granulation. The sequestra may be irregular or dentated in outline.

Necrosis may be central, composed of tissue within the bone; complete if it represents the entire thickness of the bone and cortical if it represent the external compact layer only. A pathological fracture will occur in complete necrosis if separation takes place before a

firm involucrum has formed. Restoration of the continuity of the bone is affected by new bone. In central necrosis the sequestrum is always incased in an involucrum.

In cortical necrosis spontaneous elimination of the sequestrum frequently occurs, if the bone separates before an involucrum does form, or, if an involucrum does not form on account of destruction of a corresponding portion of the periosteum. The medullary canal in the new bone after central or total necrosis is seldom restored to perfection. The new bone is harder and heavier than normal bone (osteosclerosis) or it may remain soft and porous (osteoporosis) a condition described by Volkman and Schede and which may become the cause of various degrees of deformity from bending of the shaft. Separation of a sequestrum will take place in from four weeks to three months, according to the age of the

patient and the location and extent of the necrosis.

The medical treatment should be a mercurial salt, free purgation as the gastro-intestinal canal is a frequent route through which pathogenic micro-organisms enter. Opium should be given freely to ease pain. The affected limb should be elevated. The ice bag is an anodyne, anesthetic, and antiphlogistic.

An accurate, and early diagnosis, antiseptic and aggressive, skillful conservative surgery have wrought a great change for better in saving both limb and life.

The diseased medulla is no longer a "*noli tangere.*" but should be attacked with skillful antiseptic surgery the same as the soft tissues outside of the bones. The incision should be long enough to meet the demands of the case. The early evacuation of pus in osteomyelitis saves both limb and life and is the most valu-

able prophylactic surgical measure against death from sepsis.

It is self evident that every case of acute osteomyelitis should be treated with prompt life-saving surgery. It is next to criminal to wait for fluctuation before resorting to surgery in acute osteomyelitis. Open the bone, remove and antisepticise the infected medulla before suppuration has extended to the periosteum and soft tissues.

An honorable, ethical and skillful consultant should be called to protect and assist in the operation that every word may be established and a mal-practice suit prevented by the non-medical society physician and fakir lawyer. Early operation should be done soon as a positive diagnosis can be made and before external swelling has appeared.

1. It removes pain.
2. It enables the surgeon to remove the local cause of the disease completely or in part.
3. It prevents extensive necrosis.
4. It is the best prophylactic measure against fatal septicaemia.
5. It prevents extensive destruction of the periosteum and other contiguous parts.
6. It cuts short the attack and expedites recovery.

The primary focus of osteomyelitis is generally in the epiphyseal line and is found by searching for the tender point over this or near to it. The incision should be made down to the bone, following the intermuscular septa, and at an early stage the periosteum will be found vascular and easily separated from the bone. The bone is then opened with the small round chisel near the epiphyseal extremity, no pus may be found, but there will be softness and vascularity of the tissues and escape of bloody serum from the myelitic focus. The opening in the bone will give drainage, relieve intra osseous pressure and enable the surgeon to remove in all or part of the infected tissues and to antisepticise same. The opening in the bone should be enlarged and extended in the direction of the shafts to the extent of the disease in the bone. If suppurative inflammation is extensive, involving half of the bone, or its entire shaft, the bone should be opened at several points in the same line in place of a large incision.

After the medullary cavity has been explored it should be everted and antisepticised, mopped and dried and packed with iodiform gauze, and dressed from time to time as the necessity of the case demands. The lowering of pulse, temperature, freedom from the peculiar pain and comfort of the patient will indicate the betterment by early surgical treatment.

The intermediate operation will consist in

incising and evacuating the infected tissues and drainage: small multiple incisions and openings into the bone are preferable to a large opening into the bone and a pathological fracture. The limb should be placed on the proper supporting splint.

#### LATE OPERATIONS.

Late operations in osteomyelitis are for the removal of dead bone. This operation is called necrotomy or sequestrotomy, and should be postponed until complete separation has taken place and the involucrum is strong enough to furnish the necessary mechanical support. If the operation is done too early, healthy bone may be removed, or a part of the sequestrum may be left.

Necrosis is not a disease, but a sequel of bone inflammation. The sequestrum of a metacarpal bone may separate in 4 or 6 weeks. A cortical sequestrum of a long bone may be separated in six weeks or two months; while detachment of half, or an entire shaft of bone as femur or humerus may take three to six months.

Should the patient's general health continue to improve there is no haste in the removal of the sequestrum. Much may be gained by waiting. Giving plenty of time for the sequestrum to become detached. Esmarch's bloodless *tourniquet*, anaesthetics, antiseptics, proper surgical equipments and a skillful common-sense surgeon have worked wonders in bone surgery, in saving both life and limb. Let us take warning and not have pressure paralysis from too much elastic constriction following sequestrotomies. Again, the surgeon should avoid injury to important vessels and nerves.

Be sure to follow the line of the inter-muscular septa in the dissections. The incision through the soft tissues should be long enough to meet the demands. The inter-muscular septa ought to be separated with the fingers and blunt instruments.

The periosteum must be incised and separated and reflected with the soft tissues. The involucrum in cases of long duration may be hard, dense, in a state of osteosclerosis and difficult to chisel; the surgeon must be careful or a pathological fracture will result. The bone cavity should be placed in an aseptic state, and packed with decalcified ox bone chips, with due antiseptic precautions, with or without capillary drainage, and the necessary antiseptic dressing applied and the limb properly splinted and placed in a position of rest and elevation.

J. B. S., age 12 years, former health and family history good, had an attack of inflammation of the right lower leg called by his family physician "white swelling." This at-

tack occurred early in the year of 1903. June 1905 the boy was brought to me for consultation and treatment. Other physicians having attempted surgical treatment, but gave up the case as not amenable to successful surgery. The boy was in a very good condition for surgery, though the osteomyelitis had existed for 18 months in a chronic or subacute form with large amount of suppuration and destruction of bone, the tibia. The osteomyelitis extended from near the cartilages of the knee joint, involving the cancellous tissue of the tibia to the middle of the tibia: quite a trough had to be made of great length to expose the diseased medullary canal. Numerous sequestra were lying loose in the diseased area from one to three inches long and one-fourth to one-half inch wide. These were extracted and all dead bone removed down to the middle of the tibia. The bone cavity was thoroughly cleansed with a 1-2000 bichloride solution, dried with aseptic gauze and then packed with decalcified ox bone chips nicely and thoroughly approximated and filling the entire diseased bone cavity, 10 per cent. iodoform emulsion was poured over the chips filling up interspaces. Drainage was made from upper to lower end of wound with a few strings of silk worm gut and removed on the fourth day.

The edges of the skin and periosteum were surgically approximated and healed by first intention, the silk worm gut removed at the end of six days. The wound was dressed with rubber adhesive strip, iodoform gauze, 10 per cent. and surgeon's cotton and bandage and placed upon a posterior curved splint, the latter to support the limb and give rest. For 48 hours there was much wound secretion and the dressing had to be removed every 12 hours and new one applied, and the limb and wound kept sterilized and at rest.

The patient was kept three weeks in the Joseph Price Infirmary, Stanford, then sent home in the country 20 miles.

The wound healed without pus and no loss of the ox bone chips and a useful limb was restored with no loss of function.

Senn's *Principals for Surgery*, pages 225-256, and pages 257-258 will be found a description of decalcified ox bone chips in the treatment of disease of the bone.

The writer has seen Dr. Senn treat bone lesion attended with extensive destruction of bone by this method with entire satisfaction and primary union with restoration of bone and a useful member saved. Two years after patient was dismissed he returned for consultation, with pain, redness, tenderness, and swelling, localized and circumscribed, of the left tibia—epiphyseal line of the inner malleolus and shaft acute circumscribed osteomyel-

itis. The pain was excruciating, of a boring, tearing or throbbing character. The pain caused by pressure *per se* was greatest over the epiphyseal line. The pulse was one hundred and twenty; temperature 103 degrees Fahr., and patient realized that a new focus of inflammation had begun and, therefore, begged for an early operation. He was returned to the Joseph Price Infirmary at Stanford, prepared for operation and operated on. There was an acute circumscribed osteomyelitis of the lower end of tibia as described above. The soft tissues were incised, then the periosteum incised, there was great congestion of the localized area; a soft spot detected in the bone the size of a pea, with the sharp pointed probe; the bone at this point was trephined, the instrument extending over the soft spot into healthy tissue into medullary canal, removing the infected oasis of bone. The wound was then washed with 1-2000 bichloride of mercury, then sterilized salt solution, mopped freely with carbolic acid and the latter neutralized with pure alcohol, the bone cavity or wound filled with 10 per cent. iodoform emulsion, the periosteum and soft tissues coaptated and drained; the wound dressed antiseptically and with abundance of sterilized gauze and cotton and placed in a fracture splint; wound secreted freely for 24 hours, dressing removed and a new one applied; drainage removed in 48 hours, stitches removed on fifth day with wound healed by primary union and patient sent home on the 10th day after operation. Recovery complete.

The writer desires to extend his sincere thanks to Dr. Nicholas Senn, of Chicago, for his individual teaching in bone and all other general surgery, and for all personal and professional favors received at his hands. The writer has not only quoted Dr. Senn's ideas, but, in many places, has made numerous and extensive quotations from his book—Senn's Principals of Surgery, which should be considered a "Pathological Bible" for the general surgeon and student of medicine, and will prove a surgical light to every honest, industrious and faithful student of pathology and successful surgery. No physician's library is complete without Senn's Principals of Surgery.

#### REPORT OF A CASE OF ABDOMINAL PREGNANCY WITH REMARKS.\*

By C. R. GARR, FLEMINGSBURG.

I was called to see the following case in consultation with Dr. Minish, on November

22nd, 1907, which, I think, is of sufficient interest to report:—

Mrs. W., wife of a minister, age twenty eight, mother of one child eight years old. This pregnancy and delivery were normal in every respect; had never been pregnant before or since until the present time. Her general health has been uniformly good all her life. There had, at no time, been any disorder of the menstrual function. She stated her expected confinement would be in January. Her last menstruation occurred about May 1st., 1907, which would have made her confinement due about February 1st., 1908. This period was normal in every respect. She experienced no trouble until four weeks later, when she complained of a sudden pain in right lower quadrant of abdomen, followed by shock with symptoms of hemorrhage. She was attended by two physicians, living in a distant county. Her condition, as described by her was most serious for about sixteen hours; was confined to bed about a month. Her subsequent recovery was never well established. Daily vomiting was prominent symptom; so much so, that she was greatly reduced in flesh and strength. Pelvic and abdominal pains were complained of during the time.

Her present attack began on the night of November 15th., 1907, Dr. Minish, of Poplar Plains, being called. Upon his arrival he was told by the husband he had been aroused by the peculiar breathing of his wife. He could only partially arouse her. She remained in a semi-conscious condition for fully an hour but, before the doctor arrived, the consciousness had fully been established. On the following Monday he was again called; found she was suffering pain in abdomen, paroxysmal in character; also complained of dimness of vision. Believing that this visual defect was due to uraemia, he treated her accordingly. On Friday, we found her condition as follows:—There had been no pain since Monday last; temperature normal; pulse 96; no headache nor muscular twitching; vision about the same as on Monday last. Her kidneys all along had been acting freely; passed a pint of urine while we were there, which was examined by Dr. Minish and found to contain large quantities of albumin; feet and limbs oedematous; appetite was good. Since the spurious pains complained of on Monday last, she had felt no fetal movement. Upon examination per vagina, found a high vertex presentation. There was no lochial discharge. Diligent search failed to locate the os, being a high position, and not wishing to give her unnecessary pain. We did not attach any special

\* Read before Fleming County Medical Society, December 18, 1907.

significance in not finding it, as, in many normal pregnancies, I have often failed to find the os on account of it being out of my reach. I must confess at this visit I was woefully ignorant as to this woman's true condition. Not for a moment did we suspect that we had a case of abdominal pregnancy to deal with. Our special thought and attention were directed toward relieving convulsions that would certainly follow, if not relieved. Dr. Minish had very properly given her *Elatarium* and hypodermics of pilocarpine, a few days before, which seemed to have acted well. We decided, if the case did not do well by his next visit, it would be best to empty the uterus of its contents. Late in the afternoon of the following day I was again hurriedly called; found patient had four rather severe pains five minutes apart. During the last pain she had a severe convulsion which lasted about five minutes. At this time she could not hardly distinguish light; temperature normal; pulse 100. She passed about one pint of urine after regaining consciousness. Believing, as we did, that the life of the mother depended upon prompt action, we agreed to empty the uterus at once. Dr. Minish asked me to deliver her. He incidentally remarked that she had a very peculiar cervix and that he was unable to enter the uterus nor directly feel the child's head. Under profound anaesthesia, I found the os almost behind the pubic arch. It was large, soft and well dilated; by a little traction could pull the cervix down. The finger could not be introduced into the uterus on account of the acute angle of flexion. Several examinations were made before we were entirely satisfied that we had an empty uterus. During this examination several large clots were passed as well as black, liquid blood. At least a pint was passed. After we made the diagnosis of abdominal pregnancy, we could then readily understand the cause of pains, just before convulsions, was the uterus trying to expel the clots. We explained to the husband her condition, who consented to have the abdomen opened next morning. Early the following morning Drs. Aitkin and Briece saw the ease with us. There had been no convulsion during the night; practically no vision; temperature normal, pulse 130 and weak. There had been no urine voided since the evening before nor was any found by the use of the catheter. Her mental condition was not at all good; did not notice what was going on nor was she conscious of her condition. With the assistance of Drs. Minish, Aitkin and Briece, I opened the abdomen. Examination of the sack, before it was opened, showed extensive adhesions on each side and

to the back. There was a formidable hemorrhage arising from the free abdominal cavity. Investigating the source of this hemorrhage, found the sack had ruptured at its superior surface and slow bleeding had been going on for, at least, twenty-four to thirty-six hours. A quart of clots and liquid black blood was removed from the free abdominal cavity. The sack was opened, bleeding surface clamped, child removed, which showed evidences that its death had taken place days before. The placenta showed no signs of life and was easily removed. It was attached to the left side of sack, extending well down to the original site of rupture. On account of the dense adhesions it was thought best to repair the rent and sew the cut edges of the sack to the peritoneum and then to the abdominal wall. A pint of normal salt solution was left in the abdominal cavity. The sack cavity was cleansed and packed with iodoform gauze. An opening 2 1-2 inches was left for future irrigation and drainage. After the dressings had been made, she was put to bed, between hot blankets, in a desperate condition; pulse hardly perceptible at the wrist. One quart of saline solution was given her in the breast; *strychnia* and *nitroglycerin* given hypodermically. After one hour she was decidedly improved. In opening the abdomen, we found the pregnancy had taken place in right tube. The peritoneum showed the appearance common after a protracted distention with its consequent attendant pressure. The sack, containing the foetus, was evidently the folds of the right broad ligament, the pregnancy having been of the isthmie variety, as was shown by examination of the sack after removal of the foetus and placenta. The blood supply to the sack was very poor and, no doubt, the foetus perished some days or weeks prior to the operation, for want of circulatory nourishment. The omentum had played an important role in supporting the sack containing the foetus, as was evidenced by the continuous adhesion to the sides of the sack. Where there were no omental adhesions, the sack wall was thin and in a semi-necrotic state.

While I saw the ease, for several days with Dr. Minish and, at times when he could not possibly see her, I am indebted to him for the skillful after treatment of the ease. The wound was dressed daily by irrigation and packed with plain sterile gauze. While the discharge, for ten days, as would be expected, was free and odor intensely offensive, yet, at no time were there any pronounced symptoms of active sepsis. After the third day,

had a slight elevation of temperature, never reaching above 100 degrees; pulse 96 to 110. The only symptom that gave us any alarm, after the first twenty-four hours, was the continued and unimproved visual defect. This condition remained about the same for two weeks. In the last week, this albuminuric retinitis has rapidly improved until now she has almost normal vision. Her kidneys are acting freely but still show trace of albumin. Living seven miles from her physician and dependent upon untrained nursing, we consider it remarkable that her recovery seems now assured. The infrequency of ectopic gestation is well established by Bandl, being one in twelve thousand cases. Price found eighty-three in eight thousand pregnancies. So far as we are concerned, these statistics are wholly valueless, for, having a large obstetrical practice for years, it has not been my misfortune to encounter but two cases of abdominal pregnancy. One I saw in consultation with Doctors Morford and Aitkin years ago, in which, to our certain knowledge, she had carried the dead foetus for ten years. She was operated upon when she was intensely septic and died in a day or two. I have only encountered one case of ectopic gestation where a diagnosis was made at the time of rupture. However, this diagnosis was not verified by an exploratory laparotomy: the patient absolutely refusing any operative work. That many cases of tubal pregnancy rupture and the patients either die or get well and a diagnosis never being made, there is no question. If the abdomen was opened in those cases which present the classic symptoms of rupture, we would save many cases from submitting themselves to a more formidable operation which will be sure to follow if the foetal sack has not been interfered with. While it has not been my privilege to witness the operation for a primary rupture, it does not occur to me a difficult one, certainly it could not be compared with the operation at a later date. It would also add many cases to the unrecorded tubal pregnancy list if autopsies were held in cases of sudden and unexplained deaths. That some of these cases recover without an operation, is well established. But, compared to the number that die or live out a miser-

able existence the rest of their lives should not be an excuse for us in giving them the best chances for their lives by an operation.

### THE USE AND ABUSE OF THE FORCEPS.\*

G. H. FREEMAN, PLANO.

The forceps have been used more or less continuously since they were first introduced by the Chamberlins. The forceps first used were a very rude instrument, although it may be said to be a type of the short-straight forcep which has been more employed than any other and which, perhaps finds its best representative in the short forcep of Derman, the greatest difference being in the lock. The forceps have been many times modified and finally Simpson combined many excellent parts selected from other forceps with some original ideas, and succeeded in making a forcep that stood the test for many years, and to-day it, with some slight modification is in use not only in America, but in almost all civilized countries where lying-in women are attended by learned physicians who are abreast with the times and who are prepared to render the best services to those who come under their care.

I do not consider it prudent in this little paper to give a detail description of the forcep, but we would say for the limit of this paper that they might be described as a pair of artificial hands with which the foetal head may be grasped and drawn through the maternal parts by a *vis a fronte* when the *vis a tergo* is deficient. The first thing essential to the introduction of the forceps is a thorough knowledge of the anatomy, physiology and chemistry of the pelvis in order that we may be able to give our patients the best services both as to the safety of mother and child, that we may be able to introduce the forceps skillfully and accurately and that we may be able to make traction at the right time and in the right direction. Before the introduction of the forceps the membranes must be ruptured, and it is very necessary that the os be thoroughly dilated and the cervix retracted over the presenting part. Sometimes we are compelled to use forceps before the cervix is completely dilated, then manual dilatation should be resorted to before

\* Read before the Warren County Medical Society.

the application. To properly apply forceps with least damage to the tissues it is essential to know the position of the head. Before the application the bowels and bladder must be thoroughly emptied, the hair on the lower labia clipped, the parts thoroughly scrubbed with soap extending up the thighs and bathed with bichloride. A fountain syringe filled with hot sterile water, suture material of cat gut and silk worm gut all threaded and ready for use should be in readiness before the anaesthesia is administered. Anaesthesia should be given to the complete degree in every application. The forceps can be applied, bringing head to the vulva and then removed, allowing the patient to come from under the influence of the anaesthetic and deliver herself. This method prevents perineal laceration and favors contraction after delivery. If possible the application should be made to the sides of the child's head, each fenestra fitting over the ears of the child. This is called cephalic application. For those not skilled in the use of forceps pelvic application, that is, applying the forceps without regard to the position, is easier if they are removed frequently and re-applied, they will finally become cephalic application as rotation is accomplished.

The late Dr. Barnes claims that we may do what we will in applying forceps to the child's head, they will find their way to the sides of the pelvis.

I always introduce the left blade first, take it in the left hand between two fingers and the thumb, guided by the index finger of the opposite hand, pass the blade gently, taking care not to produce any injury or include any of the soft parts in the blades. If the blades meet with any obstruction it is best to remove the blade partially or completely and start again, when finally the blade passes over the head it is held in position by an assistant and the right blade introduced in the same way, only with the right hand and guided with the index finger of the left hand, when it has passed over the head opposite the left blade the handles should be brought together gently and if they will not lock without using some force, one blade should be removed and reapplied more directly opposite its fellow with the same precaution as before, care being taken when they

lock not to catch any of the material structures. Once they are introduced and locked they should be grasped firmly to prevent the blades from slipping from the child's head, then we should make traction at intervals in the direction of the axis of the part of the pelvis in which the head lies, taking pains not to operate too fast, as the head passes over the perineum the handles should be raised toward the abdomen to protect and prevent laceration. While making traction we may and sometimes should impart to the handles of forceps a worm-like motion, but we should at no time try to produce flexion or extension by any peculiar motion of forceps; we should operate slowly and cautiously and rotation, flexion and extensions will as a rule occur as in natural labors.

The forceps have a very important field in high application when the presenting part will not engage in the pelvis and version is contraindicated. When the head is not engaged at the brim it is necessary to apply pressure externally so as to hold the head while the forceps are applied. In the high operation the axis traction forceps are more easily applied and better to use; we should be very cautious to introduce the blades to the inside of cervix. The forceps also may be used with great impunity in delivering the after coming head in breech presentation, they have no doubt when in skilled hands been the means with which many a child's life has been saved.

The abuse of forceps is of two kinds, the lack of use and the too frequent use or non-skillful use. They are often, no doubt, applied too soon, and by the unskilled, by those who do injury both to the mother and child, by laceration of the cervix, vagina or perineum or rupturing of varicose veins, thus leading to a thrombus or as result of contusion of soft parts we may have a pelvic abscess, or they might be so badly used as to fracture some part of the bony pelvis in the above-named results. The forceps are not to blame, but the one who has abused the use of the instruments.

The dangers to the child are lacerations of the scalp, forehead, contusions of the face, partial or temporary paralysis of face from pressure of a blade on the facial nerve, compression

or fracture of skull, also injury to brain from undue pressure, all of the above accidents possibly could be avoided, but many of them no doubt are the results of the instrument in unskilled hands. "The abuse of the use."

### DIFFERENTIAL DIAGNOSIS OF MEMBRANOUS CROUP AND DIPHTHERIA.\*

BY W. L. MOSBY, BARDWELL.

Six years ago I was appointed to discuss this then somewhat complex and paradoxical subject, and to-day I am called upon to perform this same pleasant duty. In my former efforts those of you who were present then remember I had to stoutly defend the position I then assumed that membranous croup and laryngeal diphtheria were one and the same disease; to-day, however, the dissemination of modern teaching along the lines of bacteriology and pathology in the last few years has practically eliminated the doubt as to their identity and all will agree as to the etiology and sameness of the two conditions. In the investigation of the subject I find Anders and Osler refer to membranous croup as laryngeal diphtheria or a complication of diphtheria. Holt, on disease of children claims 95% of all these cases of membranous croup show the Klebs-Loeffler bacillus bacteriologically and states:

(1) Membranous inflammation beginning in the larynx is almost invariably true diphtheria.

(2) Occurring above the larynx it is in the majority of cases true diphtheria.

Kerley on diseases of children classes all cases of membranous croup as true diphtheria and advocates large doses of antitoxin as necessary in its successful treatment.

In two hundred and eighty-three cases subjected to bacteriological tests by the board of health of New York City two hundred and twenty-nine cases or 80% showed Klebs-Loeffler bacillus as the etiological factor thereby demonstrating their identity. In eighty-seven autopsies in cases of membranous croup made by Dr. Northrup the membrane was distributed as follows: Nine cases from the tip of the nose to the smallest bronchi, six cases from the nose to the bifurcation of the bronchi, seventeen cases from the pharynx to the smallest bronchi, seventeen cases larynx and trachea, three cases larynx and pharynx, one case larynx only. According

to McNaughton and Maddren (Med. News, May 15th, 1895) the mortality has been reduced to 21.12% (being formerly about 95%), by the introduction of antitoxin a strong and convincing argument as to membranous croup being diphtheric in its nature.

Sheffield says "should the medical profession accede to antitoxin the high position as a curative agent it so well deserves in the early stages there would be few if any occasions to use either intubation or tracheotomy. Musser, Butler, DaCosta, Rotch, Sahli and all of the available authorities at my command on clinical medicine or physical diagnosis discuss and treat membranous croup and laryngeal diphtheria as one and the same disease. It is further believed by the latest available authorities that the bacillus xerosis or the pseudo-diphtheria bacillus is only an attenuated form of the Klebs-Loeffler bacillus, the difference in virulence or effect being due to individual condition or susceptibility or more properly speaking, the factor of immunity. Toxins are absorbed from the diseased membrane by the lymphatics and blood vessels, hence anatomical reasons for the constitutional symptoms in laryngeal cases of croup or diphtheria being quite different to nasal and faucial diphtheria where there is rapid absorption and often intense toxic infection. It is my conviction that our diagnostic troubles and confusion as to etiology come from these border line cases, i. e., severer forms of catarrhal laryngitis or the milder forms of membranous laryngitis etiologically the Klebs-Loeffler bacilli would be responsible in the one and the streptococci or the staphylococci or some pus producing germ in the other, hence the successful or at least scientific direction of the remedies to alleviate this dread and so often fatal disease depends on a knowledge of its cause. Gentlemen of the society, we cannot afford to brush aside the opinions of these men of science, who have given so much time and study to these pathological conditions for mere dogmatic opinions often not well founded or based solely on limited bedside experience with insufficient data, not backed up by laboratory investigation and research. Individual opinion and great scientific medical facts may not be in accord, and if not which shall we accept? If our authorities or text books are correct, let us accept their teaching, if not, let the profession demand their revision. Experience is our best teacher, but the principles by which it is acquired must be true and correct. Theory is knowledge reduced to principles, but science is more exact and may be reduced to practice. I deem it altogether unnecessary for me to consume your time in giving the diagnostic consideration of other than

\* Read before the Carlisle County Medical Society, December 3, 1907.

the laryngeal forms of diphtheria nor do I consider it necessary to give you the symptomatology of catarrhal croup or spasmodic croup, the treatment of which should be timely and well directed. Laryngeal diphtheria or membranous croup is usually slow in its development, the Klebs-Loeffler bacillus usually makes its first influence felt upon the mucous membrane of the larynx. The pharynx and nose giving no evidence of membranous formation, it may, however, be secondary to nasal or faucial involvement, in which case there will be a harsh metallic cough of a ringing character, once heard, never to be forgotten and easier of recognition than of description; this gives evidence of the membranous formation. The constitutional symptoms are almost nil, temperature at or only a little above normal, being only a limited amount of toxic absorption. The local symptoms are usually, however, very alarming and out of proportion to the general, being due to direct and often eminent laryngeal obstruction with resulting extreme dyspnoea, causing labored efforts for breath, we will soon observe a retraction of the intercostal and subclavicular muscles and as effort at breathing increases or rather laryngeal stenosis advances the epigastrium and lower chest walls likewise sink in, cyanosis develops and increases as the stenosis advances, oxygen is reduced as the lumen of the larynx is reduced by membranous formation, the little sufferer becomes more restless and is now forced to sit up to breathe and advances the chest and retracts the head, so as to straighten the larynx mechanically, thereby more easily admitting the necessary air. We will notice interference with breathing is both inspiratory and expiratory, therein differing with other forms of croup. The little patient is now burning rapidly the candle of life and is doomed to perish by gradual suffocation unless relieved by a kind Providence or a skilled physician. Most of these cases occur in children between the ages of two and ten years and slightly more in boys than in girls; we might say the age of choice for diphtheria. A clinical symptom which should strongly suggest itself to the physician and should not be overlooked is the presence of albumin in the urine, it is present in membranous croup just as it is in diphtheria. The author has frequently observed cases of membranous croup occurring in families where diphtheria had recently existed and *vice versa*.

MEMBRANOUS CROUP.—REPORT OF  
TWO CASES, INTUBATION OF  
EACH CASE, AND RE-  
COVERY.\*

BY L. B. COOK, STANFORD.

From the days of Hippocrates, to the present, the identity of membranous croup and diphtheria has been a battlefield of discussion, and many names have been given it. During the early part of the first century a physician gave a description of a disease that was evidently diphtheria, however, the earliest accurate description was made by Bretonniau in 1821 who called it diphtheritis. He placed diphtheria and membranous croup under the same head, and as we believe they have the same specific identity he very properly classified them. The name was later changed to diphtheria by Trousseau. Diphtheria is a specific infection produced by the Klebs-Loeffler bacillus manifested by an exudate on the mucous membrane, and attended with constitutional symptoms. When the membrane is invisible the diagnosis is attended with difficulty, such cases often occur in laryngeal diphtheria, but more frequently the membrane is visible. Klebs in 1883 discovered the bacillus, and also obtained pure cultures, but failed to make the announcement until Loeffler in 1884 gave a description of the germ and its cultivation, hence, it is now known by the Klebs-Loeffler bacillus. Diphtheria at first is a local disease, then systematic, and afterwards may become septicemic or toxemic. This disease is bounded by no geographical lines though it is more frequent in the temperate zone. Bad domestic environments, damp soil, vegetable decomposition, uncleanness, and winter months favor the growth of the germ. The bacillus is disseminated by dust, and by articles of clothing associated with patient. It is more frequent in urban than rural districts; there is an individual as well as a family predisposition to diphtheria. I have attended the family from which I report these cases through three attacks of this disease. Children with enlarged tonsils, adenoids and nasal catarrh are most subject to it.

These enlarged tonsils are studied with crypts in which the bacilli find ready soil for multiplication. Scarlet fever and measles predispose to it. It is also estimated that 2% of well persons have the bacillus in their throats and of these 17% are virulent. It lives in the throats of those recovered for five or six weeks. Diphtheria does not often

\* Read before the Lincoln County Medical Society.

spread by milk, Lenox Brown thinks the lactic acid of the milk partially destroys the germ.

A pseudo-membrane may be formed by the streptococcus, such cases are often hard to differentiate from diphtheria, streptococcal infection in my opinion is attended with a more acute and painful inflammation, and the membrane peels off more readily. Diphtheria rarely attacks infants under one year of age, still, I have seen it in a malignant form in an infant of ten months. The laryngeal form of diphtheria is limited almost entirely to children. After the tenth year the susceptibility of all varieties diminish very rapidly. Diphtheritic septicaemia occasionally occurs, as the bacillus has been found in the blood, and in almost all the organs of the body, this however is the exception.

The incubation period varies from one to eight days, this depends upon the virulence of the organism or the susceptibility of the individual. The diagnosis is made chiefly by the membrane which has been described as resembling wet chamois skin.

Septic diphtheria is distinct from anything else, the pale swollen, waxy face with enlarged glands and facial expression are characteristic of this form of sepsis. Nasal diphtheria is more often attended with the above mentioned systemic manifestations than any other variety, the toxemia is often profound, epistaxis may be severe, and post-diphtheritic paralysis frequently follows. Heart failure and toxemia resemble each other in symptoms. Toxemia may be ushered in with vomiting or may not occur till after exudate has disappeared. The pulse at first may be feeble, later slow and irregular, the extremities cold and death comes slowly by asthenia, or sudden from cardiac paralysis. The fever of diphtheria (which is not very high) does not continue longer than three or four days unless the infection is in the larynx, or sepsis is present. In toxemia the temperature is normal or subnormal. Laryngeal diphtheria is not often attended with toxemia or post paralysis, but is frequently attended by bronchopneumonia. The larynx is the seat of exudate in 15%, when not in view the diagnosis is often doubtful. The following suggestions of Kirley will assist in making a diagnosis: Diphtheritic croup has gradual onset obstruction persistent and present in both inspiration and expiration, there is little or no response to emesis, inhalation, or sedatives, while in catarrhal croup the obstruction is intermittent with gradual increasing severity, and the obstruction is only present in inspiration, there is response to emesis, inhalations,

and sedatives. He further observes that the onset cannot be relied upon absolutely in differentiation as occasionally catarrhal laryngitis may be gradual while that of diphtheria may be sudden.

I have never seen a case of true croup come on suddenly, I am always suspicious of those cases that come on insidiously. Watch the croupy little runabout that seems well he will surprise you some day. The prognosis cannot be foretold with any degree of certainty as the mild cases may become malignant or pseudo-membrane may extend into the trachea.

Some epidemics are worse than others, also some families are more susceptible, though delicate children stand the disease as well as the robust. The mortality is greater with children under 5 years of age, the younger the patient the greater the mortality.

The following abridged report of two cases which have occurred in my practice will probably prove of interest.

*Case I.*—A child age 5 years presented the characteristic exudate covering the tonsils, but at this time was not croupy, the following day, however, croupy symptoms became pronounced and it gradually grew worse till intubation, which was practiced on the third day from my first visit. Dr. J. F. Peyton was called in consultation, and while we were present the breathing became so embarrassed that we decided to intubate; the child was hastily placed in position, and a tube suitable to age was selected and I tried to introduce it, but failed. On removing it I found it filled with membrane, a smaller tube was selected which we passed without difficulty, the introduction of this tube, however, was not followed with the relief which was expected in fact the breathing became much worse, the child growing livid, and evidently death would have supervened had not the tube been removed. After removal the respirations became regular and were never very threatening after this. I could only account for the relief in this way; the first tube cut out a disk of membrane like a leather punch, while the smaller tube opened the trachea which fortunately did not close again. This child would have died had the tube not been introduced, and would have died had the tube not been removed; the serious condition was manifested by the deep cyanosis and by the calm which often precedes death. With the removal of tube, color was restored, and the child revived. The circulation the remainder of the day being 180 and weak, the following day 170 and afterwards there was a gradual decline. The respiration was also better but labored for some

two or three days.

*Treatment.*—Antitoxin was administered, as follows, I gave in the first injection 3000 units, this was followed the next day by 8000 more, in 48 hours we had complete detachment of membrane. This case required both antitoxin and intubation, the antitoxin would have been too slow for the asphyxiation, and the tube certainly would not have exerted any specific action upon the membrane. I did not use local treatment as the child was restless and any attempt at this time would only have aggravated the symptoms.

When the exudate is faucial, and the child is not too rebellious, irrigation from a fountain syringe, with normal salt solution, as a temperature of 120° F. is a most excellent remedy, this is best given with child lying on side with head held over edge of bed and pus pan, the tube is to be introduced between teeth and the flow interrupted, occasionally. You can use one-half gallon in very short time and this serves a much better purpose than strong antiseptic washes. Do not have too much pressure, have the bag about two feet above patient, this will insure a thorough toilet. Throat irrigation is the best remedy I have ever tried in any variety of tonsillar inflammation, it cleanses, and thereby prevents glandular enlargement.

*Case II.*—An infant at the breast ten months old, was taken a few days later. This child was unusually exposed, as the mother nursed the other child and was nursing this one at the breast. When I saw it the membrane was very extensive covering the tonsils and had also extended into the trachea breathing at that time was heavy which increased very rapidly the following few hours. At 9 P. M., eight hours after my first visit, and 4 hours after injection of antitoxin, I was called hurriedly by phone, saying the baby could not possibly live but a few minutes without relief, when I reached the bedside it seemed almost useless to intubate, but knowing that death was imminent and certain I introduced the smallest size tube and to my surprise and pleasure I saw the infant (cyanotic and almost breathless) began breathing easily and the color return to the cheek, that was truly delightful to behold. It had another chance for life, though not very bright, as the tube was small and antitoxin had been administered only four hours prior, and the mortality being so great in infants. The tube became occluded during the night, and had to be removed. I left it out for a few hours, but the breathing became so hard that I reintroduced it which gave relief. The child could nurse better

than it could drink, and took nourishment heartily, but with difficulty, it seemed always thirsty. I began the treatment of this case by injecting the specific serum. I intended to give 6000 units but after giving 3000 units I thought I would let it rest until I could give immunizing doses to the other children, but this seemed to frighten them so that I let them off and gave it to the sick infant, twelve hours later I gave 3000, and the following day 4000 more making in all 11,500 units. This appears rather a large dose for a ten months' infant but it takes so much for an infection whether in an infant or adult; and the larger, and earlier the dose the better. I am confident under the old line of treatment both of these children would have died, and I also believe that without intubation they could not have recovered. I used crop kettle with both cases, and at times made respiration easier, or at least parents who are intelligent think so, and I have learned to respect the opinion of the anxious mother, as she generally sees any change in her child's condition.

The tube was not worn all the time, some cases doubtless do better to remove it at times even if it has to be reintroduced, the patient can then take nourishment and water which helps very materially to tide them over the crisis. No two cases are alike in every detail neither are intubations governed by any fixed rules, remove tube often enough to see if patient can live without it, if it can so much the better. There were no complications in these cases, except the first one had an urticaria the second week after recovery.

If I were to treat a case of laryngeal diphtheria under the old line of treatment I would be very much handicapped, however, I believe many lives have been saved under such treatment. Well do I remember a case of an infant three years of age with membranous croup, it had been having difficult breathing for two days when I fumigated it with calomel, and filled the room with vapor, this gave the little fellow so much relief that he would ask his mother to smoke him, so she would smoke him with vapor and fumigate him with calomel. This case also recovered. I believe the best substitute for antitoxin is bichloride of mercury in large doses, I would give to an infant a few months old 1-60 grain every two or three hours until 1-2 grain is given daily. I gave this remedy to an infant sick with membranous croup at the same time the two cases of croup reported above. I added Tr. Iron to the bichloride. This child recovered. I shall not attempt to enumerate the many things both local and general that have from time to time been

used in the treatment of this disease.

I have given in a very brief way a mere outline of the new and old treatment of diphtheria in connection with the two cases reported in one family.

### HYDROCEPHALUS — FACE PRESENTATION — RUPTURE OF UTERUS—REPORT OF A CASE.\*

By J. C. BRICE, FLEMINGSBURG.

I wish to present for your consideration three unusual obstetrical conditions and to report a case in which all three of these rare complications were present.

#### HYDROCEPHALUS.

This is rare; different statistical tables show a frequency of from 1 in 1,000 to 1 in 3,000 cases. We know nothing of the causes of intra-uterine hydrocephalus, and therefore can not prevent it. It does not present any peculiar symptoms during pregnancy, and therefore, we cannot diagnose it without an examination. It formidably obstructs delivery and is a potent cause of rupture of the uterus, especially if the head presents, because (1) the head is so large that it cannot enter the pelvic brim, and therefore if no relief is given, tonic contractions follow, ending either in death or uterine rupture. (2) Owing to the head being unnaturally large, the lower uterine segment has to be unnaturally stretched, as the retracting uterine body pulls the lower uterine segment up. Abnormal stretching and therefore abnormal thinning bring about liability to rupture.

Hydrocephalus is not always diagnosed because it is rare and accoucheurs do not think of it. If the vertex is presenting, diagnosis should be easily made, (1) by the great size of the head, (2) by the wide separation of the cranial bones at the sutures and fontanelles.

*Treatment* is to tap the dropsical head, and deliver either by podalic version or by the aid of instruments.

#### FACE PRESENTATIONS.

Face presentations are not common. Various statistics give 1 in 200 to 1 in 500 cases.

The causes of face presentation are, (1) a disproportion between the size of the pelvis and the size of the head. Contraction of the pelvis often leads to face presentation. The same thing may happen if the head is very large, although the pelvis is not contracted. Enlargement of the head from hydrocephalus will have the same effect. (2) Uterine obliquity. The obliquity consists in a deviation

of the body of the uterus towards one side. Now if the head be so far extended that the occipito-spinal joint is in front of the line along which the uterine force acts, the effect of uterine contraction is more to increase extension till a face presentation is produced. (3) Conditions which hinder normal presentations, favor malpresentations of all kinds, face included (a) Excess of liquor amnii. When there is so much liquor amnii that the child floats freely in it, instead of getting engaged in the pelvic brim it may happen that when the membranes rupture, the child is in such a position that the face comes down into the os uteri. (b) Dead Children. In the case of dead children the tonic force of the muscles which help to maintain the foetal spine bent, and to keep the chin flexed is absent, and therefore extension is more apt to occur than with living children. (c) Twins. In plural pregnancies abnormal presentations are common, because both children cannot engage in the brim. Face presentations are therefore more common than in natural labor, but they are not more likely to occur than other malpresentations. (d) Rare conditions of the foetus, such as monstrosities, the cord being rendered short by being coiled around the child's neck; prolapse of a hand or foot by the side of the head, may prevent the vertex from engaging in the brim and bring about face presentation.

*Treatment.*—If it be possible to change the face presentation into a vertex, this should be done. But it is not always possible. It is impossible when the head has descended into the pelvic cavity. It is practically impossible when the presentation is produced by contraction of the pelvis or to the very large size of the child's head. Although it may be impossible to get the vertex to present at the brim, it will be very difficult to get it to stay there. There are two ways to change a face into a vertex presentation (1) by pressing the face up with the fingers in vagina, and pressing occiput down with hand over the abdomen; (2) pressing on the shoulders and breech. If you cannot succeed, leave the case to nature. If the pains are regular and frequent, the os fully dilated, and the head is not delivered in two hours after being engaged in the brim, help delivery, either with the forceps or perform podalic version, exercising care on account of liability to rupture of the uterus. If however, the chin is posterior, rotate the chin forward by the nearest route.

#### RUPTURE OF UTERUS.

Rupture of the uterus is one of the most appalling and also the most fatal of the ac-

\* Read before the Fleming County Medical Society, December 18, 1907.

cidents of midwifery. It is the most terrible as in most cases it can neither be foreseen nor averted. The frequency of this rare occurrence may be stated as about 1 in 4000. The elaborate statistics of Dr. Churchill show the accident to have occurred in about 1 in 1331 although it is most always during labor that rupture occurs, yet there are a certain number of well authenticated cases recorded as the result of violence or over-exertion of some kind.

*Causes.*—Anything which mechanically impedes the course of labor is a cause of rupture of the uterus. Among the causes that might be enumerated are disproportion between the pelvic outlet and size of the child's head; faulty presentations; forcible compression of lower uterine segment between the child's head and the bony pelvis; conditions which lead to excessive distension of the uterus, as hydramnios, multiple pregnancy; hydrocephalus; operative violence; the improper administration of ergot; malformations of the uterus; submucous fibroid; cancer; and other degenerative changes in the uterus. The womb may be also ruptured by external violence, or perforated in criminal attempt at abortion.

*Symptoms.*—The causes being so various, the symptoms are far from being uniform. Very violent uterine contractions with labor making little or no progress should excite our apprehension. There may also be excessive crampy pains through the lower part of the abdomen between regular contractions. The presence of Bandl's ring marking the distinction between the upper and lower uterine segments may also be noted. Patient's expression becomes anxious. Pulse quicker, breathing more hurried, but these are not sufficiently characteristic to arouse suspicion of the impending danger. Suddenly labor pains cease, the presenting part recedes or can easily be pushed up. There is hemorrhage from the vagina, patient becomes collapsed.

*Treatment.*—Extract child and placenta as rapidly as possible; control the hemorrhage; repair rent, if practicable.

I wish to report the following case.

At midnight, on January 24th, 1907, I was called to see Minnie G. a negress, age thirty-one years, in her ninth confinement. All of her previous labors had been normal. A neighboring midwife had been summoned on January 23, at 8 P. M. after the waters had ruptured. There had been no pains prior to the rupture of the membranes. The midwife reported that there must have been an excessive quantity of liquor amnii on account of so much saturation of the bedding, also that large amounts had escaped during the night. As the pains were feeble and far

apart, she returned to her home next morning, not being called again till 8 P. M. After her second arrival the pains increased in frequency and power without any appreciable progress of labor till midnight when I was sent for. Upon my arrival, I noted the pains were almost continuous, though not appearing very powerful. Cramping pains in abdomen not subsiding with uterine contractions were complained of. Patient begged for chloroform. Upon examination, I found a face presentation with chin posterior pointing to left sacro-iliac symphondrosis. I wish to state here that on account of the high position three examinations were made within one half an hour before the exact presentation was appreciated. In the meantime, the pains were almost continuous. The face had not yet engaged in the brim. Without an anaesthetic I passed my right hand well anointed into the vagina and with two fingers pressing up the face, and with left hand pressing over the right iliac region of mother against the head of the child, attempted to convert the face into a vertex presentation. Before I could congratulate myself upon the ease with which I had succeeded in accomplishing the change of position, to my horror, a gush of blood poured from the vagina and the child's head rapidly receded. Realizing the condition of affairs, I immediately despatched a messenger for Dr. C. R. Garr. In the meantime, I brought down a foot and delivered the body of the foetus, without trouble till the head engaged in the brim. With much difficulty, however, the head which subsequently proved to be hydrocephalic was finally delivered. The child, a female, was dead, in fact, I had felt no foetal movements after my arrival. At this time, Dr. Garr arrived, and without telling him the nature of the trouble except to state that he would find an unusual condition, asked him to deliver the placenta. On introducing his hand, his fingers could be plainly felt through abdominal wall of the mother, the contracted uterus lying in the right iliac region. The placenta was removed without difficulty. The shock to the mother was profound, deepening into collapse; pulse at wrist imperceptible; extremity to knees and elbows cold. Despite the hypodermic administration of strychnia and nitro-glycerine and local applications of heat, her condition showed no improvement. She lived until 7 A. M. January 26, about thirty hours after delivery. At no time did patient's condition warrant a laparotomy, besides the sanitary surroundings were such that an operation would have been almost homicidal. I feel sure that any such an attempt would have but hastened her death. Autopsy showed the abdominal cavity filled

with dark liquid blood. The rent in uterus extended through the os, almost to left cornua. The posterior vaginal vault was also badly lacerated, caused either by the extension from the rupture of uterus or else by my efforts to deliver the hydro-cephalic head which required much force. Hydrocephalus was not diagnosed until after delivery. The child's head measured between parietal eminences 8 1-2 inches, occipito-frontalis measurement 11 1-2 inches.

### THE WORK OF COUNTY SOCIETY OFFICERS.\*

By J. W. CRENSHAW, VERSAILLES.

#### *A Short History of Woodford County Society.*

During the year 1902, J. N. McCormack, the secretary of the State Board of Health addressed to each physician in the County of Woodford, a personal communication, requesting him to meet the secretary in Versailles on the 8th of July, on a matter of vital concern to each and every physician in the county. To this request, I find, on referring to the records, that every doctor in the county, with the exception of four, were present to meet the doctor, either from curiosity or a higher motive. Dr. McCormack gave a long talk, but one that seemed to be appreciated by his audience, the drift of his remarks being in the direction of a necessity for at least unity and a better acquaintance among doctors. The talk was illustrated with many examples of very recent occurrence and I think we all quite agreed with Dr. McCormack that we were all mutually dependent upon each other in a very large measure. The meeting had not adjourned before there was organized the Woodford County Medical Society, with John C. Lowry, of Troy, as its first president; S. M. Worthington, of Versailles, vice-president, and W. C. McCauley, also of Versailles, as secretary.

At this meeting, called by Dr. McCormack there were present twelve doctors out of a total of sixteen in the county.

July 12th, four days later, was appointed as the time of a preliminary meeting, at which meeting there were seven present. A program was appointed consisting of three papers, and as the regular time of meeting the second Tuesday in each month was chosen. When the second Tuesday of August came, there were present one reader of a paper and five other doctors. From this date till the 7th of January, 1904, there is no rec-

ord of any meeting having been held. Two or three of the doctors of the county, during that interval did all it was possible to keep even a little life in the society, but the thing was so cold it seemed dead. Meeting after meeting was appointed and a program arranged, but to no purpose. The thing was, to all practical intents, dead. Finally two or three decided to try quarterly instead of monthly meetings. The 7th of July, 1904, found seven present and a paper was read. At the next quarterly meeting, occurring in April there were present eight and a supper was served, but no essayist. There was no more meeting till October of the same year, which took place in Midway, when there were ten present, and the society was regaled with three papers. The next quarterly meeting took place in January, 1905, with eight present. From this date we jumped to the 21st of May, 1906, when Dr. McCormack again visited Versailles. Since that date, the society has been meeting quite regularly on the first Tuesday in each month, and the men appointed to duty have served quite regularly with only an occasional failure. There were no meetings for two months this past summer, but a good many of the men were away, amongst them the secretary.

#### CAUSES OPERATING AGAINST THE WELFARE OF THE SOCIETY.

There were many causes which served to prevent a healthy growth of our society from its inception, but I think they can all be summed up in the one word, "selfishness," and that selfishness blind, for to seek one's own good at the expense or slight of others is not policy, certainly not humanity nor Christianity. Doctors—some doctors—I mean, are constantly afraid that their fellow practitioners will take advantage of their absence to undermine their influence or to rob them of a patient. I have repeatedly heard it said that all medical societies were gotten up by a few and were controlled by these few purely for their own aggrandizement and profit in the shape of advertising and that the common herd who ministered to such success were mere tools to make the other fellow successful. Of course, if a man always carries a chip, he may expect somebody to knock it. If one never looks for nor seeks any good, he is very sure not to find it. The day is past when the utterance of such sentiments can find a respectful listener. As to the condition of our society at present, I should say it is good. We have, it is true, only about 66 per cent. of the doctors of the county who claim any connection with the society, but give us a chance. Rome was not built in a day, and to build the best society it must

\*Read before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

take time. It takes, sometimes, a long time to convert many a man to the most obviously correct way of thinking and there are some who never will be convinced that medical societies are anything but frauds and delusions. This work of "converting" falls mostly on the shoulders of the secretary, and he being a man who most likely has to paddle his own canoe, cannot give his whole time, and again he has to study his man. Some strongholds can only be captured by one way of approach and that hard to find out, and even more difficult of accomplishment.

#### AN IDEAL MEDICAL SOCIETY.

This is something that I shall not hope to see in my day, nor can it ever be accomplished till we have learned to fulfill the third petition in the Lord's Prayer: Thy will be done on earth as it is in Heaven. In other words, altruism—the seeking and promoting of others' good at the cost of one's own. The time may be long in the future, but I believe it is certainly coming, when every doctor will feel that his brother's reputation and welfare are his own. The older or the more successful practitioner will attend his society meetings as much to help others as to be benefited himself. Stop and think but a moment that no man, no matter how great his accomplishments can rarely attend any medical meeting without either communicating or receiving some good. In this ideal society let every man be strictly conscientious and then he can not help but see the direction in which duty calls him and that will be, not so much in aggrandizing himself personally, as in exalting to the highest plane the noble profession to which he belongs.

#### THE DOCTOR'S DUTY TO THE LAITY.\*

BY A. W. CAIN, SOMERSET.

First of all the doctor should be a gentleman in the true sense of the word, refined in manner, mild, amiable, not loud, but gentle, and last but not least, sober, truthful and honest. (2). The laity have a right to expect that the physician has at least a fair preliminary education. That he has received his diploma from an accredited school and that he has license to practice from the state board in the state where he proposes to practice.

(3). The laity have a right to expect that the physician give counsel to the public in relation to the subjects especially pertaining to our profession as in questions of sanitation, public hygiene, as to the location of

slaughter houses, the water and ice supply and legal medicine.

(4). The laity have the right to expect that the physicians give counsel in regard to quarantine and other measures to prevent epidemics of contagious and infectious diseases. In our experience this has always been cheerfully done by physicians and little, if at all, appreciated by the public.

It is the duty of the physician to respond readily and cheerfully to the calls of his patients, if made at reasonable hours. The laity have the right to expect that in a case of emergency that the physician in his ministrations should unite with firmness, cheerfulness and tenderness. The public have a right to expect that when patients are entrusted to our care that secrecy and delicacy should be observed and the familiar and confidential intercourse to which physicians are admitted should be guarded with the most scrupulous care and honor. The physician should be a minister of hope and comfort and should not be forward to make gloomy prognosis. Frequent visits are often necessary and desirable but should be made as near as possible at expected times. Unnecessary visits at irregular intervals are usually best avoided. They give undue anxiety to the patient and his friends.

(5). The public should not expect the doctor to do the nursing, and particularly to spend a large share of his time with one patient, much less should they expect him to spend the night. They should remember that he has other patients to look after, besides the doctor who does this becomes on such familiar terms with the family that he at least loses to a certain degree his influence as a physician and finds more difficulty in having his orders carried out. Besides this, in his constant presence he is apt to give too many drugs instead of adopting a recognized plan of treatment and adhering to it.

(6). The doctor should never abandon a patient because the disease is incurable for by continued attention he may greatly lessen the suffering of the patient and give comfort to the relatives.

The public have the right to expect that the doctor stay in his office as much as possible when he is not making professional calls or away in the interest of his profession or taking his annual vacation which every doctor should take both in the interest of his patients and himself.

Habit makes us what we are and the public have the right to expect that their physician's habits are good. The doctor should be truthful, industrious, sober and clean in both habits and dress. He should be, above all

things, punctual in meeting his engagement both with his patient and his brother physician.

The public have the right to expect that the doctor does not accept more patients than he can give proper care. I once heard of a young doctor boasting that he had seen fifty patients in one day. I have had the pleasure of an intimate acquaintance of an older physician who seldom spends less than one-half hour, often much longer, in making an examination and advising and prescribing for his patient. Which one of these would you prefer to attend you if you were sick? The public have the right to expect that the physician who undertakes to treat them have the time to give them the proper care and is not as a so-called doctor who was once here and who gained a considerable practice by his long and loud talking heard to remark when asked if there was much sickness, "O, yes, a great deal. I am now two weeks behind with my practice." Who ever heard our own, the lamented Geo. Perkins, Wyatt Norfleet or the now active, honored and most respected member of this society, Dr. J. W. F. Parker, standing on the street corner telling the public how awfully busy they were? I hope you will pardon this slight digression.

The public have the right to expect that the doctor is an active member of his County, State and National Societies. Without this he cannot be even a medium practitioner. He does not get started right. The poor fellow gets to thinking that the whole profession is against him. He grows self-conceited and thinks he makes no mistakes because he does not associate with any one to point them out to him. He has no papers to prepare, he enters into no discussions, he reports none of his cases and he discusses no cases reported by others. Without specific subjects upon which to work he fetters his energies upon useless literature, he is not called to see the difficult cases in his own town or county by other physicians because he has given no one a chance to know him. He only calls consultation when the family demands it or when he thinks it necessary for his reputation. The doctor who does not belong to his county society does not lay the foundation for that unity and friendship which is so essential to the dignity and usefulness of his society. He too often lets his angry passions arise against his professional brother. He may have had 500 cases of pneumonia and not have the understanding of the disease which comes from the intelligent study of a half dozen cases.

The public has the right to expect that this family physician is in good standing

with the organized medical profession. It is easier for him to select the best help for his difficult cases. His cases are better taken care of when he is sick or away from home, in fact he is a better doctor every way.

The public has the right to expect that the family doctor will not attempt to do what he is not competent to do. If the physician is in doubt as to a diagnosis he should ask for consultation. The patient is at your mercy in many ways, his life, character and money. If you are not competent be just and honest and tell him so.

The subject as here outlined we hope will be thoroughly discussed.

### THE LAITY'S DUTY TO THE DOCTOR.\*

BY A. W. CAIN, SOMERSET.

The paper preceding this one, to wit: "The Doctor's Duty to the Laity," was much more easily prepared because the literature on the subjects which is largely the writings of physicians is much more abundant on the former paper than on the latter. It is rather surprising that the medical profession has written so extensively on the duties of the profession to the laity and so sparsely on the duties of the laity to the profession. Yet this is in keeping with the noble profession of medicine. The only profession known who are working against their own interest in so far as finances are concerned. You have never yet heard of a lawyer spending his time and means in teaching his clients the evils of litigation and advising them how to get along in peace and harmony, nor have you ever heard of the clergy in any way advising his congregation in such a way as to reduce his salary. Yet it is an every-day occurrence among the practitioners of our county, State and Nation to hear of the family doctor advising his patients and their friends about the value of pure air, pure food, proper dressing and perfect sanitation. In this way reducing his annual income very largely for the benefit of the families who depend upon him as their medical adviser. In view of these facts it seems but fair that the physician is entitled to some consideration from the laity.

We submit some of the duties below and hope that many others will be brought out in the discussion of this paper.

First: Every family should employ a family physician. They should not wait until they are sick to do this, but while they are

\*Read before the Pulaski County Medical Society.

well they should select with the same care their physician as they would their spiritual or legal adviser. After this selection is made they should so inform the physician selected and give him an opportunity to become acquainted with the family and if any idiosyncrasies exist he should be so informed. A family who has no regular physician, but who has been heard to remark that they always got the first physician accessible and that they have no choice is pretty sure to have poor service and to have physicians who do not appreciate their practice. We all know families in this town who are good pay, who have no regular family physician, but who call one doctor after another often in such rapid succession that by the time one doctor arrives at the house from two to four more usually arrive to the embarrassment of the family and to all the physicians concerned. So much so that in a case of emergency the family would probably have difficulty in getting prompt and competent medical aid.

It is the duty of the family, after having selected a family physician to not employ any one else without his sanction and advice unless it be in a case of emergency or his absence, when such should be explained to the physician called, who, if he is a gentleman, will cheerfully relinquish the patient on the arrival of the family physician.

Of course if at any time the family desire a change in their family physician they have a perfect right to discharge the one employed and select another. But the families who are constantly making such changes at least show poor judgment and little knowledge of human nature.

The laity should call when possible, and if generally is possible, their family physician during the day. The physician but little if any below the angels in rendering service, still has enough human about him to require some sleep. He works or is ready to work from daylight till dark and we think that it is an imposition for him to be called up after he retires at night to see some one who has been sick for two or three days, or even for one day. Some of us have very painful recollections of making fifteen or twenty mile rides in the dark and storm and sleet to see patients who on our arrival have told us that their condition was the same as it was ten years ago when we prescribed *asafoetida* to them for hysteria. Again we remember on many a cold night with the icicles freezing on our faithful saddle horse's tail and fetlocks making ten mile visits in the country and finding our patient sound asleep, her husband undressed and retired, the fire all out and the house cold.

It is the duty of the laity to the profession not to call us at our regular meal hours. It seems to be a rather common practice here in town for calls to be made so that the husband can be present at the time of the doctor's visit and for this reason one of the meal hours is selected, never thinking that the doctor has to eat and usually tries to eat at the same time as other people do. The laity should never call and ask a physician to "come down at once" unless it be in a case of emergency and in this case the facts should be explained. No doubt every physician in town have families who make every call an emergency call. So much so that we become accustomed to it and when they say "Come at once," we recognize the family and our previous experience with their emergency calls makes us feel that there is no urgent demand to hurry. In this way the family have placed themselves in a condition that should an emergency arise that their family physician will not rush as he would otherwise to reach his patient.

The laity should not be in too great a hurry to call another physician if their family physician is not in his office. Many times we have known other physicians to be called and not knowing the patient or probably the exact location where he lives the family physician would have been able to have reached the patient much sooner and the embarrassment of a new doctor to a new patient and the turning over of the patient to the regular family physician would have been avoided.

These are only some of the duties of the laity to the profession, and we, as physicians should each of us attempt to educate our patients along this line.

## COUNTY SOCIETY REPORTS.

**Allen.**—Owing to the bad roads in Allen County, and as most of the members live from eight to twelve miles from Scottsville, we have decided not to have any meetings of the Allen County Medical Society until the fourth Tuesday in April. Our post-graduate course is doing good work here in Scottsville. We meet every Tuesday night. We complete the first six months of the course with this month. Those of us who are taking the post-graduate course think it is the grandest work our county societies have ever engaged in. The town that has as many as three doctors in it and is not taking this course is missing the treat of their lives. Some think that you can not run with this small a number, but you can; we only have four, and we have interesting meetings, and if you don't believe it, come over and we will show you. All that you have to do is to quit cussing each other,

decide that you want to know more medicine, join the post-graduate course, and you will soon be regretting that you did not join sooner.

A. L. WAGONER, Secretary.

**Adair.** — The Anti-Tuberculosis meeting in Columbia:—On the night of January 6th, 1908, a meeting was held in the Methodist church, for the purpose of appointing delegates to the Louisville Anti-Tuberculosis Convention. U. L. Taylor, the health officer for Adair County, in calling the house to order, said: "I have called this meeting at the request of the State Board of Health, for the purpose of having delegates appointed to attend a convention or conference in the city of Louisville, sometimes in the near future to take into consideration the best means of prosecuting the war against tuberculosis. It is a subject in which every man, woman and child should feel a deep interest. The public health has come to the front in late years as the subject of most importance of any that confronts us. The medical profession and other scientific men are waging a mighty war against the great white plague, as it is called. It is at this time the greatest enemy of mankind, and has been so for years. Its victims are more numerous than that of any other disease. When the great white throne shall have been erected, and the ancient of days shall sit upon it, and all the diseases of earth and their victims shall pass in solemn procession before him, consumption will head the largest and longest procession of any other disease. Statistics show that in later years, in the world, the victims of consumption have been more numerous than the combined victims of war, pestilence and famine. It has heretofore been considered incurable, and when its deadly fangs are fastened in any person, that person has been doomed to death. What adds greatly to its awfulness is the fact, that it seizes on the brightest and best of our young people, as well as the old. It knows no difference on account of race, color, of previous conditions or servitude. The young as well as the old are liable to be cut down by it. Several young people of this vicinity have lately fallen victims to its ravages. Heretofore it has been contended that it is spread altogether by heredity, that it descends from one generation to another. From father to son, from mother to her children, it sometimes skips over two or three generations and seizes on those of later years, and later generations. That theory has been opposed by some of our greatest medical thinkers, and they think that the theory of heredity has been exploded, and that consumption is spread by environment, or contagion. They are scattering many what they call facts and data, in support of their theories. This Louisville meeting is for showing to the delegates who are to be sent there the reasons

for the hope that is in them. Their plans and purposes are still in a crude state, but they want to show to the people that there is really something in their claims. There is a call also at that meeting for delegates from the county health boards to meet the members of the State Board of Health to consult about the best means to meet and combat all manner of diseases as well as that of consumption. A goodly number of the States have established sanitariums for tuberculosis patients, and claim that many cases have been cured by that means. But that would not be of much advantage to people living in the country. The State Board of Health want us to send delegates to the Louisville meeting in order that the delegates may see and learn for themselves the manner of treating this terrible scourge, and bring it to the country, to be used among our own people. Many diseases have been shorn of their terrors by modern sanitation. Small-pox, once the most dangerous and loathsome disease known to man, has been stripped of its terrors. Diphtheria, once the bane of childhood, and the terror of mothers, has lost much of its alarms. Yellow fever, always the scourge and the dread of the South, has been driven from the face of the earth. Why not consumption? But in order that this meeting may have the semblance of an organized body, I pause for the election of a president and secretary.

On motion U. L. Taylor was elected president, and Rev. A. R. Kasey secretary. The meeting was a representative one, composed of quite a number of our most prominent citizens. Four preachers, four doctors, four lawyers, and others. We had speeches from quite a number; all who spoke enthusiastically endorsed the movement with one exception. Judge Baker made a good speech, praising the doctors for their unselfishness in trying to prevent disease, and knock themselves out of business. He spoke of what had been done by sanitation; of quite a number of diseases that had been shorn of their strength by modern sanitary measures. A. R. Kasey, the Methodist minister made a very fine speech. He commenced by saying, that if preachers could do all they tried to do, there would be no more need for preachers. And if doctors could do all they are trying to do, there would be no more need for doctors. Doctors are trying to prevent all diseases, and thus throw themselves out of business. W. H. C. Sandidge, a Presbyterian minister made a speech in which he was fully alive to the importance of this move to stop the spread of consumption. All the doctors present made speeches along the same lines. But the speech of the evening was from James R. Hindman, ex-Lieut.-Governor of Kentucky; ex-Captain in the Federal Army; ex-representative in the Legislature, and ex-several other things. His

speech was the only cold water thrown upon the meeting. But the meeting was so warm and enthusiastic that it rapidly dried up all the cold water he could throw. It was intended for a burlesque, but it did not amount to the dignity of a burlesque. He positively denied that consumption was contagious, but he gave no reasons for his denial. He said that this meeting at Louisville had lost a car load of their supplies, consisting of 80,000 boxes. He said the doctors had too many theories of late days, and one can't keep up with them. Spoke of health officers visiting the schools, and trying to find out if any of the children had consumption, and he supposed if they did stop the consumption from school, they would have to stop the children from school and thus prevent them from getting an education. He spoke of Dr. Osler proposing to chloroform men over forty years of age, who had outlived their usefulness. I don't know what he aimed to make out that, unless he himself would be in danger of Osler's recommendation were it to be adopted.

But Hindman's speech had an end, and so did the meeting. After appointing quite a number of delegates, all the doctors in the county, all the members present, and several of the lawyers, some women, and some laymen, the meeting, after a motion from Judge Baker for the delegates on their return to call another meeting, and report their conclusions, adjourned.

U. L. TAYLOR, President,

A. R. KASEY, Secretary.

**Anderson.** — This society met with Dr. Witherspoon on Monday, February 3rd, at 2 P. M. The following members were present:—J. R. Murdock, Gilbert, Kavanaugh, Paynter, Witherspoon, Toll, Simpson, J. R. Duff and Leathers. J. R. Murdock read a paper on "Surgery of the Appendix." This paper covered several important points in diagnosis as well as giving the chief points to be observed in operating.

**C. M. Paynter**, besides opening the discussion, read an exhaustive paper on appendicitis, from the view of medical treatment as well as surgical. These papers and their discussion by the whole society brought out a great many different views of the various authorities on this subject.

After the discussion of several matters of local interest the society adjourned to meet with G. D. Lillard on the first Monday in March.

J. W. GILBERT, Secretary.

**Bath.** — The Bath County Medical Society met in the office of J. H. Taulbee, with H. Waldent, in the chair. The following officers were elected:

J. M. Feland, president; J. K. Wells, vice-president; H. J. Daily, secretary-treasurer; F.

P. Gudgell, assistant secretary; J. W. Jones, censor.

The new president took the chair and promised to begin the post-graduate work at once.

There being no further business, we adjourned.  
H. J. DAILY, Secretary.

**Christian.** — The Christian County Medical Society intends to make an honest effort to build up the society and put it in the very front rank of county societies in our State. To do this it will be necessary to secure the sympathy and hearty co-operation of every reputable physician in the county.

We are going to take steps to guarantee a full program at every meeting of the society, so that members can come with the assurance each time of papers to be read and discussed. We expect to arrange with those having papers to read to at least have them in the hands of the secretary so that the papers can be read by him in case of unavoidable absence.

With these promises on our part we feel that we can ask you to attend every meeting without fail and be prepared to furnish an essay or paper when you are called on to do so.

If you are not now a member, come to our next meeting Tuesday, January 21, 1908, in the parlors of Hotel Latham, and join our society. If you are a member, come and bring one or more new members with you. Anyway, come.

F. M. STITES, President.

J. PAUL KEITH, Secretary.

Diabetes ..... F. M. Stites  
Discussion... .. J. B. Jackson

At 1:30 P. M. the druggists of the city and county are invited to attend this meeting to discuss the relation of the doctor and the druggist.

The society met as per above program, 18 being present. Five applications for membership received. The afternoon session with the druggists was enjoyed by all. Next meeting, Tuesday, Feb. 1st, 1908 (every 3rd Tuesday in the month.).  
J. PAUL KEITH.

**In Memoriam—Dr. Benjamin Franklin Eager.**

Dr. Benjamin Franklin Eager, a beloved physician, skilled alienist and noble Christian gentleman, died Saturday, December 28, 1907, at his home in Louisville, after an extended illness of cancer of the gums, borne at all times with remarkable patience and fortitude. The remains were taken to his former home at Hopkinsville and interred with tender and impressive rites. His eminence and success as a physician were widespread in Kentucky, and both as a general practitioner and as an expert in mental diseases

he rendered humanity a blessing by his splendid skill. The good accomplished during his many years of active service, the lives he saved, the persons restored to health under his professional care, the hearts cheered and made brighter by the sunshine of his lovely life are beyond estimate. No one could speak of his character and career save in terms of warmest eulogy. His life, stricken though he was in the very midst of his usefulness, was well spent, beautifully rounded and inspiring and adorned with gifts and graces unusually rare. Few physicians were his peers and he was ever faithful to the finest ideals of the profession; he was in the foremost ranks of Kentucky alienists, and he was a man in every way above reproach. His spotless Christianity, his sincere and active devotion to advancing the cause of his Master, impressed one above all else. He was a member of the Christian County Medical Society, the Kentucky State Medical Association, and the American Medical Association.

Dr. Eager was a member of an old and excellent American family of English-Scotch origin. He was born in Jefferson county, Mississippi, July, 1848, and his life to early manhood was spent in Jefferson and Hinds counties. His education was obtained at Oakland College, near Rodney, and at Mississippi College, at Clinton, Miss. He was graduated in Cincinnati, O., at the Ohio College of Dental Surgeons in 1872 as valedictorian of his class. He was graduated in 1877 from the Louisville Medical College. Immediately after graduating he located near Newstead in Christian County, where he practiced his profession four years. In 1881 he moved to Hopkinsville, and three months afterward was appointed second assistant physician of the Western Kentucky Asylum for the Insane, under the superintendency of the late Dr. James Rodman. When Dr. Rodman retired in 1889, and Dr. B. W. Stone was appointed superintendent, Dr. Eager was promoted to first assistant physician in which capacity he served until April 9, 1896 when he resigned and re-entered general practice in Hopkinsville. In May, 1904, he went to Louisville to assume charge of Beechurst sanitarium and, on account of his health, retired from that institution October 1, 1906.

Dr. Eager was married June 21, 1888, to Miss Carrie Downer, a sister of Mr. J. W. Downer, of Hopkinsville. Mrs. Eager and three children, Benjamin F., Jr., Louise and Henry I. Downer, survive him. There are three brothers surviving, Rev. Geo. B. Eager, of the Southern Baptist Theological Seminary at Louisville, Rev. Dr. John H. Eager, for many years a Baptist missionary in Italy, and now residing in Baltimore; and Prof. P. H. Eager, of Clinton, Miss. His living sisters are Mrs. I. P. Trotter, of Hattiesburg, Miss., and Mrs. J. M. Joiner, of Cisco, Texas.

**Carroll.** — The Carroll County Medical Society met in regular session in the office of the secretary, J. P. Wheeler, president presiding.

There was no business of importance except the election of officers, the following being elected by unanimous vote:

J. R. Darbro, president; W. B. Messink, vice-president; F. M. Gaines, secretary and treasurer; P. V. Ellis and J. P. Wheeler, censors.

H. J. Slocum was elected to membership.

Society adjourned to meet Feb. 10th, 1908.

F. M. GAINES, Secretary.

**Fleming.** — The Fleming County Medical Society met in Flemingsburg on Dec. 18, 1907, C. R. Garr, the president in the chair. Only five members were present. It is a matter of deep regret to the faithful few, that so many of the members do not avail themselves of the opportunity to attend the county society meetings, and that nearly fifty per cent. of the regular practitioners have never become affiliated.

The resolutions adopted by the Kentucky State Medical Association at its last meeting relative to the patent and proprietary medicine evil, were read, and enthusiastically endorsed.

**J. C. S. Brice** read a paper on Hydrocephalus, Face Presentation, Rupture of Uterus; giving the report of a case in which all these rare conditions were present.

**C. R. Garr** read a paper, reporting a case of abdominal pregnancy, with operation at about the 7th month of gestation, the patient making a slow, but uneventful recovery. The doctor was highly congratulated upon the success of the operation, and for the able report of the case to the society. The society then adjourned to meet on the third Wednesday in January, 1908.

J. C. S. BRICE, Secretary.

**Garrard.** — The Garrard County Medical Society met in J. B. Kinnaid's office in Lancaster, January 31, and after attending to the ordinary business the annual election of officers was held.

J. A. Amon was elected president, and J. B. Kinnaid secretary-treasurer by a unanimous vote. J. B. Kinnaid was selected as delegate for the coming meeting of the State Medical Association. Nelson Mays, of Point Lick, was elected to membership.

The society adjourned to meet Feb. 12th, at which time a paper introductory to the study of materia medica and therapeutics, after which our society will meet every two weeks for post-graduate work. It was decided to thoroughly study every subject proposed and to meet for general review. By meeting twice a month we believe all will become more interested in our daily work and thereby create more enthusiasm. Our members have determined not to lag behind the

procession. We expect to take up the course of study outlined by J. H. Blackburn, and you may expect to hear from us in the future.

Society adjourned to meet February 12, 1908.

J. B. KINNAIRD, Secretary.

**Harlan.** — The Harlan County Medical Society met at Harlan, Feb. 1st, 1908. House called to order by vice-president, W. T. Nolan. The following subjects were discussed:

“The Indications and Application of Obstetrical Forceps”—N. S. Howard.

“Intestinal Antiseptics”—G. P. Bailey.

“The General Treatment of all Fractures”—W. T. Nolan.

W. P. CAWOOD, Secretary.

**Henry.** — The Henry County Medical Society met in Newcastle on Monday, Jan. 27th, 1908. Meeting called to order and presided over by Geo. M. Jessee, vice-president. This being the annual election of officers, the following were elected:—Geo. M. Jessee, President; O. P. Chapman, vice-president; Owen Carroll, secretary and treasurer; Webb Suter as delegate to the State Medical Society. J. P. Nuttall, O. P. Chapman and Owen Carroll were appointed to draft resolutions upon the death of W. T. Coblin and C. F. Leudeman.

A motion was made condemning the effort to create a damage suit insurance as advocated by the State Medical Society, and the same was carried.

It was decided by the society to meet again on March 30th and the following persons were appointed to read papers:

A. P. Dowden.—Acute Parenchymatous Nephritis.

John P. Nuttall — Chronic Parenchymatous Nephritis.

Everett Morris—Prophylaxis.

**Webb Suter** reports a case of small-pox at Turner's Station; the case was immediately isolated and quarantined and has about recovered at this date, and no other cases have been reported.

Quite a number of cases of scarlet fever and diphtheria have been reported during the last fall and winter with two deaths. They have been reported from different localities of the county and as a rule have been mild; there are now eight cases of scarlet fever in and near Newcastle; all are mild and are isolated.

Jno. P. Nuttall, former secretary of the society has moved to Campbellsburg, this county and is practicing his profession with exceedingly bright prospects.

OWEN CARROLL, Secretary.

**Jefferson.**—The Jefferson County Medical Society was called to order by the vice-president, Chas. W. Hibbitt. The president, B. F. Zimmer-

man was recently operated upon for appendicitis and is yet in the infirmary, but satisfactorily convalescing. Jno. J. Moren, treasurer, is also ill, having typhoid fever.

A resolution was introduced by Sam Brown Hays providing for the organization of an ophthalmological, otological, rhinological and laryngological section of the society, which was referred to the Executive Committee with instructions to investigate the feasibility of the plan and report to the next meeting.

**Oscar E. Bloch** offered a resolution providing for the appointment of a committee to formulate a plan looking to the official registration of trained nurses in this city, which was carried. The chair announced as members of that committee, O. E. Bloch, G. S. Hanes, and D. C. Martin.

Fourteen new members were elected to membership. This totals twenty-seven new members since Jan. 1st. Those elected at this meeting were:—Coolidge, Holland, Carpenter, Davis, Edelen, Willis, Willyard, English, Lukins, Croft, Rubel, Farback, Nichols, and Haack.

**E. A. Gardner** presented his transfer card from the Butler County Society, and same was accepted. The following scientific program was given:

## HEMORRHOIDS—REPORT OF A CASE

John Mason Williams.

Mr. President and Gentlemen of the Society:—I have brought these two men here to-night that you may interrogate them on the results of treatment which I have given them for hemorrhoids. There is no need for an examination of the rectum and anus, because both are normal at this time, which statement I believe the gentlemen themselves will verify.

The first of these patients is a dentist, and for twelve years prior to last summer, when I first saw him, he had suffered with prolapsing multiple hemorrhoids. He came to me with a request that I operate on him. After examination I told him I thought I could relieve him without an operation or causing him to lose any time from his business. He consented to a trial of the treatment and was given six treatments, each one week apart and then, after three weeks, was given a final treatment. After the first treatment the prolapse, which had continued for twelve years, disappeared. This man never went to a stool without his bowel coming down. He was always able to replace it, but was sometimes compelled to lie down for an hour or two and bathe himself with cold water. He did not lose any time from his business during the treatment. Being on his feet all the time made things a little more unfavorable for good results.

Case 2.—This man is a motorman. For twenty years he has had a prolapsing, multiple hemor-

rhoidal conditon, and I think it was about the worst case I had ever seen. This man had five large, separate and distinct hemorrhoids, two on either side and one posteriorly. The bowel always came down when he went to stool, and the first time he came to my office I told him to strain down and let the bowel come out, in order that I might examine it. He told me he was afraid he could not get it back. I reassured him on this point and he finally consented. After completing the examination I endeavored for half an hour to get the bowel back, but without success. The protrusion was fully as large as an ordinary teacup. He went home to bed and the bowel went back the next morning. An action with this prolapse was so painful that he always put it off until the last thing before retiring, and even then he would make all preparations for going to bed before going to the toilet. Then he would creep back to bed with this protrusion, hoping that it would disappear before morning, which it usually did. Prior to coming to me for treatment this man lost an average of fifty per cent. of his time from his work. He lost the first day after I gave him the primary treatment, but since that time he has not been absent from his work as a motorman for a single day.

In the first case the treatment was discontinued about eight months ago and in the other case about three months ago. The treatment used in both of these cases was the old quack remedy of injections of carbolic acid. I used a solution of different strength in each of these cases. My experience with this remedy has been that, where the condition is diffused and a large area is to be treated, the weaker the solution, the better the results; on the other hand, where the trouble is circumscribed and only a small area is to be treated, a stronger solution will produce more satisfactory results. In the first case I used a 16 per cent. solution. This contains one grain of chloride of zinc to one drachm of carbolic acid, with five drachms of either glycerine or pure olive oil. If I can get absolutely pure olive oil I believe I prefer it to the glycerine, but either will serve. At no one sitting are more than two injections made, usually one in each of the lateral walls. In none of the cases that I have treated in this manner, numbering over 340, has there been any inflammatory condition resulting. In these cases I would say that the average number of treatments per patient was seven or eight. It takes anywhere from four to twelve treatments, depending upon the degree of prolapse. In the above number of cases, making something over two thousand injections, I have never seen any signs of inflammation nor have I ever had any complaint from a patient; on the other hand, I have never had a patient who did not experience almost instantaneous relief.

In the second case reported to-night I used a solution of 33 per cent. The strength of the so-

lution used years ago varied anywhere from five per cent. to pure carbolic acid.

**Bernard Asman:** My opinion is that some hemorrhoids can be cured by the injection method, and that under certain conditions the injection method is quite justifiable and should be employed. I presume that Dr. Williams did not mean to say that he would use the injection method, indiscriminately, in all classes of hemorrhoids.

Soft, spongy internal hemorrhoids, that are distinctly separate from one another and well-defined, can be treated in this way and very successfully in a majority of instances, but it must not be forgotten that this form of the disease comprises but a comparatively small proportion of the total number of cases with which we have to deal.

Solid hemorrhoidal tumors, large or small, those in which there is a preponderance of connective tissue, if treated in this way are likely to become immensely swollen and painful and, even though ulceration does not take place, failure to cure will most probably result. I remember one case in which the hemorrhoid, originally quite small, attained nearly the size of a hen-egg following injection and a hard fibrous deposit was present for years afterward, in fact until the patient, after having suffered a great deal, consented to its removal by operation.

While it is true that a certain number of cases can be relieved by the injection method, I believe it is much easier and simpler, as well as much safer, to give the patient an anesthetic and remove the hemorrhoids. Then we can make a clean job of it, and be sure that the patient is completely and permanently cured. In certain instances where for some reason or other the patient can not be given an anesthetic, and the case is a suitable one, the injection method is well worth a trial, but even in these cases I usually prefer to remove the hemorrhoids under local anesthesia, as being a safer and surer mode of procedure. It must not be supposed that all hemorrhoidal operations require a general anesthetic. Many cases, in fact nearly all uncomplicated by other rectal or anal disease, can be successfully treated by means of local anesthesia.

**G. S. Hanes:** I am sorry I heard so little of Dr. Williams' remarks. I presume there has been as much said about the treatment of piles, as any physical affliction man has ever had. It matters not whether man grew by the process of evolution into a biped, or was so made, in some miraculous manner, the fact remains, that the erect posture, and the absence of valves in the veins, conveying the blood from the pile-bearing area, is the dominant cause of this trouble. It is easy to see that the thinnest and weakest part of the vessel wall, which is at the lower extremity of the bowel, is exposed to the maximum amount of pressure, consequently, we always find piles

produced at this point. Then we believe, that man has always been exposed to this affliction. Palliative agents have been used in the treatment of piles, ever since we have had a history, and no doubt, at a time, long before this. The number of remedies brought forth would be beyond estimation, even at the present time, almost every newspaper and magazine contain advertisements of some new and certain remedy, which, in a short while, is forgotten and replaced by another of no more virtues or reliability. The injection of a chemical irritant, into a pile tumor, has been practiced for a number of years, and was for some time in the hands of advertising quacks. Later the medical profession ascertained the nature of the treatment, and from that time to the present, the very best men, who do rectal work in this country and abroad, have tested its merits, time and time again, and I speak the truth, when I say, not one of these men rely upon this method, except in the most limited way. It is the concensus of opinion among all leading rectal specialists, that in the vast majority of cases of hemorrhoids, the application of this method of treatment is entirely irrational. Dr. Kelsey, of New York, thoroughly tested this method of treatment. At one time he became quite enthusiastic in its use, but when all the evil consequences and complications had arrayed themselves before him, he frankly retreated from his enthusiastic grounds and said himself, that it could only be practiced in selected cases. Dr. Edwards, of London, who has done more rectal work than any man living, told me he had employed the injection method many times, and he looks upon it really as a palliative measure in more instances than that of a cure. He said he often used this method in the treatment of busy doctors who will not go to bed, for a week or ten days: the majority of these cases return from time to time for treatment. It is absolutely certain that any man makes a mistake who attempts to treat hemorrhoids by this method, only. In fact, the most successful treatment of piles, as they occur in one's practice is not, by any one method, but the means employed to affect a cure should depend entirely upon the pathological condition with which we have to deal.

If Dr. Williams could see the vast number of cases, treated by the injection plan, who have just one complication, and that is ulceration, the ardor of his enthusiasm would be much reduced.

**E. O. Witherspoon:** My experience with the injection method of treating hemorrhoids has been confined to the removal of two eicatricial tags following treatment by that plan. I had the pleasure of two weeks' stay with Professor Morton, of Philadelphia, who uses this method extensively for reasons which I think are exceedingly good. First, the patient wants to be re-

lieved of his suffering; second, they will not submit to being anesthetized for an operation. Morton, however, will not use the injection method for external or mixed variety of hemorrhoids; he confines himself strictly to treating internal hemorrhoids in this manner, and he says his experience is that a cure does not always result; that patients who have been subjected to the injection treatment frequently have a relapse in from three to five years.

I believe with Dr. Williams and Dr. Morton, that this plan of treatment should be used in cases where the patient does not take kindly to an operation. However, I think if an absolute and permanent cure is desired, operation should be performed.

**John Mason Williams, closing:** I wish to thank the members for their discussion.

First, as to the promiscuous use of the injection method of treating hemorrhoids, I agree with the gentlemen who have spoken, that no intelligent man would inject an external, protruding pile. In all such cases that I have seen recently, I have used palliative treatment for a few days, then I inject the internal hemorrhoids. An external hemorrhoid is most always associated with internal hemorrhoids, and I believe that if we can cure the internal condition, the external pile will also be cured through the circulation. Therefore, I treat these external manifestations with applications and confidently expect their cure by curing the internal hemorrhoids.

As to divulsion, how many of you have seen those cases where paralysis was the result of a too active thumb while the patient was anesthetized. Even though this only happens in one case out of a thousand, that man's condition of incontinence due to paralysis is much worse than the condition we sought to remedy.

As to the permanency of the cure by the injection method, I consider that the cure following the plan is decidedly more permanent than removal by cautery or ligature. How many patients do we find it necessary to operate on a second time following both ligature and cautery methods as a result of incomplete cures. Again we are called upon to treat a stricture, the result of removing too much mucous membrane with the ligature or clamps. Cases have also been reported as dying of secondary hemorrhage, following both the ligature and clamps and cautery. General anesthesia is extremely dangerous in rectal operations. I have never seen a stricture or incontinence resulting from the injection treatment.

## A SYMPOSIUM ON SCARLET FEVER. PROPHYLAXIS AND TREATMENT.

BY HUGH N. LEAVELL.

The prophylactic treatment of scarlet fever must, of course, take into consideration the measures used to prevent others from being contaminated by one who is already infected, since there is no known means of aborting an attack once begun. No matter how mild an attack one patient may be having, another person who presents a fertile soil may contract a most malignant case from it. Only three persons should be allowed to see a case of scarlet fever, the doctor and two nurses—one on duty during the day and the other at night. For convenience of study I divide the prophylactic treatment into three divisions:

1. The care of the patient.
2. The care of attendants and nurses.
3. Fumigation, disinfection.

The care of the patient's body deserves the first consideration since from it others must be contaminated. All discharges from the patient should be thoroughly sterilized before they are taken out of the sick room. The desquamating skin is not the only infecting medium—by some it is claimed little infection is carried in this way—any discharge pathological which ensues during an attack of scarlet fever must be considered virulent as long as it exists. A suppurative gland, an otitis media, a purulent rhinitis, a membranous angina must all be eliminated before a patient can be considered safe to come in contact with any one who is not immune—while this may be said by some to be going a little too far, cases are on record to show the truth of this statement. Holt says:—"It is possible for them to convey the disease during a period of several months. One case is recorded in which scarlatina was communicated through a purulent nasal discharge after eleven weeks; another in which the opening of a post-scarlatinal empyema in a surgical ward was followed by an outbreak of scarlet fever."

The skin of the patient should be anointed twice daily with some bland unirritating antiseptic oily solution from the incipiency of the attack. I am in the habit of using 1-200 to 1-400 solution of carbolic acid in olive oil. It is often surprising to see how much desquamation can be prevented by this technique and it certainly prevents almost entirely the dissemination of scales beyond the patient's bedside. There can be no doubt that it also lessens the tendency to development of kidney lesion by keeping this emunctory organ in a supple and pliable condition. By

gently massaging as the oil is applied it also lessens pruritus to a marked degree.

2nd. Care of attendant and nurses.

The doctor should wear a rubber coat and cape cap when making his visits, and should have them wiped off with a strong carbolic or bichloride solution by the nurse as he leaves the room.

If the doctor should not have the appurtenances at hand he should wear his overcoat in the sick room and wash his face and hands in an alcoholic solution as he makes his exit. The doctor should, if possible, make the call to his scarlet fever patient the last of the day and take a long drive before going home.

The nurse should not go out of the sick room with the same internal clothing that she wears while nursing the patient. Even more care should be given to her hands and face than is required of the doctor. All of her clothing should be fumigated and washed and boiled before going to another patient—her hair should also be washed in a 1-4,000 solution of bichloride. In regard to the third division of the prophylactic treatment I will say one word—formaldehyde.

The medical treatment of scarlet fever may be divided as follows:

1. Care of the disease and the patient.
2. Treatment of complications.
3. The serum treatment.

"Trust in God and keep your powder dry" may be applied in a medical way to all self-limited diseases by saying and using "masterful inactivity."

Too much cannot be said against the doctor who uses diuretics to prevent kidney lesions, indiscriminate use of the bromides to prevent meningitis, or dionogen in the tract to prevent middle ear trouble or glandular involvement in the neck. A slight albuminuria is expected in 49% of cases and does not necessarily mean an oncoming kidney trouble—convulsions may usher in an attack and leave as soon as it is seated. Erythematous angina merely means one of the many symptoms and may linger long enough to produce membranous angina or noma if encouraged by irritating sprays and gargles.

If an eruption is not "out" sufficient to suit you or the nurse remembers that it has been "out" long enough to suit the patient and he is the one you are treating. You will not do your patient's heart or vaso-motor system any good by making them work over time in sending a little more blood to the skin in order that you may feast your eyes on a beautiful scarlet eruption.

Hyperpyrexia is a very good index as to the virulence of the attack and may lead you to be more alert as to development of complications. Unless too long continued and a

menace in itself, do not mask this important symptom and make your patient miserable by using cold baths. To be brief, wait until you have something to treat and then go after it with all your might. Angina may be productive of a great deal of discomfort and lead to cervical adenitis, especially the membranous or more serious varieties. Benefit may be derived from irrigation of the throat with Dobell's Sol., followed by soothing oily applications.

When adenitis develops local applications of Ung. hydrarg., Ung. belladonnae and ichthyol or iodine may be used, but are useless after fluctuation is noticed. Early evacuation of pus must be the rule as it is in other surgical conditions. Poultices before and after incision are useless and may increase the necrotic area. Ice bags may be used for a short time. Hyperpyrexia, if too long continued may be controlled by the fan bath, which consists of sprinkling a sheet with cool water and the use of a fan by the nurse to hasten evaporation. If the heart action is good, no objection can be raised to phenacetin, besides being an antipyretic it also has the property of a diaphoretic and is soothing to the nervous system. If kidney lesions develop, the bowels should be used as an eliminating organ and the kidneys flushed with milk and water. If the excreting organ of the kidney is affected refrigerant diuretics or caffeine may be used. Rectal injections of normal saline solution may induce the kidney to perform its functions. I have had one case of total suppression after using blood-letting, diuretics, diaphoretics and purgatives the case went on to a fatal termination. I have never heard of a case of total suppression following scarlet fever get well.

If decapsulation ever has done any good, it might be suggested as a *dernier ressort* in this class of cases.

The ear and throat complications have been mentioned by the preceding gentlemen, and need no further elaboration.

The fact that a scarlet fever throat offers a fertile soil for diphtheria must not be lost sight of. Antitoxine is useful whenever and wherever the Klebs-Loeffler is found.

Antitoxine has been used as an immunizing agent in scarlet fever, but reports of results are lacking in authenticity and it might be well to suggest that it had better "stick to its specialty." Antistreptococcic serum is useful in those cases presenting great toxemia due to any suppurative trouble complicating scarlatina.

It is confidently expected that in the future we will have a serum which will do for scarlet fever what antitoxine has for diphtheria. A great deal of research work must yet be done,

however, as we have not been able so far to find the germ itself, which is responsible for the trouble. It is well not to fire into the brush-pile of uncertainty to kill something we can't see.

#### POSSIBILITY OF IMMUNE SERA.

BY E. S. ALLEN.

The very fact that scarlet fever has the period of incubation, that it is both contagious and infectious, eliminates all doubt from our minds as to the class of etiological factors that are responsible.

The general paralysis of the vasomotor system with death of the epithelium most distant from the nutrition, prove the presence of an increasing vegetable or animal poison. The immunity following the attack makes it appear bacteriological. Many investigators have endeavored to isolate the specific micro-organism but without success.

Loeffler, Frankel and other German physicians first demonstrated the presence of streptococci in cultures prepared from secretions taken from the throats of scarlet fever patients.

In 1891 Kurth found in the throats of scarlet fever patients, in pus from the cervical abscesses and in the viscera of persons who had died from scarlet fever, a streptococcus which formed a twisted gelatinous mass when thrown in broth. Mervyn Gordon afterward found the same form present in 20 out of 27 scarlet fever patients, in the internal organs of most patients who died from the disease and the fluid of a scarlatinal pleuritic effusion.

Babinski and Sommerfeld contemporaries of Gordon, found a streptococcus having virulent properties and generating a toxinic all cases of scarlatinal angina, and in cultures made from the viscera, bone marrow and blood of 142 children in whom the disease terminated fatally. Before considering the serum treatment of scarlet fever we must establish definite idea as to which micro-organism plays the greater role as a causative agent.

It seems apparent that streptococci have some part to play, either as a causative factor of the disease proper or the sequelae and complications, for streptococci are generally present in the throats of scarlet fever patients, and these are often found in the blood and internal organs, but the fact that they are found in the throats and blood of healthy people suffering from other conditions than scarlet fever prevents us from holding the streptococcus responsible as a causative agent. But we must not forget the fact that there are possibly as many different varieties of streptococci as there are breeds of horses and perhaps

we have as many peculiar characteristics, so after all it is possible that some variety of streptococcus is responsible, though Mallory has demonstrated a protozoa which he believes plays some etiological role, yet other investigators are of the opinion that these protozoa are nothing more than degenerated cells. After all the streptococci are the only class of germs that we have any evidence against, so our prophylaxis and therapy must be in connection with them.

We must ask ourselves just why a person becomes infected and why do children under the age of fifteen have scarlet fever out of all proportion to all other ages?

It is possible that the molecular make of the young cell is not stable enough to generate side chains or receptors in sufficient amount and rapidly enough to antidote the toxic group before it fixes on the cell or the agglutins and lysins of the blood chemically imperfect at this age or do the alexins fail at this young period to opsonize the micro-organism so that the phagocytes can feast.

Let us suppose that streptococci does play some part in scarlet fever, either as a causative agent in producing the disease proper, or as only influencing the complications. We must bear in mind that we have not isolated the exact class of streptococci that figure in this disease, so it is quite evident that the antitoxine with which we are to immunize our patient must be of multivalent origin, then we are at once confronted with the proposition of taking chances as to whether the variety of streptococci used in the production of the serum, include the class that play a part in scarlet fever.

Are we to generate an immunity by inoculating the individual with receptors generated by some susceptible animal, allow these receptors or thrown off side chains to unite with the heptophore group of the toxine radical, giving nature a chance to generate her own receptors in excess while the artificial side chains are rendering inert the toxine of the streptococcus, or are we to stimulate the appetite of the phagocyte by increasing the sensitizing property of the alexines of the blood, thereby rendering the bacteria more palatable to the phagocytes.

It has been demonstrated by Nuttall that normal serum possesses bactericidal properties. Pfeiffer has shown that immune sera possesses bacteriolytic properties in the absence of cells. It has been found, however, that cases of protection results from the use of animal serum where no such bacteriolytic action could be demonstrated. Such is the case with the streptococcus. It is now pretty generally accepted that immunity in these cases

is due largely to the phagocytic action of the leucocytes.

It was Elie Metchnikoff who taught us that susceptibility to, or immunity from infection is essentially a matter between the invading bacteria on the one hand and leucocytes of the tissues on the other. He believes that the serum constituent played a very important role, but this role consisted in their stimulating the leucocytes to take up the bacteria. Thus if a highly virulent organism is injected into a susceptible animal the leucocytes appear to be expelled and unable to deal with the microbe which multiplies and causes the death of the animal. If, however, the suitable immune serum injected into the animal before inoculation, the phagocytes attack and devour the invading micro-organism. Admitting that the phagocytes play an important role in certain infection, the question must still be considered whether the immune serum has acted on the injected microbe or on the phagocytes. From experiment with the streptococcus on the lower animals and man and their relation to immune serum and phagocytes, it appears that serum therapy must be along the line of increasing attraction between streptococcus and the leucocytes and in order to do this we must ascertain what the opsonic reading for each class of streptococci with the class for which the index is the lowest, must be the one that the body is least protected against. I should think it necessary that all of our streptococci with which we are to experiment, should be gotten from the throat, blood or excretions of scarlet fever patients, for as immune sera against the streptococcus is bacteriolytic for the streptococcus alone and has no influence on the staphylococcus so the immune sera against one variety of streptococci has no bacteriolytic action for the other varieties and as injection of one variety of dead streptococci increases phagocytosis for the variety injected, then you see how necessary it is to be certain that the streptococci which we are to use must be the variety always associated with scarlet fever.

Russian investigators report encouraging results from the injection of dead streptococci into those exposed to scarlet fever. It seems to me that if immune sera so disarms the streptococci as to make it an easy prey for the phagocyte and possibly at the same time stimulating the bacteriolytic action of the phagocytes, that this method of immunity would be more rapid than inoculation with dead streptococci. For when dead streptococci are injected for the purpose of raising the streptolytic property of the white cell, the opsonizing substance is made by the individual and there is necessary delay and then we

are taking chances as to whether we have energy enough to generate alexines.

While, if we inject the individual with an immune sera for streptococci, then the alexine is already chemically prepared by our first animal to sensitize the streptococci and make them more attractive and palatable for the phagocytes.

A Russian investigator reports having vaccinated 767 children in exposed districts and only eight of 767 had scarlet fever, and these 8 were only vaccinated once. In a district where the percentage of those who had scarlet fever was 16, of the infected children, only 1.4% had fever. It is an accepted fact that streptococci are intimately associated with scarlet fever from the very first, and there is no doubt but what injection of suitable doses of streptococci or of immune sera, for streptococci might have some influence on the disease.

#### "EAR AND THROAT SEQUELE."

BY GEORGE A. ROBERTSON.

There are three degrees of severity in scarlatina angina.

The catarrhal form with a diffuse blush of bright red over the pharynx, tonsils and fauces in very mild cases. In severer cases the redness is more intense. The swelling and oedema greater, small patches of yellowish deposits appearing on the tonsil the second or third day. These look like follicular tonsillitis and can be wiped off.

The membranous form with greater redness and swelling and about the second day patches appear upon the tonsils of a grayish exudate. This may confine itself to the tonsil, but more frequently spreads along the faucial arches and the posterior wall of the pharynx till it fills and covers all the mucous surfaces. There are a few marked differences between this form of inflammation and true diphtheric exudate; it being of softer texture and slightly less adherent. There is a greater tendency for the exudate to advance upward. The nose and the naso-pharynx are usually covered with the false membrane. True diphtheria more frequently involves the larynx. The exhaustion is greater and the time of appearance is later than is usual for cases not complicated with true diphtheria infection. There is a tendency for reformation of the membrane more quickly when removed than in the pseudo membranous variety, the color of the exudate and the deeper red and congested appearance of membranes helping to make the diagnosis. True diphtheria complicates the severe cases of scarlet fever more frequently than may be

generally believed and the use of antitoxine should not be delayed, though a positive differential diagnosis is often very difficult. This inflammation may even spread rapidly into the Eustachian tube and to the tympanic cavity.

The third and worst form of angina is the gangrenous variety. Where necrotic patches appear on the tonsil and also upon the palate and pharynx. There is practically no reparative process made by nature and the cases are rapidly fatal.

In scarlet fever we find the mucous membranes infiltrated with streptococcus. They develop in such enormous proportions that much time and effort has been made to pin down upon this micro-organism, the responsibility for the disease. However the best authorities agree that the streptococcus is not a cause, but rather an accompanying evil, that the conditions are most agreeable for its rapid development and it takes advantage of the situation.

Investigation shows that every case where the tonsils are hypertrophied, where the lymphoid tissue of the pharyngeal ring is excessive, the streptococcus abounds. So it seems reasonable to expect more severe throat symptoms in these cases. With a nidus of infection and a good culture medium, the inflammation proceeds from the tonsils to the naso-pharynx involves and spreads rapidly among the many foldings of the adenoid tissue, pushes forward into the nose and gathering strength as it advances, rapidly, includes the ear, and all the accessory spaces. The antrum of Highmore being also involved.

It might be well right here to comment upon the excessive secretion from the nose and mouth, and that during the time there remains any discharge, during that time there is a constant danger of infection being carried. Many observers lay more stress upon this source of infection than upon the desquamating skin. Likewise the pus from a discharging ear may spread the disease.

Infection of the middle ear is the most serious complication.

How easy to understand this condition when we realize the large proportion of cases having adenoids. Here exist a cause for trouble, even when no scarlet fever has lowered the vital resistance. This growth in the vault of the naso-pharynx keeps up a sufficient amount of venous engorgement to obstruct the circulation in all the adjoining tissues. There is constant irritation and fullness of the Eustachian tube and a hyperaemic state of the tympanic cavity. The streptococcus lurking to the folds of the adenoid tissue ready for business, certainly needs

little more encouragement to jump in and infect the ear.

Shall we wait for definite symptoms of otitis before we examine the ear? Hardly a wise plan! Daily or at least frequent looking will give us earlier evidence and a better chance to abort the trouble.

Fully 20% of the cases of scarlet fever develop otitis. In severe throat cases the percentage runs higher. The otitis is generally bilateral, often most insidious in development. In very young children or those too ill or delirious to notice their condition, the complication may be overlooked till we find pus running from the ear.

Examination brings out three distinct pictures of the tympanic membrane.

In one degree we find upon examination the tympanic membrane bulging, very red and some swelling of the walls of the auditory canal, great pain and fever. Only a free incision offers any hope of abating the pain and the destruction. Unless the discharge is free enough to keep the incision open, the operation will have to be repeated.

In the second degree the drum may or may not be bulging, the membrane has a macerated appearance, is lusterless and all landmarks are obscured or lost. In these cases there is little or no pain and only a rise of temperature gives the cue to the situation. Early perforation may here take place. If not, a free incision will deplete the membranes. It also gives us the point of election for the perforation.

The third variety is subacute. The drum is more or less transparent, slightly pink in color, some effusion in the cavity. There is little or no pain, perhaps a transient ear ache. There is always an indication of trouble shown by a slight rise of temperature. An opening made in the drum will usually relieve the condition. Incision of the drum is made as follows: Thoroughly cleansing the surrounding parts, the canal is douched with solution of bichloride and carefully wiped out with pledgets of sterilized cotton till dry and a clear view of the bulging drum gained. Then a narrow bistoury introduced and an incision begun on the posterior upper part of the drum, above the most prominent point of swelling. It is continued along the posterior edge of the drum till a long semilunar cut extends to the very lowest point of the membrane. The pus and discharge from the middle ear cavity is absorbed upon pledgets of cotton, and a wick of gauze introduced down to the incised membrane. This covered with a piece of cotton. Changing the cotton frequently and the wick twice or three times in

the day as is necessary to keep perfect drainage.

Infection easily advances from the middle ear into the mastoid cells, here to set up those destructive changes that may end in infection of the meninges or thrombus of the sinus. Pain behind the ear that does not lessen after free incision of the drum or in cases where a profuse discharge from the meatus persists even if no tenderness is found over the mastoid are indications for opening the mastoid cell, not only to relieve the pain and stop the discharge, but especially to save the hearing.

As a cause of permanent deafness and deaf-mutism, no disease of childhood compares with scarlet fever. In collected statistics of nearly 6,000 deaf mutes, 10% owe their condition to otitis following scarlet fever. From destruction of ossicles, from caries of semicircular canals, cicatricial closure of the auditory canal and changes of the auditory nerve.

Permanent change in the integrity of the ear of a lesser degree occur in nearly every case, fully 60 % have decidedly lowered appreciation of sound. Children under four or five years soon lose what little knowledge of speech they may have if the hearing is diminished.

Meningitis may follow the purulent otitis by advancement through the squamo-petroal fissure, even though perforation has taken place and pus is flowing from the ear. The idea should not gain credence that a running ear is bringing the infection away from the vital part, for unless there is free incision of the drum and we know a great amount of pus is not forming than is flowing out, the dangers are increasing, not diminishing.

Treatment of the throat is largely one of oral hygiene and simple alkaline washes and douching the nasal passages. Local applications are not only very difficult, but probably as injurious as useful. The dangers of Kleb-Loeffler bacillus complication demands the use of antitoxin, even though the positive diagnosis of diphtheria has not been made. In severe cases with much exudate and with septicemia, the use of streptococci serum is imperative.

As to the otitis, cleansing the naso-pharynx must be frequent and thorough, to free the pharyngeal opening of the Eustachian tube. The pain in the ear is relieved by warm application, 1% solution atropine in glycerine and water, then followed by incision as soon as any bulging or redness tells of fluid in the middle ear, and frequent douching with hot antiseptic solutions.

Many attacks of tonsillitis which develop during the period of convalescence may be but

cases of reinfection, a further emphasis upon the necessity for thorough care of the throat. The close relation of the tonsil and adenoid to the severity of scarlatinal angina, and to the frequency of middle ear complications, encourage us to feel our studies and our opinions upon the dangers of neglecting these excessive lymphoid growths in a serious menace to the individual health and increases the spread of contagious disease.

### DISCUSSION.

**W. H. Wathen:** Just a word with reference to the use of anti-streptococcic serum. I take the position that there never was a case of scarlet fever cured by the injection of this serum. It has been shown by Hectoen and others that it has no more opsonic power than does the ordinary horse serum. Therefore, it is totally worthless as a specific remedy. There are many varieties of streptococci; in fact we do not know just how many there are and never will. When we inject dead sterilized bacteria into the system they must be of the same variety as those of the conditions that are causing the disease; in other words, in streptococcus diphtheria, for instance, the serum must be made of the streptococci that cause the diphtheria. I do not believe we will ever be able to make a serum that will be of any benefit in these cases, or an emulsion that will be of any benefit unless it is made of bacteria corresponding to those found in scarlet fever.

Now, as to the question of the action of the chemical products, called opsonins, in the blood serum, that is a much-mooted point; we do not know. Up to this time it has been increased almost entirely by the injection of dead sterilized bacteria. Following the injection the opsonic index sometimes does not raise for twenty-four to twenty-eight hours. Therefore, we must conclude that we do not introduce the poison into the blood serum, but that some change occurs in the leucocytes which enables them, by some process, to come in contact with, engulf and destroy the bacteria; in other words, it creates an anti-toxic enzyme in the phagocyte that destroys the toxic enzyme caused by the bacteria.

**H. E. Tuley:** The society is to be congratulated that Dr. Allen was asked to prepare this paper as he has given us one of the best papers on the opsonic index and serum therapy that we have heard for a long time. I wish to mention one or two points not covered by the paper. One of these is the anomalous cases we sometimes see. I consider myself fortunate that I have not seen a great many cases of scarlet fever. I know of no disease I dread as much. I lost one little patient, who developed one complication after another. She had a severe toxemia with high fever; a membranous angina following a

double middle ear involvement, an edema of the glottis necessitating intubation with a closure of the glottis over the intubation tube necessitating tracheotomy, finally pneumonia developed, followed by pulmonary edema and death.

I recall another anomalous case in which diagnosis of scarlet fever was not made until ten days or two weeks after the patient had been dismissed, and at no time was there any rash on the body, this case belonging to that class known as scarlatina sine exanthemata. This was diagnosed as gangrenous tonsilitis. This boy, who was fourteen years of age, came to my office one day after his dismissal and wanted to know why his hands were peeling. While in my office he peeled almost the entire skin off one finger. This was unquestionably a case of scarlet fever, which had been unrecognized.

In the treatment of these cases, especially in the care of the nose and throat, I think the greatest caution should be exercised in douching and irrigating these organs because of the possibility of forcing the solution, in which the mucous and material from the throat is incorporated into the middle ear, resulting in infection of the middle ear which, complication I believe, is more to be feared than any other.

It would be a good thing if we could have an opsonic index taken of all cases and bacteriological investigation made of all throats in which there is a membranous angina, but I believe when we have severe ulceration of the throat with formation of a false membrane, we should administer diphtheria anti-toxin without waiting for diagnosis of diphtheria to be made. The use of the streptococcic serum in those seven toxemic cases is a step in advance, and should be considered in all severe cases.

**Florence Brandeis:** I had an experience recently which I should like to relate. I saw a child who had complained of not feeling well Saturday, and on Sunday morning was taken quite sick at the breakfast table. About ten o'clock on Sunday morning I received a telephone message that this child was very sick, and vomiting continually. I ordered calomel and a hot bath and told the mother to report to me later. About 2 o'clock she called me and said that she believed the child had measles. I went to see him and immediately saw that the child had scarlet fever; he was covered with typical rash. I made a tentative diagnosis of scarlet fever and went to see the child the next morning, when I found my diagnosis correct. On Tuesday morning there were a number of spots on the tonsils and I gave him a dose of 3000 units diphtheria antitoxin. On Tuesday evening Dr. Barbour saw him with me and repeated the dose of 3000 units of the antitoxin, giving in addition 10 cc. of Mulford's streptococcus antitoxin. On Wednesday morning his temperature had fallen. I gave him another dose of the antitoxin in the

morning and when Dr. Barbour saw him Wednesday evening he was given another dose, one of 10 cc. on Thursday A. M., P. M., and a sixth dose on Friday morning. On Thursday night he passed complete cast of the naso-pharynx during irrigation. This is the end of the fifteenth day and his temperature is normal, and all the induration of the neck has disappeared. There was only the slightest trace of albumin in the urine.

I think this recovery was due to the early administration of antitoxin. February 8th, now at the end of the 4th week he has just recovered from a middle-ear abscess and for 48 hours he has run a normal temperature.

**W. T. Bruner:** I wish to emphasize the importance of watching the drum membrane in cases of scarlet fever. Among the most troublesome cases of otitis media we have are those following scarlet fever. In nearly all these cases we have the presence of the streptococci in the purulent discharge from the middle ear and they are very difficult to treat. A great many are never entirely cured. I think the danger of forcing the discharge from the throat into the middle ear in irrigating the throat has been somewhat exaggerated. If these douches are made with strong air pressure there is some danger, but if the Birmingham douche, or a very low air pressure is used, there is very little danger. It is important to watch this condition and keep all the secretions cleaned from the region of the Eustachian tube, as infection is more apt to occur from the accumulation of septic material in the throat, and around the orifice of the tube, than from the use of the douche forcing septic material into the tube.

**B. J. O'Connor:** Concerning nephritis following scarlet fever, it has been by observation that seventy-five per cent. of all varieties of nephritis are really bacteriological or inflammatory in character instead of toxic. I have found bacteria in large numbers, not only in the urine, but in the casts, in the epithelial cells, and in the numerous pus cells which are almost invariably present.

In every case of scarlet fever a urinary antiseptic such as Hexamethylene tetramin, should be used from the very beginning. Nucleo-albumin is usually found in the early stages of scarlet fever, but it has no pathological significance; in fact many observers say the greater the amount of nucleo-albumin the better the prognosis.

I have seen a great many cases of scarlet fever, but I believe one important thing which it would be well to do in the beginning to prevent as far as possible, throat complications and ear troubles, is to frequently use an alkaline antiseptic wash in the nose. It can be administered with a medicine dropper or something of that kind.

**G. A. Hendon:** It has been about four or five years since I have seen a case of scarlet fever, and

I presume changes and advances have been made in that length of time. However, I would like to bring before the society the result of my experience of some years ago. I have a record of thirteen consecutive cases of scarlet fever in which I used Stern's anti-streptolytic serum, and in none of these cases was it necessary for me to see the patient more than three or four times, and in no instance were there any complications.

If any of the gentlemen present have used this serum I should like to hear their experience with it.

**P. F. Barbour:** Any prediction as to whether or not we shall ever discover a serum for the treatment of scarlet fever is simply guess-work until we know exactly what we have to deal with. Nobody has yet found the specific germ of scarlet fever, if there is one. I do believe, however, that we can prevent and treat some of the complications of scarlet fever by the use of streptolytic serum. I have seen it used with very satisfactory results.

Recent statistics show that the number of cases of kidney involvement is in direct ratio to the cases of angina. If we can get rid of angina we shall, to a large extent, get rid of kidney complications.

Dr. Jacobi tells of an experience he had in one case of scarlet fever, in which he noticed a small lump or swelling in the neck. Instead of opening it and draining the pus out, he concluded to poultice it and wait a while. Finally, however, he opened it and he found that the pus had destroyed practically all the connective tissue surrounding the blood vessels, nerves and muscles of the neck. This goes to show that, whenever we find this complication, it should be opened as promptly as possible.

I believe that local applications are of considerable value in some cases of scarlet fever. I do not like to use a spray in the nose of a child, because we are apt to force the mucus and material from the throat up into the Eustachian tube. However, I believe that cleanliness of the nose and throat adds greatly to the safety of the patient.

**J. R. Morrison:** I wish to emphasize one point Dr. Leavell made, and that is that the physician, when he visits a scarlet fever patient, should use some means to prevent the infection from getting into his clothes. He should either remove his outer garments or cover them with something else, such as a linen duster, for instance, and he should also have some covering over his hair and beard (if he has one), or wash them thoroughly afterward. Some men will go to see a scarlet fever patient and then possibly go direct to see some child, without taking any precautions to prevent carrying the infection in his clothes.

**W. S. Ehrlich:** One point I have failed to hear in the papers and discussion and that is the length

of time a scarlet fever patient should be quarantined. During my connection with the health department in the city I have on numerous occasions, where the child was reported well, been ordered to take down the placard and on reaching the place would find the child playing around with other children, desquamating with a discharge from the nose and possibly from the ears. Still that placard had to be taken down and the child released from quarantine.

My training in scarlet fever was received at the Riverside and Willard Parker Hospital. No patient was allowed to leave the hospital until the scales had completely disappeared, and if there was any sign of a discharge the child was kept there indefinitely. I have seen them detained for two or three months.

As far as the diagnosis is concerned, in the first two or three cases of scarlet fever I saw I thought it was very easy, but I have since changed my opinion. I consider it one of the most difficult of all diseases to diagnose. Of course, in a typical case the parents usually diagnose it for you before you get there, but, as explained by Dr. Boggess, in those cases which so nearly resemble diphtheria, it is a different question. It is surprising how often these two conditions complicate each other.

A routine injection of diphtheria anti-toxin in all scarlet fever patients will sometimes lead to a condition that is hard to diagnose, the anti-toxin sometimes causing a rash similar to that of scarlet fever.

Another thing I have not heard mentioned is the septic rash in children which is sometimes mistaken and treated for scarlet fever. However, there is an easy method of differentiation. In the two or three cases I have seen of septic rash, it is elevated, while scarlet fever rash is never that way.

**A. Sargent:** I must apologize to the gentlemen who have spoken for differing from them as to the extreme infectiousness of scarlet fever. If it is, I would like to know why the susceptibility is confined to one class of children; why this susceptibility is increased between the ages of one to five years and diminishes at the age of fifteen? I have never seen scarlet fever go through an entire family of children, and I have practiced in the country where I have seen whole families occupying one room; possibly one or two of them would be infected and the rest escape. Pathologists and bacteriologists have not proved the infectiousness of this disease; they have not developed or cultivated any germ that will produce the trouble. I have seen healthy children occupy the same room with a scarlet fever patient during the whole course of the disease, and, for some reason which I cannot explain, never contract it.

**F. C. Wilson:** It used to be said that children under six months of age, in whom the glands are

in a rather rudimentary stage, would not contract scarlet fever. I cannot recall a case in which the mother of a nursing child, under six months of age, who was compelled to nurse another child ill of scarlet fever, infected the nursing infant. I have heard of solitary instances in which the infant contracted the disease under such conditions, but I believe, as a rule, the infant would be perfectly safe, even if the mother was allowed in the room with the patient.

**C. H. Harris:** If there is anything that doctors have learned about scarlet fever, it is that the disease is both contagious and infectious. Just why some children who are exposed to scarlet fever do not contract it is a question that is unanswerable.

Last year my whole family had scarlet fever. First the baby, and one week after my oldest child took it, and about one week after that my wife developed the disease. I did not contract it because I have had it before. Whenever I see a case of scarlet fever, I immediately isolate the patient, as far as possible, from the rest of the family.

**Michael Casper:** I came up here very much interested in this subject to-night because I am in a neighborhood in which there is a great deal of scarlet fever, and I have a child whom I am very much afraid will get it. I would rather see the child have anything other than scarlet fever, with the exception of spinal meningitis, because in scarlet fever some complication, which we cannot foresee and prevent, may develop which will be a menace to the health of the child all his life.

I believe in quarantine. If pest houses were used for scarlet fever patients, it would be better for the children of future generations. Some good would be accomplished if there were separate hospitals where these patients could be kept until they are completely cured. Therein lies our only safeguard.

**R. A. Bate:** I wish to touch upon one point mentioned by two of the essayists; that is in regard to the epithelial cells thrown out by the skin and by the kidney. Undoubtedly this is due to nutritional disturbances.

As to the character of treatment for this lesion of the kidney, it seems to me that a physician does not do his duty unless he not only anticipates such a condition, but gives medication for it when it arises.

I believe that diuretics, diaphoretics, and eliminants in general, are indicated in these cases from the beginning. Certainly the quietness brought about in these patients by the administration of some anti-spasmodic, such as sweet spirits of nitre, acetate of potash, etc., are known to us all. My conscience would not be clear if I did not administer these when I first made a diagnosis—usually administered in the form of Larrabee's fever mixture.

As to the treatment of renal lesions when they

occur, we know absolutely that we have a blocking up of the uriniferous tubules by these desquamated cells, so certainly a diuretic such as bi-methyl tartrate of piperazine is indicated.

The piperazine diuretics also eliminate toxic principles from the system. Consequently I desire to be classed with those physicians believing in rational therapeutics.

**W. F. Beggess**, closing: I am afraid that Dr. Sargent has been confusing many ordinary erythemas with scarlet fever. There is no question that scarlet fever is one of the most contagious diseases with which we have to deal.

Another idea prevalent among physicians is that desquamation is positive proof of scarlet fever. We have many types of erythema in which the peeling is quite as extensive as in scarlet fever.

Dr. Wilson brought up the point of nursing babies contracting the disease. During the first six or eight months of life there is a wonderful immunity to all contagious diseases, and I am not sure but that the milk of a perfectly healthy mother contains immunizing properties. I have had several mothers who contracted diphtheria just after confinement and in no case did I take the child from the mother's breast, and in no case did the child develop diphtheria.

**H. N. Leavell**, Closing: Referring to Dr. Bate's remarks, I think it is a little far-fetched to anticipate a kidney complication and begin the administration of diuretics. It is just as consistent to whip up a heart in typhoid fever because the necessity may arise some time during the course of the disease.

I think susceptibility and infectiousness have been confounded by Dr. Sargent. It is a well-known fact that measles is one of the most contagious of all diseases; that no one is immune to measles, while there are many who are immune to scarlet fever. I recently heard of an epidemic of measles occurring on an island in which there had not been a case of measles for 55 years, and every person on the island became infected with the disease in its most virulent form. Not as many people are susceptible to scarlet fever as to other exanthematous diseases.

**McCracken**. — The McCracken County Medical Society has held its meeting every Tuesday night in January with an average attendance of 18 members. We have added four new members recently to our roll and it is our expectation to add several more during the next few months. The society is in a thriving, prosperous condition and it is our anticipation that the year 1908 will be the most effective for good organization in the history of its course. We have 43 members now enrolled. Excepting colored doctors, osteopaths, and homeopaths, there are only eleven or twelve regulars in the county who are not

members. We have recently had several interesting papers read and discussed before the society.

**C. E. Purcell** on January 7th, gave a very instructive lecture and illustration on "Submucous Resection of Nasal Septum."

**H. P. Sights**, on January 14th, discussed "Opsonic Index and Its Clinical Value."

**Delia Caldwell**, on Jan 21, gave to the society a most interesting, pointed and concise lecture on "Present-Day Status of Tuberculosis," which paper created considerable interest and discussion among those present.

At the meeting of Jan. 21st, a motion was made and accepted that we, as a society accept and follow from week to week the post-graduate course as outlined in the American Medical Journal.

**H. T. Rivers**, on Jan. 28, lectured and quizzed on "Croupous and Catarrhal Pneumonia."

We meet every Tuesday night in winter from June to October on the second Tuesday of the month.

VERNON BLYTHE, Secretary.

**Monroe**. — The Monroe County Medical Society met at the office of R. F. Duncan and Bushong, Saturday, Feb. 9th, 1908, Geo. W. Bushong in the chair. Members present, Bedford, Bristow, Bushong, Marrs, Palmore and Simpson.

**J. F. Marrs** read a paper on "Arsenic," all taking part in the discussion and commending the paper to the consideration of the physicians of the State. All report the prevalence and severity of "la grippe," and bad roads. Some one suggests that inasmuch as there is bound to be a lot of whiskey legislation and some road legislation, that it would be a good plan to add an additional tax of twenty-five cents on each gallon of spirits distilled in Kentucky and apply it to the building of roads, and asks that it be advocated by the **Kentucky Medical Journal**.

The Committee on Program assigned Dr. Smith, "Tuberculosis," and Dr. Ray, paper of his own choosing for March. The society meets the second Saturday in each month now.

E. E. PALMORE, Secretary.

**Russell**. — The nineteenth annual session of the Russell County Medical Society was held at Jamestown, in the office of Flanagan & Brown. There being no regular program for this meeting the members gave their attention and discussed business in general, and all heartily endorsed or recommended a bill to be introduced in the next Legislature, a law that any property, wages, etc., be subject to execution for food, raiment, medical services, etc. We earnestly urge every member of the Kentucky State Med-

ical Society to urge their Representative and Senator to vote for the bill, as we feel it will be a great help and benefit for the poor, and, of course it can't hurt the scalawag, only make him honest, for when a man wants any food or raiment or medical service or other necessities of life he can get it, or he will know what he gets he will have to pay for. So let everyone help to get this bill passed.

The following officers were elected for 1908:—President, J. B. Scholl, Jobez; vice-president, W. G. D. Flanagan, Jamestown; secretary-treasurer, J. S. Rowe, Jamestown; delegate, J. B. Scholl, Jobez; chairman board of censors, W. G. D. Flanagan; censor, L. D. Hammond, censor, Jno. D. Combest.

Owing to the very muddy roads during the winter months, the society will not meet any more until April 6th, 1908.

J. S. Rowe, referee of Russell County, recommended J. B. Scholl and W. G. D. Flanagan to be members of the State Board of Health to be members of the Russell County board of health for the next year.

J. S. ROWE, Secretary.

**Washington.** — The Washington County Medical Society met in their room at the court house December 9th, being the regular monthly meeting. The president, J. W. Shehan was in the chair. Those present were as follows: M. W. Hyatt, W. W. Ray, J. C. Mudd, W. R. Thompson, W. E. Crume, J. M. Shehan, A. G. Beam, John Spaulding, J. H. Hopper.

M. W. Hyatt presented an interesting clinical case. There were no papers read, there being considerable business on hand. The secretary-treasurer made his report, which was adopted, the condition of the society being good. John Spaulding, of Springfield, made application for membership in the society. His petition was received and turned over to the board of censors who will report at the January meeting.

"The Nostrum Evil," also "The Relation of Physician to Druggist," were discussed, but no action was taken. Our druggists have agreed to meet with us at our next meeting and discuss these subjects jointly.

This being the day for the election of officers for 1908, the following were elected:—President, W. W. Ray, Springfield; vice-president, W. E. Crume, Fredericktown; secretary-treasurer, J. H. Hopper, Springfield. There were two censors appointed, D. A. Crosby for two years, and S. F. Hamilton for three years. J. C. Mudd is chairman of the board. J. W. Shehan was appointed as delegate.

There was considerable enthusiasm at this meeting and we believe 1908 will be a banner year for our society.

J. H. HOPPER, Secretary.

**Washington.** — The Washington County Medical Society met in regular session on January 9, 1908. Physicians present:—W. W. Ray, W. E. Crume, J. C. Mudd, D. A. Crosby, J. H. Hopper, M. W. Hyatt, A. G. Beam, S. J. Smoek and J. W. Spaulding. The meeting was called to order by the president, W. W. Ray. The minutes were read and approved.

M. W. Hyatt, J. C. Mudd and S. F. Hamilton were appointed as a committee on regulating county fees and to report at next meeting.

S. J. Smoek and J. M. Spaulding's applications were reported on and both found to be eligible for membership, and received as such.

J. H. Hopper resigned as secretary-treasurer in behalf of J. M. Spaulding, who was elected for 1908 by a unanimous vote.

Very interesting papers were read by J. C. Mudd, pneumonia; M. W. Hyatt, empyemia; J. H. Hopper, sero-fibrinous pleurisy.

Drs. Crume, Spaulding and Beam to read papers at next regular meeting.

No further business; it was moved, seconded and carried to adjourn to meet again at regular meeting, February 10, 1908.

JNO. M. SPAULDING, Secretary.

**Woodford.** — The Woodford County Medical Society met in regular session on Tuesday, Jan. 7th, 1908. Present, S. M. Stedman, Parker, Holt, McCauley, Blackburn, Hart, Worthington and Crenshaw. The secretary in the chair. A number paid their State and county dues. Dr. Arnold was not present to read his paper.

The society very heartily endorsed the steps taken to have a State Tubercular Hospital.

The society then elected its officers for the year 1908, as follows:

S. M. Stedman, president; W. E. Risque, vice-president; J. W. Crenshaw, secretary-treasurer; W. E. Sleet, delegate to State Society with Joseph P. Holt, alternate.

S. M. Stedman was appointed a committee to see all the doctors of the county and obtain from them the names of such parties who can but not pay their medical bills. Adjourned.

J. W. CRENSHAW, Secretary.

## THE FORUM.

LOUISVILLE, KY.

MR. EDITOR:

An important decision has just been rendered in the Circuit Court at Louisville regarding the use of the term "certified milk."

The first action was brought before the Justice of the Peace. The milk dealer was charged with having offered for sale and sold as "certified milk" which was not certified by the Milk Commission of the Jefferson County Medical Society. The action was

brought under the general provisions of the Kentucky Pure Food Law, under paragraphs 4 of Section 3 which prohibits the sale of any article of food "under the name of another article" and under paragraph 8 in the same section which prohibits the sale of an article of food "if it be labeled or branded so as to deceive or mislead the purchaser or consumer. Before the court evidence of the sale and the markings on the bottle were produced, followed by testimony from the Milk Commission, other physicians and from State and National officials that the term "certified" in connection with milk, both from its origin and its use has come to have a distinct meaning, and that therefore the sale of milk as "certified" which is not "certified" in the manner that physicians and consumers expect is misbranding.

The Justice of the Peace upheld these contentions and entered an appealable fine. The case was appealed to the Circuit Court. At the second trial the same evidence was given again and the finding of the lower court sustained. The Circuit Judge assessed a nominal fine only, but offered to make the fine large enough to allow the defendant to appeal the case to the State Court of Appeals if the defendant desired. The defendant took the smaller fine and agreed to stop the use of the term.

H. E. TULEY.

#### SPOUTS SPRINGS, KY.

MR. EDITOR:

In regard to the case where my nephew sued me for \$7,500 in Estill Circuit Court it is a pleasure to inform you that on trial on the 19th of December it took the jury two minutes to find in favor of the defendant.

The plaintiff was a young man 21 years of age, shot with a 38-calibre pistol ball at close range, intersecting the humerus at the lower third and causing compound comminuted fracture. The bullet was not extracted. The usual antiseptic dressing was applied, but the pain continued, especially in the ball of thumb and second and third fingers. There was loss of sensation and motion in these on the sixth day, blood blisters appeared in the thumb and two first fingers. On the tenth day I removed the dressing twice and found no infection, arm soft and white, with no swelling in arm and very little in hand. I did not see the case again for six days. The blood blisters at this time were extending over the hand up under the bandage, cleaned out slough with the usual antiseptics, put on a dressing of charcoal wet with vinegar until the twenty-fifth day when the line of demarkation was well defined and amputation done. Stump healed in eight days. It was

alleged in the petition that the dressing was done so unskillfully and carelessly as to cause gangrene.

H. M. WINBURN.

(This unjust suit, decided in favor of Dr. Winburn, is typical of the large class of malpractice suits. It is to save the members of this association the worry and expense of just such procedures that a Committee on Defense against unjust Malpractice Suits was formed by the State Association. — The Editor.)

TO THE EDITOR:

The following from The Druggists' Circular, February, is significant, showing the feeling of the leaders in the profession of pharmacy to the medical profession.

"Prof. Joseph P. Remington, of Philadelphia, visited this city and lectured before the College of Pharmacy of the City of New York, Columbia University, at its regular quarterly meeting held January 21st. The profession was greeted by a large audience and his instructive treatment of his subject, "Prescriptions;" was well received.

Prof. Remington opened his address with a statement of the change now going on in things pharmaca consequent on the recognition of the Pharmacopoeia as a part of the Federal laws. This change, he said, was particularly noticeable and noteworthy in the character of the prescriptions of the medical profession. The day of the scientific prescription was dawning and the role of the proprietary medicine manufacturer as an instructor in therapeutics was near its end."

J. H. B.

MR. EDITOR

A curious coincidence in Kentucky hospitality was an invitation to the undersigned to be the guest of the Harrison County Kentucky Medical Society on Jan. 6th, 1908 and read a paper before that body. What added to the interest of the occasion was the fact that this date was the fiftieth anniversary of the writer's birth and that it was at Ruddle's Mills, near Cynthiana, the county seat of Harrison County, that my father was born, in 1805, and where my grand-father lived, died and was buried. Thereabout I have numerous consins in the first, second, third, fourth and fifth degree. After a day with relatives and a visit to the scenes of my ancestors, I repaired, in the evening, to the newly opened hospital in Cynthiana where the meeting was held. There was a good turn-out, many of the doctors coming from a distant part of the county. After the meet-

## ANENT SYPHILIS.

Many problems present themselves to the active practicing physician which are difficult to solve. There are few rigid formulae or fixed methods of procedure suitable for any considerable class of cases. In fact syphilis is one of the few diseases where one can say clearly and certainly, "If you will do certain things daily for a definite length of time, you can be well." A physician should never be an alarmist, but it is an evident duty to make plain the results of neglect in this most protean of diseases. Except local antiseptic treatment for the local sore, treatment should never begin until the secondary symptoms or rash, sore throat and falling hair have made manifest even to the patient's satisfaction that the disease is a general infection which reaches every tissue in the body. The diagnosis definitely established, treatment should be active and effective from the start. It should be explained, however, that these simple secondary lesions are self-limited and would recover just as quickly without treatment of any kind, and your patient should be brought to understand fully that it is the underlying general infection that is to be treated and not any special symptom. It is for this reason that the usual trip to Hot Springs with active treatment over a short length of time until the apparent symptoms subside, with subsequent neglect is worse than useless as it only gives a false sense of security. For the first week or ten days the patient may be given the protoiodide of mercury pills, beginning with 1-4 grain q. i. d. and increasing at least one pill a day. Within two weeks at the latest he should be put on inunctions of Ung. hydrargyri, an average of 5i being used each day. In practice it is convenient to divide the body into eleven areas and to thoroughly rub this amount of the ointment into each part in succession, repeating the process each

eleven days. These parts may be; 1, the neck and shoulders; 2, the chest, especially the axillae; 3, the abdomen, especially the inguinal regions; 4, the right arm, forearm and hand, especially the palm; 5, the left arm, forearm and hand, especially the palm; 6, the upper half of the back; 7, the lower half of the back; 8, the right thigh, especially its interior aspect; 9, the left thigh, especially its interior aspect; 10, the right leg and foot, especially the sole; and 11, the left leg and foot, especially the sole. It will be noted that all but the sixth and seventh inunctions may be made by the patient, and these two may be made by the doctor or a member of the family provided rubber gloves are worn. It should take at least 15 minutes to rub in a drachm of the ointment and in some skins 30 minutes should be so employed. Explain to the patient that too short time spent in this important procedure not only defeats the object of the treatment *as it is the amount of mercury rubbed through the skin which does good*, but that it causes actual harm as the dermatitis sometimes caused by these inunctions is due either to impure chemicals in the ointment used or failure to thoroughly rub it *into* the skin. After from three to six months it will be found best usually to let the patient have a rest of eleven days after each two courses of treatment. If anemia threaten at any time, Basham's mixture or Bland's pills will be found of service. The treatment should be continued for at least two years, and you should have the patient report to you at sufficiently frequent intervals to be sure that he is continuing the treatment and that all indications are being met. A warm sponge or plung. bath before each night's inunction is very beneficial. For the groundwork of the foregoing treatment the editor is indebted to Professor Robert W. Taylor, of New York, to whom with his colleague, Prof. Bumstead, the

whole world is indebted for the present knowledge of this dreadful disease, and he has found the ointment more elegant and effective when prepared by a competent pharmacist, *secundum artem*, in accordance with the following formula:

R

Unguentum Hydrargyri U. S. P.

Vasogen can be used as the base.

---

#### TO YOU.

Under the By Laws of the State Association, this is the last number of the JOURNAL you will receive unless your annual dues have been paid to the Secretary of your county society. You will have noted that a large amount of advertising has been discontinued by the Council. There is not one single advertisement left in our columns that we cannot vouch for. Will you not help in all this good work by sending in your dues to your county secretary to-day?

---

#### AN OPPORTUNITY.

A golden opportunity is being missed by the profession in many counties. The present world-wide fight against tuberculosis has brought preventive medicine to the minds of thoughtful laymen in a way that has never before been possible. In some of our societies, notably Calloway, Adair, Webster, Fayette and Jefferson, much has been done, and well done, to stimulate popular interest in this great question. It is to be regretted that the profession has not awakened to its possibilities in many others. Dozens of cases of consumption *are dying to-day* all over Kentucky. Most of these could have been cured had the diagnosis been made early enough and had intelligent co-operation existed between physician and patient. We would be pleased to have our members tell us in the FORUM their experience with the outdoor management of consumption and what they are doing to prevent its spread.

---

#### A NEW STAR.

Another State Journal has appeared. To those who have known its editor as the distinguished Secretary of the Section on Ophthalmology of the American Medical Association, it is not surprising that the new Journal of the Indiana State Medical Association is one of the cleanest, best printed and best edited of medical publications. Dr. Bulson has a genius for practical work and we congratulate our confreres of Indiana on having secured such an editor. Its editorial pages are as clean as its advertising pages. In medical preparations no advertisement is

accepted which has not been approved by the Council on Pharmacy and Chemistry of the American Medical Association "Blessed be the tie that binds—." Let the venalists among medical editors rail as they will, the time is coming when medical journals *will clean up or quit*. Congratulations to Indiana and to Dr. Bulson!

---

#### THE MANUAL.

It is to be regretted that only about two-thirds of the physicians of the State have taken advantage of our special offer and secured the handy little Manual of the Pharmacopeia and National Formulary. We still have a small supply on hand which will be sent while they last, post-paid, on receipt of the price, 50 cents.

---

#### TO COUNTY SECRETARIES.

The Council requests that all checks for dues be made payable to the Kentucky State Medical Association.

---

#### COLONEL BOYD.

Gov. Willson has honored himself and the State in his selection of Frank Boyd, of Paducah, as Surgeon General of the Kentucky State Guard. Col. Boyd was Surgeon-Major of the Third Kentucky during the Spanish-American war and was on duty almost constantly as a medical field or staff officer during the entire war. This rare experience especially fits him for the important position he now holds. In by-gone days our military encampments were annual revels, where neither sanitation nor military problems were even considered. During Gov. Beckham's term as Commander-in-Chief of our Guard, under the wise enactments of the national Congress, what had been a mere home guard, became in reality a portion of the United States Army. This transition is going on yet. Most of the real improvements in camp sanitation have been introduced into the regular army by the militia. They are not so hampered by regulations and have more opportunity to display a proper initiative. Under our present military code the Surgeon General is in supreme command during an encampment in so far as any medical or sanitary matter is concerned. Kentuckians may well be proud that an order giving such commanding rank to sanitarians was issued in our little citizen army first amongst Anglo-Saxon peoples.

To a position of such great practical importance Col. Boyd will bring not only a ripe experience of great value, but a native tact and ability which will make him as popular with the soldiers as he will be effective in his department. For many years he was Health Officer of McCracken County. He has been

Referee for the State Board of Health since the position was created in 1885, and has also served as a State Sanitary Inspector from time to time. In each of these positions he has had numerous opportunities to prove his merit. Col. Boyd was elected Orator in Surgery at the recent Annual Session of the State Association in Louisville.

Gov. Willson could have made no other selection for this position which would have met with such unanimous approval from the medical profession.

#### A WORK OF MERIT.

It is a pleasure to announce to the profession the publication of a new work of real, practical value on Diseases of the Breast, with especial reference to cancer. That the volume is written by W. L. Rodman, of Philadelphia, an ex-member of our Association and a native Kentuckian of the highest and best type, will but add to our interest in it. Many of the medical men now practicing in Kentucky received their instructions in surgery from this distinguished lecturer.

To those who knew the author, its completeness will cause no surprise. Speaking of the anatomy of the breast, for instance, we find it stated that the glandular substance has heretofore usually been considered "to extend from the second or third rib above to the sixth or seventh below, and laterally from the outer side of the sternum to near the anterior border of the axilla." "It is now known, however," he continues, "that this description by no means always accurately defines the limits of this organ, for it has been shown that prolongations of glandular substance may extend upwards towards the clavicle, downwards toward the external oblique muscle, inwards to the sternum, and outwards into the axilla." Similar facts of the most profound practical import abound through the pages. The treatment of the blood and lymphatic supply of the breast is singularly complete. Under the various heads are described in the same simple and easily understood manner not only the methods of diagnosis and the pathological anatomy of the various diseases of the breast, but the very latest modifications of the corresponding therapeutics. As an example of this may be mentioned the description of Wright's bacterial vaccines and Bier's passive hyperaemia as two modern methods of treating tuberculosis of the breast. Other chapters are devoted to inflammatory diseases, Syphilis, Cysts, Ke-loid, Tumors, this including the various theories as to causation. Under this head are discussed lipoma, enchondroma, myxoma, angioma, endothelioma, sarcoma, and carcinoma. In this last chapter he describes his own method of removing the breast, and the splen-

did series of plates illustrating in minutest detail every step in the operation, show it to be one of the most, if not quite the most effective procedures yet suggested. The fact that, with an operative field as extensive as Halstead's, Rodman is able to bring the skin flaps together in accurate apposition at every point, makes his method superior to any yet suggested.

This work should be in the hands of every practitioner who is interested in the diagnosis or treatment of diseases of the breast. Its distinguished author is to be congratulated on this master work, as are its publishers, Messrs. Blakiston's Son & Co., of Philadelphia, upon its typographical perfection.

#### SHORTHAND

In our last few issues we have been carrying the announcement of the Chicago Correspondence School telling about a simple and complete method of teaching shorthand at home. This is proving especially attractive to many physicians, who not only find the method of value in making notes on lectures while attending post-graduate courses, but in making similar notes of discussions in medical societies, case reports, telephone conversations and other conditions. We can cordially commend this course for such purposes.

#### SCIENTIFIC EDITORIALS.

##### PUERPERAL INFECTION.

##### PATHOLOGY, SYMPTOMATOLOGY AND DIAGNOSIS.

This condition is still the subject of numerous articles in the medical press of the present day and the most elaborate and important thesis of the year is the one by Sir William J. Sinclair, M. D., in the November number of *Surgery and Gynecology*. The article not only gives a complete history of the diagnosis and treatment of the condition from preantiseptic times until the present day, but the author's personal researches practically upset the existing theories in regard to the diagnosis and treatment of the disease.

All modern text books now include under the term Puerperal Infection, all the morbid conditions that result from the entrance during labor or the puerperium, of infective micro-organisms into the female generative tract.

A division of the condition is made into Sæpraemia and Septicæmia.

Sæpraemia is the morbid condition due to the absorption of toxic products produced by organisms in the generative tract, the organ-

isms themselves not entering the blood current.

Septicemia is defined, as a disease caused by the growth and extension of micro-organisms in the uterus or other portions of the generative tract and their entrance into the blood current.

Only a few of the organisms causing Sapræmia have been isolated.

The microbes causing septicæmia are, the streptococcus, staphylococcus, gonococcus, pneumococcus bacillus coli communis, bacillus diphtheria, bacillus typhosus and the bacillus aerogenes capsulatus.

It is generally admitted, that the streptococcus is the direct causative agent in most severe cases of puerperal infection, whilst it is further claimed, that 1-10 to 1-6 of all rises of temperature in the puerperium, are due to gonococcus infection.

A distinct symptomatology is given for each of the two forms of Puerperal Infection.

In Septicæmia, three or four days after labor, there is an initial chill followed by a sudden rise in temperature of 103° or more, with an increasing lochial discharge free from odor. If the temperature is abnormally high, a diminution or a sudden cessation of the discharge.

In Sapræmia, the onset of the disease is not so sudden, the temperature is generally lower and the profuse lochial discharge is frothy and foul smelling.

The diagnosis of either condition is based upon the above symptoms and of the recognition or absence of definite micro-organisms in the lochial discharge obtained from the uterus with a Doederlein tube, in the manner described in all text books.

Recent investigations, however, have done much to place the possibility of an absolute differentiation of the two forms, by means of the microscope, in doubt.

First of all, it is admitted that a pure Sapræmia is rare, more or less septic infection being generally associated with it or the conditions in the uterus are such that the slightest disturbance of its contents will engraft a Septicæmia upon the existing Sapræmia.

The diagnosis by means of the Doederlein tube, is based upon the assertion that the contents of the uterus in the healthy woman are sterile, and this claim has led to a great deal of investigation and controversy.

The vaginal secretion of a healthy woman was also stated to be free from pathogenic micro-organisms. Sinclair in the article mentioned above, quotes Bumm, the distinguished obstetrician and bacteriologist of Halle, as follows:

“That the streptococcus is almost always present in the genitals there can no longer

exist any doubt. In almost all women during pregnancy and child bed and even during labor, the streptococcus is found in the vaginal secretion.

“What remains to be cleared up, is the quality of the streptococcus and its relationship to the streptococcus of sepsis. Are they identical with the producers of septic wound fever, deprived for the time of their virulence, or are they entirely different organisms, with only an external resemblance to the pathogenic streptococcus?”

Bumm, therefore, claims that the utter impossibility of diagnosing the presence of Puerperal Fever from an examination of the lochia, has been demonstrated.

Sinclair also makes the statement from his own investigations that we possess absolutely no criterion by which we can differentiate in the early stages sapræmia from septicæmia.

Whitridge Williams declares that at the present time one is not justified in considering a case as sapræmic unless the lochia have been examined bacteriologically and found free from pyogenic organisms.

Williams has made extensive experiments in regards to the bacterial contents of the vaginal and uterine secretion and his results vary absolutely from those of Bumm.

No streptococci were found in the vaginal secretion of 92 pregnant women when the specimens were obtained by means of a Menge tube. Bumm criticized the results obtained and claimed the results were due to the use of faulty culture media.

Considering the ability of the men and the equipment at their disposal at Johns-Hopkins, American obstetricians are inclined to accept Williams' results.

The uterine lochia of 50 consecutive women delivered in Johns-Hopkins were examined immediately after delivery and found to be sterile in 96%. It is well, therefore, to consider the vagina and the uterus of the normal woman as sterile in the beginning of the puerperium.

In view of the above, whether or not a woman can infect herself, is surely a mooted question, and it must still be conceded that in a majority of instances the infection is introduced upon the hands, instruments or dressings of the physician or other attendants.

That some women possess a greater power of resistance to infection than others, is also established by the fact that in some instances when the labor has been conducted with absolute disregard of any semblance of asepsis, the puerperium is afebrile, whilst in others, where every precaution apparently has been used, infection occurs. In the latter case, the lowered resistance may often be accounted for by the fact that the patient has suffered from

some toxæmia of pregnancy and is more liable to infection in consequence.

Briefly the pathological conditions present in puerperal infection, may be enumerated as follows:

The mucous membrane of the vagina is thickened, soft and reddened and covered with an abundant purulent secretion, or especially when torn surfaces are present, portions are covered with a pseudo-diphtheritic membrane.

When the endometrium is infected it is converted into a sloughing surface, bathed with a bloody purulent discharge.

In virulent streptococcal infection, the endometrium is smooth.

According to Bumm, in putrid endometritis a thick layer of necrotic material is found lining the uterine cavity. Beneath this lies a thick layer of small cell infiltration, the zone of reaction, and beneath this more or less normal tissue.

In septic endometritis, on the other hand, there is a layer of necrotic material thinner than in the putrid variety, the zone of reaction is either absent or imperfectly developed and micro-organisms can be seen making their way through the muscular wall of the uterus out to its peritoneal surface.

Nature endeavors to confine the micro-organisms to the interior of the uterus by interposing between the necrotic layer and the deeper portions a wall of small cell infiltration, which acts as an efficient filter when they are not virulent, but which fails to restrain them when they possess a marked degree of virulency.

Parametritis, formerly called pelvic cellulitis, is due to infection of the peri uterine connective tissue by means of the uterine lymphatics, the result being either inflammatory oedema or abscess formation.

Extension to the muscular wall of the uterus, may result either in small cell infiltration or localized abscess formation.

Salpingitis, in most instances, is due to an extension of the infection through the lymphatics, but it may also occur as a direct extension from the endometrium.

Peritonitis occurs when the infecting agents make their way from the interior of the uterus to its peritoneal surface or it may occur from pus escaping from the Fallopian tube.

Pyæmia results in consequence of the infection of the thrombi at the placental site. By the breaking down of these thrombi, small particles escape into the circulation and are carried to various parts of the body, where they cause metastatic abscesses.

Phlegmasia alba dolens occurs through an extension of a thrombosis from the uterus

to the common iliac vein and then downwards to the veins of the leg.

EDWARD SPEIDEL.

#### EXOPHTHALMIC GOITER.

Thyrototoxicosis is a name which best represents a condition or symptom-complex known as Basedow's or Graves's disease. It is generally called in this country exophthalmic goiter, from the fact that the eye symptoms and the thyroid enlargement are the most prominent manifestations of the disorder. Graves, as early as 1835, and Basedow, a few years later, called attention to the condition, but only until comparatively recent years has the disease received the careful study it has deserved. The failure of general therapeutic measures to permanently cure more than a small percentage of the cases, suggested to the surgeons to use some effort to combat the disease, either by removing nerve ganglia controlling the parts, or by removing the greater portion of the thyroid gland.

The etiology of exophthalmic goiter has been in the past, and is to-day, little understood. Recent investigations of the experimental physiologists and the surgeons have very clearly established a direct connection between an over-activity of the thyroid gland and the disease, as can be shown by the almost invariably good results when the enlarged portion of the gland has been removed. Beebe, who has done much investigation on the serum treatment of this disease, has written:

"There are two commonly accepted possibilities which explain the origin of the hyperactivity of the gland. First, as a result of nervous shock; second, as a compensatory hypertrophy during toxæmia." The recent investigations of the noted Russian physiologist, Pawlow, have clearly demonstrated what a remarkable control is exercised by the nervous system over glandular activity.

Concerning Beebe's second hypothesis, he has written: "There are some histologic studies which indicate that during the infections and also during chronic toxæmias the thyroid undergoes cellular hyperplasia which may serve in the nature of a compensatory hypertrophy i. e., the additional demand for the detoxicating action of the gland results in its growth."

The symptoms of exophthalmic goiter vary greatly in character and intensity in the different cases, but those which first attract our attention are usually a tachy-cardia, muscular tremors, a gastro-intestinal disturbance, general nervousness and often great lassitude. Sometimes a moist skin or an excessive perspiration and often an occasional rise in temperature are noted.

In females the menstrual flow may diminish or entirely cease. Characteristic changes in the blood occur, consisting of a marked increase of lymphocytes and a diminution of polymorphonuclears. The leucocyte count is normal, the increase of lymphocytes being in proportion to the degree of the disease.

The enlargement of the thyroid gland and the exophthalmos are usually seen later in the disease, but all operators claim never to have seen a true case of Graves's disease without some increased size of the gland, often only to be demonstrated when exposed at the time of operation.

The course of the disease is characterized by acute exacerbations, which sometimes have a rapid fatal end. When this disease begins slowly, the prognosis is better than in those which develop suddenly and are likely to run a rapidly fatal course.

The histo-pathology of exophthalmic goitre has recently been very elaborately studied by MacCallum, Albert Kocher and others, and while in the main their conclusions are the same, there are many points still in dispute. These changes differ from the normal thyroid gland in the arrangement of the alveoli, changes in the epithelium, which become cylindrical and with formation of papillae. The colloid material is diminished, the epithelium increased, also the fibrous tissue and the blood vessels are in larger amount than in the normal. The pinkish translucence of the normal gland has in many cases changed to a granular grayish color. With such a meagre knowledge of the etiology and pathology as possessed by the profession, even in spite of the many recent investigations, how are we to reason upon the rational treatment?

Albert Kocher (*Keen's Surgery*, 1908) who has treated a very large number of these cases and operated upon over 300 patients for exophthalmic goiter, has recently written:

"The treatment is partly symptomatic and partly causal. In accordance with the innumerable symptoms, the former call for many different drugs, but, as a rule, has only a relative value, because as one symptom is relieved another symptom is increased. Symptomatic treatment is, therefore, being relegated more and more to the background. Internal causal treatment consists in avoiding or diminishing injurious influences and, on the other hand, in modifying the function of the thyroid gland." Good hygiene, diet, the careful administration of drugs to control the prominent symptoms, occasionally the use of the X-rays, electricity and even the newer serum therapy have all yielded good and even brilliant, but usually only temporary, results, while the real and only permanent cures have been from complete removal of the greater portion of the enlarged thy-

roid gland by surgical means. Much was expected of the serum treatment, which was employed in 1902 by the Kochers and later in 1905 by Beebe and Rogers. In a few selected cases good results have followed the administration of the serum, but as it is quite difficult to prepare and hard to maintain uniform it has not been very generally employed.

The use of iodine, either locally or internally, and the administration of extracts of the thyroid gland from sheep, seem not only to be contraindicated but have produced more harm than good, as they stimulate the gland to still greater overactivity.

Albert Kocher has recently said: "To say that surgical treatment is still the best is not enough. It has proven itself superior to any other form of treatment. It attacks the organ which is instrumental in producing the toxæmia, namely, the thyroid gland. Operations on the sympathetic nerve have been given up, since it has been demonstrated that in the majority of the cases these operations are not productive of the slightest good."

The mortality from operation in the hands of those who have done much of this class of surgery has not been over four per cent.

If cases are operated early and carefully selected and prepared, there is less to fear from this disease than the average abdominal section. It is only the neglected and those of long standing which will in the future be considered bad risks. It should not be understood that all cases seen early and so diagnosed should be subjected to operation immediately, but on the contrary, if, after a few months' careful internal treatment and if the symptoms grow much worse and the patient seems to be losing ground rather than gaining, then delay of surgical treatment is a serious mistake, if we wish to offer our patients the hopes of complete recovery, as in other cases like appendicitis and gall-bladder affections. Exophthalmic goiter will probably have to undergo the small evolution in our ideas of treatment that the appendicitis and gall-bladder have passed through before the profession begin to fully realize the advantages of surgical treatment above all other measures which have been in the past employed for the relief of this most distressing disease

JNO. R. WATHEN.

#### NOTE ON THE USE OF WATER AS A DIURETIC.

We live in an age of new things. The spirit of discovery and invention which has wrought such marked changes in every department of human activity has not been wanting among medical men.

We are confronted by the same old prob-

lems that have puzzled physicians in all ages, but now as never before a great army of earnest workers is constantly seeking for new and better ways of solving them. In the field of therapeutics this spirit is dominant. New remedies and new combinations of old remedies bearing new names are appearing in such numbers and variety as to be almost bewildering. The last revision of the U. S. P. includes many things which gained recognition therein for the first time. While the list of New and Non-official Remedies grows steadily longer month by month. Great advances have been made and therefore it becomes the duty of every faithful and conscientious physician to know and to use all that is good, however new.

In this search for new things, however, it is important not to lose sight of those fundamental principles upon which all scientific treatment of disease must ever rest, nor to overlook those simple measures, the efficacy of which has long since been established.

In the losing conflict which has been waged for many centuries with the great white plague, we have but recently come to know the futility of practically all forms of drug treatment and to appreciate the value of pure air and sunlight, and of abundant nourishment in the form of milk and eggs. We have yet to realize in daily practice that which theoretically is well understood, the prophylactic and curative properties of pure water.

In the routine examination of patients it is quite a common error to neglect entirely, or only casually to consider the very important question as to the function of the kidneys. Theoretically we know that thorough elimination of those poisons which are excreted chiefly by the kidneys is essential to health; yet practically we often wait until some definite, if not alarming, symptoms direct attention to this quarter. As the blood stream must be constantly purified of its carbon dioxide, as it passes through the lungs, so there are other excrementitious products of metabolism which must be unloaded and thrown off just as constantly by the kidneys. Any disturbance of this function, such as may be produced by even a slight illness, is accompanied by perceptible changes in the quantity and character of the urine while in those cases, fortunately rare, in which the function is suspended, we have a condition of the utmost gravity, which if not relieved must terminate fatally within a few hours. These considerations should emphasize the importance of carefully investigating the kidney function by means of urinalysis as a part of the routine examination of patients.

The simple chemical tests which may be made in a few minutes, together with microscopical examination when indicated; furnish

most valuable and reliable information to the careful diagnostician.

Diuretics, or medicines used for the purpose of increasing the flow of urine, may produce this effect either by acting directly upon the secreting structure of the kidney or in some indirect way as by raising blood pressure and increasing the blood supply to the kidney. The pathological conditions present and the physiological action of the particular drug to be chosen must therefore be considered in each individual case. The error of administering an irritating diuretic, in the presence of acute inflammation of the very structures which are to be affected is at once apparent, while it is equally evident that where the secreting cells have been destroyed, as in advanced Bright's disease, no good result may be expected from diuretics, old or new, however broad may be the claim of the manufacturer.

The principal indications for the use of diuretics have been summarized as follows: 1. To maintain the action of the kidneys. 2. To evacuate fluid, as in the various forms of dropsy. 3. To soothe and diminish irritation of the genito-urinary organs. 4. To alter the urinary secretion so as to prevent the deposition of calculous material.

The drugs used to meet these indications may be divided rather roughly into three general classes:

1. The Hydragogue Diuretics. Drugs of this class simply increase the quantity of water excreted by the kidneys, and are therefore used chiefly for the relief of the various forms of dropsy. Squill, Broom, Digitalis, Sweet Spirits of Nitre and the Xanthin Compounds are the principle members of this group.

2. The Depurant Diuretics. Drugs included in this class do not markedly affect the quantity of water excreted but modify the character of the urine in one way or another, rendering it less irritating and producing a sedative effect upon the whole genito-urinary system.

The potassium salts, lithium and urotropin are the principal drugs in this class.

3. Alterative Diuretics. While not necessarily increasing the flow of urine, the active principles of drugs of this class are eliminated chiefly by the kidneys and thus by direct contact affect the mucous membrane of the genito-urinary tract. Buchu, Juniper, Turpentine, Copaiba and Cantharides are typical of this class.

Before referring in detail to any of these drugs, however, and, in fact, before employing any of them, it is well that we consider fully the most important and the most generally useful diuretics which we have at our command, viz., pure water.

Here, again, we find a most unfortunate discrepancy between our theoretical knowledge and actual practice. If we review the indications given above for the use of diuretics, we learn, upon abundant authority, that with the exception of the second one mentioned, pure water in sufficient quantity meets every one of them, and that more satisfactorily in most cases than any of the drugs now recognized by the pharmacopeia. It must be remembered that the very remarkable properties claimed for many of the preparations of which we receive samples, are possessed only by those which have not yet been passed upon by the Council on Pharmacy.

But in the use of this great remedy so abundantly provided by nature there is one serious difficulty. Sick people are quite willing to take medicine in teaspoonful doses from a bottle, but they hesitate when the daily dose is measured by pints or quarts and the medicine is so common place and inexpensive a thing as pure water.

The physician who would successfully employ such simple means must possess the courage of his convictions, the confidence of his patient, and the faculty of securing a faithful compliance with directions. To this end the directions should be explicit and definite as to the size of the dose and the hours when it should be taken. It is not enough to say, "Drink plenty of water." It is surprising how small a quantity of water is ingested in the twenty-four hours by a large number of people who for one reason or another consult a physician. Urinalysis in many of these cases, shows a urine practically normal but for high specific gravity and increased acidity. Not one of the drugs in the whole list of diuretics can correct these conditions so satisfactorily as a sufficient quantity of water. In order that the quantity of water ingested may be known to be sufficient it should be measured and taken at the proper times.

It is not an uncommon occurrence for an individual, who may have suffered for months or years with some form of indisposition which is variously ascribed to kidney trouble, or bladder trouble, or stomach trouble to discover that, by taking a large draught of water upon rising daily, the symptoms which had caused him so much anxiety gradually disappear. The explanation in such cases is quite simple. By the ingestion of a sufficient amount of water the great "sewers" of the body are being flushed, and therefore the waste products are being more thoroughly removed.

The marked benefit which such people experience after even a short residence at a watering place, where a large amount of water is taken daily, is to be accounted for

in the same manner. Perhaps in a majority of cases the benefit is due rather to the quantity of water so taken, than to any of the salts which it may hold in solution.

In many acute diseases the diuretic action of water given at regular intervals and in sufficient quantity, is most valuable both in relieving the condition present, and in protecting the kidneys from serious complications. Thus in acute Bright's Disease, where we have the kidney function directly interfered with, it has been found that large draughts of water not only serve to greatly increase the flow of urine and thus maintain the excretory function of this organ, but to lessen the irritation of the kidney itself. Even in the very grave forms of this disease accompanied by violent inflammation of the kidneys and suppression of urine it was pointed out originally by Porak and Bernheim and abundantly confirmed by other observers, that water given in large amount, by mouth, by bowel and by hypodermoclysis, is of the greatest benefit.

The prophylactic value of water when taken in sufficient quantity should not be overlooked. In the treatment of even so mild and ordinarily harmless an affection as measles this point is well emphasized by Sajous, who in a recent article says:

"A powerful adjunct, one in fact which tends greatly to limit the duration of the disease and the liability to complications, is the free use of fluids to insure copious diuresis. This facilitates the elimination of the virus, wastes, etc., which greatly irritate the kidneys and cause the high vascular tension which underlies the morbid phenomena of the disease.

"The tastes of the child should be consulted in order to secure its co-operation, either warm or cold drinks, lemonade, barley water, mallow tea, etc., being ordered in fixed quantities during the twenty-four hours."

The same principles apply with even greater force in other acute infectious diseases, particularly scarlet fever, where there is always danger of renal complications. Instead of leaving this important matter to be governed entirely by thirst or caprice of the patient, the ingestion of fluids for the purpose of securing thorough diuresis should be regulated by the medical attendant with the same care which he would give to the proper evacuation of the bowels, the election of diet and the giving of medicines.

Perhaps the most important field in which the general principle has application, is in the preparation of pregnant women, particularly those who have had renal trouble, or who show symptoms of impaired kidney function, for successful and uncomplicated parturition. Whatever may be the etiology

of that dread condition which we know as puerperal eclampsia, and whether or not it is due wholly or only in part to imperfect elimination of the kidneys, it is practically certain that constant and thorough diuresis which is best secured by the ingestion of water in sufficient quantity during the later months of pregnancy holds a most important relation to its prophylaxis. It would be undesirable, if not unsafe, to exhibit most of the drugs used as diuretics over such a long period of time, but here we are fortunate in having in the most reliable and useful diuretic, one that is absolutely harmless. If necessary to secure the co-operation of the patient it is often wise to direct something which the patient will recognize as medicine, e. g. the harmless and sometimes useful lithia tablet, to be taken at regular intervals, dissolved in a measured quantity of water. In other cases it is possible to secure at small cost a pure spring or well water, put up in bottles and bearing on the label the impressive chemical analysis, which will help wonderfully to induce the patient to take it in such quantity and with such regularity as to secure the desired result.

In the preparation of operative cases, the value of securing such thorough diuresis by means of large draughts of water given at regular intervals is coming more and more to be appreciated. Particularly in those cases where an elective operation is to be done for the relief of conditions which have existed for some time, we find the most positive indications for this plan of treatment. Not only is it desirable to remove through this channel so far as possible waste products which have accumulated in the tissues, but the urine is rendered less irritating and the kidneys are prepared for the increased work of taking care of the anaesthetic, and of any complications which may arise following the operation. In short, it is not too much to say that the urinary system should receive the same careful attention in such cases as is given to clearing out the alimentary tract.

Women as a class are more prone to err in the matter of taking an insufficient quantity of water than men. Perhaps a sedentary occupation, and lack of muscular exercise has much to do with this; but it is a fact that upon inquiry it will be found that many women drink scarcely any water at all, and the total ingestion of fluids in the twenty-four hours is much less than is actually needed for proper elimination, either by the kidneys or by the bowel. They are habitually constipated and the urine is of high specific gravity and often irritating to the bladder and urethra. The taking of a sufficient quantity of water, together with such other measures as may be indicated in any given case, will

not infrequently result in prompt relief of symptoms, with great improvement of the general health.

In conclusion it may be stated that in the whole list of diuretics, water, in one form or another, holds the first and most important place, and that its administration should be directed with the same care on the part of the physician, as he would naturally exercise in prescribing the less reliable and useful drugs employed for the same purpose.

T. C. HOLLOWAY.

### EXOPHTHALMIC GOITER.\*

By JOHN G. CECIL, Louisville.

A perusal of the current literature on the subject of Exophthalmic Goiter cannot but leave in the mind of the reader the impression that the surgeons who have operated most, and who are thereby best qualified to speak, are expressing themselves with increasing confidence as to the most satisfactory methods of dealing with this disease. But with both surgeons and internists working in harmony toward the same end, the day of a better understanding of Exophthalmic Goiter is near at hand.

It is passing strange that disease of an organ so prominently situated should with a few exceptions, have been ignored by the ever alert and intrepid surgeons. Since the classic descriptions of Exophthalmic Goiter by Graves, in 1835, and by Basedow, in 1840, little progress in its treatment was made by either surgeon or doctor, until within a comparatively recent period. For decade after decade such cases were regarded as hopeless and helpless and were simply relegated to the class of incurables. Spontaneous cure was occasionally seen, some were cured by rest, diet and such agencies, all received medical treatment as bounteous as it was useless. Still there existed no remedy in the pharmacopeia that would stay its progress; and the surgeons, many of them even to this good day, bold enough in other and perhaps less inviting fields, appeared to be strangely chary about assuming responsibility here. To that incomparable surgeon of Berne, and to those scarcely less notable brothers of Rochester do we owe more than to all others combined the positive demonstration that Exophthalmic Goiter is amenable to treatment and cure. While these marvelous men, with dauntless courage and with their scalpels, have shown to the world "a thing already done," the internists, less bold but none the less zealous, have furnished a serum, an an-

\*Read before the Kentucky State Medical Association Louisville, October 15-17, 1907.

titoxin, not yet perfected, but of unquestionable value.

In the light of recent reports and investigations it would be unwise to assume that all cases may be treated most satisfactorily by either surgeon or internist. Careful selection should be the rule. Kocher, with the widest experience of any living man, selects his cases for operation with the utmost care and does not operate more than a fourth or a third of those presenting. Any case when seen early should have the benefit of rest, medical and serum treatment for the twofold reason that some are benefited or cured by these means and some succumb to operation even when it is applied by the most skillful hand. Practically all the most dexterous operators of the present day agree that cases should be treated with the serum before the knife is resorted to. It must be admitted that up to the present day the surgeons have the best of the argument and exhibit the best results: therefore, under no circumstances should therapeutic measures be persisted in that will in the future give rise to criticism so just and so true as that recently made by C. H. Mayo. Says he: "The public has learned that operations on goiter are not as fatal as were supposed from the results obtained when operations were made as a last resort on patients suffering from this disease in a moribund state. The fact is that the mortality attending the operation (excluding cancer and advanced cases of exophthalmic goiter) compares favorably with other major surgery. The surgery of the neck never seemed to enjoy the popularity of that of the abdomen, and goiter operations are not even to-day sought by the majority of surgeons. Those who were competent did not sufficiently often encourage operative relief until absolute necessity rendered the mortality so high as to be almost prohibitive. The lay impression became such that operative measures were permitted only in the most advanced cases, while semi-surgical, medical, mechanical and electric treatment flourished. In most cases death came slowly and was looked upon as a relief from suffering, a result which satisfied everybody; but the death which follows operation is a shock to all, and in but a few instances is there a consideration of the fact that medical treatment has previously failed. Neither is the urgent necessity of the operation nor the desperate condition of the patient taken into account, but the death is made a debit against the surgical side, especially is this true in cases of exophthalmic goiter."

The cause of exophthalmic goiter is generally conceded to be some perversion of the thyroid gland, probably hyperactivity and hypersecretion, the gland not being necessarily

much enlarged. The same condition as that existing in Graves' disease may be produced by feeding a person with thyroid gland or thyroid extract. The nervous system is affected more or less profoundly in all cases, but these manifestations should be regarded as the result of absorption of the secretion of the diseased gland rather than as the cause of the disease. The gratifying results of partial thyroidectomy confirms the opinion that this disease is caused by disturbed secretion of the gland rather than by disorder of the sympathetic or vagus nerves. Mental shock, worry, grief, pregnancy and excessive fatigue have been assigned as exciting causes. Certain diseases, as rheumatism, typhoid fever and gastro-intestinal ptomain poisoning have likewise been held as etiological factors, all these are doubtless only coincidences. The parathyroid glands and the thymus gland appear to bear a close relation to this disease, just what that relation is, is not yet demonstrated. Myxedema with atrophy of the thyroid the antithesis of Graves' disease and the cachexia thyreopriva following complete removal of the thyroid are both alleviated as to their symptoms by exhibition of thyroid extract all of which support the contention that the disease is one due to hypersecretion and hyperactivity of the thyroid gland.

The three cardinal symptoms are enlargement of the thyroid gland, exophthalmos and tachycardia: any one of these may be absent or in abeyance. In a certain number of cases the thyroid gland can be palpated only with difficulty, and the exophthalmos is not noticeable in about 20 per cent. Tachycardia varies from 90 to 180 per minute. In addition to the above there are many other symptoms of minor importance but generally pretty constant in typical cases, of these the more important are, nervous flashings, Von Graefe's sign, Stellwag's sign, pulsation of the retinal arteries, a lack of convergence of the two eyes, irritability, restlessness, insomnia, muscular tremor, hyperidrosis, gastro-intestinal disturbances including nervous diarrhoea, hyperemesis and anoxia. Rapid respiration and intermittent albuminuria are frequent. "Fits of depression alternate with buoyancy, while the moral nature may also be changed to a degree amounting to melancholia or mania."

The onset of the disease may be rapid, developing within a week or two, and running a short course or as is more probable the onset will be slow and gradual, requiring months or years for full development. By far the larger per cent. of cases occur in females developing between the ages of 15 and 40.

The diagnosis in typical cases present little

difficulty. There may be doubt in the beginning which time will quickly settle. Some confusion may arise in cases of exophthalmic goiter being grafted on to the simple or colloid variety, and in others of the neurasthenic type where the gland is not perceptibly enlarged. Mayo states that "we have operated on exophthalmic goiter which were hardly palpable, and have been surprised at the increased size of the gland over the normal when exposed. After all it is a question of increased secretion, absorption and delivery by the lymphatics, not necessarily the retention and development of a tumor. If the ophthalmic gland was no larger than normal it would be many times more active."

The majority of cases run a chronic course, and when death comes, it is from failure of the heart, this is generally preceded by aggravation of all symptoms, the gastro-intestinal group and general exhaustion being especially prominent. In others, death may be sudden as from syncope. Spontaneous recovery occasionally occurs, independent of, or without any kind of treatment.

Treatment by administration of the dried thyroid substance or the thyroid extract has long since been abandoned; in place of relief the condition was aggravated. About a year ago two papers referring to a specific serum or antitoxin for the treatment of Graves' disease appeared in the *Journ. A. M. A.* the authors being J. Rogers and S. P. Beebe. These two men have been working together and their work represents the best that has been done in this direction. They have used both a normal serum and a pathologic serum, but time forbids any extended account of the mode of preparation, the details of administration or other interesting incidents of its use, other than their conclusions which are herewith appended in their own language. Ninety cases have been treated with the serum, of which twenty-three have been cured of all symptoms of thyroidism, fifty-two have been more or less improved, eleven have failed to improve and four have died. Dr. Rogers sums up as follows. "In the administration of the different sera a certain proportion of the patients hitherto have not reacted at all to the normal serum, or if they did the result has appeared harmful, rather than beneficial, and few patients have not improved unless given the very best grade of the pathologic serum which can be obtained only from exceptional animals. There is much yet to be learned, however, both about the dosage of any given serum and the frequency of its administration and I have hopes that the normal serum can be made effective in a much greater proportion of cases than it has in the past." Dr. Beebe concludes as follows: "When all the condi-

tions are considered, I believe it is fair to conclude that the serum is an agent of considerable value in the medical treatment of exophthalmic goiter. It has been used in all manner of cases in which it was possible to make a diagnosis, and in some cases in which the diagnosis was doubtful. Only a comparatively small percentage of these have been of recent development. A small percentage of trials have resulted in failure, a much larger number in improvement. While an encouraging number of individuals have been completely cured, the number of instances of cure and improvement are so large that they can not be ascribed to coincidence, and under favorable conditions I believe much can be accomplished by careful serum therapy."

No paper on this subject would be complete without some reference to the surgical treatment. In deed it may be truthfully said that the successful treatment must be very largely accredited to surgery. Inasmuch, however, as it is not my province in this symposium to elaborate this phase of the subject only a short reference will be admissible in this connection.

Partial thyroidectomy for the relief of exophthalmic goiter constitutes one of the most successful, brilliant and attractive chapters of modern surgery. The prominent operators have been few in number, and the greater part of the operations have been done in the last ten years. Kocher in April, 1907, reported at the German Congress for Internal Medicine 167 cases operated on with 9 deaths and 72 per cent. of cures. A little later at the last meeting of the American Medical Association, at Atlantic City, he stated, "We have had in the last 91 operations on 63 patients not a single death, and in the whole we have lost only 9 patients out of 254 that is to say, 3.5 per cent." He has operated in all 315 times on 254 patients. He says again, "There is not a single case of ours, that survived the operation, in which the patient has not been benefitted by the thyroid operation. We have cured by our operation the patients in 83 per cent of all our cases." It is indeed refreshing to hear him say in answer to the question "When to operate?" "It depends not alone on the physician, but also quite as much on the patient. Often the surgeon thinks it is the doctor's fault that he is consulted so late, and does not imagine what an unsettled and sick mind the patient has. It is necessary to advise people to see the doctor in the early stages of the disease."

In the *Jour. A. M. A.* Jan. 1, 1907, C. H. Mayo reports operation on 110 cases with 9 deaths, only 2 deaths in the last 64 cases. A short time after that date he reports 176 cases with only 9 deaths. He is much pleased with the results of surgical treatment of

the disease, which are as follows: "of those who survive the operation 50 per cent. make early recovery, 25 per cent. improve of the main symptoms and 25 per cent. while greatly improved have occasional temporary relapses of tachycardia and tremor." He now considers hyperthyroidism a surgically curable disease and thinks that the preservation of the posterior capsule of the gland whatever be the method of its accomplishment will protect against many of the dangers of thyroidectomy. W. S. Halstead who reports 90 cases with 2 deaths, thinks that the surgery of exophthalmic goiter centers in the problem of removing the greater portion of the thyroid gland without sacrifice of the parathyroids.

### THE SURGICAL TREATMENT OF GOITER.\*

By THOMAS C. HOLLOWAY, LEXINGTON.

A review of the literature of this interesting subject for the period of the last ten years, brings before us one of the most brilliant and inspiring triumphs of modern surgery. Before the anatomist had completed his researches, and told us of the minute blood supply of the parathyroids, before the physiologists had satisfactorily worked out the difficult problem as to the function of these ductless glands, and before pathologists have been able to arrive at definite conclusions as to the nature and effect of the morbid processes observed, the surgeon has come to the relief of this class of sufferers, and won almost unaided a signal victory over the disease which is otherwise hopelessly incurable.

The field is not an inviting one to any but the bravest heart. Dangers seen and unseen lurk on every hand. The ever present danger of infection may be practically avoided by the employment of aseptic and antiseptic methods now well understood, but there remain so many other possibilities unpleasant to contemplate, that no operation for goiter may be lightly undertaken.

The horse-shoe shaped thyroid gland rests upon the trachea, one lobe on either side, connected by the isthmus which covers the upper tracheal rings. The lobes are about two inches in length, the right lobe being usually somewhat the larger, and the weight of the entire gland being one to one and one-half ounces (Mayo). The gland is enclosed by a thin fibrous capsule, which divides posteriorly into layers. One of these passes behind the oesophagus to unite with that of the opposite side, while another layer passes between the oesophagus and the trachea. It will readily be seen, therefore, how the growth

of a tumor within this limiting capsule may make pressure upon these structures. In intimate relation with the gland posteriorly are the recurrent laryngeal nerves, which pass up by the side of the trachea, on either side. On the right side this nerve is very close to the inferior thyroid artery, passing either over or under the vessel, and is therefore exposed to injury. On the left side the nerve is somewhat more deeply set, and is not so close to the artery. On the posterior surface of the gland, usually outside the capsule, but sometimes within it, are the parathyroids. These little gland-like bodies, more or less variable both to number and position, and positively identified only by microscopic examination, are of supreme importance. While comparatively little is known as to their function the surgeon has learned, in the hard school of experience that they must not be removed, and that their blood supply must not be recklessly disturbed. Another danger requiring most vigilant consideration is that of hemorrhage. The blood supply of the thyroid gland is remarkably abundant and anastomosis is very free. In the diseased conditions requiring operative interference, this vascular network is greatly increased in size and anatomical relations are distorted. The principal arteries, four in number, are the superior thyroids arising from the internal carotids, and supplying the upper poles, and the inferior thyroids arising from the thyroid axis, and entering the capsule at the hilus. The superior and inferior thyroid on either side are almost directly connected by a well defined anastomotic channel. From this channel or from the inferior thyroid, arise the parathyroid arteries, upon the preservation of which, depend the life and continued activity of these mysterious though all important structures.

Such is the delicate and difficult situation confronting the surgeon when he is called to invade this field.

While not strictly within the scope of the present consideration it is interesting to find in a paper on the "Etiology and Symptomatology of Goiter," by Prof. Adami, at McGill University, read in 1900 this statement:

"The persistent and recognizable enlargements of the thyroid gland which we classify under the name of goiter or bronchocele, are from almost every aspect a pain to the pathologist, even if, like so many human ills to so many patients an interesting pain. He knows not their cause: when he comes to study them histologically, the changes they present are bewildering in their manifoldness: his medical and surgical friends have provided him, perhaps it would be more courteous if not more correct, to say can pro-

\*Read before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

vide him with singularly few data whereby to recognize different forms of disease associated with different forms of anatomical lesions, and so to establish a useful classification; where when symptoms are present, the explanation he can offer as to the mode of development of the same, are such that he has found it hard even to convince himself that they are correct." (1) Further in the same connection after discussing the many and varied theories which have been advanced as to the etiology of goiter he questions the correctness of regarding, as has been the custom, ordinary goiter, and exophthalmic goiter as two distinct diseases. He says on this point "I do not wish to indicate that the causation of the two diseases is identical, for my opinion is that the causation is absolutely different,—but I do wish to emphasize the fact that the sharp limitation which is usually held to obtain between ordinary and exophthalmic goiter is often non-existent, and that the one condition not infrequently is accompanied to a greater or less extent by symptoms of the other."

Adami concludes this interesting study by submitting the following outline of a classification of the various conditions affecting the thyroid gland:

1. Disturbances of the thyroid so extensive as to lead to atrophy of the gland tissue, cretinism or myxedema.

2. Generalized colloid goiter—due to retention of the glandular secretion—with myxedematous symptoms.

3. Nodular goiter—due to local disturbance similar to that producing generalized colloid—with the absence of general symptoms, but with possible symptoms due to pressure of the enlarged portions of the gland upon surrounding organs.

4. Ordinary nodular goiter—with transient symptoms of Graves' disease.

5. Secondary Graves' disease,—i. e. persistent symptoms of hyperthyroidism following upon an ordinary goiter.

6. Primary Graves' disease,—with accompanying enlargement without retention, and exophthalmos.

7. Relative or absolute increased activity of the thyroid gland without at first any recognizable enlargement.—The *formes frustes* of Graves' disease.

In a recent discussion of the pathology of exophthalmic goiter Prof. McCallum of the Johns Hopkins University, says "The symptom complex which we know under various names as, exophthalmic goiter, Graves' disease, etc., has been extensively studied but even yet there is not perfect unanimity of opinion as to the anatomic changes which underlie these conditions, and in speaking of the changes which he had observed in the

study of some sixty cases, he says they seem in each instance to be the response, or reaction to some fundamental or primary disturbance of which as yet I think we have no very clear notion." (2)

Beebe concludes a careful study of the physiology of the thyroid gland in its relation to exophthalmic goiter with this statement: "I must again call attention to the dearth of our knowledge of the physiology of the thyroid gland and of the pressing need of systematic and careful investigation both on the part of the laboratory worker and the clinician." (3)

Passing however from these questions which possess all the absorbing interest of unsolved problems, we come to consider the subject somewhat more practically from a surgical standpoint.

Chas. H. Mayo whose work in this field has been monumental, and whose statistics compare favorably both as to volume and mortality with those of the great Kocher, finds that goiters may be classified very simply into two varieties; viz: diffuse and circumscribed.

The diffuse variety includes general colloid, diffuse adenomata, and many cases of hyperthyroidism.

The circumscribed growths are single or multiple nodules, developing in one or more lobes, and appear as foetal rests, adenomata, and cysts. These rounded tumors, developing within the capsule may cause injury or destruction of the gland tissue by pressure atrophy.

Of the exophthalmic type for which he prefers the term hyperthyroidism, Mayo recognizes four subdivisions:

1. The soft vascular pulsating tumor associated with hyperthyroidism.

2. The hard dry gland of the hyperthyroidism, which is the usual type.

3. Hyperthyroidism developing in previously existing goiter.

4. Pseudo-hyperthyroidism, in which with enlargement of the gland the symptoms of Graves disease are transient or intermittent. (5)

For the relief of these conditions various operative procedures have been advised and practiced. Partial thyroidectomy, ligation of one or more of the thyroid vessels, resection of portions of the cervical sympathetic nerves and ganglia, exothyropexy, or partial displacement and exposure of the gland and operations upon distant parts of the body, have all at one time or another found advocates. By a process of evolution we have arrived at what appears to be a very satisfactory solution of this difficult problem.

The results which are to-day being achieved by Mayo compel not only the respectful attention, but the admiration of the surgical

world. It shall now be my purpose to present a concise statement of his method based upon recent reports of his work and a personal observation at his clinic at St. Mary's Hospital in Rochester, Minn.

#### 1. Preparation of the patient.

Great stress is placed upon the condition of the patient at the time of operation. In exophthalmic cases it may be necessary to delay the operation for weeks in order that this may be improved.

Rest in bed, the exhibition of belladonna and quinine, and the use of the Roentgen Ray, are found useful. Usually these measures are sufficient to control in a measure at least the rapid heart action, extreme nervousness, and other symptoms of acute hyperthyroidism which contra-indicate operation.

Ether, given by the open drop method, is the routine practice. One hour before the operation 1-6 grain of morphine and 1-120 grain of atropin is given hypodermically. In the hands of a competent anesthetist, this is considered quite as safe and much more satisfactory than local anaesthesia.

The patient is placed in the reversed Trendelenberg position, head up and shoulders elevated. This position not only affords good exposure of the operative field but markedly lessens hemorrhage.

The transverse collar incision of Kocher is made through the skin and platysma myoides, this muscle being retracted above and below with the skin flaps. In tumors of moderate size separation of the superficial muscles covering the gland will permit exposure and delivery of the tumor. Where necessary one or more of the muscles of the sterno-hyoid group are cut between clamps near the point of insertion, the clamps remaining until the ends of the muscles are to be reunited.

In those cases which present encapsulated tumors or cysts, the capsule of the gland is opened, and the tumor is enucleated. Often two or three or more small tumors are thus removed from the substance of the gland, the cavity being closed and obliterated by a running lock stitch of catgut.

In diffuse adenomata, and in hyperthyroidism, one whole lobe is usually removed, care being taken to preserve posterior portion of the capsule and with it the parathyroid. By blunt dissection with the fingers the lobe is separated from the attachment above and externally. All vessels entering and leaving the thyroid are double clamped and cut between forceps. The capsule is now opened along the side and is then brushed off the gland with gauze, the lobe being retracted firmly toward the median line.

When the dissection is complete the isthmus is cut across, and the cut surface promptly swabbed with Harrington's solu-

tion No. 9. The composition of this solution which tends to inhibit absorption through lymph channels is as follows:

Alcohol . . . . .	40 parts
Water . . . . .	300 parts
Hydrochloric Acid . . . . .	60 parts
Bichloride of Mercury . . . . .	8 parts

At this stage of the operation a large number of clamps are usually still in position, and these are now removed one by one as the vessels which they control are included in the running lock stitch of catgut. Important vessels are carefully ligated separately. Great care is necessary to avoid including in these ligatures any muscle fibres as post-operative hemorrhage in one or two cases was thought to be due to this error.

All exophthalmic cases are freely drained. A rubber tube of medium size slit longitudinally and including a small strip of gauze is inserted through a stab wound in the lower flap. This is removed after one to three days. The skin wound is carefully closed by a subcuticular suture, care being taken to approximate the platysma.

Up to the present time Mayo has operated on about 500 cases of goiter. Of these more than one-third have been exophthalmic. He has lost three cases in his last 150 operations—a mortality of 2 per cent. As to results 50 per cent. of those surviving the operation make early recovery, 25 per cent. improve of the main symptoms in several months, and 25 per cent. while greatly benefitted, have occasional temporary relapses of the tachycardia and tremor.

Albert Kocher at the last meeting of the American Medical Association reported 254 cases of exophthalmic goiter, upon whom 315 operations had been performed with only 9 deaths—a mortality of only 3.5 per cent. All of the cases surviving the operation were benefitted, 83 per cent. cured.

Kocher ligates one or more of the thyroid arteries and later performs partial thyrectomy. He prefers local anesthesia, produced by cocaine. He lays great stress upon the importance of preliminary preparation of the patient, combining medical and electrical treatments with the ligation of the arteries of supply.

He also emphasizes the importance of careful and thorough examination of the blood, determination of blood pressure, and of wisely choosing the time to operate in each individual case. (6)

In a personal letter recently received from W. L. Rodman, that brilliant Kentuckian whom we could ill afford to lose to Philadelphia, he defines his own position and refers to the present practice of Kocher, with reference to some important points in operative technique. He says:

"I am just from Berne where I had the privilege of seeing Kocher, the most famous if not the greatest operator on goiter in the world. I saw him do a number of operations.

"My impressions are as follows: (1) The collar incision is nearly always the best and I find Kocher using it almost invariably at this time. On a former visit to him twelve years ago he was using the angular or 'Y' incisions. At a dinner he gave me, he expressed a preference for this incision, in case the tumor extends high up in the neck behind the angle of the jaw. In all other instances he prefers the collar incision and almost invariably uses cocaine as an anesthetic. In his hands it is fairly satisfactory, yet the anesthesia is never complete. I must say that I do not like it, and, having had a reasonably large experience in goiter where general anesthesia has always been employed with perfectly satisfactory results, I would be unwilling to do the operation under cocaine.

It is absurd, as some of the Hopkins men have claimed, that the mortality from general anesthesia is very great in goiter operations. I have never lost a case from *any* cause and during the past year had seven or eight of the largest and most difficult goiters that I have ever seen in my life. Charles Mayo's experience settles this point definitely. If general anesthesia be given properly, it is just as safe as cocaine and very much facilitates the operation.

2. It is of some importance, I think, to elevate the shoulders. I have operated in almost the half-sitting position and, undoubtedly, had less hemorrhage than is usual in the recumbent position.

3. If the muscles are to be cut across, I prefer to do it at their insertion—the cosmetic effect is better.

4. Kocher will bury from 75 to 150 silk ligatures in an ordinary goiter operation. They never give trouble in his hands. For several years I have used, in lieu thereof, Pagenstecher, whose tensile strength is greater and it buries even better than silk.

5. Another point of great interest, Kocher removes the sutures and drainage tube within twenty-four hours. The wound is then covered over with collodion. His wounds are beautiful; almost no scar at all.

8. The dressing of these cases is of importance. It should be an abundant one and applied so as to avoid making undue pressure."

As late as 1904 Deaver advocated Bilateral cervical sympathectomy after the method of Jonesco and Jaboulay as the operation of choice and reported some excellent results from this procedure. (7). Replying to my

inquiry as to his present position he writes me as follows:

"Since the paper on Bilateral Cervical Sympathectomy to which you refer was written, I have changed my views very much indeed, notwithstanding the fact that I have had some very excellent results.

In treating exophthalmic goiter I now extirpate the greater part of the organ, preceded by ligation of one or both thyroid arteries, first on one and sometimes on both sides. In some instances doing two or three operations on these patients; in some cases I am able to do the operation at one sitting. The preparation of these patients for operation is very important, as you doubtless know, if you are familiar with Charles Mayo's work."

Working in connection with Halstead, Herbert M. Evans, of Johns Hopkins, has recently reported an interesting study of the parathyroid glands, with especial reference to their blood supply. He shows that the parathyroids are always supplied by definite parathyroid arteries; that these parathyroid arteries, superior and inferior usually arise from the inferior thyroid artery, but frequently from the anastomosing channel connecting this vessel with the superior thyroid; and further that few if any direct vascular connections normally exist between the parathyroid glands and the connective tissue envelope of the thyroid gland. These observations would seem to be of the greatest importance to the surgeon and this phase of the subject is fully considered in the paper referred to by Halstead. He thinks it quite certain that in most instances of complete excision of one lobe of the thyroid gland as reported by surgeons the world over, both parathyroids of the operated side have been sacrificed, whether the trunk of the thyroid arteries are ligated at some distance from the gland or the ultimate branches of distribution at their points of entrance into the lobe. Even where the posterior of the lobe is resected and left undisturbed, he thinks that in the efforts to control hemorrhage the parathyroids are often destroyed. He therefore advises a method which he terms the operation of ultra ligation for which he claims that without undue loss of time, it is possible to do a clean bloodless operation, preserving the parathyroids with less danger of injuring the recurrent laryngeal nerve because in the absence of hemorrhage this structure is easily seen. He says that for the removal of a thyroid lobe in a moderately difficult case of exophthalmic goiter ten minutes is ample time if the skillful operator is well assisted.

In the 490 cases operated on by Mayo at the time of his last report only a single case of mild tetany which ultimately recovered,

was observed; so that the importance of these observations may be theoretical rather than practical. This whole question of tetany thyreo priva has been very fully considered in a recent paper by Pool, which represents an interesting study of the embryology, anatomy and physiology of the parathyroid glandules and of the pathological processes resulting from their removal.

The conclusions which he reaches may be summarized as follows: (1) The removal of all and possibly even of a part of the parathyroid bodies result in tetany. The symptoms of this disease are striking, the diagnosis easy, and the efforts directed towards its cure have not as yet been proved to be successful.

2. While many questions pertaining to the parathyroids are still unsolved, two important points may be accepted as proved by the evidence of experimental and clinical observation: First, that tetany following goiter operations is due to the operative interference with the parathyroid bodies, and second, that in the operative procedures the parathyroids and their blood supply must be maintained inviolate.

In view of these considerations we may conclude:

1. That the operation of partial thyroidectomy is the rational treatment of goiter.

2. That in the hands of skilful operators the mortality is exceeding low and the results almost uniformly brilliant.

3. That notwithstanding the difficulties and dangers and the special skill required, operations for goiter are much less common than the present state of our knowledge would seem to justify.

## A PHARMACOLOGICAL CONSIDERATION OF THE THYROID GLAND.\*

BY VIRGIL E. SIMPSON, LOUISVILLE.

*Preparations:* Glandulae Thyroideae Siccae (U. S. P.)

The thyroid gland of the sheep (*Ovis aries* Linne) freed from fat, cleaned, dried and powdered. It is a yellowish and a morphous powder with a slight meat-like odor and containing the active ingredient of the thyroid tissue; partially soluble in water. One part of the official preparation represents approximately five parts of the fresh gland. Dose 0.250 gm. (4 grains).

Iodothyrim, (unofficial). A milk sugar trituration containing 0.03 per cent. iodine, brown in color, amorphous and having an odor suggestive of the pyridin bases. Almost insoluble in water, with difficulty in alcohol and more so in dilute alkalis. The gland can be boiled for a long period in a ten per cent. solution of  $H_2SO_4$  without destroying its iodothyrim. It constitutes about three per cent. of the gland. It was isolated by Baummann in 1896. It does not exist as such in the gland, but is manufactured from thyroglobulin and liberated during the process. The commercial preparation is a milk sugar trituration and is absorbed readily from the stomach. Dose 1 gm. daily. Tablets have been introduced each containing gr. 1-60 of iodine.

Iodine:—A new preparation obtained by precipitating with tannin the iodo-albuminate. Fifteen grains corresponds to 150 gr. of fresh, or 300 of dried gland.

Iodin:—Precipitated from solution of thyroid in normal salt solution by means of tannin. Contains greater number of extractive principles than those preparations hitherto obtained.

Antithyroid Serum:—The blood serum of sheep, whose thyroid was removed six weeks previous to the first venesection; it is marketed after addition of phenol under various names as: Moebius Serum, Rodagen, and when dried, as thyroidectin. Dose 4 Cc (1 dram) every second day in wine, or 0.3 gm. (5 grs) of the dried three times daily.

The Iodin Content:—In 1895 Baummann demonstrated that the gland contained an iodine body. Roos proved that this iodine-containing body accomplished the chief functions of the gland. It was known before Baummann isolated this thyro-iodine, as named by him but now generally called iodo-thyrim, that iodine locally or internally was beneficial in cases of goiter; we now know that the iodine accomplishes its results through in-

\*Read before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

creasing the iodo-thyrim of the gland. There are two proteids found in normal glands of interest here: (a) A nucleo-albumin present in small quantities derived from cells lining the acini, (b) colloid matter, made up of a proteid and non-proteid; the latter containing the thyro-iodin. Hutchinson experimented with both and found that while some benefit resulted from the former, yet the latter gave, by far, the most favorable results. It is this colloid substance, consisting of thyreo-globulin and nucleo-proteid which is the active secretion of the gland and of these the thyreo-globulin is the most active as it contains all the iodine.

*Pharmacological Action:*—Exact knowledge of the action of the gland dates properly from 1882 when attention was called by Reverdin to the profound effects which attend complete removal; it is however, yet problematical to a degree, whether the quasi-external secretion of "colloid" which contains iodo-thyrim which collects in the alveoli of the gland and passing slowly out by way of the lymphatic system is the exact role of the gland, or whether there is common, in addition, some other substance like the glycogen of the liver that does not find its way into the lumen of the ducts at all. It has also been debatable whether it is the function of thyroid to destroy toxic bodies, or if it forms some substance advantageous or indispensable to the body by virtue of furnishing a stimulus necessary for proper metabolism. These views may be stated thus: theory one: There are toxic substances, the product of metabolism in the blood normally which being removed or rendered harmless by thyroid, accumulate when it is withdrawn and produce the effects characteristic of thyroidectomy; theory two: There is an internal secretion which, when it reaches the tissues, is identified with metabolic processes. Certain it is that, clinically, two distinct phases are presented as the result of gland activity: First, a neutralization of toxins—the failure of which yields myxedema, and second, if not itself neutralized, Basedow's disease results.

*Circulatory System:* Thyroid given by the mouth, or iodo-thyrim which represents the glands pharmacological activity, injected intravenously, accelerates the heart's action. This is due to a stimulation of the accelerator center and to some direct action on the heart itself; it is not due to a stimulating influence on the inhibitory mechanism. While this is stated to be the action of the agent, it is but fair to record that such authorities as Vamossy and Vas contended that iodo-thyrim has no effect directly on the circulatory system urging that such symptoms as are manifested after ingestion are but the results of

metabolic disturbances. Opposed to this view were Ott, Schafer, Oliver and others equally competent who contended that a direct influence on the circulatory apparatus did occur. More recent observers attribute this difference in experimental results largely to dosage; small doses increasing the heart's activity, while large ones lessen the force of contractions and increase the excitability of the inhibitory mechanism. The blood vessels are dilated by stimulating the vaso-dilators, as well as diminishing the vaso-constrictors activity. The gland, in the living subject, contains powerful vaso-dilator fibres by which the blood pressure in the carotids can be greatly reduced and therefore regulate cerebral circulation. Cyon and others have long maintained that the gland is intimately connected with the regulation of the blood supply of the head. The general blood pressure falls in consequence of the dilated condition of the vessels and in spite of the fact that the heart is accelerated. Cyon further believes that a function of the gland is to transform iodine salts introduced into the body into organic combinations thus preventing them from acting as poisons on the nerves of the vessels and heart. Iodine salts thus formed are not merely made harmless but by their union with proteid's iodo-thyrim is formed whose function is beneficial to the vascular system. He also attributes the circulatory symptoms following the removal of the glands—constriction of vessels, increased and consequent weakening of the heart with diminution of output—to the loss of this regulative influence. Haskovec pioneered the view that fall of tension was due to depression of the heart muscle and that the increased rate was the effect of accelerator stimulation.

Perry found that in feeding thyroid to the insane no change in white cells of blood occurred so far as number was concerned, but a marked diminution of percentage of the multinuclear, and corresponding increase of mononuclear leucocytes. These results were confirmed by Mosely, Ball and Vas, on the other hand, claimed to have found an increase in the number of leucocytes. Osborne believes that the thyroid has something to do with the production or destruction of red cells. That such contention is reasonable is borne out clinically by the improvement in blood count under thyroid treatment of chlorotic anemia.

*Nervous System:* The action of thyroid on nervous matter directly connected with special systems, circulatory, etc., is discussed under their respective headings. It exerts a direct influence on the central nervous system. Bruce says it is a distinct cerebral stimulant. Subjects of goiter, according to

statistics, become insane about nine times as frequently as normal individuals. In the special types of mental aberration in goitrous cases the degenerative and puerperal forms of insanity predominate.

Shepherd has pointed out that in young women afflicted with chronic genre psychoses are not uncommon e. g., nervous disposition, fearful, inability to continue sustained work, etc. Among other effects of thyroid feeding, a stimulation of mental activity even to sleeplessness occurs. In those cases with thyroid deficiency the impaired or completely absent intellectuality together with prompt improvement of mental symptoms labels important on the gland influence upon the nervous system. The gland is readily stimulated or excited temporarily, by grief, sexual excitement and emotion. The nervous, excitable, irritable girl at puberty is so, not infrequently, as a result of the gland's unstable condition; it may be either under or overdoing its normal function. Insomnia, headache, vertigo, polyphagia and tremors of the extremities follow repeated, though small dosage. It has been suggested that the nervous phenomena are due, in part at least, to changes induced by the drug in the blood supply of the nerve centers.

*Metabolism:* We are now in possession of considerable knowledge of the relation of parenchymatous disturbance in the thyroid to the resultant disturbance of general body metabolism. The research work of Roos, Davis, Napier, Mendel, Ord and others of like ability leave no room for doubt that there results an increased destruction of proteid substances under thyroid medication. In Anderson's report the katabolic waste amounted to only 18.8 calories per kilogram of body weight before treatment, whereas after nine months treatment it amounted to 32.3 calories or almost normal. Frequently more nitrogen is eliminated in the urine than is taken into the body in form of food. This loss may be arrested or prevented for a time, at least, by augmenting the intake of nitrogen. Increased oxidation is still further shown by the increased amount of oxygen absorbed and  $\text{CO}_2$  exhaled. Cushny states that iodo-thyrin specifically increases proteid waste though he admits the nitrogenous loss equals one-sixth of the total loss of weight and that the remaining five-sixths must be due to increased oxidation of fats and removal of fluid. Vandelstadt asserts that fats are so oxidized. Schondorff says that destruction of nitrogenous tissue does not begin until the reserve fat is exhausted. Sollmann agrees that the first effect is on fats, and that proteids are acted on only after the former is reduced to a minimum. The removal of fluid is the greatest factor in the loss of weight. This loss is

often rapid at beginning of thyroid administration amounting to several pounds per week.

Thyroid seems to have some considerable influence on sugar metabolism. Glucose not infrequently appears in the urine under thyroid administration and diabetes is often aggravated by such medication. Cretins have likewise developed glycosuria under treatment. It is of singular interest to note that diabetes often complicates acromegaly in which latter condition the thyroid gland is always diseased. Thyroid secretions undoubtedly presents colloidal and fatty degenerations of the internal organs—liver, kidney, etc. Hutchinson states that thyroid hastens cell activity and increases rapidly of combustion. The metabolic increase is shown by: (1) the increased appetite (2) increased absorption of nitrogenous food (3) increased temperature (4) nitrogenous excretion exceeding the ingestion (5) facilitated growth of skeleton in the young (6) greater activity of mucous membrane, skin and kidney and finally (7) the loss of weight.

Levy's conclusions may be summed up briefly as follows: loss of weight is not due to loss of water and albumin alone, but in part to loss of fat; that the loss of weight does not occur in all persons who take it; that the proteid deficit may continue even with superalimentation and is, therefore, a specific toxicogenic effect; and that absence of gland function causes defective growth, serious bodily and physical degeneration, decrease of gaseous interchange and heat production. Recent experiments show that leanness attending rapid growth can often be attributed to exaggerated activity of the gland.

*Urinary System:* The quantity of urine is increased by thyroid. Issai and Garg state that it is uniformly diuretic in its action. It is yet interesting speculation as to how the increase is produced. Cohen says it is due to stimulation of the kidney cells; that the gland acts much like iodine combined with a nitrite, and that sodium nitrite and sodium iodide will give the same physiological effects as thyroid. Cushny attributes this effect to either a specific action on the kidney, or to changes taking place in the circulation. That the kidney is directly involved is evidenced by the occasional appearance of albumin while under thyroid administration. There is also an increase in output of solids; sodium chloride and phosphoric acid are participants in this increase. Schondorff states that the early increase of nitrogen in urine is not necessarily due to increased proteid metabolism, but is due to removal of urea and other products formed in tissues before administration of gland, and are now excreted in larger

amount through on increased activity of the kidney. In a considerable percentage of cases under thyroid feeding sugar appears in the urine. Iodin in form of iodides is found in urine after iodo-thyrin administration. Such finding shows that the iodo-thyrin is decomposed in the body, in part at least, while the rest of the iodine is appropriated by the gland, no preliminary composition taking place here.

*Reproductive Organs:* While the best known and most evident functions of the gland are connected with certain nervous phenomena and metabolic processes, it has also a decided, though less widely recognized, influence on the sexual functions, particularly of the female. In an address before the physiological Section of the British Medical Association in 1896 Gaskell pointed out that in forms regarded as occurring along line of vertebrate ancestry, the primeval sexual organs lie in close connection with the laryngeal depression or groove from which the thyroid is developed and that, in fact, the gland is a sexual organ. The gland is relatively larger in the female than in the male and also becomes more frequently diseased. It swells during menstruation, sexual excitement and pregnancy. The gland does not functionate to a great degree before birth and the mother, therefore, must furnish thyroid secretion for both self and child. Halstead observed in his experiments that puppies, whose mothers had had the greater part of the gland removed before pregnancy, had very much larger glands at birth than normal ones, clearly indicating an attempted compensatory hypertrophy. Lanz noted that herbivora have apparently less need for the thyroid than carnivora or man, but that even in them the reproductive and sexual capacity is much diminished when it is missing, and that their young if they have any, are small, abnormal and poorly developed. In the genus homo myxedematous patients are usually sexually inactive, while cretins generally fail to mature. Lanz and others have reported cases of men who were deprived of all sexual functions by complete removal of the gland and which were restored when thyroid was administered as a therapeutic agent. In like manner suspended menstrual function following thyroidectomy in women has been resumed under its use.

The slighter sexual disturbances of the gland are in the nature of a hyperemia, but if continued this process, now physiological, may easily lead to extensive parenchymatous changes. A large number of cases of goitre can be traced back to the period of puberty or other marked disturbances in the sexual organs in both men and women. (Freund). In this connection it is interesting to note

what might be called the antagonism that exists between the thyroid and the ovaries: (1) The thyroid seems to favor the growth of the osseous system as is evidenced by the defective development in myxedematous cases. The contrary action of the ovary is noted in osteomalacia, a disease very rare in children and the aged, the great majority of cases occurring in women and of these chiefly among those who have borne children or who are pregnant; ovariectomy is productive of such results as to warrant the contrast of the influence of thyroid and ovary on the bone development. (2) Thyroid by its influence on the metabolism is antagonistic to an increase of adipose material, while the normal ovarian functions have a tendency to an increase of fat in the body. (3) The ovary seems to suppress to a degree the growth of hair as is noted in the appearance of hairy growths at the menopause, while thyroid favors hair growths. (4) On the circulatory system thyroid increases the pulse rate and raises the tension, while ovarian secretion has an opposite effect. (5) Similar antagonisms may be cited in the output of urates, phosphates and chlorides, the elimination of iodine and calcium, as well as, the regulation of the secretions. (6) It is a question of interest whether analogous antagonisms obtain between the testicle and thyroid. In young males who have atrophy of the testicles and in emuuchs there is a tendency for the long bones to continue growing far beyond the normal period. This has been shown by the Rontgen Rays to be due to a delay in ossification of the epiphyses. Newmann writes that thyroid exerts an inhibitory effect on the pelvic genital organs and the uterus particularly and especially on the epithelial elements of the endometrium. Adams sums up his conclusions by asserting that there is a very close relationship between the disorders of the thyroid and the sexual functions though of the exact nature of this relationship we know too little.

#### THERAPEUTICAL APPLICATIONS.

*History:* The therapeutic use of organs, or extracts therefrom, of animals and man in disease is usually associated with Brown-Sequard. But the earliest records of medicine show such use. Homer tells how Achilles fed Achilles bone marrow to give him strength. Pliny in "The Natural History" tells of a number of instances of this kind. Messalina, wife Augustus Cæsar, as well as, the sensual and dissolute youths of Greece and Rome drank the dried testicles of the cock and dog mixed with wine. Thomas Watson recommended for malaria the spider and its web, from which later was isolated by Bruce Jones an albuminous substance analogous to Cinchona.

*Myxedema*: There are three varieties of this condition recognized. (1) True myxedema. Since the primary object of organo therapeutics is to supply a deficiency of a normal secretion and as myxedema is due with few exceptions, to a loss partial, or complete, of function of the thyroid its use in such conditions is based on rational grounds, its action specific and the results obtained are uniformly satisfactory. To Harseley is due the suggestion of thyroid medication and we are indebted to Murray and Ord whose investigations showed that the disease could be relieved by its use. Murray introduced the subcutaneous injection of thyroid juice and his results were brilliant from the start. He recommends a division of the treatment into two stages: (a) removing symptoms of the disease, (b) maintaining condition of health attained. The first must be conducted carefully and gradually accomplished, the latter, by continued small dosage. In myxedema a poisonous proteid is formed in the tissues and finds its way into the blood: it is fixed by the thyroid administered and rendered innocuous by an enzyme which splits it up into two parts: (a) a proteid constituent which unites with thyro-iodin and (2) a carbohydrate.

(2) Congenital Myxedema or Cretinism. As Osler expressed it, "our hopes have been realized fully. The change noted under thyroid feeding in the pitiable, idiotic cretin metamorphosed into an intelligent and healthy child is scarcely short of the marvelous. The younger the child more marked the change. The mental alteration is generally noted within two months under proper dosage, the size of the dose must largely be determined by each individual case; with this as with all therapeutic agents it must be given for its effects. Patterson states that not only can it be used as a curative agent but that if a mother who has born cretins is fed thyroid during pregnancy that cretinism can be prevented. Edwards (1907) writes that "in thyroid extract we have one of the few actual specifics in medicine." In dwarfing, associated with idiocy or not, it is of much benefit. Virchow contended that much of rachitis and dwarfing were dependent on disease of the gland and thyroid was a rational treatment.

(3) Operative Myxedema or Cachexia Strumipriva: In 1882-3 Kocher and Reverdin published their observations of patients whose glands had been completely removed and who manifested a set of symptoms which they called cachexia strumipriva. These symptoms are identical with myxedema, as well as the cretinoid state. Partial removal is not followed by such symptoms nor is complete thyroidectomy if accessory glands are

present. In the case of partial removal, the remainder seems to undergo a compensatory hypertrophy. The administration of the gland must of course be continued throughout life with occasional intervals of withdrawal.

*Goitre (Simple)*: In the older fibrous and degenerated or cystic forms surgical measures are generally imperative but in some of the other types and especially in the simple parenchymatous enlargements thyroid feeding has proved beneficial in about two-thirds of reported cases. The most favorable results are obtained in adolescents and young adults and appear in a very short period; usually within two months the therapist should be able to measure the value of continued treatment satisfactorily. Murray explains the modus operandi by allowing the hypertrophied gland to pass into a resting condition. Even in those cases where surgery is imperative a preliminary treatment to the operation by giving rest and relief from the dyspnoea, etc., as well as a reduction, though it be slight, in the size of the gland is rational and desirable. It must be admitted, however, that occasionally thyroid may stimulate the gland to an increased or abnormal activity and project Graves' disease as a result. Exophthalmic goitre and its serum therapy is an inviting field just here, but the limitation of this paper precludes its exploration.

Hypothyroid anorexia is a frequent and annoying accompaniment of the above condition. In a series of a hundred cases Levy and Rothschild (1906) noted such a distinct increase in the appetite that they concluded the gland was a factor as a physiological regulator of the sense of hunger. They cited as strongly suggestive of this assumption the crises of bulimia in exophthalmic goitre and the diverse favors of hunger occurring during pregnancy. The most pronounced improvement in this respect is noted at the beginning of treatment and diminishes during intervals of suspension. It is also noteworthy that as the hunger increases the appetite becomes normal and the caprices are overcome.

*Generative System*: Conditions influencing the genital apparatus—puberty, pregnancy, fibroid tumor—frequently cause enlargement of the gland and a deficiency of gland secretion—myxedema, cretinism—is often associated with atrophy of this same apparatus. This indicates a direct association between the gland and the generative system and would suggest its use. It seems especially indicated in hemorrhagic conditions and splendid results have been obtained in functional forms such as menorrhagia at the menopause. The more recent the case, the better the results. Profuse menstruation

of young girls is frequently due to an excessive activity of this gland, while amenorrhea and chlorosis are associated with and often caused by a hyperactivity. The latter will often yield to thyroid as successfully as has many of these cases done to iron. Osborne has repeatedly noted the blood count in chlorotic anemia under this treatment alone. He also urges its use in epistaxis and uterine hemorrhages occurring in stout, overweight women. Lanz has observed patients who were unable to procreate following thyroidectomy become mothers subsequent to thyroid medication.

The exact cause of eclampsia is yet in dispute, in fact more than one factor may operate in its production. But very recently Branson in the Jour. Am. Med. Assoc., Sept. 28, 1907, made the contention with some considerable show of reason that the symyctium was the responsible factor in its occurrence. Whatever it may be concerns us little here, except the fact that good results have been obtained in dealing with the attack and its sequelae by thyroid administration. It is claimed that in eclamptic women the thyroid is not normally hypertrophied during pregnancy. Fothergill considers that eclampsia followed by puerperal melancholia are striking examples of toxic states associated with defective metabolism and absorption from intestinal canal. He recommends along with diet, rest, packs and irrigation of the bowel, the giving of thyroid extracts to stimulate metabolic change. Other competent observers state that in pregnancies accompanied with headaches, nervous symptoms and imperfectly functioning kidney, thyroid extract relieves the symptom, and they believe, prevents eclampsia.

From the flattering reports published by Stawell, Cheren and Hertoghe it appears that thyroid is of great benefit in many cases where lactation is imperfect. It does have a stimulating influence on the mammary gland and to such extent that observers have denominated it specific and uniform.

*Obesity:* Thyroid is a fairly constant ingredient of antifat remedies, its selective action on fatty tissue and decided augmentation of nitrogen excretion constitute the basis of the use of thyroid in abnormal fat accumulation, a use originated by Yocke-Davis. A serious objection to such use is found in the fact that the system seems to become accustomed to the drug and while marked benefit is sometimes noted primarily yet relapses are apt to occur in spite of continued use of the drug. Its effects on the whole may be said to be irregular. Porges says the majority of cases do not improve. Various French authors claim little benefit is derived from its use in young, vigorous, pethoric, good

liver. In many instances the results at first are promising, but is seldom maintained and the daily loss of weight becomes less and less until it ceases, altogether. Magnus-Levy estimated the loss of fat to be trifling and but little more than could be had under any judicious dietary and exercise. There are, however, some conditions in which its effects are satisfactory. In women under forty obesity accompanied by a scanty menstruation its use is worthy of trial. Women who take on much fat after the menopause often have glands that are undergoing, or have undergone degeneration; the adiposis dolorosa is manifestly due to undersecretion and much benefit will be derived by thyroid administration. Finally, in those pale soft, flabby, fat persons with an inclination towards oedema, thyroid feeding results in rapid loss of fat and increased oxidation with general improved nutrition. In all cases insistence upon a maintenance of abstemious habits must be made.

*Cutaneous Disorders:* Its use in dermatology is naturally limited, but since there are not a few skin lesions which appear as the result of perverted or absent thyroid secretions it follows that in such cases its use is productive of some good results. W. J. Robinson says it is of special benefit in senile eczema, not because of specific effect on the disease but rather on account of the improvement of the peripheral circulation. J. William White reported excellent results in producing absorption of contracting cicatricial masses resembling true keloid. Bergman recommends it in psoriasis. It is probably as frequently beneficial in this as in any other skin affection. A critical review of reported cases shows very good results in a reasonable proportion of cases by thyroid treatment. It seems that in many cases the first effects of treatment is an extension of the eruption and this is peculiarly true in those cases in which treatment proves most beneficial ultimately. It also appears that long standing cases show a larger percentage of recoveries than recent ones. It is strongly advocated by Byron and Abraham while Hare says that treatment is barren of desirable results. Crocker writes he has "used it largely and in a limited number of cases its action is often both efficacious and rapid.

Its value in some cases of ichthyosis is indisputable. Hyde and Montgon cry in speaking of the results obtained in their hands characterize them as brilliant, while Don reports he has used it with decided value.

It has not been extensively tried in lupus, but quite a number of cases have been reported benefited. Crocker says "the only agent which has a direct effect on lupus tissue when given by the mouth is thyroid ex-

tract; Hyde while accrediting it with some value says it rarely cures a case of tuberculosis cutis. It may be said in summary, that the failure of other treatment and the apparent benefit in cases reported warrants its further use.

*Nervous Disorders:* Kimmieutl thinks as thyroid treatment in a large per cent. of cases is valueless with occasionally striking good results indicates that in this small number benefited thereby the trouble depended upon, or was connected with a diminished or perverted secretion or function of the gland. If the authority just mentioned wrote under the impression that thyroid was considered a panacea for nervous affections by those using it he was in error; if he meant merely to caution against an indiscriminate use it is desirable to here emphasize his statement. The management of nervous disorders, then so far as thyroid medication is concerned, resolves itself into determining previous to treatment, or experimentally by careful use of the agent, whether or not a given case depends upon disturbed or lost gland function.

Melancholia connected with the menopause is not infrequently so dependent and probably shows a higher percentage of benefit than any other mental disturbance. McPhail advises against its use in acute melancholia with rapid loss of weight and marked mal-assimilation of food. In such cases in which it may be used it is desirable to confine the patient to bed rigorously during the treatment and as long as from 7 to 10 days afterwards, on account of the profound effect on the circulatory system.

Osborne thinks that the various hysterical manifestations of women are often due to this emotional gland being over active in secreting. He also attributes this condition largely to be the cause of nervous wrecks seen so frequently from excessive venery and suggests it may have something to do with the typical hoarse voice of prostitutes.

Since functional neuroses, as epilepsy, may follow thyroidectomy it would seem that some of these conditions may result from perversion of gland function and therefore the administration of thyroid extract would give relief. The author has seen one such case which has had to date a continued recovery.

The theoretical basis for thyroid medication in cases of ophthalmic hemicrania presenting decided periodicity in the female is that the migraine attacks are induced through vasomotor changes the result of certain toxins circulating in the blood and that they in turn are the product of a disturbance in balance of internal secretion between the ovary and thyroid, or from a deficiency in thyroid function. Consiglio reports such

cases where attacks occurred about every 28 days and were entirely relieved by thyroid. It is well to here recall that the urotoxic coefficient rises to nearly double after removal of the gland and that the toxicity of the blood serum always increases after thyroidectomy (Spots). Also the only theories now extensively accepted as to the gland function is (a) antitoxic theory (b) thyroid secretion promotes or regulates normal metabolism, (c) or both.

Levy and Rotheild claim that certain obstinate forms of headache are due to thyroid deficiency and that such patients in their hands were relieved by thyroid medication. They further advise in every ungrain of unknown cause that inquiry be made into functions of glands for symptoms of hypothyroidism.

In insanity with menstrual function in abeyance the return of flow accompanies other signs of improvement and does not occur alone (Elliott).

#### ADMINISTRATION.

Not a few methods have been used in carrying out thyroid medication. Some of them are of interest chiefly as a part of thyroid medication history.

(a) Transplantation: In 1859 Schiff showed that intraperitoneal transplantation in dog after thyroidectomy prevented cachexia strumipriva. Koehler and Reverdin in 1883 demonstrated the same phenomena in man. Schiff and Esselsberg (1884) made grafts in the abdominal cavity and in cellular tissue. Buch transplanted sheep thyroid into the peritoneal covering of myxedematous patients. Eiselberg stated emphatically that intra peritoneal grafting protects patients from consequences of thyroidectomy so long as the glands so transplanted remained functional. In the latter part of the last century King of London showed experimentally, that the colloid substance of thyroid passes directly in the lymphatics. In all of these reports the results were uniformly good for the time, but after a variable period absorption took place or atrophy occurred and the usual symptoms of deficient or absent gland function appeared.

(b) Hypodermic injection: The implantation of gland tissue beneath the skin was early replaced by the hypodermic administration. Pisenti in 1890 began this method securing the fluid by extracting the juice from the glands and injecting it into the tissues. Others followed this method but while the results were fairly uniform comparing favorably with other methods, it was objectionable first, because it required the constant attendance of the physician and second, it not infrequently caused abscesses.

(c) Epidermic: The physiological action

of the gland can be obtained by absorption from local application. Blake speaks in commendatory terms of injection. McKenzie used this means to a considerable extent and recommends the following:

Thyroidin, . . . . .parts 10.  
Etheris . . . . .parts 60.  
Adeps Lanae Hydrosis . . .480.M.

This method has nothing to recommend it; is troublesome, objectionable to patients, slow and less certain.

(d). Vicarious Administration: Mosse reports a case of goitre in a new-born child cured by submitting its wet nurse, who also had goitre, to thyroid treatment. The child was well in 6 weeks, while the nurse's gland became much smaller and general condition considerably improved. But few cases of this kind are on record and while the good results obtainable are not to be questioned, the plan for obvious reasons can not be often made use of.

(e). Per Orem: Horwitz in 1892 demonstrated that the gland itself could be administered by the mouth with as happy results as obtained by extract injection. Ballet's elaborate experiment showed that in from one to one and one-half hours after ingestion of the fresh gland there occurred an increase of temperature and pulse rate. The gland was given at first raw or partially cooked administered as food. The taste was not pleasant and difficulty was experienced in keeping the glands fresh, as well as the impracticability of securing a supply in districts remote from large slaughtering interests. Gastric disturbances were not uncommon in hot weather. Murray's method marked some advancement in administration, he cut the glands in small pieces, macerated them with equal parts of glycerine and obtained an extract by pressure and filtration which was given in 1-5m doses. The glands of young sheep give the best results. Much care is necessary in the selection of the glands; nearly 50% deviate from normal. Tuberculosis in these animals is extremely rare. Dissatisfied with the then present methods of administration, Hutchinson began a series of experiments which resulted in determining conclusively that the albuminous colloid material elaborated by the gland cells carried or contains the active principles of the gland, and that if this colloid substance then isolated be given to myxedematous patients it has all the pharmacological effects of the whole gland. The active principle or principles are absorbed from the gastro-intestinal system and it appears that no particular activity is lost in this process (Horwitz). The gland is now almost universally administered in this country, at least, as a desiccated powder. One gland

yields about 7 grs. of this substance. The chief objection to this preparation is the odor which is obviated by dispensing in chocolate-coated tablets or capsules and confections. The dose varies with the individual patient and it is advisable to begin with a minimum dosage (gr. 1-2 per dose) and gradually increase it. As much as 15 grs. daily may usually be administered with no untoward manifestations. If one preparation gives rise to such phenomena a change to some other is often all that is necessary in order to continue its use. If stomach absolutely rebels, it may be given per rectum; the official powder may be so used.

Since the action of the gland is to convert iodine salts into iodo-tyrin it seems logical that it is advantageous to administer the gland in form of iodothyrim. It has been urged that since iodine is the active agent of the gland that it be given instead of iodothyrim for goiter, myxedema and cretinism. That such therapy would be theoretically, and is practically, productive of good results is a fact; but it must be borne in mind that the quantity of iodine necessary to act in such conditions is much larger than the iodine content of iodothyrim necessary, proving that the latter does not act as an iodine compound merely, but as a specific substance of the gland (Cushny). Further, various iodine compounds such as iodo-spongin (the iodine compound of the sponge) and iodo-albumen have been experimented with and shown to be practically inert in goiter.

Thyroid preparations should preferably be given on an empty stomach allowing the patient to chew the tablets or take an uncapcapped capsule with hot water thus hastening solution and absorption.

#### UNTOWARD EFFECT.

During the course of administration the cardiac and respiratory apparatus must be especially watched. Extreme precaution and constant surveillance must be exercised in every case. The patient should never know what he is taking; this is peculiarly true with cases of obesity; patients receiving some benefit from its use will advise others to use the agent and the majority of ill effects reported, have occurred in this class of patients.

The dangers depend to a degree, upon the manner of administration. When pure gland is used the phenomena of over dose present themselves; when dried powder is given symptoms of ptomaine poisoning may be added. The manifestations in general may be classified as:

(a). Immediate: Palpitation tachycardia, vertigo, swelling of face, headache, tremor, insomnia, respiratory distress, anorexia, diarrhoea, erythema and occasionally, aphasia,

neuralgia, delirium and convulsions.

(b). Delayed: Disturbances of nutritive character as: loss of strength, wasting, mental depression, polyuria, phosphaturia, choluria and leucosuria; Ewald noted moderate albuminuria with casts which disappeared on withdrawal of treatment. Injurious effects on certain anatomical elements, especially nerve cells, has been observed.

Arsenic has been used to prevent or combat the ill effects of thyroid. The explanation of its action is that it antagonizes thyroidal intoxication through its energetic restraining influences on oxidative processes (Sajons). This observation has been confirmed by Mabile. Ewald thinks it lessens liability to thyroidism, which is after all rather an infrequent condition. It has not been used sufficiently to form, as yet, an accurate judgment. When all is said it remains that on appearance of not ward symptoms of any magnitude the drug should be withdrawn.

It is impossible to establish statistics as the public obtains and uses preparations, directing their own treatment. In view of this fact, the Academy of Medicine of Paris, has suggested that the sale be regulated by the government under head of dangerous drugs and sold only on the prescription of a physician.

#### PERMANENCY OF EFFECTS.

Thyroid is a dead product and its administration can only be considered a substitution therapy and its action must of necessity be transitory in character, disappearing as soon as supply is eliminated from the body (Croftan). Relapses are common after withdrawal of the drug and in many cases it becomes rather a food than a medicine. Burns says that complete recovery in chronic goitre is the rule in young and that recovery becomes less common in proportion to age: complete return to normal size is not to be expected later than 20th year. Angerer in a series of 100 cases of chronic goiter, reported relapses occasionally occurring after cessation of treatment.

In cases where the gland has been removed, operative myxedema, the treatment must be given through life of course. It is not necessary to give it daily as the drug is slowly eliminated and periods of rest may be had.

In such manifestations as are due to a perverted secretion with altered chemistry permanent cure may occur.

Cretinism, like operative myxedema, can be cured in so far as symptoms and health are concerned but the gland must be continued and the good effects are maintained only so long as the drug is kept in the system.

### DISCUSSION.

**George H. Hendon**, of Louisville: Mr. President.—Perhaps I can best utilize the time at my disposal by considering those influences which deter the surgeon from operating on these cases of goiter, notwithstanding the fact that I consider the surgical treatment the only one worthy of application according to our present knowledge. I make this statement with a full realization of the brilliant work that has been accomplished by Beebe and Rogers, of New York, with nucleoprotein serum. This is the only therapeutic measure that is really worth any serious notice.

The things which are most likely to bring about disaster in the operation for goiter, are, first, improper consideration of the condition of the patient, more particularly with reference to the patient's condition. The main point in that connection is the rhythm of the heart's action rather than the rapidity or the arterial tension. However, I heard Dr. Mayo make the statement that, in cases where the heart beats with regularity, it matters not as to rapidity, but if he counted the pulse for a certain space of time, say as much as half a minute or fifteen seconds, and in the next count of fifteen seconds the rate of circulation was the same, he considered the case much more favorable for operation than a case with a lower rate of rapidity, yet with inequality in the rhythm of the heart's action.

In order to impress you with the importance of the consideration of the general condition of the patient, I will say that Koehler recently made the statement that he has only operated on one-third of those cases who applied to him for treatment. When we consider that this surgeon has, up to date operated on 3,500 cases of goiter, we can realize how important this preliminary consideration must be. What are we to do with patients who come to us and are not proper subjects for operation? In such cases we can compromise and emulate, first, the example of Mayo, of bettering the condition of these patients with diet, quiet and rest, and with the use of the Roentgen ray, and then, further, emulat-

ing Koehler, who even goes so far as to ligate one thyroid artery at a time, until the patient has improved sufficiently; it matters not if it requires years to accomplish the result. He only operates by ligating one thyroid artery at a sitting, ligating another artery at another sitting, and at a future sitting removing a portion of the gland, and at a still further sitting removing another portion of the gland until by fractional removal he has reduced the gland to a size compatible with health and comfort of the patient.

When we consider the operative steps of this condition, the point that strikes us most forcibly, at the outset, is the great danger of hemorrhage. These of us who have worked about the neck always approach this region with the most profound respect. Abdominal surgery is easy compared with operative procedures in the region of the great vessels of the neck. One of the most valuable means of preventing hemorrhage in these cases is the reverse Trendelenburg position. You cannot realize its value until you have tried it. It was brought to my mind very forcibly while removing malignant growths of the parotid gland, of which comparatively recently I have had three cases. If a patient came to me for this operation, in which I especially feared hemorrhage or my ability to control it, I would not hesitate to ligate the common carotid artery either permanently or temporarily, obstruct the flow of blood by the application of Crile's clamp, which can be easily accomplished, and will give you a free field to work in. By resorting to the reverse Trendelenburg position, you can reduce the danger of anesthesia; presuming you are using a general anesthetic, you can reduce that danger seventy-five per cent. by following out the plan suggested by Crile of supporting the capillary circulation on the surface. He has accomplished this in a perfect way by the application of his pneumatic suit. This has the objection, however, of not being always obtainable, and we can make a good substitute by using Martin's bandages, which I have employed on three occasions with most satisfactory results. By enveloping the trunk in cotton, applying Martin's bandages from the feet up to the arm-pit, we are enabled to support the capillary circulation, prevent shock, and can put the patient in almost any position we choose.

After considering preliminary ligation, the next question to be thought of is the ligation of the arteries. We know that the superior and inferior thyroids are the ones which deserve more special attention. Halstead has pointed out that by following a certain technique in the operation the superior thyroid can be readily brought into view by splitting the capsule of the gland, by pulling the gland upwards and towards the median line, thus bringing the superior thyroid into view, which is caught, and that releases the gland, and it can then be pulled

down and the inferior thyroid ligated.

**George B. Jenkins**, of Louisville: This subject has been covered in such an admirable manner by the essayists, that there is very little left for one to say except to coincide largely with what has been said.

Dr. Cecil spoke about this condition as a disease of the gland, and not primarily of the nervous system. Of course, this disagrees with the opinions held by a number of neurologists, but that view seems to be gaining favor at the present day, that it is primarily a glandular condition, with secondary involvement of the nervous system. The nervous system requires for its proper functioning and the maintenance of bodily health a certain amount of secretion from this body; that any excess in its secretion is followed by symptoms of hyperthyroidism, such as tachycardia, tremor, psychoses as have been mentioned under the head of exophthalmic goiter; and that any deficiency in the secretion may be followed by myxedema, cretinism, infantilism, etc.

As to the etiology and treatment, some remarks were made concerning the causative factors or pathogenesis. Whenever one uses everything that is mentioned in the *materia medica* as treatment for a disease, it is sufficient evidence that we do not know what to do for it, and when it comes to the etiology, the appalling ignorance of body chemistry under which we all labor is a sufficient commentary upon our knowledge of the causative factors of this disease.

A most important and interesting feature about the condition to me is its embryology, which I do not believe was mentioned in any of the papers. Dr. Simpson stated its connection with the generative apparatus. That was new to me. The only point I wish to note in connection with the embryology is that it is developed like the lungs from the gut tract, being pushed down from the pharyngeal pouch, and remains in connection with the alimentary canal from the top, extending from the base of the tongue down to the properly developed gland, forming a duct or canal which may remain through life patent or closed. In some of the lower animals it remains patent throughout life. Even in the human being there is a foramen cecum at the base of the tongue, which is the remains of the beginning of this canal. It is a body common to all vertebrate animals. Another feature about it is that it develops at the reproductive period of life ordinarily, coming between puberty and the menopause in the vast majority of cases. It is more common probably in the female. It is influenced, of course, in that sex by menstruation, pregnancy, and such epochs as these. There are many other things which interfere with the nervous system that are largely erethistic in character, such as hysterical and neurasthenic manifestations, these influencing

necessarily the generative apparatus. It seems to be the tendency nowadays to think that generation influences everything. The mental condition as noted by all is markedly influenced by this gland. There being a definite psychosis mild or severe in all exophthalmics. It may not reach any further than a mere *neurasthenia*, or it may go on to mania, melancholia, etc.

The time to operate was brought out by our distinguished friend of surgical proclivities. When a case is brought to the surgeon, unless the patient is in perfect health, the surgeon is very apt to say that it would not be good judgment to operate at the present time. That is not the exercise surgeons are looking for at the present day. We want surgeons who will take a patient at any stage of the disease and do something for the betterment of his condition. The time to operate on any patient is before the disease has reached such a severe stage as to produce a moribund condition.

Of all the symptoms mentioned, tachycardia or heart hurry is the most important. This is not a condition of the heart itself, but of the regulating mechanism of the heart, as is shown by the fact that cardiac disease, when present, is only a complicating affair, and not due in any way to the diseased gland, but to the influence of the nervous system. I have reference, of course, to organic disease. The condition of the heart is the most important feature not only for prognosis alone, but of the patient's ability to stand operation.

Surgery of the gland, whilst attended by fairly satisfactory results has never been followed by such relief as to make it the means of election; but as the "dernier resort" and it is more than a hope that some method of a less radical nature will be discovered which will enable us to deal with the condition of exophthalmic goitre in an eminently satisfactory manner. Perhaps the serum which Buse and his associate are perfecting will prove to be the thing, at least the medical world is interestedly watching the outcome of the experiments while they calmly meet symptoms as usual.

**B. Merrill Ricketts**, of Cincinnati: It has not been my fortune to have listened to better papers on this subject than those that have been presented to us this afternoon, and I do not know that I can add very much, if anything, of interest or value to what has been said. However, there are two or three things I might mention. I will not speak of the pathology or physiology of the thyroid gland, for they are not understood, but will briefly refer to the medical treatment.

In looking over the history of this subject, I found that the early treatment was purging and burnt sponge internally. After listening to what the gentleman had to say with reference to iodine treatment, the suggestion came to me that there might have been some iodine in the sponge,

the sponge itself having grown in salt water. Another treatment was pulverized egg-shell, strophanthin and the extracts, so we have had a great variety of medical treatments for goiter of various kinds.

The surgical treatment, in brief, is this: Up to 1866 there had been 51 operations for goiter of any kind. Up to 1876 there were 175 operations; up to 1886 there were 376 operations, and since that time the entire subject has been developed and the operation for goiter revolutionized. Blackman, in 1854, said that the operation was such a bloody one that surgeons refrained from doing it, and he predicted that the future operation would be ligation of the thyroid body in segments.

Now, with reference to exophthalmic goiter, I was among the early operators of this country. I was criticised severely by my confreres. However, the patient survived the operation, with relief. There is not a class of the more desperate surgery that gives greater satisfaction than exophthalmic goiter. Jonnesco's operation, which consists in the removal of the cervical sympathetic, has been practically given up, and I do not know that it will be done any more. There were some good results from this operation reported at the time, but they were not sufficient to justify us in resorting to do it.

As to the operation for exophthalmic goiter, some patients will recover with operation, and others without it. The wife of a physician who sits in this hall came to me with exophthalmic goiter. She had tachycardia, polyuria, glycosuria, and exophthalmos. She left her home for a twelve days' rest, during which time she gained twelve pounds. No operation was done in this case. Since that time she has not had exophthalmic goiter. Why do they not all recover permanently, and why are not all of them successful? We must consider the anomalies. I have one patient with submaxillary goiter (probably all she has); it is about the size of the little finger; occasionally enlarges to the size of a goose egg. We have goiterous tissue in the subclavicular and subscapular regions; in the pharynx and in the tonsil. Five years ago a case was reported, supposedly a benign neoplasm of the tonsil. The tonsil was removed, myxedema followed. If we remove a gland for goiter, we may have multiple glands situated in different parts that are involved. A diseased gland may be removed from the right or left side, and there may be one or more glands remaining that are normal. We may remove one of these glands, or both, or leave the stump of one gland or the stumps of both, and yet fail to get any result. We may remove the entire gland, and feed the patient upon the extract, yet fail. Why? Because we may have a bit of thyroid tissue somewhere within the body. Those are some of

the reasons why all of these patients do not recover.

I want to congratulate the authors of the papers and this society on having this subject presented to them in such a masterful way.

**Dudley S. Reynolds**, of Louisville: I deeply regret the unfortunate mixing of the nomenclature of this subject. Exophthalmic goiter is an unfortunate term, for the reason we have goiter without exophthalmos, and we have exophthalmos or bullthalmos without goiter. The condition of the heart would seem to determine the exophthalmos, and, until goiter has existed long enough and is of specific character to disturb the central nervous system and indirectly the heart, the two conditions are seldom seen combined.

I noted some reference in the first essay to the use of thyroid extract or the desiccated thyroid gland as a remedy for goiter, or, as the essayist termed it, exophthalmic goiter. This, in my judgment, is most irrational, and is without the warrant of any respectable authority in therapeutics. Surely, no scientific writer of prominence within my knowledge has ever mentioned the use of thyroid as a remedy for any form of goiter. I am impressed also with the conspicuous absence of the name of David Murray, of Edinburgh, in connection with the treatment of the condition which follows the removal of the thyroid gland or its entire destruction by disease. Not one of the essayists even mentioned his name; yet, it was David Murray who first directed professional attention to the value of the thyroid glands of sheep in the treatment of Strumi-priva, which is the condition of great nervous depression, with frequent and feeble pulse, exophthalmos, and profound anemia, with other well-known symptoms. No reference to the treatment of the condition following goiter and accompanying myxoedema should fail to mention David Murray and his great discovery.

**P. H. Stewart**, of Paducah: There is one point I would like to emphasize regarding the use of the X-ray. The X-ray has been used for almost all other troubles and has been incidentally employed in the treatment of goiter. But Mayo is very positive in his opinion regarding the use of the X-ray, that it does no good, but, on the other hand, it does harm. In some cases he uses the X-ray for one purpose, namely, for hardening the capsule of the goiter prior to operation. That is the extent to which he uses the X-ray.

Another point brought out by one of the essayists was with reference to drainage and asepsis. It is very essential, in order to secure primary union, to put the stub drain immediately under the incision.

Another point I wish to emphasize is the preservation of the posterior part of the capsule, which was mentioned also by the essayist, and if you are particular in that respect you are

likely to meet with less trouble.

Another class of cases upon which it is not safe to operate are those just before or at the time of puberty. These goiters very often originate at or about the time of puberty and subsequently disappear of themselves without operation.

**John R. Wathen**, of Louisville: In the brief time at my disposal, I wish to call attention simply to one point, namely, the blood supply in connection with the surgical treatment of goiter. We have in our classification eight or ten types of goiter. Mayo classifies under exophthalmic goiter four distinct types. From a surgical standpoint we can make three classifications. One, a classification of goiter as regards the blood supply, where we have a colloid cyst developing in part of the normal gland, with practically a normal circulation. We have another type of gland in which there is adenomatous development. This means a slight increase in circulation. We have, then, the exophthalmic type, which has a blood supply that is many times greater as compared with that of cystic goiter or adenoma.

As regards the surgical treatment, Dr. Holloway said that the typical treatment for all cases is to ligate the superior and inferior thyroid arteries. It seems to me, in so doing, the surgeon wastes time. In cases of cystic goiter we can strip the capsule and enucleate the goiters as we would an intraligamentous cyst from the broad ligament in gynecological work, and it would hardly require the use of an artery forceps. These goiters have no large vessels running into them as in the other cases.

In dealing with the exophthalmic type of goiter we have an increased blood supply. Here we should first ligate the superior thyroid, but we should next ligate the inferior thyroid inside the capsule and ligate also any other vessels inside the capsule to avoid cutting off the blood supply to the parathyroids as has been demonstrated by Halstead and others.

I would like to show some specimens (exhibiting specimens) illustrating the blood supply. These specimens have been selected from cases in my surgical work, and they demonstrate beautifully the question of circulation and how to control hemorrhage.

**J. Garland Sherrill**, of Louisville: These papers have been extremely interesting to me, and there are one or two points which deserve emphasis. The work of Halstead and Evans, presented to the American Surgical Association, and published in the October issue of the *Annals of Surgery*, is well worth reading. They speak of the parathyroid bodies and say that if these bodies are left, tetany will be prevented, and do away with that condition which is so dangerous after this operation. These parathyroids are supplied entirely from the inferior thyroid artery.

Formerly, when surgeons resorted to partial excision of the gland (and Koehler has worked along that line, trying to excise at times the lower two-thirds of the gland), frequently these cases were followed by tetany, the reason being that two of the little bodies on either side, four in all, lie largely below the lower two-thirds of the gland. In making a dissection of the gland it is very essential to leave the parathyroid bodies. There is a short artery, single, without anastomoses, coming off from the inferior thyroid, and if this artery is cut, you cannot preserve the parathyroid body. That is very important, and therefore at that point the gland should be ligged closely. This point was brought out by the essayist, but that accounts for the non-occurrence of tetany if the capsule was left posteriorly. We should be careful in doing that operation.

As to the point brought out by Dr. Reynolds, I will say that we do give the thyroid extract where the gland has been removed, and with benefit. We also find much benefit from the use of thyroid extract in cases of simple goiter where there is a deficiency in the secretion. I must differ from the doctor in that this exhibition of the thyroid gland is not only scientific, but absolutely beneficial. Sometimes we do scientific things which are not beneficial, but in this instance the exhibition of thyroid extract in a case where the gland does not secrete enough is beneficial, and in the highest degree scientific. Again, it is a diagnostic measure, in that if it is too much, the symptoms get worse; if there is too little secretion, they immediately are benefited.

**J. G. Cecil** (closing the discussion on his part): I regret that Dr. Reynolds has left the room, because if he had listened very attentively to my paper he would have heard me say that thyroid extract in the treatment of exophthalmic goiter has been practically abandoned, it having been found that the condition is aggravated rather than relieved by this treatment.

With reference to the treatment by serum, it has been suggested and carried out so successfully by Drs. Beebe and Rogers and others, that it is a significant fact every one of the great operators I have seen and heard of through reports mentioned this serum in a most complimentary way, and advocated its use. Koehler, Mayo, Halstead, all three of them, the greatest operators in this particular line, advocate the use of this serum. Of course, I refer especially to its use in exophthalmic goiter. It is not, therefore, a mere coincidence when out of ninety or more cases that have been treated by a given serum twenty per cent. or more of them get well. There must be something in it. I hope there is. I have not had any personal experience with this serum. So far as I know to the contrary, it is not on the market, outside of the laboratories of the gentlemen who make it.

My own experience with exophthalmic goiter has been limited to a few cases, one of which has recovered completely without any treatment whatever, except that of rest. One of the last cases I had went on to die because I could not enforce rest. She died and did not have the benefit of surgery; she would not submit to it. Some of these patients recover regardless of treatment. All of the operated cases, it must be remembered, do not recover.

**T. C. Holloway** (closing the discussion): I did not exactly understand the rather sweeping criticism of one of the gentlemen who took part in this discussion. If I am not mistaken Dr. Jenkins said that the question of treatment had been adroitly avoided, and that such surgery was not the kind of surgery needed. I have been unfortunate in presenting a paper, the title of which is the surgical treatment of goiter if the question of treatment has been omitted. What I intended to say and what I wished to make quite clear was embraced in a single sentence, namely; that the rational treatment of goiter is distinctly surgical. While this is true I wished also to emphasize the importance of carefully selecting the time and method for applying surgical treatment, in order that these measures which are considered best may be applied at the right time and in the right way.

#### LOCAL HEALTH BOARDS.\*

BY R. L. WOODARD, HOPKINSVILLE.

A great deal has been said and written within the last few years about sanitation and preventive medicines, but after a somewhat exhaustive review of what has been written and the laws that have been enacted one cannot but be impressed with the dearth of practical application of the principles that have been clearly proven to be of great benefit to public health.

There is a vast space between writing a paper on sanitary science and getting out in the field and putting the theory into practice and getting results. Results are the aim and object of the practical sanitarian, and results can only be obtained by practical application of a good sound theory, coupled with sound common sense. Conditions will not be the same in any two given localities, and the sanitarian, to get results, must be able to apply such principles as are practical in his particular locality.

A matter of great importance is the selection of the local board of health. They should be men of good sound judgment and who have the physical welfare of the community at heart and men who will not hesitate to do that which is best for the commu-

ity at large, even at times when individuals are greatly inconvenienced. They should be men who take an active interest in public affairs and should be so thoroughly organized and informed that they will be ready to act at once and act with judgment upon any subject brought before them by the health officer. In the past all matters that properly came to the attention of the health boards have been left almost if not entirely to the health officer and the board never hears of it. I am convinced that great good could be done by having regular meetings of local boards and sufficiently often to enable the health officer to make reports of what is going on and to get the advice and cooperation of his board. In the great majority of cities the duties of local health officers are more or less well defined, in so far as the abatement of nuisances, the inspection of food stuffs, milk inspection, inspection of sewage, quarantine, the care of contagious and infectious diseases, etc., are concerned, but I am sorry to say that in a great majority of instances little or no attention is paid to the various ordinances, until some epidemic starts and continues to spread. Then the health officer gets busy and attempts to stamp out a thing, which has favorable soil in which to spread and is well nigh impossible to handle satisfactorily, a thing that could easily have been handled if the proper sanitary regulations had been enforced prior to the outbreak. Thereby furnishing a sterile field in which to fight.

There is such an intimate relation between the spread of disease and insanitary conditions that all ordinances and regulations pertaining to the preservation of public health should be strictly enforced at all times. Giving special attention to those things which are the most frequent carriers of disease. In this connection I would call attention to the water supply, the local health officer should know beyond any reasonable doubt that the community is supplied with pure water. The careful inspection of all food offered for sale, and let this inspection extend to the slaughter houses, and dairies, to be sure that proper measures, to insure their purity, are carried out. While the abatement of nuisances, the inspection of food products, dairy products, water supply, local quarantine, etc., form a large and important part of the duties of the local health officer, the field is rapidly broadening and the day is not far distant when his sphere will be greatly enlarged and his usefulness correspondingly increased. One of the most important duties, which the local board will shortly be called upon to take charge of is the medical inspection of schools.

The education of children must fall far be-

\*Read before the Kentucky State Medical Association, Louisville, Oct. 16-17, 1907.

low the standard unless they are healthy. The questions of heat, light, ventilation and overcrowding has received quite a good deal of attention, and in a great majority of the public schools of the country, has been fairly well solved, yet there is room for improvement in these matters especially in the old school buildings.

Only a few schools in this county have tried the medical inspection of each student but in so far as tried it has proven to be of great value. I am convinced that every school should be under the direct supervision of a medical inspector, who shall inspect the schools sufficiently often to become thoroughly familiar with the physical condition of every student who is below the standard in advancement. In a large per cent. of those students who cannot keep pace with children of like age there will be found some physical defect which in a majority of cases can be remedied, and the child promptly take its place with children of like age and development. It is evident that the inspector must depend in a great measure upon the teachers in the schools for information and teachers must be selected who have some fitness along these lines. Teachers to have this fitness must have had some previous training and every normal school, and every course of instruction for teachers, should have included in its curriculum, a course which will give the teacher sufficient information to enable them not only to be able to help the inspector, but to teach the child the element of personal hygiene and the importance of sanitary matters. If we hope to educate the public to the importance of absolute cleanliness as a prevention of disease, we must of necessity begin when the mind and character of the child is being molded so that these things may grow as the child develops, and ere he or she has reached maturity it will be second nature to them, and when they take their places in the business and political world it will be easy to have proper laws enacted and easier still to have them enforced. If we hope to accomplish any permanent good along the line of preventive medicine it must be done by education.

Teach the child properly in his early days and in old age he will not depart therefrom.

The registration of vital statistics is the firm basis on which the whole structure of sanitary science, and practice must rest. In order to learn the laws of disease, to devise remedies and to test them we must have an accurate knowledge of the movements of the population, and of the number and causes of deaths, also a table of infections and contagious diseases, giving exact location and probable cause of the disease. Not only is the knowledge of these required, but also an ac-

curate census showing the distribution of the population as to age, sex, civil condition, race, etc. Correct knowledge of the population and its movements is valuable, not only to the sanitarian, but to the economist, educator, and indeed to every student of any branch of social science.

A subject which is of such vast scientific importance should receive most careful attention and every aid should be given in assisting its investigations. The work of recording vital statistics should unquestionably be under the control of the local board of health. These reports can only be accurately gotten by the aid of physicians and every physician should gladly lend his aid to the furtherance of a scheme which means so much to the betterment of the community in which he lives. Unfortunately, scientific consideration has little weight with politicians and it is a difficult matter to have proper laws enacted for the getting together of this data. These records should be so kept that they will be of benefit not only to the sanitarian, but to the student of social economy, the politician the educator, and all persons interested in any branch of civic conditions. By doing this we will in a short time have at our command statistics that will be of inestimable value.

The progress of sanitation within the last few years has been marvelous, and what has been accomplished has been done through thoroughly organized boards of health with competent men at their heads with well trained assistants whose hearts and souls were centered on the one thing—the prevention of disease. The work of stamping out yellow fever in Cuba and on the Isthmus and the prevention of its spread in the United States could not possibly have been done except through well organized forces working in perfect harmony with each other.

The work of combatting contagious and infectious diseases must of necessity vary somewhat in different localities dependent on local conditions, density of population, social position, intelligence of the people to be dealt with, etc.

Science, has clearly demonstrated that much of the disease and misery of mankind is avoidable, that disease is a terrible punishment inflicted on the human family for living out of harmony with the laws of health. When one pauses to consider the enormous annual loss to the government and to society through disease; the terrible suffering attendant by the temporary or permanent, partial or complete disability of individuals; the tendency to degeneracy and crime in succeeding generations; the losses in the business

world due to the serious interruption in business; the money value to the government from the wasted lives that are needlessly sacrificed it becomes evident that it is the duty of the government to protect its people from these perils.

The medical profession as a whole, up to the present time has taken little interest in sanitary matters. What has been accomplished has been done by comparatively a few men. The time now has come when the united profession must give active attention to sanitary matters. The public are gradually becoming educated to the importance of, and the results to be attained by well-organized health boards. The public are demanding now as never before that health boards give attention to those conditions which are known to be detrimental to health. It is by facts and figures, and not argument that the public is being brought to see the importance of sanitation, and as the education of the public goes on the demand for active, well trained sanitarians will increase.

The education of the public in any matter is a slow process, and in sanitary matters it must necessarily be slow from the fact that it is hard to get people to do anything which at times, seems to deprive them of their personal rights for the benefit of his neighbors.

How rapidly this education is accomplished is in the hands of the physicians of the country. It seems to me that the physicians should not wait to be forced into taking an active part but should be the ones to lead. Organization is the foundation on which the success in the campaign of preventive medicine must rest and the physicians are the only ones who can make that organization perfect. One great drawback heretofore, has been the lack of harmony, not only between state boards of health but also between local boards. Nearly all the states now have more or less well organized boards, but there is a sad need of the clear, distinct unity of action between the various state boards. Until this is brought about there will always be clashes and misunderstandings which will greatly hinder the good which should be accomplished. We need a secretary of health with a position in the president's cabinet who should have control of all state boards in an advisory capacity. This national board should frame such laws as will bring all the state boards to working in perfect harmony.

This secretary should have full control of all international matters relating to public health and absolute control of all quarantines. It has been proved beyond argument that the Federal control of quarantine is far more effective than any other method, even under present conditions and surely under a perfect organization the work could be very

much improved. The value of the statistical matter which in a short while could be gotten together would be of very material advantage, not only to us but foreign nations as well.

There are a great many organizations working for the betterment of public health, nearly all of which are doing more or less good. They could all be made to accomplish much more good if they all could be brought to working in harmony.

This could be brought about by bringing them under the advisory control of the Secretary of Health. The state boards then should have advisory control of all its county and municipal boards, adhering as far as possible to the democratic principle of self-government. The local, county and municipal boards of course are the ones that have the active, practical work to do, and they should be given some latitude in the carrying out of their work in their respective localities. It is absolutely impossible to frame a general set of laws that will cover the various emergencies which arise in the every day work of local health boards. All municipal and county health boards should have the authority to pass rules and regulations to cover special emergencies which may arise. By act of legislature these rules and regulations should become laws. By this arrangement we would have an organization that would be effective. The national organization at the head, the state boards depending on the national board, the county and municipal boards, depending on the state boards. The federal control of quarantine is admitted to be the most practical and satisfactory method of dealing with those diseases, which require rigid quarantine between states and I am convinced that with such an organization as mentioned above it would be only a short time until all the known preventable diseases, will be practically unknown in America and the moral, social and political aspect of the country will be as far above what it now is as we are at present above the "Heathen Chinese".

#### DISCUSSION.

M. K. Allen, of Louisville: Mr. President, Dr. Woodard has covered the ground so thoroughly that there is very little left to be said. Of course, at the outset, it is a difficult proposition to undertake to inaugurate public health work and its administration is beset with trouble. I find it is difficult frequently to enforce the laws we now have, and so far as the city of Louisville is concerned, we are lacking in some laws that are needed to protect health and life.

The essayist mentioned the inspection of public schools. There is nothing more important than that. It has been recommended in this city

for a long time, but up to the present it has not been put into practice. We notice that when the schools convene each year preventable and infectious diseases prevail to a much greater extent than before, and these diseases cannot be properly combatted or prevented promptly unless medical inspection of schools is undertaken.

The matter of food inspection is a very large question, and up to this time, so far as the city of Louisville is concerned, we have neither enough inspectors nor sufficient authority to inspect all food products. We hope to be in a better condition soon.

He spoke about organization and what municipal boards of health should do. Of course, grave responsibility rests upon public health officials, as the protection of the health of the people and their lives is of the greatest importance, more so than anything else with which any municipality or county has to contend. I regret, however, to say that it is not so recognized by those who control our fiscal and official affairs frequently. It takes money to do this work, and it is not recognized to the extent that the State or city furnishes sufficient money to carry on the work as it should be carried on. But I think in time all that has been suggested by Dr. Woodard will be carried out, so far as Louisville is concerned; at least, I hope so.

**T. J. Shoemaker**, of Morganfield: I was very much gratified in listening to this excellent paper which deals with municipal sanitation, and I rise to speak of one or two points.

First, with reference to the health officer inspecting all of the schools in the county. That is impossible, especially when he is supposed to do it on no pay. However, I have managed to do this work in my county fairly well. We have hygiene and physiology taught in all the schools. We have a superintendent of schools who is thoroughly educated in sanitary matters. It is his duty to visit the schools regularly every two weeks, and I have made arrangements with him in our county to not only visit the schools, but inspect them, and let me know if there is any sickness among the pupils. And the trustees of the schools, especially in the towns, send a child home and keep him there whenever sickness occurs, until the health officer looks after the case. In this way we have succeeded in keeping children with scarlet fever and diphtheria out of our schools. We have a good many meat shops and meat places, but they are all screened in well, with a thousand pounds of ice over the meat, and the meat is not put out to exhibit it. The people meet inside, and if they want to buy any of the meat they do so. I think this is much better than having the meat lying in a window like I have seen it here in Market street.

**T. A. Frazer**, of Marion: There is one point I would like to emphasize, which was referred to by Dr. Woodard, and that is the members of

the Board of Health should not only receive our support, but the support of the profession at large. I have been struggling along for the past seven years in one of our small counties, having a hard battle to fight, from the fact that the profession at large will not stand behind the health officer. If you take them to task for it, they will say, "Yes, you are right; go ahead." They will pat you on the back, but they do not want anybody to see them do the patting. What we need in this State, according to my own experience, is for the profession to stand united. If the profession of Louisville stood behind Dr. Allen, he would get whatever he asks for. If the profession will stand united in any county, behind the health officer, that health officer will get such appropriations and such support as are needed.

With reference to the inspection of schools, this has been done more or less in our graded schools, and one inspection was made by a very competent specialist whom I assisted. We found thirty-one per cent. of the pupils defective out of four hundred and some odd. I consider medical inspection one of the most important things we can undertake. The boys and girls in our schools to-day will be the men and women of this country in the future, and there is nothing more important than to preserve their health, and many of these defects can be readily corrected, if they are recognized in time and the attention of the family physician called to them. But many of these cases are allowed to drift along with adenoids and other defects, with trouble of the accessory sinuses, of the ears or the eyes, until it is too late before they fall into the hands of the specialist, and I hope to see the day when every school in the State of Kentucky will be inspected at least once a year by competent physicians.

**Dudley S. Reynolds**, of Louisville: To my mind, the great trouble we experience is that we are entirely too exclusive in the work we do. The reason why the medical profession does not and has not stood by and assisted as best it can the efforts of the local health officer is because public sentiment has not yet been turned that way. We should educate the leading members of the community and appeal for support to people who are prominent as citizens, men who have something to do with making the laws. We want the school teachers educated; we want the parents of the children who go to school educated, and then and not until then will we be able to secure the enactment of efficient laws for the proper execution of those principles so ably laid down in the essay.

**Dr. Woodard**, (closing the discussion): The people should be educated as to the importance and necessity of these regulations. There is no man or set of men who know how much trouble it has been in the past for local health officers

to get a little money to do something with. Nobody knows that better than the health officers themselves. I have had the same experience that Dr. Allen has had, and Dr. Frazer, but if we can educate the people as to the importance of this work, we will get the money with which to do it. We have got to hammer along and do the best we can, beg for some money, bluff some, and do some of this work without any money. But education is the main point I wanted to emphasize in my paper.

#### A FEW SUGGESTIONS TO THE YOUNG PRACTITIONER.\*

BY E. B. McMORRIES, CLINTON.

When first asked by Dr. Richmond to write a paper to be read before this intelligent body, I declined. I also declined when he asked me the second and even the third time, but after thinking the matter over, I remembered how vexed I had become from time to time as Secretary of our own County Medical Society, when I would have to work from one meeting to the other trying to get up a program, and as I say, after thinking over these things, I should at least make an effort. So while I have made the effort when I have finished reading this paper, please at least give me the credit of the effort.

My subject, gentlemen, as you will notice, is a few suggestions to the young practitioner. Please understand me in the beginning not to be the one doing the suggesting alone, but I propose to call attention to a few things, which seem to me, are continually suggesting something. Especially to the young practitioner, I would like to review the four years of hard work and a few necessary hardships the medical student of to-day has to encounter, but I think we are all familiar with these. So I will notice him first as he leaves his Alma Mater with that much coveted object, his sheep skin.

No doubt during these four years of hardships he has said to himself, time and time again, give me my sheep skin, and I will do wonders. Now the poor fellow has his sheep skin and wonders what he will do, and just here, gentlemen, I wish to say that this time is the most important period of his career, for upon his decision at this particular time, depends his ultimate success or failure. And allow me to say just here is where the old and experienced men of the profession play their part.

This young man needs council and advice, whether he solicits it or not. Pardon me to give a little personal experience just here. I am ashamed to say that I thought all of the

older doctors were jealous of me when I began the practice of medicine, but I was mistaken, for I now believe they were only sorry for me, and were willing to help me in any way they could, and as stated above just here is where the young man needs the old man's advice, and as the father advises his son, even though he heeds not the advice, so it is the duty of the old practitioner to the young.

You older doctors must remember that this young man has had nothing but four years of technic and hardships and very little attention has been paid to medical efforts. I shall mention a few things here that I think the young practitioner should be advised on. I think we all concede that as a rule the young graduate is financially embarrassed. I remember myself that after buying an extra trunk to bring home my free samples of proprietary and patent medicines, which some of the concerns were so anxious to have me to give a fair trial, I scarcely had money enough to pay my way home. So taking him shipwrecked financially, so to speak, naturally he is over anxious to make some ready money as soon as possible. And certain people knowing this have taken particular pains to find out where this young fellow locates and to give him a job, from which he can realize some ready money. I speak of corporations known as life insurance companies, which companies, prior to a year or so ago, refuse to give a young practitioner a commission as their examiner until he had practiced from two to five years. However, since the recent action, taken by some of the medical societies in regard to this matter a young practitioner can now receive a commission as examiner almost as soon as he has hung out his shingle, provided he accepts it in accordance with their graded fee schedules. I remember to have accepted three or four such commissions myself but shortly afterwards I joined our County Medical Society, which society passed a resolution of approval of the actions of the State Association in regard to this matter and I at once returned my commissions to the Companies without ever making a single examination, nor will I ever make one unless paid at least five dollars for it.

This is only one of the few traps into which the young practitioner may fall. Showers of life-saving remedies are given him for his trial, and as a rule he uses some of them and they are pretty palatable, and his patients take a few doses and return and ask the poor fellow for some more of that medicine. Well he begins to look around for a substitute, for his sample has all gone. May be he substitutes with something as near like the original as possible but the patient doesn't like it. It

\*Read before the Kentucky State Medical Association, Louisville, Oct. 17-18, 1907.

is not so palatable as the first bottle was. It don't act the same, and so the patient becomes dissatisfied and the doctor amid his confusion goes by the village post-office and as is often the case receives a letter, which reads something like this:

Dear Doctor:—Have you any patients suffering from such a such a complaint. If so, you had better send them to us. We have a better climate than you have, which may or may not be so. We also have a better method of treatment than you can institute, which if the young fellow would only admit is the truth. Because a change of any kind at this particular time would help the patient and doctor too. There are various other ways too numerous to mention, in which the young practitioner is influenced to be used as a tool to further the interests of some corporation to his own detriment.

I will mention in passing one other pitfall into which he may enter, which he can never say was through ignorance of what he should or should not do. This, gentlemen, is the most horrible and abominable practice of criminal abortion, which I maintain, if any man, young or old, ever stoops to do, should be ostracized from his profession and ever afterwards treated as a man unworthy of the respect of a gentleman. I have mentioned a few of the traps and connivances set for the young practitioner, and in conclusion I wish to make a few suggestions to the young practitioner, which if followed, will merit for him the admiration and respect of his profession and the laity at large. And not this alone but by such a course he renders himself worthy of membership in that greatest of all professions, to be a member of which, should arouse the dignity and honor of any man. Realizing as he does his responsibility as guardian of the life and health of his fellow-man, and as stated in the beginning I maintain that it is a pressing duty for the experienced physician in his community to advise him from time to time as to the things that he should and should not do. He may not take your advice kindly at first, but eventually he will come to know you as his friend and a well-wisher of his success. Suppose that you did not advise him, are not his chances to pursue the proper course hampered by the lack of that advice? I propose to lay down a few rules which I know cannot be complete, for they are only those which I have arranged myself, but I would not ask any young man to adopt the ones that I mention. First, if possible, cast your lot in some fortunate place where they have a well organized County Medical Society, join that society at once, for they will help you and you can help them. If you do not join them you are neither helping them or yourself. After you

have joined, be a member not in name only, but attend the meetings. Write a paper when you are placed on the program. Your paper may not be a very scientific or interesting one, but you must first begin if you ever wish to attain a position in which you will be recognized. Treat your brother practitioner with the application of the Golden Rule. The rule may seem an old one to some, but if you will begin applying it you will find in many instances it will seem very new indeed. Having joined your County Medical Society, hence the State Society, and, by the way, I think, the greatest Medical Society in the Union, join the American Medical Association, but some may say that is lots of joining, but my brother that is the cheapest and at the same time the most beneficial joining you will ever do. This is not all, take as many good journals as you can read and read those you take. You will note that I say good journals. I mean journals who advertise only such remedies as are approved by our National Council on Pharmacy and Chemistry. Abide by the deliberations and resolutions of any Society which you may join, accept no commission from any life insurance company who set a price on your work, who will without consulting you take from you your commission at their own deliberation. Adhere as much as you can to the old pestle and mortar, for I fear that with the new fad, some of us are falling into, that is buying our drugs ready compounded that we will lapse into an ignorance of our chemistry. Carry out these few suggestions and attend your associations and we will have a body of young men, who in the next decade or so of years, will be equipped and ready to grapple with the problems, which will confront us, even as our honorable body in present session are grappling with them. In closing I would urge that you follow out these few suggestions and some better ones that older and experienced men can offer you and I take it that after having done this, if then you fail to succeed in this most honorable of all professions, you have missed your calling.

#### PREPARATION AND AFTER-TREATMENT FOR SURGICAL OPERATIONS.\*

By B. F. VANMETER, LEXINGTON.

This subject is rather more difficult to handle than I had at first thought. I wish to avoid generalities and call your attention to a few things I believe to be worth while, and bring out a discussion from which I will learn something.

\*Read before the Fayette County Medical Society, February 11, 1908.

Preparation, in a way, occupies the same position to after-treatment that preventive medicine does to therapeutics. With marked exceptions, I believe surgeons of today and yesterday have erred in two ways—viz: too little preparation and too much hospital and after-treatment. Let me me express it in another way. A patient who would ordinarily have to lie in the hospital three weeks I believe ought to be there three or four days before the operation. He would be able to leave sooner than he otherwise would, and his post-operative comfort, if not mortality, will be vastly influenced for the good. During this three or four days the surgeon and nurse become acquainted with the peculiarities of the patient, and the patient is able to adapt him or herself to the environment. Three or four days' rest in bed on light diet with me, has been the most satisfactory means of preparing a patient both mentally and physically for operative procedure. During this time the patient's digestion can be studied, the condition of the bowels and sufficiency of kidney elimination. We all know that asepsis and the opsonins are our protection against infection. But what is our protection against shock? Can't we say, full and yet soft arteries, good kidneys and a clean gut, and still one other thing, a little intangible, but a well-toned nerve is a factor. Our most powerful means of bringing about these good things is rest in bed on a sparse diet. During this same interval I insist on the patient drinking large quantities of water and at least one high bowel irrigation with hot normal salt solution. This accomplishes two purposes—increased elimination and a full circulation.

It might not be out of place to here condemn, in the strongest terms, the habit some nurses have of talking to the patient in reference to the character of the contemplated operation, and describing in detail the horrors of the operation of the patient next door.

Cathartics, in the past, have probably been over used—at present, probably, a little neglected. I believe the average patient's intestinal tract should be thoroughly emptied the third day before operation, and that he should have a bowel movement each day thereafter, including the day of operation.

It is unnecessary to go into the details of preparation of special cases—such as goiter, jaundice, and so on without end. Preparation of the field of operation has changed from time to time. Some have followed the most elaborate routine, but the changes have been constantly tending toward simplicity, and diminishing confidence in the virtues of strong and irritating antiseptic. Simple cleanliness seems to be the order of the day. I direct a thorough but gentle scrubbing of the

skin with fine, green soap, with an abundance of rinsing water, and the application of a green soap poultice to the operative field the night before, to be left on until the patient comes to the table. Then it is removed, and the field scrubbed with gauze sponge, soap and water, followed by alcohol and ether.

A very large number of cases should have morphine administered hypodermically 1-8 to 1-4 gr., fifteen minutes to half an hour before anaesthetic. This accomplishes many purposes. With a skilled anaesthetist, it means less ether and less nerve strain and excitement for the patient.

#### AFTER TREATMENT.

All emergency cases should have their stomachs washed out, preferably before and after operation. It is generally neglected. Nearly all cases would be better off were it done. It is such a simple matter to run a couple of quarts of mildly saline water through the stomach, a pint at a time. It removes any foreign matter, with varying quantities of ether-laden mucus; if a reasonable quantity of water is left in the stomach it does no harm.

The patient, after leaving the operating room, should be put in a clean, warm bed, in a well-aired room. Right here there are two things that happen to too many patients—too little air, and too much heat. How many times have you gone to your patient an hour after operation and found him in a Turkish bath?—covered with no end of blankets, three or four hot-water bottles, and no breath of air in the room—drenched with sweat and asking for water—all of which is wrong, and should not be. There should be plenty of fresh air without draughts. The patient should be warm without being overheated, and should have water when he wants it, (and as much as he wants). I want to ask, did any one of you ever see a patient hurt by having water in any kind of quantity? I never have, and my routine has been to direct the nurse: "Give water when she wants it and all she wants." I believe on the contrary, that it does a vast amount of good. If they vomit it, it washes out ether, if they don't, it becomes the agent of secretion.

I recently had a case who probably saved her own life by drinking a four-quart hot water bottle dry. She was desperately shocked, and had lost a quantity of blood. The nurse had not comprehended orders, and was giving her water every 15 minutes in teaspoonful doses. At the same time the patient was swallowing these, she was sucking on a hot-water bottle that had been placed in her arm-pit.

I thought the days of no water after ether had gone the same road that no water during fever had gone, but less than two months

ago, I happened in the ward at the hospital late in the night. There was a patient belonging to one of you, rolling her head from side to side, mumbling, "Water! Water! Water!" I directed the nurse to give her all the water she wanted, and if anything happened to her, to tell the doctor what I had done, and I would humbly apologize to him for tampering with his case. But nothing happened except that she went to sleep before I left the ward.

#### PAIN, MORPHINE AND ITS INDICATION.

In clean abdominal cases most of the pain is due to gas. This can be reduced to the minimum by previous preparation, and the giving of physistiquinine gr. 1.50 every  $\frac{1}{4}$  to 6 hours, hypodermically, for the first 2 or 3 days. The judicious use of the rectal tube is a matter of good nursing. Gas pains after second or third day are probably best relieved by cathartics—preferably calomel and enemas. The opinion as to the indications of morphine are extremely varied. Some surgeons give it as a routine—others will hardly allow it in the house. I believe the opinion is gradually crystallizing that one full dose given at the proper time, when reaction has been established and the throat and air passages are free from mucus, is capable of doing good and practically no harm. It takes away that first night of horrors when the patient is convalescing from ether drunk, when to his mind all subjective things are greatly exaggerated. In small doses, combined with strychnine it has no equal in combatting shock. I say no equal—I mean in the way of medication, for we all know that normal saline by bowel, subcutaneously and intravenously, is the one powerful agent in overcoming shock. Adrenalin, combined with the normal salt sol. one dram to the pint, is a distinct advantage where there is much relaxation and impending collapse. We don't see as much shock now that we have stopped our windy discourses on the treatment and turned our attention to the proper preparation of the patient and thereby the prevention of shock.

#### NAUSEA.

The patient is generally relieved by vomiting, to the point of emptying the stomach. The agents most successful in my hands have been stomach washing, ice cap over the stomach, tinc. iodine, one to 3 drop doses in peppermint water, small doses of calomel, perfect quiet.

#### ATTITUDE IN BED

Generally speaking I allow a wide range of freedom. When a patient is coming out from ether the good nurse accomplishes restraint without force—the indifferent nurse often fails and resorts to force. How many times have you gone to your patients coming

out of ether and found a nurse trying to hold him hands and feet?—the patient struggling, not because he wanted to struggle, but because of the forcible restraint. Take away the force, persuasion and command will usually accomplish the desired result. I see no objection to allowing a patient to lie on the side. There are few things more grateful to the patient than change of attitude, and I think ought to be allowed, except in the face of some definite contraindication. We all agree to the advantage of the Fowler position in aggravating infection to the pelvis, which, I believe, demonstrates that if a patient can sit up with impunity for a definite purpose, they can lie on their sides without harm, but with much comfort.

This paper can't go into the question of the "relaxation of the ilio-sacral synchondrosis." A cool dry, well-rubbed back, empty stomach and an empty bladder during the first two days, goes a long way toward establishing the patient's comfort. The patient should within certain limits be made to void urine. Price of Philadelphia said that more than one catheterization should mean a change of nurses. This, I think, is a slight extreme, but there is truth in what he says. We believe the nurse should have authority and be held responsible for the condition of the bladder.

#### FEEDING.

It seems to me "slop diet" is over used. Broth—good broth, has its place in the first few days. It has some little nutrition and very considerable stimulant, and takes away that weak, gone feeling. I mean by good broth, non-greasy, properly prepared beef or mutton. Chicken broth and milk have no place in the first post-operative week.

Here again I take the stand that an intelligent, properly trained nurse is in better position to feed the patient than the doctor. I don't mean to state this unreservedly, but think the nurse should have this field, with the doctor in consultation.

I like to feed them on water until they are hungry, then if there is no definite reason why not, give them good, wholesome food—eggs, toast, beefsteak and bacon, tea, coffee and cocoa. Bowel movement on the third day is desirable.

Cathartics by mouth are not to be preferred, but are often necessary—the salines, in my experience, have been gas producers. Castor oil and calomel are favorites. High saline enemas or salts, glycerine and water are to be preferred,—when they accomplish the result. Fruits and fruit juices occupy a definite place of usefulness in convalescence.

Dressings should be done under strict aseptic precaution at any time an indication

may arise, otherwise not until the eighth or tenth day, at which time the stitches can be removed.

A rise of temperature on or after the third day usually means infection,—systemic, throat or wound. Stitch abscess should be opened wide and packed wide for the first dressing. After that little packing is needed.

In closing let me say Murphy's method of continuous saline solution by Fowel, under low pressure, is one of the most valuable agents of after-treatment that has come to surgery in my time. It is as powerful in controlling shock as it is in controlling infection of the peritoneum.

Let us pray: O Lord deliver us from the snare of routine and guide our feet safely by the pitfall of habit, and even remind us of what we would have done to us, if we were in the other fellow's place. And continually remind us, oh God, to be studious of the ways of other surgeons, but remove far from us our superstitious awe for authority; and teach us that each case is a case unto itself, and with Thy guidance to think for ourselves.

---

### THE FORUM.

---

MR. EDITOR:

At the instance of Dr. Stedman I write to ask you to say in the next issue of the *JOURNAL* that, in his paper, "The Doctor, His Business Side and His Relations to His Fellow Doctors," published in the January number of the *JOURNAL*, he quoted without giving credit, from a paper written by Dr. John Lewis, of Georgetown, ("Medical Consultations") and that he made such use of Dr. Lewis' thoughts as he thought would add to the excellence of his own paper: that he did it in no way as a plagiarist, but that he made use of the material as he would have done from any standard Text Book; that he has for Dr. Lewis the highest regard and, on ethical subjects a standard to be oftener followed. Moreover, Dr. Stedman had never entertained the least suspicion that I had forwarded his article for publication.

Dr. Stedman, several times during the meeting of the society when his paper was read, instanced the course that Dr. Lewis would pursue in such and such dilemma. I know that he in no sense desired to rob Dr. Lewis of one particle of credit which should be his, and I hope that this public disclaimer may be satisfactory to all who may have felt aggrieved by the lack of any proper acknowledgement.

Yours most truly,

J. W. CRENSHAW, Secretary.

case of rupture of the uterus. The writer was called to see the patient that had been in labor 24 hours and after three examinations found the head not engaged, chin posterior, position high. These four conditions were sufficient warning of imminent danger, yet without anesthesia and without assistance he attempted to correct the faulty presentation without first making a correct diagnosis as to the cause of dystocia. Of the 168 cases of rupture of the uterus collected by Marz eighteen were due to hydrocephalus. Excessive stretching of the lower uterine segment and the danger of rupture is favored by any factor which interferes with entrance of the presenting part in the parturient canal. The evident cause of the rupture in this case was the prolonged ineffectual labor and hydrocephalus. Had the writer thoroughly examined the patient under anaesthesia a correct diagnosis would have been made and the rupture averted. He gives as his excuse that hydrocephalus is so rare that accoucheurs do not think of it. Every abnormal condition in pregnancy always gives a note of warning if we only train ourselves as obstetricians to observe them, and realize that no pregnant woman is free from danger until the completion of the puerperium. Rupture of the uterus can be prevented and it is up to us to realize that this accident is due to our ignorance and we must remedy the condition by access to recent literature and by being ever on the alert for abnormalities as the cause of dystocia.

Very truly,

A READER.

MR. EDITOR:

In October, 1891, Thomas George Hodgkins, Esquire, of Setauket, New York, made a donation to the Smithsonian Institution, the income from a part of which was to be devoted to "the increase and diffusion of more exact knowledge in regard to the nature and properties of atmospheric air in connection with the welfare of man."

In the furtherance of the donor's wishes, the Smithsonian Institution has from time to time offered prizes, awarded medals, made grants for investigations, and issued publications.

In connection with the approaching International Congress on Tuberculosis, which will be held in Washington, September 21, to October 12, 1908, a prize of \$1,500.00 is offered for the best treatise that may be submitted to that Congress "On the Relation of Atmospheric Air to Tuberculosis."

The treatise may be written in English, French, German, Spanish or Italian. They will be examined and the prize awarded by a committee appointed by the Secretary of the Smithsonian Institution in conjunction

MR. EDITOR:

In the March issue of the *JOURNAL* I read with a great deal of interest the report of a

with the officers of the International Congress on Tuberculosis.

The right is reserved to award no prize if in the judgment of the committee no contribution is offered of sufficient merit to warrant such action.

The Smithsonian Institution reserves the right to publish the treatise to which the prize is awarded.

Further information, if desired by persons intending to become competitors, will be furnished on application.

CHARLES D. WALCOTT,

Secretary Smithsonian Institution,  
Washington, February 3, 1908.

MR. EDITOR:

The York County Medical Society of the State of Pennsylvania, in regular session assembled, hereby acknowledge, through its secretary, the receipt of the communication of the Secretary of the Kentucky State Medical Association and the resolutions passed by your body, in regard to the use of nostrums by physicians and their advertisement to the profession through a large portion of the medical press, and heartily endorse the resolutions adopted by your State Association as published in the KENTUCKY MEDICAL JOURNAL.

This Society sends greetings and congratulations to the organized medical profession of the State of Kentucky for the commendable attitude as expressed in the published resolutions which are in harmony with the excellent work of the Council on Pharmacy and Chemistry of the American Medical Association in its beneficent purpose of freeing our profession and its publications from the nostrum evil. Our County Society is ready at all times to co-operate with other affiliated medical organizations, county, state and national, in controlling fraud and deception of all kinds, and pledges its support of allied agencies in promoting ideal standards of medical practice and medical journalism.

L. C. GABLE,  
T. J. SNYDER.

## COUNTY SOCIETY REPORTS.

**Anderson**—The Anderson County Medical Society met with Dr. Lillard on Monday, March 2nd., the following members being present: Lillard, Kavanaugh, Sheemaker, Simpson, Paynter, Gilbert, and Murdock.

**G. D. Lillard** read a paper on "Broncho-Pneumonia or Capillary Bronchitis." Attention was called to the fact that this disease often follows la grippe, the extremes of age being susceptible.

On examination you find an area of dullness from the size of a silver dollar to the whole

lung, rapid respiration from forty to sixty per minute. The harassing cough is one of the most prominent symptoms. Venatrum v. or aconite when the pulse is strong and bounding, strychnia when indicated, and often stimulating expectorants.

**S. Simpson** opened the discussion and after expressing his appreciation and approval of Dr. Lillard's paper, gave an interesting talk on "Lobar Pneumonia."

Pneumonia should be treated according to its pathology, that is the stages through which it passes. In the first stage or stage of congestion, the versatility of the physician is taxed to its utmost. Digitalis is said by some to be an abortive agent. It does tend to force the blood through the engorged capillaries of the lungs.

A great many of the profession have discarded the local applications. Mustard plaster or menthol paste are of benefit but any others are detrimental.

In the second stage you do not want to use any local applications except something for protection.

Whisky, caffeine, strychnia, etc., are used as indicated, of course, the proper amount of caution is necessary in the use of these stimulants especially strychnia.

When the heart's action is fairly good, alternate the strychnia with digitalis.

Ergot is good to use in the delirium of pneumonia, in the form of ergotol. Chloral can be used in single doses, forty-eight hours apart, where there is no disease of the heart.

Be sure and not neglect the after treatment of your cases of pneumonia, giving the proper tonics, etc.

**C. W. Kavanaugh:** Our treatment of pneumonia can only be symptomatic. Watch the patient closely and strengthen those organs that are showing degrees of failure. We have nothing to abort pneumonia, it is a self-limited disease, sometimes we strike cases that are of short duration but we never abort any. Local applications only divert some of the engorged from the seat of inflammation to the superficial capillaries.

**C. M. Paynter:** As a rule we do too much "treating" in pneumonia. What treatment you do use, be sure and use it at the proper time. Broncho-pneumonia is really a bronchitis and stimulating expectorants should be used. Belladonna is an excellent remedy for the delirium of pneumonia. In lobular pneumonia, use turpentine in four to ten drop doses every four hours in mucilage until hemorrhage ceases.

**J. R. Murdock:** Don't use any heart stimulants except what is absolutely necessary. Local applications are indicated where there is pleuritic involvement.

"Caphenin" is an excellent remedy in 5 gr. doses one-half an hour apart for two doses, then every hour until relieved.

**G. D. Lillard** closed the discussion: No intelli-

gent physician ever uses strychnia except as it is indicated, which is generally at the time of the crisis. Local applications are beneficial in pleuro-pneumonia especially dry-heat. Another good application is camphorated oil with turpentine. Sometimes we are compelled to use morphine but we should be very careful in using opium in any form. Fresh air and plenty of it should be used.

**C. M. Paynter** told the society of the interest the commercial club of Lawrenceburg was taking in the hospital; and the secretary was given addresses to write to and obtain some idea as to specifications to be submitted.

The society adjourned to meet with Dr. Paynter, on the first Monday in April.

J. W. GILBERT, Secretary.

**Anderson**—The Anderson County Medical Society met with Dr. Witherspoon on Monday, February 3rd, at 2 P. M. The following members were present: J. R. Murdock, Gilbert, Kavanaugh, Paynter, Witherspoon, Toll, Simpson, Duff and Leathers.

**J. R. Murdock** read a paper on the "Surgery of the Appendix." This paper covered several important points in diagnosis as well as giving the chief points to be observed in operating.

**C. M. Paynter**, besides opening the discussion, read an exhaustive paper on Appendicitis from the view of medical treatment as well as surgical. These papers and the discussion of them by the whole society brought out a great many different views of the various authorities on this subject.

After the discussion of several matters of local interest, the society adjourned to meet with G. D. Lillard on the first Monday in March.

J. W. GILBERT, Secretary.

**Bath**—The Bath County Medical Society met in the office of J. H. Taulbee with A. W. Walden, president, in the chair. The following officers were elected:

President, J. M. Feland; Vice President, J. K. Wells; Secretary-Treasurer, H. J. Daily; Assistant Secretary, F. P. Gudyall; Censor, I. W. Jones.

The new president took the chair and promised to begin the post-graduate course at once.

There being no further business we adjourned.

H. J. DAILY, Secretary.

**Adair**—The Adair County Medical Society met in regular session in Dr. Cartwright's office on Thursday, March 12th, 1908, with the following members present: S. A. Taylor, U. L. Taylor, W. F. Cartwright, W. R. Grissom, J. H. Grady, R. Y. Hindman and E. T. Allen.

The minutes of the last meeting were read and approved. H. B. Simpson's name was proposed for membership, and on motion he was elected. U. L. Taylor being on the program to read a pa-

per chose rather to give a talk to the society about his attendance at the Anti-tuberculosis Convention, which met at Louisville in the month of January, last past. The health officers of the State had been summoned to meet, and discuss the sanitary conditions of the State, and the best means of still further combatting the various diseases that afflict the people. About eighty-five of the counties were represented. Represented by earnest and unselfish men, men who had risen above selfishness, and seemed willing to do anything for the uplifting of their race, in spite of the fact that such a course was damaging to themselves, and the whole medical profession, we undertook to find out and agree on plans for not only tuberculosis, but all other contagious and preventable diseases. Nearly all the delegates had gone there on the various lines of railroads, and each one seemed to have constituted himself a committee of one to look after the sanitary condition of the coaches. I attended also some of the scientific lectures on the best means of preventing, treating, and curing consumption. This is a big subject, and one which requires much thought.

W. R. Grissom was also a delegate to that Louisville meeting. He gave us some timely talk about what he saw and learned while there. He told us of the lectures to which he listened, and was somewhat astonished to learn the control that the Health Officials had over the railroad managers. He urged the physicians of the county to stand by the Health Board of the county and give them whatever assistance from a moral standpoint that they were able to give.

John H. Grady gave us the benefit of his rich experience along the lines of sanitation. One of the members, W. T. Grissom, paid his annual dues, and all the others proposed to pay at the next meeting, which will be a year from the time they paid last. There being no further business on motion the meeting adjourned.

U. L. TAYLOR, Secretary.

**Carlisle**—The Carlisle County Medical Society met in regular quarterly session in R. T. Hoeker's office, in Arlington, March 3rd, 1908, at 10 A. M. The following members were present: R. T. Hoeker, Owen, Peek, Jackson, Simpson, Payne, Mosby and Cronch.

Rain and muddy roads prevented several members from attending. We think the Carlisle County Medical Society is in as good working order as any county medical society in the State. Fourteen working members and two who have retired from active practice because of old age. We have two more doctors in the county who are entitled to membership and hope to have them with us soon.

In the absence of the president, J. R. Owen was elected to preside during the meeting. After report of the committees and other preliminary business, J. R. Owen read a very interest-

ing paper on "Syphilis, Its Diagnosis and Treatment." Discussion opened by Dr. Jackson and was freely discussed by all present. Society then adjourned for dinner at the Victor Hotel.

Reassembled at 1 P. M., when G. W. Payne read a most excellent paper entitled: "Causes and Treatment of Un-united Fractures." Discussion opened by W. L. Mosby. This subject brought out a long and lively discussion, the essayist and other members reported cases of un-united and delayed union in fractures which would not unite until the bones were sutured with wire. The subject of fractures and their treatment was considered of more importance in these latter years than formerly, because mal-practice suits against surgeons were getting to be distressingly frequent and the members of our society decided that it is always good and protective practice to have another surgeon or physician to assist in putting up all fractures no matter how simple they may seem to be.

**J. M. Peck** read a paper on the "Heart Complications of Rheumatism and their Treatment." It was short, pithy and to the point. He laid especial stress upon the rest cure, long continued until the organ could regain its tone.

**F. N. Simpson** gave us a paper entitled, "The Home Treatment of Consumption." This subject was just what we were all looking for. The essayist proved himself equal to his task, giving all of the modern modes of prevention and best lines of treatment. R. T. Hoeker opened the discussion which was freely indulged in by all present.

This concluded the scientific program.

The society unanimously indorsed the action of the committee appointed by the State Association in regard to its adoption of the defense fund.

The society then adjourned to meet at Millburn the first Tuesday in June.

H. T. CROUCH, Secretary

**Christian**—The Christian County Medical Society met in regular session in the parlors of Hotel Latham, President Stites being in the chair, and the following members present: T. P. Allen, Erkiletian, Bacon, Wright, Jackson, Harned, Sandbach, Harris, Ketchum, Beazley, Anderson, Woodward, Boyd, Edwards, Lackey, Thomas, Blakey and Keith, of the county, and W. D. Haggard, of Nashville, Tenn.

**J. B. Jackson** reported a case of Spina Bifida and a case of Labor in which pus was discharged from uterus around sides of forceps, without any subsequent symptoms of an infection. F. M. Stites reported a case of atresia of rectum in newborn, in which an operation was performed after which one stool was passed, the patient dying nine hours later.

**J. P. Keith** reported a case of miscarriage of twins of opposite sex attached to same placenta

by separate cords. No indications of there ever having been two separate placentas.

**D. H. Erkiletian** read a splendid paper on, "The Intrinsic Value of the County Medical Society to the Doctors of Christian County," and W. D. Haygood read a paper entitled, "Practical Deductions in the Diagnosis and Treatment of Appendical Affections." This was a special treat to everyone present. Both papers were discussed freely by those present. Drs. Woodward, Anderson and Keith were appointed to draft resolutions and act for the body in regard to the pending legislation in our State. Drs. Young, Thomas, Anderson, Rice and Broadus were received as members of this society.

J. PAUL KEITH, Secretary.

**Cumberland**—The Cumberland County Medical Society met in the offices of W. C. and Oscar Keen, at Burkesville, on March 11th, 1908. The house was called to order by the president, H. L. Cartwright, and the following business was dispensed with, which should have been done some time ago, but for various reasons was neglected.

A board of Censors was elected which are as follows, Dr. J. H. Myers, of Whetstone, for one year, Dr. A. L. Sharp, of Kettle, for two years, and Dr. R. L. Richardson, of Waterview, for three years.

H. L. Cartwright was elected delegate to represent our society at the next meeting of the Kentucky State Medical Association.

Cases were reported by Keen, Owsley, Cartwright and Keen, and lengthy discussions were indulged in in each case reported, every one present taking an active part in the discussions. No papers were read.

The society adjourned to meet again the second Wednesday in April.

OSCAR KEEN, Secretary.

**Garrard**—The Garrard County Medical Society met in J. B. Kinnaird's office in Lancaster, January 31st, and after attending to the ordinary business the annual election of officers was held.

J. A. Amon was elected president and J. B. Kinnaird, secretary-treasurer, by a unanimous vote. J. B. Kinnaird was selected as delegate for the coming meeting of the State Medical Association.

Nelson Mays, of Point Liek, was elected to membership.

The society adjourned to meet February 12th, at which time Wm. Burnet will read a paper introductory to the study of materia medica and therapeutics, after which our society will meet every two weeks for post-graduate work. It was decided to thoroughly study every subject proposed and to meet for general review. By meeting twice a month we believe all will become more interested in our daily work and

thereby create more enthusiasm. Our men have determined not to lag behind the procession. We expect to take up the course of study outlined by J. H. Blackburn, and you may expect to hear from us in the future.

The society adjourned to meet February 12th 1908.

J. B. KINNAIRD, Secretary.

**Greenup**—The Greenup County Medical Society met in regular session February 13th, in H. T. Morris' office, Greenup. The society was called to order at 2:45 P. M., by the president, H. T. Morris, the minutes were read and adopted. Members present were: H. T. Morris, A. S. Brady, R. C. Biggs, A. D. DeBard, of Greenup, O. P. Clark, J. I. Rathburn, and E. R. Fitch, of Russell.

J. I. Rathburn gave a very interesting quiz on the "Anatomy of Rheumatism."

E. R. Fitch followed him with a quiz on "Diagnosis, Symptoms, Prognosis and Treatment of Acute Rheumatism."

J. I. Rathburn then read a paper on "Pathology of Rheumatism."

A committee on resolutions appointed composed of J. I. Rathburn, A. S. Brady and A. D. DeBard. The following resolutions were unanimously adopted:

Resolved: That the Greenup County Medical Society recognizing the great sacrifice made by Jesse W. Lazear and Maj. Jas. Carroll in entering the yellow fever infected districts and sacrificing their lives for the investigation and treatment of the unfortunate victims of this dread disease:

We earnestly request of the Hon. J. B. Bennett that he use his influence and vote in behalf of the widows and children of J. W. Lazear and Maj. Jas. Carroll in securing for them a pension commensurate with the great sacrifice they made. (Signed) COMMITTEE.

The meeting March 12th, will be in Greenup. Subject, "Pneumonia, Diagnosis, Pathology and Treatment," O. P. Clark. "Anatomy of the Lungs," A. S. Brady.

A motion to adjourn at 4:30 P. M., was carried.

E. R. FITCH, Secretary.

**Harlan**—The Harlan County Medical Society met at Harlan, February 1st, 1908.

House called to order by Vice President W. T. Nolen. The following subjects were discussed:

N. S. Howard discussed the indications and application of Obstetrical Forceps. Intestinal Antiseptics was discussed by G. P. Bailey. W. T. Nolen discussed the general treatment of all fractures.

W. P. CAWOOD, Secretary.

**Henry**—The Henry County Medical Society met in New Castle on Monday, January 27th,

1908, meeting called to order and presided over by Geo. M. Jessee, vice president.

This being the annual election of officers, the following were elected:

George M. Jessee, President; O. P. Chapman, Vice President; Owen Carroll, Secretary-Treasurer; Webb Sufer, as delegate to the State Medical Society.

J. P. Nuttall, O. P. Chapman and Owen Carroll were appointed to draft resolutions upon the death of W. T. Coblin and C. F. Leudemau.

A motion was made condemning the efforts to create a damage suit insurance as advocated by the State Medical Society and the same was carried.

It was decided by the society to meet again on March 30th and the following persons were appointed to read papers: A. P. Dowden, on "Acute Parenchymatous Nephritis; Jno. P. Nuttall, "Chronic Parenchymatous Nephritis," Everett Morris, "Prophylaxis."

Webb Sufer reports a case of smallpox at Turner's Station. the case was immediately isolated and quarantined and has about recovered at this date and no other cases have been reported.

Quite a number of cases of scarlet fever and diphtheria have been reported during the last fall and winter with two deaths. They have been reported from different localities of the county and as a rule have been mild, there are now eight cases of scarlet fever in and near New Castle, all are mild and are isolated.

Jno. P. Nuttall, former secretary of the society has moved to Campbellsburg, this county and is practicing his profession with exceedingly bright prospects.

OWEN CARROLL, Secretary.

**Hardin**—The Hardin County Medical Society met at Elizabethtown in the City Hall, Thursday, March 12th, 1908, with the following members present: Ligon, Mobley, Willis, Rogers, Hubbs, Bowen, And, Brandon, Strickler, Flanigan, Nusz, O'Comer and English. Minutes of last meeting read and approved. W. H. Gardner's application for membership was read and motion made by F. P. Strickler to make him a member by a unanimous vote, seconded by Aud. Motion carried.

C. Z. Aud reported that the Kentucky State Association had not been incorporated and that the Council had taken steps to incorporate. Moved and seconded that Secretary show in the minutes that the Hardin County Medical Society approved of the action of said Council, motion carried. Report of cases: Dr. Strickler reported a case of anasarca in a woman forty-four years of age from valvular insufficiency. Said all the tissue in the body seemed to be filled with fluid. Used digitalis, both tincture and infusion but to no avail. Had resorted to elaterin and the abdominal ascites was greatly reduced and he

wanted the opinion of the society whether or not it would be safe and wise to perform paracentesis abdominalis or try to further deplete by drugs as it was his experience tapping at this age was not best. Dr. Bowen in discussion said he got better results from digitalis and elaterin than tapping. Advised against tapping unless diaphragm be pushed up to interfere with heart action.

**C. Z. Aud** asked if he had tried magnesium sulphate, recommended silk weed root infusion as he had gotten good results from it.

**Dr. Ligon** said he preferred elaterium to elaterin. Dr. Willis also recommended silk weed root; tapping if heart action was interfered with.

**F. P. Strickler** (in closing): Said he tried silk weed but she threw it up and was compelled to abandon it.

**W. A. Ligon** reported the following: Was called to attend a primipara tedious labor, os rigid, gave hypodermic of morph. sulph. In 8 hours after I ruptured the bag of water. I saw after waiting that I would have to use forceps. After I got the head through bony canal she had a convulsion. I disengaged the forceps as I feared the perineum, but head came through alright. When shoulders came through there was a tear and when hips were born, a complete rupture occurred. She had convulsions afterward. I gave veratrum and chloroform. The doctor said he never repaired it as he had no help and the woman's condition was bad. Dr. Bowen in discussion said he never called consultation for use of forceps in his life but that a man ought to. Said he never had a complete rupture in his practice. The result to perineum should have been repaired immediately as results would be better.

**C. Z. Aud:** I never saw a case where rupture of bag of water did any good. The repair to perineum should have been right away, as better results are obtained. Authors do not agree with my views in regard to secondary operations. I say two weeks is long enough provided all discharges have ceased.

**F. P. Strickler:** I agree with Dr. Aud as to rupturing membranes. I also differ with authors in regard to secondary operations. I believe that this case should have been repaired immediately, two weeks is plenty of time to wait for secondary operation provided discharge has stopped.

**W. A. Ligon** (in closing): I always rupture the bag of waters, believe it lessens pressure and lets the womb contract down solid and better.

Motion to adjourn for dinner.

Afternoon session was called to order at 1:30.

Dr. Strickler moved, and seconded by Dr. Aud, that no essay be of more than twenty minutes in length. The post graduate work was then taken up. Dr. Hubbs gave a fine talk on cardiac depressants in pneumonia.

**C. Z. Aud** gave an elegant lecture on pleurisy,

its diagnosis and treatment.

After the post-graduate work, Dr. O'Conner reported a case as he was absent at the morning session: A man came to my office and said his son of twelve years complained of a pain on inside of knee joint; gave him a prescription and next day was called out to see him; examined him about hip and made a diagnosis of hip-joint disease of tubercular origin. After intervention of one day went out again, found him semiconscious. Next day found his face and elbow joints very much swelled, also abscess on hip. I opened and drained. Next time I called abscess on both elbows. I opened and drained. All three of these abscesses were large. I want information as to what it is and outcome.

**S. T. Hubbs**, in discussion: I do not know what the trouble is or what the outcome will be.

**F. P. Strickler:** Possibly it is diabetic trouble; examine the urine.

**D. C. Bowen:** I do not know what is the trouble, possibly diabetic; test the urine and let the society know at next meeting how it comes out.

Motion to adjourn.

J. M. ENGLISH, Secretary.

**Jefferson:** The regular meeting of the Jefferson County Medical Society was called to order by President Zimmerman. Pathological specimens were reported by Irvin Abell, as follows:

#### UTERUS BICORNIS UNICOLLIS.

IRVIN ABELL,

The first specimen is that of a uterus bicornis unicollis; the patient, 24 years of age, had been married for four years, but had not been pregnant; her menstrual life began at the age of sixteen, each period being attended with severe pain as a rule of sufficient severity to confine her to bed and at times to require the use of an opiate for relief. Her attending physician, Dr. P. S. Ganz, made a bimanual examination the latter part of August, finding a small tumor, about the size of a marble, to the right of the uterus; he examined her again in November and found that the tumor had increased in size until it was as large as a hen's egg; at this time I saw the patient with him; the tumor was hard, not sensitive on pressure, was attached to the uterus, which, with the tumor was freely movable; an abnormality with the fundus of uterus was noted but its character was not suspected. During the three months between the first observation of the tumor and the time when she was subjected to operation, frequency of urination and an inability to hold the normal quantity of urine in bladder was noted. At the operation, Nov. 28th last, the abnormality of the fundus was found to be an uterus bicornis; the tumor was attached to the uterus at the junction of body and cervix and extended out between the layers

of the broad ligament; in attempting to separate the peritoneum from its anterior surface, the bladder was opened and examination revealed that the bladder wall was infiltrated by the tumor as far as the mucous coat, which appeared free; after separating the uterus from the tumor, the uterus was removed so as to afford greater working space; on account of the infiltration of structures by the tumor and the locality in which it was situated, it was deemed best to remove it piecemeal; this necessitated resection of a piece of the posterior bladder wall, one inch wide and two inches long, the ligation of the uterine artery at a short distance from its origin from the anterior division of the internal iliac, and the exposure of the ureter for a distance of two inches above its entrance into bladder wall. The bladder wall was closed by superimposed Lembert sutures, a rubber drainage tube carried into vagina, and the entire surface covered over with peritoneal flaps. A retention catheter was kept in bladder for ten days with the head of bed elevated. Union occurred by first intention and the patient went to her home on the eighteenth day.

The tumor was very vascular and showed multiple points of thick tarry fluid; the specimen was referred to Dr. B. J. O'Connor for a microscopic analysis, who reported that the tissue showed considerable infiltration with blood and blood pigment from old hemorrhages; some portions of the tissue were distinctly fibrous and others showed round and spindle cells of embryonal type. Diagnosis; fibro-sarcoma.

The second specimen is a gall-stone and the gangrenous gall bladder which contained it. These were removed Jan. 30th, last from a female patient, 40 years of age, referred by Dr. H. B. Ritter. The patient had suffered for years with digestive disturbances and had had her first attack of colic during last April. The second attack began on Jan. 23rd, the symptoms not being particularly severe; highest temperature 101, and highest pulse 110. Both had become lower when I saw her and spontaneous pain had about ceased, although a distinct mass over gall bladder area was present and exquisitely tender. Operation Jan. 30, one week after beginning of attack; on opening the abdomen the stomach was found adherent to liver and upon separating this adhesion pus was encountered; carefully walling off the infected area with sponges and separating further adhesions, this gangrenous gall bladder containing the one stone imbedded in cystic duct was found; the bladder had perforated at a point below the fundus; it was separated from the liver, and after ligating the cystic duct, removed.

The patient's convalescence has so far been uneventful.

### MASTOIDITIS.

#### DIAGNOSIS AND INDICATIONS FOR OPERATION IN ACUTE MASTOIDITIS.

S. G. DABNEY.

The mastoid antrum should properly be considered as a part of the middle ear. It is present at birth with the mastoid process consists of only a thin piece of cartilage. Its connection with the upper portion of the tympanic cavity—the so-called attic—is constant and close there being an invariable communication by the narrow tube called the aditus ad antrum. Indeed the attic is more closely associated with the antrum than it is with the lower portion of the tympanic cavity from which it is separated by the processes and ligaments of the ossicles. These anatomical considerations are important in considering the subject of mastoid diseases. Inflammation of the mastoid is most frequent in suppurative otitis media following the grippe and next to that is more frequent after the exanthemata, namely measles and scarlet fever.

The great increase in number of mastoid operations is due first, to the wide prevalence of the grippe and second, to the fact that surgeons have realized more fully that intracranial complications and chronic suppurations of the middle ear may often be prevented by a mastoid operation. It is claimed that when the streptococcus or pneumococcus are present in the antral discharge, mastoid complications are more frequent than when only the staphylococcus is found. It is generally conceded by writers that pus in the mastoid antrum will usually be found in the early stages of any acute suppuration of the middle ear. Certainly this is what we should expect from the anatomical relations. An inflammation of the mastoid is not to be diagnosed therefore by simply finding pus at this stage in the antrum but only when the surrounding bone shows evidence of disease. In considering the symptoms of acute mastoiditis it is of great importance to observe the time of their occurrence and their duration. Tenderness, pain and fever, if present only for the first four or five days of the disease, might indicate only an inflammation of the middle ear, but should they continue for a week or more or should they begin after the antral discharge has been going on for five or six days, then there would be strong indications for opening the mastoid.

The ordinary symptoms of acute mastoiditis are: first, tenderness on pressure.

This tenderness is generally most marked either over the mastoid antrum above and behind the auditory meatus or at the tip of the

mastoid process or in the lower posterior portion of the mastoid at the point of exit of its emissary vein. Either one, two or all three of these situations may be tender. The pressure required to produce pain varies with the thickness of the cortex of the bone. Tenderness at the tip, in my observation is nearly always present in the early stages of acute suppuration of the middle ear. Tenderness over the antrum also is often found at this stage. More significant is the tenderness over the point of exit over the emissary vein above mentioned. When a periostitis is present these three typical points may be ill defined and there may be general tenderness over the whole bone. Only in rare cases of acute mastoiditis is tenderness on pressure entirely absent.

#### Second: Pain.

Pain may vary in intensity from a slight feeling of heaviness or discomfort to agony so great as hardly to be relieved by powerful opiates. It is generally referred to the mastoid region and is said to radiate from this locality towards the temple and often all over that side of the head. It is occasionally said to be deep in the ear. In most cases it is so great as to prevent sleep, to produce debility and to require sedatives which disturb digestion and as a consequence we find the patient, if the disease has lasted any length of time, weak and anemic. It need hardly be said that one of the most dangerous mistakes a physician can make is to continue the use of opiates or other sedatives which conceal the very symptoms, the recognition of which is of vital importance. In a few cases particularly in tubercular subjects pain may be very slight or even entirely absent.

#### Third: Discharge.

In mastoiditis the pus discharge from the middle ear is generally profuse and continuous. Indeed, an abundant discharge lasting over two weeks, with fever, even in the absence of pain and tenderness, provided there is a free drainage from the ear, is most significant. I would go further and say that a profuse discharge lasting several weeks and attended by fever for which no other cause could be found, the opening in membrana tympani being free, is in itself strongly indicative of mastoiditis. In a few cases the mastoid complications are ushered in by a sudden cessation of the aural discharge with an exacerbation of all the symptoms pointing to the mastoid. Though this paper is not intended to touch upon treatment, it is necessary to make one brief reference to it in connection with the symptoms already described.

The tenderness, pain and profuse discharge are often quickly controlled by free incision of the drum membrane. This incision should be carried well into the attic and should be

prolonged a short distance along the upper posterior wall of the auditory canal. It is a common experience to see a rapid subsidence of mastoid symptoms after such an incision. Local anaesthetics are unsatisfactory and the pain though brief is very intense. General anaesthesia is desirable and gas answers every purpose.

Fourth: The appearance and situation of the perforation.

Perforation in the upper posterior portion of the drum membrane is most characteristic of mastoiditis. A pouting perforation showing that the drum membrane is pushed forward is often seen and is a strong indication of a free opening. It is said that a pulsating reflex from the perforation, continuing for more than two weeks, is strongly indicative of a mastoid complication. I have observed this symptom myself in several cases.

#### Fifth: Sagging of the wall.

Sagging of the upper posterior wall of the auditory canal near the drum membrane is considered by most writers very strong evidence of an involvement of the mastoid. In my experience the importance of this symptom is overestimated. It is often absent, and I have seen two mastoids thoroughly opened when this symptom was very marked and in neither of these two cases was there pus in the bone. Sagging at this situation has been attributed to two causes. By most authors to a disease of the mastoid cells. By a few to a periostitis which is extended along the wall of the canal from an inflamed attic. The last explanation in my opinion is the correct one.

#### Sixth: External signs.

Tumefaction and redness over the mastoid bone, rarely observed until the disease has lasted several days or longer, generally indicate that there has been a rupture through the cortex of the bone or that some septic material has burrowed from within outward along the vascular channels. Such conditions will, of course, be found in a mastoid periostitis. They will also be found in inflammation of the soft structures over the bone, consequent upon furuncle of the auditory canal. The diagnosis of this condition is of great practical importance. It can generally be made by observing that the tenderness in furuncle is greatest on pressing the ear forward and that pain is elicited by pulling on the auricle. Whereas, when the disease is in the bone the tenderness is most marked by firm inward pressure.

#### Seventh: General symptoms.

Fever is very variable. In children it is generally considerable, ranging from 102° to 104° or more. In adults it is more frequently low, varying from 99° to 101°. It is sometimes entirely absent. Dizziness is not nu-

common. A general pyaemia with inflamed joints and abscesses about the body may be a sequel of neglected or wrongly diagnosed cases.

In one type of acute mastoiditis, namely the so-called Bezold's variety, the pus breaks through the digastric fossa and makes its way below the mastoid. In such cases the tenderness will be most marked at the tip and in the later stages swelling will also be found there.

Indications for operation: As each case must be judged by itself it is impossible to lay down invariable rules for the opening of the mastoid. I would suggest the following, assuming that the free incision already described has been made and that relief has not been obtained by rest in bed: Irrigations of the ear with carbolyzed hot water and hot applications or poultices to the mastoid. In my observation cold, even in the early stages, has been less comfortable than heat. First: Generally operation is not indicated within the first seven or eight days after the disease has begun in the ear. There are two exceptions to this, first, when a swelling appears over the mastoid not due to furuncle, and, second, when there are symptoms of meningeal irritation not relieved by free opening of the drum. Second: If the classical symptoms above described, namely, great tenderness, severe pain, profuse discharge and fever continue over eight or ten days, the indications for opening the bone are positive. Third: With decided tenderness over one or all of the three points above mentioned and with profuse discharge continuing for over two weeks and fever, even in the absence of pain, operation is advisable. Fourth: Immediate operation is indicated should there be any symptoms pointing to cerebral complications. Fifth: It is true that cases are occasionally observed in which every symptom demanding operation is present and nevertheless the patient makes a perfect recovery without it. It is equally true and far more important to remember that the operation in itself is very rarely fatal and that many deaths have occurred from its too long postponement.

INDICATIONS FOR THE SO-CALLED RADICAL MASTOID OPERATION.  
I. A. LEDERMAN.

In contradistinction to the operation for acute mastoiditis the recognized procedure for the cure of certain cases of chronic middle ear suppuration is the so-called radical mastoid operation. When chronic suppuration of the middle ear is associated with acute or chronic mastoiditis the indication for this operation is absolute. Hence the title of the subject assigned to me is somewhat misleading as it is necessary to consider chronic

suppuration of the tympanic cavity complicated with mastoiditis in a study of the indications for the radical operation. It may be in order since this communication is addressed to a body consisting mainly of general practitioners to define briefly what is meant by the radical mastoid operation. This operation must not be confused with complete mastoidectomy which refers to the eradication of the entire mastoid process together with all pneumatic spaces leading from it, such as are found frequently extending posteriorly into the occipital bone and above in the base of the zygoma. This complete removal of the mastoid is often called for both in acute and chronic mastoiditis. The essential feature of the radical operation is the removal of the posterior portion of the bony auditory canal and the external wall of the attic of the tympanum. While it is our duty to always remove every vestige of diseased tissue from the mastoid, the radical operation is confined to the middle ear cavity and the antrum unless at the time of the operation we find the mastoid cells diseased.

Two methods of procedure are in vogue, the most popular of which is the operation by which we enter the antrum of the mastoid primarily and gain free access to the middle ear by removal of the bony partition constituting the auditory canal. By the Stacke method the tympanic cavity is first entered, then the posterior bony canal removed and the antrum reached in this manner. This accomplishes the same purpose in a reverse manner. There are many modifications in detail of the operation, but all methods have one aim in view, the conversion of the tympanic cavity and the antrum of the mastoid into one common space, free of all diseased tissue. Dermization aided or unaided by skin grafts takes place by growth of epidermis from the internal end of the auditory canal and when this process is complete a smooth, non-secreting cavity should be the result.

When this operation sprang into favor some years ago many operators threw conservatism to the wind and patients were unnecessarily subjected to it. The most competent observers and operators, both in this country and abroad, have recently shown a tendency to a healthy conservatism with reference to the radical operation which is not without its dangers. They resort to it only in the presence of distinct indications. As a result the operation is rapidly being placed on a rational basis and is already being well established among the operators of aural surgery. It is imperative in the face of certain symptoms and conditions and no other procedure can be substituted for it.

Chronic suppuration of the middle ear may terminate in, first, cure, with cessation of suppuration and complete restoration of hearing. This happy result can be expected in a small proportion of cases and only under the most favorable conditions. Second, cessation of suppuration with permanent deafness of different degrees. The remains of the drum membrane become cicatricial, connective tissue adhesions form in the tympanic cavity rendering the ossicles immovable but leaving otherwise a safe and symptomless condition. In other cases partial or complete dermitization of the tympanic cavity takes place through a large defect in the drum membrane, which condition may also remain innocent of harm. On the other hand such ears are constantly in danger of a recurrent attack of acute or chronic inflammation from slight or severe irritation or infection, such as may occur through the auditory canal or from the naso-pharynx, besides being predisposed to the influence of colds and intercurrent general diseases. Numbers of these cases show a tendency to recurrence with apparent cause. The more serious forms of chronic middle ear suppuration are those attended by, third, the formation of cholesteatoma and these in which, fourth, the ulceration and cario-necrotic processes exist in the temporal bone. The latter complications render the patient liable to the most serious sequela, namely intra-cranial infection. During the course of a chronic middle ear suppuration the external meatus undergoes pathological changes through extension of the diseased process and from contact with the secretion. Among them are inflammation and hypertrophy of the skin structure of the canal, granulations and polypi. The periosteum of the bony canal may become inflamed and thickened, caries and necrosis of the bony meatus or gangrene of the cartilaginous meatus may take place. The origin of cholesteatoma is frequently in the canal from an excessive growth of epidermis which finds its way into the tympanic cavity.

In chronic as in acute middle ear suppuration the antrum and mastoid cells are more or less involved in the inflammatory process. Besides being due to direct extension of the disease the conditions of drainage play an all important part. Any one of the many factors causing retention of pus favors the probability of a mastoid involvement. The character and extent of this involvement are influenced by the type of middle ear affection, duration of the disease, general condition of the patient and the anatomical variety of the mastoid. While the antrum is almost invariably the seat of disease, extensive suppuration of the mastoid process is seldom found in the diploetic or compact bones, more

frequently in the pneumatic varieties. Quoting Politzer we find the most important pathological changes in the mastoid process to be, First, hypertrophy of the lining membrane of the antrum and mastoid cells caused by a proliferation of round cells, the mastoid cells becoming filled up and obliterated by the proliferated mucous membrane. Second, persistence of this tissue or its transformation into bone with partial or complete ablation of the mastoid process. Third, granular otitis and carious softening of the walls of the antrum which is frequently abnormally widened; or rarely narrowing, or complete obliteration of the antrum with extensive sclerosis of the mastoid process. Fourth, circumscribed or diffuse caries and necrosis of the mastoid process with or without the formation of a sequestrum. Fifth, cholesteatoma in the antrum and mastoid cells or a collection of pus and thickened, careous masses similar to tubercular material. Sixth, hyperostosis and osteosclerosis of the bone substance surrounding the seat of disease. These changes may occur singly or in combination with each other.

Not infrequently an intercurrent acute mastoiditis occurs and when these attacks are slight they may subside without forming mastoid abscess. There is no doubt, however, that such inflammations may be the starting point of any of the pathological changes referred to. What are the ultimate effects of such pathological processes which may endanger life? The ever present danger of extension to the vital structures adjacent to the mastoid, and middle ear cavity must be borne in mind. Meningitis, serous and purulent, ulceration and abscesses of the brain, thrombosis of the lateral and petrosal sinuses and jugular vein, infection of the internal ear through erosions of the internal wall of the tympanum, involvement of the facial nerve, causing facial paralysis and rarely, erosion of the carotid artery. In addition to these sequelae a small number of chronic middle ear suppurations with or without mastoid involvement give rise to a low form of sepsis from direct absorption of pus products. When we have concluded from the study of a case that one of these serious conditions is present or is imminent it is our duty to operate at the earliest possible moment for we must guard the unfortunate patient against the danger of a smoldering volcano which when once in eruption may render all our efforts futile. In this then we have the imperative indication for opening the mastoid. The symptoms upon which we must depend in diagnosing conditions of the mastoid are unfortunately extremely variable. They are so inconsistent with the extent and type of bone involvement that we

are no longer surprised at anything we may find upon opening a mastoid. The most extensive processes may run a latent course for years with absolutely no symptoms leading to even a suspicion. On the other hand a few cells filled with granulation tissue or pus may be the cause of the most severe re-active symptoms.

In the diagnosis of acute mastoiditis occurring during the course of a chronic middle ear suppuration, we find no characteristic features presenting, except that all the symptoms both objective and subjective are apt to be more pronounced than when occurring in acute middle ear abscess. It is in those cases showing slight or no evidence of mastoid involvement in which our judgment is severely taxed. Postmortem examinations and clinical proofs have demonstrated to us that chronic mastoiditis may have existed for an indefinite time without being recognized. We must conclude that the mastoid is involved if a persistent suppuration is present, associated with perforation of the posterior superior quadrant of the membrana tympani or with fistulous opening in Shrapnell's membrane. The diagnosis is made more probably if by rarefying the air in the external meatus we can aspirate a larger quantity of pus from the posterior portion of the attic than the tympanic cavity is capable of holding. Add to this boring pains in the mastoid process and we must consider the diagnosis of mastoid abscess established. In the absence of pain over the mastoid either spontaneous or not to be elicited by pressure or percussion we may still justify our diagnosis when granulations and cholesteatoma exist in the middle ear with marked narrowing of the external meatus together with symptoms of pus retention. These are fever, chills, headaches, nausea and vomiting.

In the treatment of chronic middle ear suppuration our efforts are directed to controlling the foetid discharge, saving as much of the function of hearing as possible and guarding against the extension of the disease, so as to protect the patient from complications endangering life. The non-operative treatment requires skill and judgment on the part of the aurist and an unlimited amount of patience on the part of both the physician and the patient. Many cases of the favorable kind and some of the most unfavorable would yield to the various methods of treatment were the patient willing to undergo the discomfort of the treatment, the loss of time, required, and remain faithful for months when little or no benefit is immediately apparent.

A certain number of cases which have proven intractable to treatment are benefitted by ossiculectomy and curdettng of the tympanic

cavity. Some of our most prominent men have practically discarded this operation, others claim to get good results and insist on reserving the radical mastoid operation for such cases in which the minor operation has not proven successful. Ossiculectomy can no doubt be applied with some promise of improvement to selected cases for instance, where no evidence of mastoid involvement exists where merely better drainage is called for and where caries is circumscribed or limited to the ossicles.

Politzer enumerates the following indications for the operation: First, caries of the temporal bone associated with chronic middle ear suppuration. Second, extensive growth of polypi with pus retention especially if the growth arises from the attic and antrum and recurs after complete removal. Third, Fistulous openings on the mastoid process and in the osseous meatus and caries in the walls of the tympanic cavity or cholesteatoma in the attic. Fourth, cholesteatoma in the middle ear cavity, if suppuration continues after a long removal and if masses of cholesteatoma can be washed out after a long continued treatment by intra-tympanic irrigation. Fifth, in obstinate aural suppuration in which the septic discharge contains masses of epidermis and in which peripheral fistula is present in the posterior superior quadrant of the drum membrane and the remnant of the drum membrane is adherent to the promontory wall. Sixth, membranous strictures of the external meatus or those due to hyperostoses, on account of the danger of pus retention. Seventh, paresis or paralysis of the facial nerve in the course of a chronic suppuration in the middle ear, with caries of the temporal bone or developing in an intercurrent attack of acute middle ear inflammation. Eighth, acute mastoiditis with mastoid abscess occurring during the course of a chronic middle ear suppuration. Ninth, chronic middle ear suppuration with symptoms of commencing tuberculosis. Tenth, foetid middle ear suppuration resisting every method of local treatment. Here we must assume that there is a carious cavity or cholesteatoma in the temporal bone. To these may be added when associated with other symptoms, First, fever, remittent or continuous rising to a high degree after a chill or rigor, or having the characteristic variations of septic fever. While the presence of high fever causes us to suspect sinus thrombosis it may also be due to direct absorption of septic material from the temporal bone. Second, vomiting, associated with head aches and symptoms of cerebral irritation, which may be regarded as a serious symptom. Third the condition of the fundus oculi, Delstanehe,

in a collection of cases found changes in the fundus consisting of dilatation of the blood vessels, optic neuritis and choked disc, in fifty per cent. of the cases of middle ear suppuration with intra-cranial complications. Politzer considers this especially a sign of increased cerebral pressure hence a serious symptom. This is not necessarily true, however, as cases showing signs of intracranial pressure have been entirely relieved by mastoid operation.

The subjective symptoms indicating the radical operation only however when associated with undoubted objective signs are, First, pain, continuous or recurring, located in the ear or mastoid, persistent on the corresponding side of the head and a feeling of pressure and weight in the head. Second, temporary or repeated attacks of dizziness. These may be caused either by increased labyrinthine pressure induced by cholesteatoma or polypi in the tympanic cavity or by erosions of the semi-circular canal or by caries of the labyrinthine capsule. The examination of the ear with a tuning fork assists us in defining the cause. If with total deafness bone conduction is entirely wanting the labyrinth is most likely involved. It is in these cases that Jansen removes the labyrinth in order to prevent the suppuration from extending to the internal auditory meatus and thence to the cranial cavity.

We conclude first that all cases of chronic middle ear suppuration presenting no symptoms immediately endangering life should be given the benefit of conservative treatment. This is especially true if the treatment can be carried out faithfully and under favorable conditions. The length of time necessary for a cure or at least placing our patient on safe ground, varies according to the individual case from several months to several years. Other circumstances surrounding the patient must also be taken into consideration such as the social standing, occupation, and age. A young lady of otherwise attractive qualities would probably choose the risk of a radical operation rather than be permanently handicapped by a full discharge from the ear. Likewise the presence of a discharging ear may interfere with the usual vocation of the patient. In children we must especially refrain from performing the radical operation unless absolutely necessary. McKernon has pointed out that frequently in children opening the antrum and draining the middle ear cavity posteriorly suffices to cure many cases of chronic middle ear suppuration.

The operation must be performed when a diagnosis of acute or chronic mastoiditis can be established. When symptoms of intracranial complications supervene and granulations, polypi and cholesteatoma persist af-

ter complete removal.

As to the effect upon the function of hearing resulting from the radical operation, experience of different operators vary. Dench reports fifty per cent. of cases improved. Others do not agree and claim that if any considerable degree of hearing is present at the time of operation it is likely to be reduced. Because of the liability of diminishing what hearing power remains we would not operate where useful hearing is present except to save life. For the same reason if a double chronic suppuration exists we would select the poorer hearing ear for operation, except in the face of menacing symptoms. In a certain number of individual cases the presence of a suppurating ear seems to influence the vitality of the patient. Constructive treatment together with local measures having no influence we may be justified in resorting to radical means to rid the patient of the source of trouble.

Incipient tuberculosis is rather an indication for the operation as it has been known to have a good influence on the general condition. Advanced tuberculosis on the other hand is a contra-indication.

Finally what are the dangers of the operation? There is little likelihood of injury to the dura, sinus or internal ear if they are not already diseased and if we observe proper precautions but the most skillful surgeon exercising the utmost care cannot always avoid injuring the facial nerve. Fortunately this nerve has great power of regeneration and unless it is completely severed or enclosed in a hard mass of callus the facial paralysis resulting is usually transitory. Can we expect to cure every case of chronic middle ear suppuration and mastoiditis by means of the radical operation? A very small proportion are not benefitted, in others a slight discharge recurs, but the greatest number will be completely relieved. Due to the exfoliation of the delicate epithelium covering the new epidermis of the cavity some successful cases require attention occasionally.

When our results are not satisfactory we may be sure we have not removed every particle of diseased tissue. In practically every case, however, we can be happy in the conviction that we have protected our patient from the probability of a preventable complication which may have proven fatal.

#### THE MASTOID OPERATIONS.

A. O. PEINGST.

In the short time allotted me to review the methods of operation for the relief of mastoid disease the most difficult task will be the selection, from the many points of interest, those features which will appeal to a general body of physicians, without omitting any-

thing of importance. At the outset of my discussion I wish to emphasize the fact that the procedure indicated in the cases of chronic mastoid disease and the one employed in acute mastoid abscess are different operations, the latter being but a step in the former or radical mastoid operation. It is my belief that the difference in the technique of the two operations is understood by but few of those not actively engaged in aural surgery. You are all familiar with the simple operation which is known as the Schwartz operation and which has for its object the evacuation of pus from the bone and the removal of all necrosed bone structure. Its technique does not differ materially from that originally proposed by Petit in 1765, who penetrated the bone by means of chisel and mallet, though the present day surgeon is much more thorough in the removal of diseased cells. The steps of the operation given as briefly as possible are the making of the familiar incision 1-4 inch behind the ear through the soft parts to the bone, and retraction of the soft parts including the periosteum until a good field is exposed for operation. The antrum is then approached by removing with chisel and mallet the bone in Macewen's triangle or a point just behind the external meatus and just below the temporal ridge. When a fistulous opening exists it can be taken as a guide to reach the pus cavity. The thickness of the layer of cortex covering the antrum differs in different subjects. It varies from 1-8 to 3-4 inches. In searching for the antrum it is important to work in a direction forward and inward, using the posterior ossous wall of the canal as a guide. When the antrum is situated deeply it becomes necessary to work very cautiously. All necrosed bone should be carefully removed, communication with the tympanic cavity established, rough corners smoothed down, overhanging ledge of bone removed and the wound packed with gauze.

In keeping with the advance in aural surgery the simple mastoid operation of to-day is more thorough in the removal of bone cells and granulation tissue than formerly and the necessity for a second operation has become very much lessened. Nothing has done so much to bring this about as the adoption by otologists, almost as a routine measure the exploration of the root of the zygomatic process, the cells of which are frequently involved in the diseased process. These cells, as well as those extending backward toward the occiput and the cells of the tip of the mastoid when found unhealthy should be thoroughly removed. American surgeons did not take kindly to the suggestion of Politzer in his last text-book on otology, to avoid the antrum in cases of diseased cells with appar-

ently no communication with the antrum.

Politzer believes that in the majority of cases of mastoid disease the antrum is not involved and that the antrum should not be explored when pus cavities are found more superficially situated unless meningeal symptoms be present. I have never seen a case in which I would have felt scrupled to leave the antrum unexplored. The simple mastoid operation is not beset with the same dangers of injuring vital parts as the radical operation. In removing bone posteriorly the lateral sinus which is rather irregular in its course and may extend well into the mastoid region may be wounded. In working upward and forward the middle cerebral fossa may be entered. Neither of these accidents are looked upon as serious.

To sum up I would emphasize the following points; the section through the soft parts should be large so as to explore a large area of bone, including the entire mastoid process and the root of the zygoma; diseased cells should be followed up and removed so as to leave a cavity lined with healthy bone; free communication should be established between the antrum and tympanic cavity by way of the aditus and all overhanging ledges of bone or rough surfaces should be smoothed as well as possible.

Time will not allow a discussion of the instruments employed in this operation, the landmarks for entering the bone or the after treatment.

Until a few years ago the described operation was employed in acute and chronic cases alike with but little success in the latter. In 1887 a new method applicable to the chronic cases was introduced by Kuester. It had for its subject the conversion of the antrum, attic, tympanum and ear canal into a common cavity and was accomplished by removal of the superior posterior wall of the ossous canal. The radical mastoid operation as it is practiced to-day involves the same principles as the method of Kuester but has been modified in its technique, especially with reference to the plastic method of covering the bony cavity. To arrive at a proper conception of the method it is best to divide it into the operation upon the bone and the plastic operation employed to cover the bone cavity.

The skin section in this operation does not differ materially from the one for the simple operation. It is made a little closer to the auricle, does not extend as far towards the tip and curves forward over the tip of the ear slightly so as to facilitate the exposure of the ear canal. The membranous ear is separated posteriorly from the bony canal by means of a blunt separator. The antrum is then opened by removing bone over the re-

gion of Macewen's triangle and following close along the posterior osseous wall of the ear canal in an inward and forward direction as in the simple operation. The overhanging ledges of bone are then removed so as to leave a funnel-shaped bony cavity.

The aditus is found in an inward and forward direction from the antrum and a probe inserted through it into the attic to act as a safeguard and guide to the next step, that of removing the superior portion of the posterior wall of the canal. The bone is removed until the attic is reached, care being taken to remain well above the probe so as to avoid the facial nerve. Notwithstanding the utmost precaution the nerve is not infrequently wounded owing to the irregularity of the course of the facial nerve through the bone. At the completion of the work upon the bone one large cavity is visible representing the antrum, tympanum and ear canal, which is easily accessible and which insure drainage. Posteriorly the facial spur projects into the cavity. The object of the plastic step of the radical operation is to bring about an epithelial covering of the bony cavity and thereby insure a dry nonsecreting surface. To prevent a subsequent reinfection of this cavity from the naso-pharynx the Eustachian tube is gently everted through the tympanum before undertaking the plastic step. Many methods have been suggested to cover the bone all of them bringing about only a partial covering at the time, to furnish starting points for subsequent epithelial development. The operation now most in vogue is the one introduced by Koerner. Two horizontal incisions are made through the membranous ear canal one at the junction of the superior and posterior surface and the other at the junction of the posterior and inferior surface well back into the concha, thereby creating a tongue-shaped flap. The cartilage and fat is dissected from the back of this flap to make it more pliable. It is then pushed backward into the bony cavity where it is held by means of a tampon over rubber tissue or by a periosteal suture.

The incision behind the ear is closed with silk or silk wormgut. To hasten dermitization of the parts not covered by the flap some surgeons apply skin grafts either at the time of the operation or subsequently. The necessity for observing rigid asepsis in this operation need hardly be emphasized. It is also hardly necessary to point out the importance of a thorough knowledge of the anatomy of the temporal bone before undertaking a radical operation. The proximity of the facial nerve and the horizontal semicircular canal to the field of operation must constantly be borne in mind. Good illumination with direct or reflecting light is of the utmost im-

portance. Equally so the keeping of the field of operation as dry as possible. Troublesome oozing from the bone can be controlled with hot compresses, solutions of adrenalin. The points to be emphasized in performing the radical operation are the necessity of a thorough bone operation so as to leave a well-formed inverted cone-shaped cavity; careful watching of the facial nerve, the curettage of the tube and the observance of strict asepsis.

I regret that my time is too short to say something of the instruments employed in this operation and also to speak of the method and length of the after-treatment.

#### DISCUSSION.

**W.M. Cheatham:** I have very much enjoyed hearing the papers, and the ground has been covered so thoroughly that there is little left for me to say. Dr. Dabney spoke of furunculosis complicating diagnosis, but he did not mention the rest of it; that we frequently have suppuration of the middle ear combined with furunculosis, making a very dangerous condition of things. The diffused infection of the canal might be so great as to conceal the condition of the middle ear. Dr. Dabney also omitted to mention trans-illumination as an aid to making diagnosis in mastoiditis. I have never used it, and do not know of what value it is. I remember very distinctly, that, when the mastoid operation was first introduced, it was nothing but a Wildis incision, not going into the bone at all. The next step in the progress of the operation was making a small opening in the bone with a gimlet or drill. This was as far as it got for several years, and then the radical operation was introduced.

Incidentally, I would like to mention the new Calumet method of making diagnosis of tuberculosis, which may be of some assistance in making diagnosis of tubercular mastoiditis. I would suggest that it be tried in these cases.

In young children, where the attic is involved, good results will be obtained in many cases by making an incision behind the auricle and extending it down to the attic between the bone and cartilage, and establishing free drainage behind, without going into the mastoid at all. I have seen a number of cases get well under this treatment.

Dr. Pfingst spoke of the chisel and the mallet, both of which I use only in cases where the bone is very hard. All that is necessary can be accomplished with the gouge and small bone forceps much more safely than with the chisel and mallet.

**W. B. Pusey:** There are some cases, especially in young children, where it is not necessary to go into the bone. I have had occasion, within the past two or three years, to see four of these cases, three of them in children and one

young woman, in which incision through the perio-osteum was followed by entire recovery.

**G. C. Hall:** I have a couple of specimens which I should like to show the members of the society. I think they will serve to illustrate the difference between the simple operation and the radical operation very nicely.

The upper specimen shows a simple mastoid operation. There are three anomalies present in the specimen which complicate surgery in this region. The first is that the antrum is situated very high up, is very small and narrow, and could be easily overlooked in opening the bone. The second is that the lateral sinus projects forward in the usual situation of the antrum, so there is a small space between the posterior canal wall and the lateral sinus. The third is the development of a large posterior tip cell which has really developed behind the forward curvature of the lateral sinus, and in this situation could be easily overlooked in either the simple or the radical operation.

The simple operation is the cleaning out of all the structures of the mastoid, while the radical operation not only includes the cleaning out of all cellular tissue, but the conversion of the tympanic cavity and the antrum of the mastoid into one common cavity.

I have also brought one or two instruments, which facilitate the work of operating in this region a great deal. One is Jansen-Allport retractors, very light and strong and very efficient in those cases where we have to get a wide exposure of the field, and it does away with the necessity for an assistant. The other is a bone gouge for deep work.

The essayists have gone so thoroughly into the subject that there is no necessity for my taking up time to discuss it.

**W.C. Dugan:** There is one point I wish to mention, and that is the absence of local symptoms. A number of years ago I saw a case in consultation with Dr. Coomes. There were no local symptoms whatever, except that in pressing over the tip of the mastoid I got evidence of pain, that is, she would draw that side of her face. The patient was in a comatose condition and had been thus for hours. We operated, using the mallet and chisel, and found some pus which was removed and the patient entirely recovered. There was absolutely no discharge from the ear at time of operation, but there was history of middle ear disease.

**J. R. Wathen:** I would like for some of the gentlemen in closing to give some statistics in regard to facial paralysis following these operations; also the anastomosis which seems to be most popular.

**P. F. Barbour:** This is an exceedingly interesting subject, not only to the eye, ear and throat men, but to the general practitioner. We all see these cases of middle ear trouble, followed by

mastoid complications. I was in hopes that some of the essayists would give us some points by which we might absolutely diagnose mastoiditis. I recall rather unpleasantly one case which I referred to a specialist here, in which the child died of brain fever following mastoid trouble, and never gave any evidence of pain. Dr. Kerley, in a report on this subject several years ago stated that there is only one symptom which is found in all cases of inflammation of the middle ear and mastoid, and that is fever. Most of them have a combination of symptoms, but that is the only one which is found every time.

**G. S. Dabney (closing):** Referring to Dr. Barbour's remarks, I do not know whether Kerley is a pediatricist or ocologist, but I am sure he is mistaken. I have seen a number of mastoid cases in which fever was not present. Within the last few weeks I operated on a lady from a neighboring town for mastoid abscess; she had no fever. I can understand this view better, however, from the standpoint of the disease in children because fever is far more unusual in children than in adults; it is nearly always present in them. Dr. Barbour seemed to be under the impression that when brain trouble arises it is always through the mastoid. That is a mistake. Many brain complications occur when the mastoid is not involved. I am confident I have seen such cases. I thought of bringing in the point which Dr. Cheatham mentioned, and one which he did not. I did not think much of trans-illumination or percussion and desired to limit my paper. Both of these have been experimented with, but as yet nothing practical has been accomplished.

I was very much interested in Dr. Lederman's paper on indications for operation in chronic suppuration of the middle ear and I am glad to note that he has observed the backward swing of the pendulum and that surgeons do not now operate unless the symptoms are threatening. Five or six years ago operation was advised in simple persistent chronic otorrhea, even if no other symptoms were present. That position has been abandoned, and surgeons now believe that there must be more serious symptoms than a chronic discharge to warrant operative procedure. In regard to one of the indications for operation in the chronic condition, I think Dr. Lederman was wise when he said a good deal depended upon the intelligence and persistence of the patient. It may be necessary to frequently clean the ear out. I have in mind just such a case. A lady came to me with a history that for years she had suffered with fainting spells, which she attributed to a disordered stomach. She was also quite deaf. There was an opening in the upper posterior part of drum membrane on that side and cleaning out the attic and removing cholesteatomatous masses partially relieved the deafness and cured her dizziness and fainting.

She never had any more fainting spells. That lady does not require a radical operation, because she is intelligent and she lives close enough to a specialist to secure his services promptly in case the necessity arises. She comes in from time to time to have her ear cleaned out. I think much depends upon the intelligence and persistence of the patient. If that patient belonged to the laboring class, or was situated where prompt surgical attention could not be secured, I should certainly advise operation.

**I. Lederman:** I agree with everything Dr. Dabney has said in his paper, as the points were brought out so clearly that there is no room for argument. The swing of the pendulum is in the opposite direction to that of some years ago. Ten years ago the radical mastoid operation was not well known, but no later than five years back it was recommended in all cases of chronic otorrhea, irrespective of other symptoms. The great weight of authority is now in favor of conservatism, but it is grounded altogether upon the constant observation and care of the patient. Much depends upon the patient himself and his surroundings. If I had a case of chronic otorrhea, with disease of the middle ear, who lived in the country, I believe I would advise the radical operation; on the other hand, if the patient lived in the city, within reach of surgical attention, I would let him go and watch it.

Dr. Pflugst stated that Politzer advises leaving the antrum alone in cases of acute mastoiditis until we have a pus sinus leading toward the antrum. I have done this only one time and that was in a case in which an abscess in the middle ear had run its course, and in which, upon opening the mastoid, I found only one large cell, with absolutely smooth walls and no sinus indicating disease in any other direction. The operation was a very simple one; I did not enter the antrum, and within two weeks the wound had healed. That was absolutely the only condition in which I felt safe in not entering the antrum. I do not believe I have done my full duty, in cases of acute suppuration of the middle ear, accompanied by mastoid symptoms, if I do not open the antrum. The only thing to be gained by letting the antrum alone is to shorten the time for the healing of the wound, and that is a small consideration when there is a possibility that we may have to subject the patient to a second operation.

With reference to the use of the chisel and mallet, I use both as little as possible. I can accomplish nearly everything for which these instruments are used with the gouge and bone forceps. Of course, in taking away the posterior bony wall of the meatus in the radical operation it is necessary to use the chisel to a certain extent. In children especially it is very seldom that everything necessary cannot be done with the forceps and gouge.

I believe that, by making the incision farther back, away from the field of bone surgery, we will get primary union in a greater number of cases by making the incision farther forward, as recommended by Dr. Pflugst. We frequently have infection in the cavity of the antrum and in the tympanic cavity and by having the incision immediately over the opening into the antrum, we are almost sure to have infection of the external wound. It is not always necessary to drain the external wound even if there is some infection.

Drs. Cheatham and Pusey stated that young children can frequently be relieved by repeated paracentesis. While that may be true in a great many cases, I feel perfectly safe in opening the antrum of a child. There is no reason why we should not make the incision down to the periosteum, and we get union almost as quickly as in the skin incision.

**Adolph Pflugst (closing):** I would like to emphasize a few practical points in Dr. Dabney's paper. One is that tenderness is often present over the mastoid, during the first few days following acute middle ear inflammation. This is an important practical point, because it is often mistaken for the mastoid abscess and operation is performed when it could be avoided.

Another point of considerable importance is the amount of discharge. We must be agreed as to what is meant by profuse discharge. The tympanic cavity may continue to discharge a scant amount of pus for quite a while, which, in the absence of symptoms has no significance, but if the ear discharges so freely that within ten or fifteen minutes after the canal is wiped, it again fills up, it is rightly called a profuse discharge. The essayist is right when he says that if a profuse discharge extends over a period of two or three weeks we are justified in opening the mastoid. Even with no other symptoms, a profuse discharge for two or three weeks would, in my judgment warrant operation.

The absence of classical symptoms is a point which I had impressed upon me recently. A patient was referred to me from another city, where he had been under the observation of a very good man. He had profuse discharge, but no other symptoms, except at one time a slight elevation of temperature and some stiffness of the neck. Percussion over the bone elicited no pain. Upon operation I found very extensive bone involvement with a thrombus of the lateral sinus.

As to the question of deciding upon operation in chronic running ears, this is one of our most difficult tasks. Often patients will come in to be treated for a running ear, and you know that treatment will do them no good. The question is what to tell the people. There are several factors to be taken into consideration,—the presence of recurrent symptoms of any kind, especially

daily headaches, or recurrent granulation tissues springing up in the canal. The position of the opening in the drum is an important point. If up high the prognosis will not be so good as if situated in the lower part of the drum, where free drainage may be obtained. I make it a point to let the family know exactly what might be expected without operation and the dangers of not operating and let them decide whether the case should be treated surgically.

I do not look upon it as a dangerous operation, but the results have not been so good as we have been led to believe, and this may be the reason it is not as popular as it was several years ago. We cannot get these patients well in two or three weeks; in fact, if, after watching them for six or eight months, we get a dry surface, we are well pleased, and even then a recurrence of pus discharge is possible. I had one case like that several months ago, where several months after an apparent cure the patient came back with pus running from his ear.

It would be a very difficult matter to answer Dr. Wathen's question as to facial paralysis, because very few men report unfavorable cases. I believe facial paralysis results more often than we believe. I have had two such cases after the radical operation. It is very uncommon after the simple operation.

I. Lederman: I agree with everything Dr. Dabney has said in his paper, as the points were brought out so clearly that there is no room for argument. With reference to the radical operation the swing of the pendulum is in the opposite direction to that of some years ago. Ten years ago the radical mastoid operation was not well known, but no later than five years back it was recommended in all cases of chronic otorrhea, irrespective of other symptoms. The great weight of authority is now in favor of conservatism, but it is grounded altogether upon the constant observation and care of the patient. Much depends upon the patient himself and his surroundings. If I had a case of chronic otorrhea with limited necrosis of the middle ear, who lived in the country, I believe I would advise the radical operation; on the other hand, if the patient lived in the city, within reach of surgical attention, I would try conservative treatment and watch the case for a long time before advising the operation.

Dr. Pfingst stated that Politzer advises leaving the antrum alone in cases of acute mastoiditis unless we find a pus sinus leading toward the antrum. I have done this only on one occasion and that was in a case in which an abscess in the middle ear had run its course, and in which, upon opening the mastoid, I found only one large cell full of pus, occupying the tip of the mastoid, with absolutely smooth walls and no sinus indicating disease in any other direction. The operation was a very simple one; I did not enter the

antrum, and within two weeks the wound had healed. This is the only condition in which I feel safe in not entering the antrum. I do not believe I have done my full duty, in cases of acute suppuration of the middle ear accompanied by mastoid symptoms, if I do not open the antrum. The only thing to be gained by letting the antrum alone is to shorten the time for the healing of the wound, and that is a small consideration when there is a possibility that we may have to subject the patient to a second operation.

With reference to the use of the chisel and mallet, I use them as little as possible. I can accomplish nearly everything for which these instruments are used with the curette and bone forceps. Of course, in taking away the posterior bony wall in the meatus in the radical operation, it is necessary to use the chisel to a certain extent. In children especially it is very seldom that everything necessary cannot be done with the forceps and gouge.

I believe that, by making the incision farther back, away from the field of bone surgery, we will get primary union in a greater number of cases than by making the incision farther forward. We frequently have infection in the cavity of the antrum and in the tympanic cavity and by having the incision immediately over the opening into the antrum, we are almost sure to have infection of the external wound. It is not always necessary to drain the external wound, even if there is some infection.

Dr. Cheatham stated that young children can frequently be relieved by repeated paracentesis, and Dr. Pusey reports cases of cure in children by the simple periosteal incision. While that may be true in a great many cases, I feel perfectly safe in opening the antrum of a child. There is no reason why we should not explore the antrum; if it is not diseased we obtain healing almost as quickly as in the Wilde incision.

CAST OF THE NASAL CHAMBERS REMOVED IN A CASE OF NASAL DIPHTHERIA.

G. C. HALL.

*History.* C. V., age 12, was taken sick on New Year's day, but it was not considered of sufficient import for her to consult a physician. The next day however she was worse, the family physician was called but the throat presented nothing characteristic. The symptoms, however, progressed and on January 4th, a membrane occupied the whole pharynx, extending forward as far as the teeth. This had not been present except as a mere spot on the evening previous. Symptoms of nasal obstruction began with a thin bloody discharge from the nostrils, which excoriated the upper lip. I saw the case in consultation with the family physician at noon on January 4th.

He had already made a diagnosis of diphtheria which was confirmed by the microscope, which also showed a complicating streptococci infection.

There was moderate temperature, 102.5; pulse 120; respiration slightly quickened. Weakness of voice and foul odor to breath. The lips swollen, covered with crusts and bleeding.

The cervical lymph glands were very markedly swollen and painful on pressure. Swallowing was difficult.

Patient was given 4000 units of anti-toxin, calomel followed by a saline, biniodide of mercury, salol and phenacetin. Loeffler's solution every two hours to throat. Jan. 5th, improved. Part of membrane detached from throat. Nose tightly blocked up. Membrane extends to anterior nares and discharge persists. Jan. 6th, attempts to remove membrane with forceps failed, as only a small portion could be removed and this was followed by profuse hemorrhage. General condition improved.

Jan. 8th, membrane detached from one side of nose with forceps. Removed from the other by syringing. Nasal obstruction at once relieved. Membrane did not reform. All symptoms promptly disappeared. Pulse, temperature, etc., became normal and patient made a very rapid recovery. This case is rather typical of this class of cases which, while not medical curiosities are comparatively rare except in institutional practice.

Membranous rhinitis is not a particularly rare affection and in the majority of cases is not caused by the Klebs-Loeffler bacillus. Bacilli resembling it however, and found in the membrane are supposedly the pseudo diphtheria bacillus of Hoffman, which, however, is regarded as an attenuated *K. L. bacillus* by many.

The membrane which is composed of fibrin some leucocytes and blood cells tangled in its meshes appears in the nose after operative work, cauterization of the turbinates and particularly in affections of the ethmoid after removal of the middle turbinate and curetting of the ethmoid cells where polypi have been present. Various thermal and chemical agents may produce such a membrane. Also the presence of a foreign body. The streptococci are capable of producing a membranous rhinitis, particularly the former.

I mention all of these other causes only to emphasize that in a case of membranous rhinitis, particularly in childhood and in the absence of any history the cause should be regarded as diphtheria and treated as such till the reverse is proved.

The points to be noted in nasal diphtheria are the involvement of the pharynx, great swelling of the cervical glands severity of

the symptoms, hemorrhage on attempting to detach the membrane and very offensive odor to the breath, all of which are characteristic of membranous rhinitis due to Klebs-Loeffler infection and not to the other varieties.

The treatment of nasal diphtheria demands antitoxin in relatively larger doses than elsewhere as the toxemia is marked and there is rapid absorption from the nasal chambers. Loeffler's solution while useful in the throat is entirely unsuited to the nose even if diluted and I do not think that early attempts should be made to detach the membrane, for spontaneous separation without hemorrhage is the rule. It is not an unusual thing for patients to expel a cast of the nose while sneezing or in cleansing the nose.

The complications most to be dreaded are paralysis of the soft palate. Atrophic rhinitis following the inflammation. Involvement of the accessory sinuses of the nose and suppurative otitis media.

For internal treatment I prefer the biniodide of mercury with phenacetin and salol in the early stages, with Elix. Ferri Quinin and Strychnine in the late stages and convalescence.

REPORT OF A CASE OF SYPHILIS OF THE EPI-  
GLOTTIS—CURED BY INTRA-MUSCULAR  
INJECTIONS OF MERCURY.

On July 9th, 1906, Mrs. M. E. G., came to me with the following history. Age 53 years. Always been healthy, children likewise. No previous family or personal history gave any information as to the present trouble. No history of injury. Has a growth over right eye which was ulcerated, surrounding skin indurated but not very much raised. Some pain. Tender on pressure. Place was about three-fourths inch in diameter. It was slowly spreading. Duration of growth two months. Various kinds of plasters and salves had been tried without relief. She had consulted another surgeon who told her it was malignant and advised the X-rays.

Growth removed. Microscopical diagnosis epithelioma. Healing with scar slightly depressed.

In July, 1907, after the lapse of a year patient returned on account of a troublesome cough and pain in the throat. She claimed to have contracted a cold in June which persisted and was becoming worse. Her husband saw me privately and expressed an opinion that she had tuberculosis. She had lost about twenty pounds in weight, had a cough that at times was very severe especially at night. Slight hoarseness. Pain chiefly on eating. Worse on left side. Free expectoration, at times blood tinged.

Examination showed reddened pharynx. A small spot of ulceration at base of epiglot-

tis left side. Larynx and cords not visible on account of swelling. Patient's sputum was examined several times with negative result also scrapings from ulcer.

Cantonization of ulcer with lactic acid, enurettage, soothing applications and internal medication with tonics were tried without benefit. Both general and local conditions became slowly worse.

The most searching inquiry both of the woman and her husband, to whom I explained the whole situation failed to reveal the slightest suspicion of specific history. My opinion at that time was that the condition presented an inoperable epithelioma of the epiglottis and the patient was doomed. Notwithstanding this I gave the patient the benefit of the doubt and prescribed ℞ Hydrargyri Bichlorid gr. ij; Potassi Iodid ʒij; Fld. Ext. Phytolacca ʒss; Fld. Ext. Stillingia ʒij; Syr. Sarsap. Comp. q.s. ad. ʒviij—Teaspoonful in milk after meals and at bed time. This was taken regularly for over a month, but the condition became steadily worse. Patient was losing ground rapidly. There was complete aphonia—great pain in the throat, so much so that eating was extremely painful. The ulceration had extended over the whole epiglottis and into each tonsillar fossae so that it almost met at the uvula. There was also some odor from the throat. At this time I asked consultation and another laryngologist saw the case with me; he inclined to the belief that it was tubercular, in view of the negative result from anti-syphilitic treatment and I was inclined to a belief in its malignant nature on account of the past history.

Orthoform powders were prescribed before meals to admit the patient taking nourishment and a bichloride of mercury gargle was prescribed for the throat. I also wrote to procure a supply of trypsin from Fairchild Brothers and Foster to try the effect of that remedy. Before this arrived, however, the patient reported herself improved by the gargle I had given her so I decided to try mercury by intramuscular injection.

The first injection was given on Nov. 16th, an equivalent of four grs., of metallic mercury being given. The former prescription I had given her being continued as well as the gargle. Trypsin injections were also given using five ampules, but from the first injection of mercury improvement was marked and rapid.

The ulceration healed, the pain subsided, the patient's voice grew better, she could eat without first using orthoform and her weight increased. Injections of mercury were given every two weeks with no inconvenience. By Jan. 1st, 1908, she was practically well and for the first time could a view of the cords be obtained and they were found intact.

This case is a signal demonstration of the effects of intra muscular injections of mercury and the method deserves a wider use than it now enjoys.

I have given over a thousand of these injections with the greatest satisfaction and no ill effects and except in the cases of two patients without complaint.

The case incidentally demonstrates that one can't afford to be too certain in making a diagnosis and that the ordinary tests with mercury and iodide are apt to be inefficient.

#### DISCUSSION.

**M. F. Coomes:** I was particularly interested in the first case reported by Dr. Hall. These cases are a little curious in their history and the way they run, and, as Dr. Hall said, we cannot be too sure about the management of them. They are infrequent, however; I do not remember to have seen over half a dozen cases in my life. One of the first cases I saw was in the paralytic stage. The patient was a mulatto girl, with nasal diphtheria and when I saw her she had paralysis of the palate muscle. However, she went along and made a nice recovery.

In another case I was called to remove a child's tonsils and upon taking her temperature found it to be 101. I could see nothing wrong except the temperature, but declined to do any operating and the next day I was called and found that the child had a case of nasal diphtheria. I have always thought that I had a very narrow escape in not removing the child's tonsils.

The other case was also very interesting, and shows that syphilis is not always amenable to mercury and iodide of potash administered in the usual way.

**A. O. Pfingst:** I am inclined to believe, from my experience with nasal diphtheria, that it occurs more frequently than we are led to believe. I have seen six or seven cases, and in four of them I am sure that I was called to see the patient without any suspicion as to the nature of the disease, merely on account of nasal bleeding.

One case, in which four children in the same family were affected, is particularly interesting. I was called to see one of the children on account of nasal bleeding, and the mother mentioned to me incidentally that three of the other children had had a similar nasal trouble of an acute nature. At that time one of the children had paralysis of the soft palate. Two of the other children had membranes in the nose. A culture was made and showed true diphtheria bacillus.

I cite these cases as evidence that nasal diphtheria is more frequent than is generally supposed.

**G. C. Hall (closing):** I want to thank Dr. Pfingst for his mentioning the symptom of bleeding, because I am sure that in all the cases I have certainly seen cases recover which I be-

lieve could not have been cured by any other method. I recall the case of a man who came to me about two years ago with tertiary syphilis of a malignant type involving the bones of the nose with impending perforation of the palate.

The patient informed me that he had been taking Protoiodide and Iodide of potash for the last seventeen years and the disease was still raging despite all this.

He weighed less than 110 pounds and was a mere shadow of a man. Three injections at weekly intervals stopped all symptoms. I gave in all about six injections when he passed from observation. Several months later he returned, and I failed to recognize him. He was in fine health and weighed over 150 pounds.

I have recently had two other cases of this type, which cleared up with equally happy results. I have seen practically no bad results follow these injections and have never had an embolism or abscess follow, though many of the cases injected were clinic patients and were dirty and careless.

The technique of the injection is simple. The site of the injection is in the buttock alternating sides—one dose a week with active symptoms, afterward every two weeks. At end of four months rest six weeks. The skin is cleansed with soap and water, followed by alcohol. The all-glass syringe with platinum needle and solution being sterile the needle is jabbed rather than pushed deep into the muscles. Syringe is detached for a few seconds to see that no blood flows from it indicating the puncture of a vessel and the injection given slowly. Considerable force is necessary.

The injections are practically painless, the site becoming a trifle sore and stiff after two or three days, but this soon passes away.

The method possesses every advantage over the administration by mouth and inunction and has none of their disadvantages.

Its advantages are—absolute control of patient, regular attendance, infrequency of dosage, potency of same freedom from irritative symptoms and loss of weight caused by deranged digestion and absolute control over the disease.

I commend this method to the members of this society, it has served me well when all other methods failed and I believe that it will do the same for you.

## PNEUMONIA.

PNEUMONIA, THE ETIOLOGICAL FACTORS THEREOF.—LOBAR, CROUPOUS OR FIBRINOUS

PNEUMONIA, PNEUMONITIS OR LUNG FEVER,

FLORENCE BRANDEIS.

One of the most widespread of acute infectious diseases of which the chief characteristic is an inflammation of the lung and which is invariably accompanied by constitu-

tional symptoms of more or less severity, and with constant findings of the diplococcus pneumoniae in the diseased areas. Pneumonia prevails at all ages, infancy and old age furnishing a large proportion of cases, the male sex predominates in reported cases—possibly due to the more exposed, strenuous lives led by the sterner sex. However as alcoholism is the most important factor in the causation of pneumonia, this greater frequency in men would explain itself.

Dwellers in cities, those leading lives of hardship and exposure and those debilitated by exhausting diseases, such as Bright's, diabetes and nervous affections, protracted fevers all furnish their quota. No acute disease recurs with such frequency as pneumonia, individuals having as many as ten attacks being among the medical curiosities.

In children the disease may be primary or secondary to the acute infectious diseases among which measles heads the list, grippe (or influenza), diphtheria, whooping cough, scarlet fever and chicken pox follow.

Traumatism is a not infrequent etiological factor, and aspiration pneumonia and decubitus involvement of the lower posterior portions of the lungs are bug bears and stumbling blocks in the path of all physicians whether general practitioners or surgeons.

*Season:* Cool, damp, frequently changing weather, more prevalent during months between December and May with a rising scale in the spring.

*Climate:* Latitude seems to be a small factor in the causation of the disease as in our country it is reported as far more frequent in our southern states than in the north, the negro being more susceptible than the white man, while travellers in the Arctic regions say that the trouble is practically unknown there. In the Panama zone it stands near the top of the list of fatalities from disease.

A noteworthy fact is that the newcomers to a region where pneumonia prevails are not the most frequent victims, the old residents rather being the favored target.

That pneumonia is an infectious disease is readily demonstrated by the house epidemics, as many as four cases developing in rapid succession in one home; or ten under one roof.

*Institutional epidemics,* usually traceable to over-crowding or some other unhygienic condition; the most remarkable outbreak having occurred in one penitentiary at Frankfort, so ably described years ago by Dr. W. B. Rodman in which in a prison population of 735 souls, 118 cases with 25 deaths were noted.

Before leaving the purely physical causes we must mention the infection from buccal cavity and the naso pharynx especially in

children in whom expectoration is not to be relied upon—therefore especial stress must be laid upon local hygiene during illness and health.

In nearly all the primary cases of pneumonia the diplococcus pneumoniae is found and usually alone, but may be associated with the streptococcus, the staphylococcus aureus and albus, with Friedlander's bacillus and even with Loeffler's.

In secondary cases it is the rule to find a mixed infection. Those organisms found alone or associated in primary cases can be traced in the secondary, the bacillus of Friedlander being the one most rarely found alone.

The micrococcus lanceolatus or pneumococcus of Frankel is constant in lobar pneumonia of infancy either alone or associated with the above named organisms.

This organism is a somewhat elliptical coccus, lance-shaped occurring in pairs and usually encapsulated. It is found in the lungs and blood and in the cerebro-spinal fluid, although constant in pneumonia it has been found in the peritoneal cavity and fluid and in meningitis without pneumonia.

#### PNEUMONIA\*—SYMPTOMS AND COMPLICATIONS.

##### LOBAR OR GROUPOUS PNEUMONIA.

R. HAYES DAVIS.

What is more striking than a perfectly typical case of Lobar Pneumonia. A healthy adult has a severe chill immediately followed by high fever, a pain in the side, and a harassing cough. He lies in bed on his back or on the affected side. Both cheeks or only one is flushed, his eyes are bright, the expression anxious, his breathing rapid, and the expiration followed by a grunt; the skin is dry and hot, the pulse full and bounding, and in severe cases the alae of the nose play markedly with respiration, however, like all other diseases the typical picture is by no means always present and at times the diagnosis is extremely difficult.

The onset is usually sudden, but in some cases there may be slight prodromes for one to five days. In adults there is a severe chill, in youth often vomiting, and in young children a convulsion. Occasionally fever alone may be present for several days before other symptoms are recognized. Rarely there are repeated chills. In mania a portu, during the course of other diseases, in debilitated subjects, and in the aged the onset may be very insidious.

During the chill fever becomes evident, which within a few hours reaches its maximum of 103 to 105 or higher. It is of a continued type but very exceptionally may be distinctly remittent, and during certain epidemics an intermittent variety has been

noted. At times the acme of the fever shows distinct recurrences due to spreading to additional lung tissues. Pneumonia developing during menstruation shows exceptionally high fever.

The final fall in temperature occurs in five to nine days by crisis, requiring twelve to twenty-four hours to reach normal or sub-normal. If defervescence occurs by lysis one should look for complications, although this is the natural termination in a few cases. With the fall in temperature all the symptoms disappear. At times just before the crisis there is a temporary fall in temperature termed the pseudo-crisis. In the aged fever is often entirely absent.

An important symptom is the characteristic pain or "stitch" in the side, beginning about the time of the chill and only exceptionally lasting longer than a few days. If severe it may cause dyspnea and is then indicative of a severe infection.

Dyspnea is conspicuous. In adults the respiratory rate is 24 to 40, in children 50 to 60, or higher. In the early stage dyspnea due to pain or cerebral irritation is only transient and of no important significance. If playing of the alae nasi is marked the prognosis is grave.

Cough is always present in the healthy. It may be slight or severe but like the sputum is often absent in pneumonia of the upper lobes, in delirious patients during other diseases, and in the aged.

Sputum is at first tenacious and glairy, but it soon becomes red due to admixture of blood and constitutes the characteristic rusty, tenaceous sputum, which is pathognomonic of pneumonia. The quantity is about 150 in 24 hours. Children have no expectoration.

Examination of the sputum shows blood, mucous, desquamated and degenerated alveolar epithelium and masses of the fibrin which may often be seen with the naked eye. The casual organism, the micrococcus lanceolatus, is in varying numbers, and at times the bacillus of Friedlander and the ordinary pus organisms are present. Streptococci indicate slowness in the loosening of the filtrate.

In pneumonia there is marked emaciation, which loss in weight is soon happily regained after the crisis.

The physical signs of lobar pneumonia are of great importance. Inspection of the chest shows diminished or absence of expansion on the affected side. The diaphragm phenomenon shows decreased motion. After consolidation increased tactile fremitus is elicited by palpation. Percussion in the early stage shows a hollow, slightly tympanic note usually over the base, which soon gives way to dullness. If the upper lobe is affected the tympany may not be so replaced. Just above

the dullness of consolidation Skodaic resonance is present due to relaxation. Rarely even a cracked pot sound is heard at the junction of the consolidation with the non-consolidated lung. By auscultation the respiratory murmur is at first faint. Then the characteristic crepitant rales develop and finally there is distinct bronchial breathing without rales. When resolution begins bronchial breathing gradually disappears, crepitation is resumed to be followed by subcrepitant or mucous rales. Resolution is usually complete in a few days to two or three weeks, but at times is prolonged indefinitely. If the voice is normal and loud, bronchophony is pronounced, and at times there is pectoriloquy or even eugophony. In cases of pleural effusion or thickened pleura complicating pneumonia, or where the larger bronchi are plugged with mucus the characteristic palpatory and auscultatory signs may be diminished or absent.

During the early stage of pneumonia the pulse is full and bounding. Later, if toxemia is marked it becomes soft, easily compressible, weak and rapid. The pulse rate is increased, but not in proportion to the respirations, and this ratio is of distinct diagnostic value. The more severe the case the more disproportionately increased are the respirations. In the children the proportion is greater than in the adults. If irregularity occurs in a heart not previously the seat of myocarditis it is a grave sign, but after the crisis it is not important. Occasionally the pulse is dicrotic, and in the aged it is rapid and weak.

The heart is often enlarged, especially in the right side. second sound is always accentuated, and lessening of this accentuation is a sign of failing right heart. A systolic murmur is heard as in other infections, but is of more interest than importance. Collapse may occur at the beginning of the disease, during its course, during defervescence, and after the crisis, and the later the time the more grave the result.

The leucocytosis of pneumonia is characteristic and progressive till the crisis, at which time it drops. It is not affected by pseudo-crisis. The count ranges from 12,000 to 40,000 or more. If there is no increase in leucocytes, recovery is extremely doubtful. The red cells are decreased somewhat in proportion to the fever.

**Nervous System:** Headache is usually present and may be severe but is rarely intense. Insomnia is not of importance, unless aggravated by cough. In adults somnolence is a grave symptom. Delirium is more marked in apex pneumonia. In drunkards it may even be maniacal, simulating delirium tremens.

After the crisis delirium or a confusional

condition may be present for a few days due to exhaustion. Hallucinations are not very infrequent and very rarely functional hemiplegia may develop. Cases are occasionally seen with retraction of the head and resemble meningitis. In children the nervous symptoms are very much more marked. The onset is often with a convulsion. The child may be very delirious and show a conspicuous unrest and at times even coma.

Epistaxis often occurs, but is rarely of importance.

The urine is decreased in quantity, concentrated, and often shows febrile albuminuria. Peptonuria is common in pneumonia. The diazo is often present. The chlorides are decreased or absent. This occurs in other diseases, but is more constant and pronounced in croupous pneumonia than any other disease.

**Digestive Organs:** Vomiting ceases after the onset and unless precipitated by coughing is likely a sign of complication.

Swallowing may cause severe coughing spells and thus prevent the taking of food, water or medicine.

Bowels are constipated or normal. Diarrhoea occurs as a complicating colitis at times and is more common in certain epidemics.

Abdominal pain may be severe, is most common in upper quadrants and has caused mistaken diagnosis to be made.

The spleen may occasionally be enlarged.

The skin may at first be cyanosed due to dyspnea, but this disappears quickly. When, however, edema of the lungs is its cause the prognosis is extremely grave.

Herpes is a very frequent symptom and is most often situated about the nose or lips, but may occur elsewhere.

Perspiration is rarely present during the acme. It is usual at the crisis and often very profuse and may be accompanied by sudamina. In children perspiration is more frequent.

There is a form of lobar pneumonia which begins in the central part of the lobe and requires two or three days to reach the periphery. Thus physical signs are delayed for that length of time.

**Complications:** Pleurisy is always present to some degree, but is termed a complication only when it requires special treatment. There may be serous effusion or empyema. If leucocytosis does not disappear with the crisis, if fever fails to subside or reappears, pleurisy should first be thought of.

Pericarditis may be present, and it occurs with or without effusion and often with pus.

Endocarditis has been shown by Osler to be more frequent than was formerly supposed. It is usually of the malignant variety and often presents difficulty in diagnosis

Meningitis is not an infrequent complication. It presents the usual signs of inflammation of the meninges.

Nephritis may complicate pneumonia and is of the hemorrhagic desquamative variety.

Abscess is a rare complication. Its presence may be diagnosed if there is continued fever with expectoration of pus with elastic tissue in the sputum.

Gangrene is recognized by its horribly foul odor, which, however, can only certainly be differentiated from putrid bronchitis by expectorated elastic tissue.

Colitis is more common in certain epidemics and may increase the danger materially.

Arthritis, plebitis, peritonitis, otitis, parotiditis, conjunctivitis, general mucous membrane inflammation, and symetrical gangrene are complications worth mentioning. Angina and erysipelas are very occasionally present at the onset of pneumonia.

Croupous pneumonia terminates in 1 to 3 weeks. If there is longer delay it is an indication of spreading of the infection to other parts of the lungs or of complications. Resolution should be complete in a few days to two or three weeks. If delayed for a longer period it may resolve in the course of time without danger or there may occur:

1. Death from cardiac failure.
2. Abscess.
3. Gangrene.
4. Chronic intestinal pneumonia.
5. Possibly tubercular phthisis, but this is improbable.

#### BRONCHO-PNEUMONIA OR CATARRHAL PNEUMONIA.

This is primarily an affection of the young and may be idiopathic or complicate the infections of childhood. It may occur in the aged or people debilitated by disease. Antecedent bronchitis is usually present.

There is always cough to which is added fever, requiring three or four days to reach its height of 102 or more. The breathing becomes rapid, 60 to 80 respirations a minute, being common, and dyspnea is distressing. The symptoms increase, and the face becomes cyanosed. The cough may be incessant with little or no expectoration, and the patient presents a picture of great suffering. Finally the blood becomes charged with carbon dioxide, and the symptoms subside, except the frequent pulse and cyanosis which are progressive till the fatal end.

At first the physical signs are only those of bronchitis—diminished breathing with moist rales. With this however and the age, the history, the high fever and other symptoms, the diagnosis may be made. Slight dullness in most cases is elicited or a tympanitic note may be present over small area, or broncho-vesicular or even bronchial breathing

may be heard. The physical signs depend entirely upon the extent and proximity of the consolidated area. Indeed the signs may closely resemble lobar pneumonia.

The termination is by lysis, and the duration depends largely upon the cause. A primary infection in a healthy child last from one to three weeks. After measles or pertussis broncho-pneumonia may end fatally in three days or last for weeks. In scrofula or rachitis the termination is usually fatal, and requires one to three months. The slowest course is probably in whooping cough.

Influenza pneumonia is apt to resemble a local infection with termination in a few days by crisis, and even a very small quantity of rusty sputum may be present, but the physical signs are those of broncho-pneumonia.

Aspiration or deglutition pneumonia most common in unconscious states or after throat operations and shows symptoms similar to catarrhal pneumonia.

#### Complications:

Pleurisy is probably a rare complication and may be serous or purulent.

The relation of tuberculosis is most important.

A catarrhal pneumonia is frequently caused by the tubercle bacillus, but a tuberculous infection ingrafted on a pneumonia is probably very rare.

Abscess, gangrene, pericarditis, and cirrhosis of the lungs are very rare complications.

Sometimes it is difficult to distinguish broncho-pneumonia from the lobar form. But the history, the age, the gradual onset, the distribution in both lungs, the preponderance of the physical signs or bronchitis over those of consolidation, the extreme dyspnea with cyanosis with temperature lower than in croupous pneumonia, the onset of carbon dioxide poison, the long duration, and the gradual decline are usually sufficient to make a diagnosis.

Tuberculosis often presents difficulties. Here the history, or a focus elsewhere in the body, the longer course with dyspnea occurring late, the rapid emaciation and profuse sweating, and the presence of consolidation with subsequent cavity formation at the apex instead of at the base, are important points of distinction. Finally if tubercle bacilli can be found the diagnosis is unquestionable.

#### EMBOLIC PNEUMONIA.

Non-septic variety or hemorrhagic infarct. If the artery is large there may be sudden death, if very small no symptoms. If moderate there is sudden pain in the side, dyspnea, and cough with bloody expectoration.

Physical examination shows the signs of a localized consolidation.

The diagnosis is made by the presence of thrombosis in the veins or presence of disease favoring clotting, the sudden onset, and absence of fever. The sputum is never the bright red of that of eroupous-pneumonia and is thinner in consistency.

The symptoms of the septic variety are simply those of pyemia followed by abscess of the lung.

#### CHRONIC INTERSTITIAL PNEUMONIA OR CIRRHOSIS OF THE LUNG.

This disease runs a very chronic course, attended by a cough with more or less copious expectoration. The appearance of the chest is characteristic. There is absolute loss of expansion over a retracted lung with displaced cardiac impulse. The physical signs are those of consolidation with the presence of rales. The intensity of the palpatory or auscultatory pneumonia will depend greatly upon the presence or degree of thickened plenra, which is common in this affection. However, it must be borne in mind that over a dilated bronchus the percussion may be tympanic and the breathing hollow.

The source of error in diagnosis is fibroid phthisis. The history of the case and the duration may be of value, but the diagnosis may be impossible unless tubercle bacilli are found in the sputum.

#### THE TREATMENT OF LOBAR PNEUMONIA.

JOHN G. CECIL.

More appropriately and correctly the treatment of a patient suffering from lobar pneumonia. Lobar pneumonia is an acute infectious disease and due to a specific micro-organism and until a specific treatment is devised, it is not strictly correct to speak of treating the disease. The nature of the disease is to run a definite, well-defined and well-known course and this is practically uninfluenced by any treatment. The day of the crisis varies not a little, and to assume that the critical period arrives a little sooner because the patient happens to be under any given treatment is very short-sighted therapeutics. The sooner our therapeutics is raised to the level of our pathology the better it will be for the patient. Notwithstanding the truth of the foregoing generally accepted statement, the inference must not be drawn that there is nothing to be done, on the contrary there is very much that may be done both necessary and helpful: attention, however, should be directed to the patient and not to the disease. The selection of the wisest course to pursue in the management of a given case is the supreme test of wisdom and sagacity of the attendant. While the course and progress of the disease may be regarded as fixed, the condition and character of the patient at the time of the attack will certainly modify these

in a most decided manner. Says, Wood and Fitz, "In the treatment of pneumonia it is essential to recognize that though the disease may be a unit from a pathological point of view, therapeutically it comprises essentially diverse diseases. A pneumonia whose physical signs can not be made out in the beginning, but gradually creeps up towards the chest wall; a pneumonia whose expectoration is in the beginning, prune-juice, whose crepitant rale is never typical, whose physical signs are obscure until complete consolidation gives percussion dullness; or a pneumonia occurring in the alcoholic, in the old, in the victim of renal disease, in the broken-down debauchee, in the wornout city merchant or professional man, is in its management essentially distinct from a pneumonia the result of a strong, healthy country-man to a western blizzard or other cold. In one form of pneumonia sedative treatment may kill the patient; in another form sedative treatment at the beginning of the attack may be necessary for the saving of the patient."

It will be convenient to consider separately the management of the two types, the sthenic and the asthenic.

In the healthy young individual the management of sthenic pneumonia resolves itself practically into promoting the comfort of the patient and permitting the attack to run its course unmolested.

An initial purgative dose of calomel followed by a saline will anticipate and prevent much subsequent discomfort in the gastrointestinal canal.

A bright, airy, cheerful, well ventilated sick room is absolutely essential. The management of pneumonia in tents in military practice and the out-of-door or roof-garden treatment in civil life have proven beyond cavil the efficacy of the fresh air plan. There should be no compromise on this; and all the fears and foibles of those who are afraid of fresh air for the sick should be ignored. The responsibility will bear heavily but back of this both common sense and science will sustain the contention, and the grateful appreciation of the sick man will uphold the argument and the practice. Cold weather offers no objections to this practice and the temperature of the room may be kept at 65° F. or lower. The patient should be covered with light warm blankets and all heavy underwear removed. A light flannel shirt opening in front will be comfortable and favors easy examinations. Not more than two persons, other than the patient should be in the room, visitors and over-anxious relatives should be denied entrance.

For pain, which varies according to the extent of pleurisy, small doses of morphine, or

its equivalent in other preparations of opium, will afford the surest and safest relief. The objections to the use of opium in lobar pneumonia and in the asthenic type of lobar pneumonia does not hold in the management of the variety of pneumonia now under consideration. Opium not only quiets pain, but it allays the cough which is often harassing and never of much benefit. A very small proportion of the fibrinous exudate is disposed of by cough and expectoration. There is therefore little danger of seriously interfering with excretions through this source. The small dose of morphine tranquilizes the patient, gives rest and sleep, does not interfere with the progress of the disease, and answers every purpose of a cough medicine. A single dose of one-eighth grain of morphine given at bed-time is generally sufficient. Pain is also combatted in a successful way by the use of an ice-bag, which is a great improvement on the time-honored hot poultice.

The fever of pneumonia, even when it rises to 104° or 105°, is not necessarily such a bad indication; it demonstrates a resistance that is very desirable and often very essential to successful issue. The course of this fever is short, and even though a high grade is maintained, it need not be fought with the same zeal that fevers of long duration demand. A daily tepid bath is desirable and cold sponging may be done to lower the temperature when necessary. The ice-bag to the affected side exerts a good influence in reducing temperature as well as in relieving pain.

Hyperpyrexia can be controlled by cold sponging or the cold pack. The cold-tar derivatives have no place in the management of this or any other kind of pneumonia. *Veratrum viride* and *aconite* are indicated in just such cases as demand no treatment at all; consequently can hardly claim a place in the therapeutics of pneumonia. Their action is to depress the heart; certainly no specific action can be claimed for them. If lessening blood-pressure by their use is the intention, we have better and safer means at our command.

The pathological condition confronting us is certainly not materially altered by slowing the pulse. If the heart maintains a steady ratio to the height of fever, neither heart-tonics, stimulants nor sedatives are very essential. Should, however, a tendency to heart failure, first generally shown by loss of accent to the second sound, manifest itself, the indication for tonics and stimulants is plain, and they should be exhibited for effect regardless of dose. A heart-action that gains in rapidity day by day, independent of variations of temperature, is of serious import and should awaken the most active resistance. The key to the successful manage-

ment of pneumonia lies in the wise and judicious adjustment of therapeutic agents to meet a progressively failing heart. Of all agents for this purpose whisky and strychnine are the most reliable. Strychnine should always be given hypodermically, the dose repeated every three or four hours, should vary from one-sixteenth grain to one-twentieth grain; the effect alone should determine the size and frequency of the dose. Whisky is best administered without sugar in plain or aerated water, one, two or three hours intervening between doses. The ancient art and practice of bleeding robust, healthy patients with pneumonia is not honored in the breach. It would be wise to return to the practice of the fathers in this particular. If done it should be done early and enough blood should be taken to make an impression. There is no question but that in cases that set in with great intensity and high fever it is beneficial in relieving pain and dyspnea reducing temperature and allaying cerebral symptoms.

*Digitalis* is inferior to strychnine as a heart-tonic; the over-burdened heart is more certainly relieved by dilating the peripheral capillaries and inviting the blood into them. This is what is done with whisky and nitroglycerine.

In cases of extensive involvement of the aerating space with marked cyanosis we have in oxygen gas a remedy of usefulness; its administration may help to carry many a one over a rough place and enable him to reach and pass in safety the crisis. The use of it should not be delayed too long, nor should the apparent hopelessness of the case ever be used as an argument against it.

The feeding of a pneumonic patient is of no little importance; he is far more likely to be over-fed than to be under-fed. These patients are seldom, if ever, hungry; more often they have no appetite at all, consequently digestion will be a very uncertain problem.

Indigestion resulting from forced feeding favors the accumulation of flatus in stomach and bowels, which in turn embarrasses the heart and lungs in their action. Meat broths and milk with aerated waters should constitute the regimen. Solid food, egg-nog, and milk punch are not desirable, and should be forbidden. There is no danger of starvation in the short course of this fever, and little can be done to maintain strength by giving of food during its activity.

As to examinations of the patient. Having made the diagnosis, frequent examinations during the progress of the case are both unnecessary and injurious. To turn the patient over is annoying and painful; to raise him to a sitting posture is dangerous.

and needless. The course and progress of the disease can be determined without daily or bi-daily examinations, and even though new areas are being invaded, the management will hardly be varied. The heart's action, the rapidity of respiration, and the distribution of pain will usually give all necessary information without frequently repeated examinations.

The management of lobar pneumonia in the healthy and robust resolves itself into making the patient comfortable, relieve pain and cough with an opiate and the ice-bag, sponge with cold water for excess of fever, do not force the feeding and do not harass by frequent examinations. Watch the heart with jealous care, and be ever ready with tonics and stimulants at the first sign of failure. For delirium and sleeplessness apply cold to the head. Do not overfeed; do not overtreat; do not meddle.

The management of pneumonia in the aged, diseased, or the dissipated asthenic type is an entirely different proposition; the fight begins with the initial symptoms of the attack, and every energy is bent in sustaining the already crippled heart. The policy must be prompt, active and alert. To guide these patients over the crisis calls for the most constant and watchful care, and will tax to the limit the skill of the therapist. No disease requires more skill and attention in the nursing, and the services of at least two faithful and skillful nurses will be demanded. A successful issue in such a contest is a feat to be proud of, and one scarcely equaled, never surpassed, in the realms of medicine and surgery.

The chief aim in the management of such cases will be to sustain the heart; the agents at our command are practically identical with those used in the threatened heart-failure of sthenic cases. Opiates may be necessary to relieve pain, but its administration and dosage must be most widely adjusted. Small doses of morphine or heroin repeated as the occasion may demand will be safest and most efficient.

It is only when fever is excessive that it requires any attention whatever. Much oftener will it be found that the temperature will be comparatively low, indicating a lack of resistance, a very unfavorable indication. The application of cold in any form as a rule is not well borne, and other antipyretics are out of the question.

Delirium, which is very constantly present, is best met by the use of stimulants as brandy, whisky or caffeine. No medicine of depressing character is at all admissible.

Strychnine, digitalis, nitro-glycerine, strophanthin, cocaine and atropine comprise the medicinal agents for combating heart-failure.

They should be given by the needle. Their administration should be determined by the effect, and should be under the immediate supervision and direction of the physician himself.

The whole question of feeding is of secondary importance; in some cases it is better to leave off food of all kinds and preserve the stomach in its integrity for such stimulants as whisky and brandy. The amount of whisky which may, with advantage, be given will be largely determined by the ability of the stomach to digest it. Oxygen gas will often prove useful; it should be used early and persisted in until the last ray of hope is gone.

After all, and in the face of all efforts, let them be never so prompt, never so wise, never so assiduous, pneumonia in this class of patients will ever remain the most destructive and deadly of all common acute diseases, and the winner of these hard fought battles, justly entitled to high commendation.

#### DISCUSSION.

**J. B. Richardson, Jr.:** I should like to ask the gentlemen in discussing this paper, and Dr. Cecil in closing, to say what experience they have had with the use of chloroform inhalation in pneumonia. I have recently heard it praised very highly.

**J. B. Marvin:** I believe that pneumonia is an acute disease in which microorganisms invade the air cells of one or more pulmonary lobes and grow in a fibrous medium exuded from the bronchial capillaries and germinates a toxin. I think we ought to grasp the idea that while croupous pneumonia is an infectious disease it is not dependent upon the organism alone, and that seems to me to diminish hope of a serum treatment.

There are two or three things in the treatment to which we should pay especial attention. Every man with pneumonia has a fight for his life and that ought to be recognized in the beginning. The sword of Damocles may fall at any minute and the feast of the baellus be turned into a funeral for the patient. Death generally occurs from the heart and not from the lung, and the failure is in the right heart; not in the left. If we would remember our anatomy a little more, we would make fewer mistakes. The so-called fibrinous inflammation in croupous pneumonia is not like an ordinary inflammatory process elsewhere in the body. The lung has two separate circulations—the nutritive, supplied through the bronchial arteries from left heart, and the functional, supplied through the pulmonary arteries from the right heart. The trouble has to be with the functional supply, and the right heart is the one that fails. There is no greater room for improvement in methods of diagnosis than in percussion for superficial cardiac dulness. The man who cannot map out an area of superficial cardiac dulness has lost a most valuable indication

in the management of pneumonia. I watch that, and that alone, and if the patient exhibits any dulness in the fourth interspace to the right of the sternum, I consider it most significant.

I beg to differ with the statement of the second essayist in regard to sleeplessness. If the patient does not sleep the first two or three nights, he is in serious danger. I believe sleep is absolutely necessary and ought to be obtained at all hazards. In such cases I swallow my prejudice against opiates and will produce sleep by that means if it cannot be obtained in any other way.

I am a firm believer in blood-letting where we find a dilated right heart. I sometimes use leeches and sometimes wet cups and I believe it is the best thing to do to relieve the heart. Why whip up an overworked and tired horse? Why give diuretic and external applications in an over-distended bladder? The poison of the disease does not spend its force on the left heart. Why try to stimulate a left heart before relieving the right heart? Why not relieve by the catheter?

Next, the diet. I think we can kill the patient with too much feeding, or we can overburden him with water. I think we should keep the mouth just as clean as in typhoid fever, but we should not give large quantities of fluid with a dilating heart.

In regard to stimulants, I think whiskey and strychnine are greatly overworked, neither are they stimulants in the proper sense of the word. Strychnine is an irritant, not a stimulant, and the effect does not last long.

I have been looking up the subject of alcohol and I find that most of the authorities—German, English, French and American—use it less frequently. It is held to be a paralyzant rather than a stimulant. While its first effect does dilate the capillaries and flush the surface a little and, if kept up too long, it weakens the very part we desire to stimulate. I like camphor and caffeine, hypodermically. Digitalis and opium are also greatly misused in this disease.

Just one more point. I am glad to have heard nothing said about this Denver mud business and other methods of that kind. It seems to me that a person who would thus burden and expose the patient, has not the first idea of the pathology of the disease. An ice bag is the only external application I make in these cases.

Oedema of the lungs coming in these cases means death, in my opinion, and I doubt if we have anything with which to successfully combat it. Atropia hyperdermatically is probably our most reliable agent, in cases simulating oedema. I use oxygen with mental reservation, and believe it is of use only in cases with bronchitis or much bronchial secretion.

Reference has been made by Dr. Kelly to those cases occurring at the city hospital during the

first epidemic of gripe in this city.

I was the fourth member of the staff, Dr. Ouchterlony, Dr. Cecil and Dr. Kelly preceding me. The result in these cases was not indicative of lack of skill or ability of any of the doctors, but simply a number of cases occurring that year following influenza.

W. F. Gogges: I agree with everything Dr. Marvin has said. There is no doubt that strychnine and alcohol are capable of very great danger in pneumonia, and that camphor and caffeine are better stimulants, both for the patient and for the patient's right heart, than strychnine and alcohol, if given injudiciously.

Dr. Cecil never made a better remark than when he said "treat the patient and not the disease." Every patient with pneumonia is an individual study and every patient demands different therapeutic measures. We have no specific treatment, and it is the man who studies his patient who is going to have the greatest success in the treatment of pneumonia.

I differ with one thing Dr. Cecil said; namely, that because pneumonia is a self-limited disease (as he terms it) we should simply let it alone and allow it to run the usual course. I do not believe any disease should be left entirely to nature. We can often prevent complication; and right heart paralysis by properly treating and handling the patient.

I dislike to hear the words "Watch the pulse" in connection with pneumonia. It is not the pulse we want to watch; it is the heart and its peripheral circulation, and the man who depends upon the number of beats and rapidity of the pulse to determine the condition of his patient is a poor doctor in a pneumonia case. Dr. Marvin impressed upon us the necessity of watching the heart and detecting any increased cardiac dulness, and it is a point well taken. We would frequently fail to discover superficial dulness in the heart if we did not look for it, and it is an excellent indication of the condition of the patient.

About a year ago Dr. Weidner read an article on pneumonia in which he said that he had gotten excellent results from the use of carbonate of creosote, given in a certain way. I thought that, coming from Dr. Weidner, it was at least worth a trial, and in the past year I have used it in the manner he suggested and I know that, during that period, I have had better results in pneumonia than I have ever had. I gave thirty drops of carbonate of creosote every three hours, until the urine began to show carbonic acid. As a rule, the patient will show decided improvement in from 24 to 72 hours, and I have had many more cures than formerly. In regard to the open-air treatment, during my service at the city hospital we treated some five or six cases of pneumonia by putting them under the tubercular awnings, with their faces out of

doors. One patient, a man, with a well-marked case of lobar pneumonia, with temperature of 103, and who seemed to be a very sick person, was at once placed under the awning. The next morning when I asked him how he was he said that he was feeling fine and had slept well, but for the snow tickling his face during the night. He made an uninterrupted recovery in the usual time of seven or eight days. Every patient who was treated in this manner got well, and most of them were very discouraging cases. They were all over forty-eight years of age, and some of them confirmed alcoholics. As I said a year ago, I believe the reason a country doctor has such marked success in pneumonia, is that the patient gets purer and better air and has a greater chance of successfully resisting the disease.

**Carl Weidner:** Like the other speakers I agree, in the main, with what has been said by the essayists. Dr. Brandeis has given us the complete and, so far as we know, the correct etiology of the disease.

I wish to take exception to Dr. Marvin's remarks as to the variety of germs we will find in croupous pneumonia. Experiments have proven that the pneumococcus is found in 96 per cent., I believe, of all cases of croupous pneumonia. It is found in the blood, in the sputum, and in the lung. In view of this, I think we are justified in considering this organism the specific cause of croupous pneumonia. When the sputum is examined in the ordinary way we are liable to find all sorts of micro-organisms, but if we adopt the method of washing the sputum repeatedly in sterile water, thus getting rid of all the mucous that comes from the throat, nose and upper pharynx, we get the real sputum as it comes from the lung, and when this is done the pneumococcus is invariably found.

It is different, however, in the other forms of pneumonia. There we find various germs that may be to blame for the disease. This is an important point. The result of the infection varies, as in all of the infectious diseases, according to two things; first, the patient's resisting power, second, the virulency of the germs. We know it to be a fact that there is a difference in the virulency of germs of every disease at certain times. This, to some extent, explains the varying mortality resulting in epidemics. During one epidemic we have extremely virulent germs and, in consequence, the mortality is great; during others it will be small because of the lesser degree of virulency of the germs at that particular time.

As to diagnosis, I would like to emphasize the point made by the second essayist that, in children, the chill is not present. We may have convulsions, or we may have vomiting without convulsions. Neither do we have the patient complaining of the typical pain about the nipple. In

several cases I have seen the pain was referred to the abdomen so that, in the beginning, the trouble might be thought to be of abdominal origin.

If we compare the treatment of pneumonia of twenty-five years ago with that of to-day, we will find that some progress has been made in the recognition of indications. I sanction everything that Dr. Cecil has said, particularly with regard to rest. I lay great stress upon rest. I never allow patient to sit up. I examine him while on his back or on his side, with my stethoscope. The room in which the patient lies should be hygienic and the windows and doors should be open, admitting an abundance of fresh air, and the temperature of the room should be kept at about 65 degrees.

There is no specific treatment for pneumonia. Unfortunately the serum treatment has not been a success, because a very active serum cannot be produced. The pneumococcus is a germ with endotoxines and it does not produce anti-toxic serum very well.

I believe that whiskey does more harm than good, and that the stimulants mentioned by Dr. Marvin and Dr. Boggess, camphor and caffeine, are better. To watch the heart is most important, and if we find that we cannot relieve an overworked right heart with nitroglycerine, bleeding may be indicated under those conditions. Strychnia is less of a tonic than a whip to rouse latent energy.

Fever has been mentioned repeatedly, but I was glad to note that not a word was said about anti-pyretics which are most dangerous because they act badly on the heart. Fever means a certain reaction on the part of the system to the toxins of certain diseases and it may be beneficial in its effects. Excessive fever, however, ought to be combatted to protect the nervous system against the effect of hyperpyrexia.

Wassermann, Berlin, in speaking of the treatment of pneumonia, says, in summing up, that we have no specific treatment for the disease, so that we have to do the best we can to support the patient, and if we find that he develops sufficient immunity, which is shown by the production of a large number of leucocytes in the bone marrow, spleen and lymphatic glands, let him alone and he will get well; in other words, rely upon the leucocyte power. If there is good leucocytosis let the patient alone; if not, assist nature by the injection of 1 per cent. nucleinic acid morning and evening.

**C. W. Kelly:** During the first epidemic of the la grippe in this city, Dr. Ochterlony, Dr. Marvin and myself were in charge of the city hospital, where there were a great many cases of pneumonia.

The death rate was over 90 per cent. in spite of the most careful management. There are two forms of pneumonia, croupous and catarrhal.

The diagnosis of croupous pneumonia is not difficult, the physical signs being so marked and well defined. The temperature, pulse, and respiration are so indicative of the disease along with the rusty sputum, that a diagnosis can be easily made. However, the manifestations as indicated by the physical signs are often delayed for several days.

The cause of croupous pneumonia is believed to be due to pneumococcus or diplococcus of Frankel.

The cause of catarrhal pneumonia is in doubt. Pneumonia is not a local disease, though the parenchyma of the lung is inflamed as a result of the toxine due to the micro-organisms which give rise to the disease. Many other organs are involved, especially the heart. When we have endocarditis, pericarditis and myocarditis, the obstruction in the lung sooner or later taxes the right heart to its full capacity and often in attempting to overcome the obstruction becomes paralyzed.

In the treatment of pneumonia our efforts must be directed to the protection of the heart. I give stimulants, strychnia, and digitalis. I don't believe there is any drug equal to digitalis in combatting the tendency to heart failure in pneumonia. I give opium to secure rest and sleep. I think this very important. I do not give Aconite, Veratrum Viridi or tartar emetic. I never give an expectorant. I do not give the coal tar derivatives; they tend to overcome the heart's action. I do not believe in blood letting. I do not use the ice pack or cold sponging.

I do not blister the chest wall. I have no confidence in camphor or caffeine. Be careful in feeding.

I call attention again to the importance of securing rest and sleep by the use of opiates. Absolute quiet in bed is all important. The recumbent position must be insisted upon.

**B. J. O'Connor:** I want to make a plea for one thing in pneumonia, and that is correct diagnosis. If you have a lobar pneumonia, call it a lobar pneumonia; if fibrous, lobular, tubercular, or hypostatic, name it that, and I think there will be a decided decrease in the mortality rate in pneumonia.

The area of superficial cardiac dullness can be brought out very clearly by touch percussion, placing the finger over the end or head of the hammer in percussion, and you can actually feel the dullness, as well as hear it. This can be accomplished without the use of hammer and pleximeter, by using, as the pleximeter, the middle finger of the left hand which is extended at the first joint and flexed at the second joint, thus placing the tip of the finger over the area to be percussed and by percussing on the flexed joint with the middle finger of the right hand instead of using the hammer.

**W. A. Jenkins:** I made no especial prep-

aration to discuss pneumonia this evening, although it is a subject which must necessarily be of interest to all of us.

I have enjoyed the first and second chapters of the symposium, not so much because of the matter introduced, but because they are in harmony with what we have been taught. The third essayist has lived up to the reputation of his predecessors by being completely paradoxical. Some say the treatment of pneumonia is a simple thing—merely a jug of water and a good nurse; others that they should be attended by four or five physicians and given something or other every fifteen minutes. The chief paradox in the essayist's paper is this: he tells us that pneumonia is entirely non-influenced by drugs and then turns around and says that it takes two good nurses and all the doctor's skill to take care of a case of pneumonia. It seems to me that is conclusive proof that the disease is responsive to treatment. I agree with him, however, in the latter part of his statement that it takes a very experienced and careful physician to properly attend a case of pneumonia.

Of course, there can be no definite rule in the management of pneumonia. We are obliged, in teaching, to have a hypothetical plan, but this must be varied according to individual cases.

I want to touch on one form of treatment about which I do not believe any one will agree with me. In the asthenic cases, in which Dr. Cecil states he is willing to try blood-letting, a great many practitioners are using aconite simply as an emergency remedy, with very great success.

In so far as caffeine and camphor are concerned, they are emergency remedies, for unusual incidents; are scheduled as such and are used as such. Whiskey and a strychnin will probably always be the sheet-anchor in combatting this condition and keeping up the right heart, and when these fail to accomplish that end, the next best thing to use is digitalis.

**R. Hayes Davis, (closing):** The question of the single organism as the cause of lobar pneumonia was discussed thoroughly by Dr. Weidner. That other organisms are present in addition to the micrococcus lanceolatus is unquestionable, but these other organisms are not the primary cause of croupous pneumonia, although they may increase the virulence of the infection or cause a prolongation of the disease.

I agree with Dr. Marvin that sleep in pneumonia is a very important thing. The patient who does not sleep will probably die. But in cases which show the somnolence of severe toxæmia an entirely different picture is presented. The prognosis in these is very unfavorable.

Oedema of the lungs is without doubt one of the most fatal conditions which may occur in pneumonia, but I don't believe the rule is absolute, that every case that shows signs of oedema must die. There is no disease where the old

maxim, "Where there is life there is hope," can be more aptly applied. In some cases when death seems inevitable there will be a sudden subsidence of all symptoms, and the patient will recover. This is especially true in children. The disease may be extremely grave, showing the most severe phase of the infection, and at the last moment when there is apparently no hope there will be a turn for the better, and the little patient, to the surprise of all will begin its convalescence.

To my mind the term "Central Pneumonia" is a very satisfactory explanation of some otherwise obscure cases. In these high fever and other symptoms of a severe infection are present, and a careful examination of the chest fails to reveal any physical signs for several days, when they make their appearance and run the typical course of a pneumococci consolidation. Ordinarily the appearance of fever is soon followed by distinct signs, and the area of lung involved does not especially influence the amount of toxæmia. Therefore, in these cases of delayed physical signs it is not reasonable to suppose that the consolidation is really present at first but in a central part of the lobe and is only demonstratable by examination when it spreads to the periphery.

**Knox**—The Knox County Medical Society met in regular session, January 27th, 1908, in the office of J. S. Loek, Barbourville, with J. W. Parker in the chair. The minutes of last regular meeting read and approved.

M. Pennington, president-elect after delivering his inaugural address, took charge of the society and proceeded with the regular order of business.

**Henry T. Hubbard** was elected to membership in this society.

**Arthur Jenkins** reported a case of post-puerperal eclampsia in which he had given normal saline solution by hypodermoclysis with good effect, which was well discussed by all present.

**H. E. Hubbard** reported a case of puerperal eclampsia which was discussed by all present.

**Arthur Jenkins** read a paper on principles in the treatment of fractures with special reference to the treatment of fractures of the patella and clavical, which was discussed by Drs. Hubbard, Pennington, and Parker.

The society then adjourned to meet at Grays, Ky., in the office of J. W. Parker, on February 21th, 1908.

J. W. PARKER, Secretary.

**Knox**—The Knox County Medical Society met in the office of Drs. Parker and Petus at Gray, February 24th, 1908, with M. Pennington in the chair. The reading of the minutes of the last meeting were dispensed with. S. B. Petus was elected to membership in this society.

**J. W. Parker** reported a case of pernicious

anemia which was discussed by H. D. Hubbard, S. B. Petus and M. Pennington.

**H. D. Hubbard** reported a case of fistula in ano with complications which was discussed by all present.

The resolutions of the Warren County Medical society were read and unanimously endorsed and the secretary was directed to write our state senator and representative at Frankfort regarding said resolutions.

The secretary was directed to notify all members of this society that we will elect a delegate to the State Medical Association at our next regular meeting.

The society then adjourned to meet in the office of Parker & Petus at Gray, March 23, 1908.

J. W. PARKER, Secretary.

**Lincoln**—The Lincoln County Medical Society met February 4th in E. J. Brown's office in Stanford. Two interesting papers were presented to the society; one by G. G. Perry, entitled, "Bronchitis, Its Etiology, Pathology, Diagnosis and treatment," the other by J. G. Carpenter, subject, "Hemorrhoids, Etiology, Pathology, Complications and Treatment."

Both papers were instructive, freely complimented and discussed by each member present. The following members answered to roll call: T. H. Singleton, McKinney; L. B. Cooke, J. W. Acton, Kingsville; J. T. Morris, Maywood, J. G. Carpenter, G. G. Perry, J. F. Peyton, W. F. Hickle and E. J. Brown, Stanford. The day was a scientific love feast and the profession felt that much was gained by the association. The society adjourned at a late hour to meet in Stanford again the second Tuesday in April.

W. F. HICKLE, Secretary.

**Mason**—The Mason County Medical Society met at G. A. R. Hall, February 8th, 1908, at 3 P. M. The regular proceedings were dispensed with in order to hear an address on the needs of medical organization by that distinguished and gifted orator the National Organizer, J. N. McCormack, of Bowling Green.

Among other things of interest which Dr. McCormack told us in his happy way, was that there are (21) twenty-one counties in this State in which every doctor is a member of his county society.

He thinks that where a county society is not flourishing it is due to the officers not making it interesting to the country members. He says that fully one-half of the physicians in the State are living in poverty and disgrace and that the only remedy for such a condition is medical organization. The isolated life which the doctor leads causes him to be suspicious of his fellows and this is naturally conducive to slandering and backbiting each other. This will be eliminated if the physicians can come together and get better acquainted with each other.

This will accrue not only to the material well-fare but to the intellectual standard of the profession.

Dr. McCormack related the story of the Mayos' as illustrative of what cooperation and joint work will do for the participants. Dr. McCormack suggested that a committee be appointed to consider the installation of the post-graduate course in the county society. The committee was appointed as follows: J. B. Taulbee, Harover and Cooper.

Dr. Taylor offered a resolution of respect to the memory of the late Dr. Jno. A. Reed, who died January 25th at Philadelphia. That we recognize his constant devotion to his chosen profession throughout a practice of over forty years, his keen insight and splendid judgment, his bold and skillful methods of carrying out what he believed to be indicated for the relief of his patients.

Adopted.

The society then adjourned to meet the second Wednesday in March.

Doctors present, Hard, Hunter and Crain, from country; Taulbee, Brand, Cooper, Anderson Harover, Ellis, Yazell and Stevens, from town.

ARVID O. TAYLOR, Secretary.

**Monroe**—The Monroe County Medical Society met at the office of R. F. Duncan and Bushong, Saturday, Feb. 9th, 1908. Geo. W. Bushong in the chair. Drs. Bedford, Bristow, Bushong, Marrs, Palmore and Sympson present.

**J. F. Marrs** read a paper on Arsenic, all taking part in the discussion and commending the paper to the consideration of the physicians of the State. All report the prevalence and severity of la grippe, and bad roads. Some one suggests that inasmuch as there is bound to be a lot of whisky legislation and some road legislation, that it would be a good plan to add an additional tax of twenty-five cents on each gallon of spirits distilled in Kentucky and apply it to the building of roads, and asks that it be advocated by the Kentucky Medical Journal.

The Committee on Program assigned Dr. Smith, "Tuberculosis," and Dr. Ray, paper of his choosing for March. The society meets the second Saturday in each month now.

E. E. PALMORE, Secretary.

**Monroe**—The Monroe County Medical Society met at the office of Bushong and Duncan, Tompkinsville, Ky., Saturday, March 14, 1908. Drs. Bedford, Bristow, Bushong, Duncan, England, Palmore, Sympson and Ray, present, G. W. Bushong in the chair. The secretary presented a letter from R. F. Crabtree, Gamaliel, Ky. in which he expressed regrets at not being able to attend.

The paper, "Tuberculosis," was deferred to the next meeting on account of the absence of its author, Jesse T. Smith, but there being a tuber-

culosis patient present, the society proceeded to discuss the subject, "Tuberculosis," as presented in the subject present: Case, Mr. P., age 47, white, married. Had la grippe two years ago, has coughed ever since. Any kind of exertion brings on the coughing spell. Has night sweats. Has had several hemorrhages, not very profuse, last hemorrhage four or five months ago.

Has gained several pounds in weight since last hemorrhage. Is losing weight at present, but not very much. Family history good.

Examination shows breathing is practically all done by left lung, right side of chest much flattened; respiration 36 per minute, temperature 99.6. Treatment: Dr. Bristow: I suggest New Mexico and offer free of cost to Mr. P., my farm there so long as he may wish to occupy it, and further, I will almost guarantee a cure if Mr. P. will go there now and live out of doors and rest. There is no place like it for consumptives; 350 sunshiny days per year, a high, dry wholesome climate, where the streptococci will not live. Of course it is necessary to have plenty of pure wholesome rich food and a stomach that can take care of it. This Mr. P. has.

**G. W. Bushong:** I agree with Dr. Bristow in every particular. There are possibly some few places equal to the climate of New Mexico, but there are none that surpass it. If Mr. P. can not leave home right well at present it is possible for him to do well here from now till fall. The worst of the winter weather is over. He might live out of doors now day and night, or he might make a window tent and sleep in it, but pure air day and night, rest in bed and plenty of nutritious food are absolute necessities. Mr. P., listened to the discussions with much interest and expressed himself as pleased at the interest the society manifested in his case, and thanked them for the suggestions offered and promised to report to the society regularly through his family physician, Dr. Crabtree, at whose suggestion he had come before the society.

Another very interesting case presented in Mr. M., white, age 26, singing teacher. Had typhoid fever thirteen years ago. Has never been able to walk without staggering since having fever. Had a fainting spell about ten years ago. Fell in floor and unconscious for several minutes. Has had them infrequently ever since, but always at night. Memory is poor, at times mind is blank for several seconds. Had to quit teaching on account of loss of memory. Has palpitation of heart, pain in stomach and in region of heart. Complaints of kidney or bladder trouble. Has to get up at night to void urine. Voids from 1-2 to 1 gallon per day. Urine clear as water. Sp. Grav. 1010. No sug. or albumen. Has good appetite and gaining flesh steadily; 5 feet 10 inches high and weighs 220 pounds.

Diagnosed: Petit Mal. Treatment: 2 C.C. pills at bedtime, and plenty of bromides T. I. D., and report at next meeting.

The rest of clinical material was of no especial interest.

Committee on program assigned for April meeting, "Petit Mal," Dr. England; "The Monroe County Medical Society," Dr. Bristow.

Adjourned to meet at Tompkinsville, Saturday, April 11, 1908.

E. E. PALMORE, Secretary.

**McCracken**—The McCracken County Medical Society during the month of February held four regular meetings and one call meeting. We as a society are finding very profitable and helpful the study and discussions as outlined in the post graduate course. At the end of each paper a thorough quiz is given by the leader to which all present heartily respond. We have had a thorough review during the month of "Pleurisy, Acute and Chronic," "Empyema and Abscess of the Lungs," "Anatomy, History and Periostitis of Bone," a lecture on "Osteomyelitis," "Tuberculosis," and "Rickets of Bones."

In a call meeting at 9 A. M., February 17th, at the office of Dr. Blythe, fourteen members voting, the society passed resolutions endorsing fully the action of our State Committee on Legislation and the Bulletin which they had prepared. The society is active and thoroughly interested in the complete organization throughout the State of the Medical Profession and particularly of each individual county society for their mutual benefit and protection. We feel like the druggist should respect our rights and as physicians and as a society that they should know the Medical Practice law in regard to prescribing and the penalty of doing so. McCracken County Medical Society recently sent to each druggist in Paducah a brief of this law as a gentle reminder that all of them are not treating the doctors on the square. We want, before many months pass every reputable, legally registered white physician in our county, feeling a personal interest in its welfare and a fraternal spirit for each and every physician in it.

VERNON BLYTHE, Secretary.

**McCracken**—The McCracken County Medical Society has held its meeting every Tuesday night in January with an average attendance of eighteen members. We have added four new members recently to our roll and it is our expectation to add several more during the next few months. The Society is in a thriving, prosperous condition and it is our anticipation that the year 1908 will be the most effective for good organization in the history of its course. We have 43 members now enrolled. Excepting colored doctors, osteopaths and homeopaths, there are only eleven or twelve regulars in the county who are not members. We have recently had several interesting papers read and discussed before the society.

C. E. Purcell on January 7th gave a very in-

structive lecture and illustration on "Submucous Resection of Nasal Septum."

H. P. Sights on January 14th discussed "Opsonic Index and Its Clinical Value."

Delia Caldwell, on January 21st gave to the society a most interesting, pointed and concise lecture on "Present Day Status of Tuberculosis," which paper created considerable interest and discussion among those present. At the meeting of January 21st a motion was made and accepted that we as a society accept and follow from week to week the post graduate course as outlined in the American Medical Journal. The evening of Jan. 28, H. T. Riven lectured and quizzed on "Croupous and Catarrhal Pneumonia." We meet every Tuesday night in winter, from June to October on the second Tuesday of the month.

VERNON BLYTHE, Secretary.

**Nelson**—The Nelson County Medical Society met in the office of H. D. Rodman at 11 A. M., March 4th, called to order by President Harned. There were present H. S. Harned, W. Lucian Heizer, J. R. Cowherd, J. Sherman, Charles McClure, J. J. Wakefield, B. E. Gore, J. E. Smith, R. H. Greenwell, H. E. McKay and Hugh D. Rodman and B. A. Muster, of LaRue county, as guest of our society.

Officers for the ensuing year were elected as follows: W. Lucian Heizer, of New Haven, President; R. H. Greenwell, Bardstown, Vice-President; J. E. Smith, Bardstown, Censor for three years; Hugh D. Rodman, Bardstown, Secretary-Treasurer; Committee on Sanitation and Legislation, H. E. McKay, J. J. Wakefield and H. S. Harned.

As neither of the essayists were present a general discussion of la grippe was had, which was opened by J. J. Wakefield, who is really the Patriarch of Medicine in the County. He opened by giving a history of the appearance of epidemic influenza in the East, about 1890 or 1891, and followed up its spread all over the entire world; he then gave its symptoms, its complications and its treatment. His treatment began by elimination through both bowels and kidneys, with at the same time an anodyne antipyretic for this purpose he preferred acetanilid, soda, caffeine and camphor, generally accompanied by strychnine, and he believes that strychnine is called for all through the disease he watched for complications and treated them as they arose.

This talk was so rapid, so lengthy and so interesting, that the secretary, who is not a stenographer, could not get it all.

B. E. Gore: I can add nothing to what Dr. Wakefield has said, as the ground has been so well covered.

H. E. McKay: I do not believe in the antipyretic treatment. I believe that general supportive means are better and I prefer the arsenite of strychnine to the sulphate. I have seen

more ear and more glandular complications during this epidemic than ever before.

**J. R. Cowherd:** I do not use the antipyretic treatment. I get better results from quinine, strychnine and Dover's powders. I have seen a number of eye complications, or eye gripe as they were usually in children who could not complain of the general aches, etc., I have also seen a number of ear, nose and throat complications all of which required especial treatment.

**H. S. Harned:** Nothing has been said about the cough in gripe, which has been very troublesome in many of my cases. Almost all of the cough mixtures disturb the appetite and digestion; hence are contra-indicated in such cases, for this reason I have used successfully a little heroin or codiene, just enough to control the cough, then leave it off. I don't use the coal tar derivatives.

**B. A. Muster:** I have had a number of cases of gripe this winter, and one troublesome feature of some of my cases, which has not been mentioned to-day, is severe vomiting which required especial attention. As a general treatment, I use the acetanilid soda, camphor and caffeine, with Dover's powder to relieve pain and cough.

**R. H. Greenwell:** I can add nothing to what has been said.

**W. L. Heizer:** The typhoid complications of gripe has not been mentioned, but when we remember that we have in gripe the bacillus we know that we may have almost any complication which we must treat as they arise, and we must not be misled by the symptoms of other diseases.

**H. D. Ecdman** reported a case of compound comminuted fracture of both legs at the ankle, the result of a jump from a third story window with recovery.

**H. E. McKay** reported a case of shoulder presentation with prolapsed arm, and spontaneous delivery.

**J. J. Wakefield** reported four cases of musical heart describing accurately and fully the heart sound. I believe that the doctor has a musical ear which aids him in detecting this condition.

Adjourned at 3:30 P. M., to meet the first Wednesday, 1st day of April, at which time we expect a full meeting.

HUGH D. RODMAN, Secretary.

**Owen**—The Owen County Medical Society met in regular session in the I. O. O. F. rooms, at Owenton, promptly at 10 A. M., Thursday, February 6th, 1908, with J. H. Chrisman in the chair.

Those responding to the roll-call: J. W. Botts, J. H. Chrisman, J. A. Estes, J. C. B. Foster, W. E. Foster, G. Purdy and W. B. Salin; those failing to respond: W. G. Birchett, D.P. Curry, S. C. Davis, D. E. Lusby, K. S. McBee and M. S. Veal.

T. G. Connell, of New Liberty, and E. N.

Estes, of Owenton, were unanimously elected to membership.

**George Purdy**, under clinical cases, reported a case of diabetes mellitus with interesting complications. The case was discussed freely.

**J. C. B. Foster** read a paper, the subject of which was, "Our Individual Responsibility in the Fight being waged against Patent and Unethical Proprietary Medicines. This subject was considered one of the most important that has ever been presented to this society. It was handled very ably and, in the after discussions, highly complimented. The essayist classified the factors which we have to fight and said the undertaking seemed a stupendous one. Our individual duty, he says, is as man to man—physician to patient. It goes without saying, we should discard from our use the very things that we are fighting. In his opinion some legislation is needed and we, as individuals, should see to it that our law-makers know the people's need. Just such a paper was needed and many more along the same line would do good. W. B. Foster opened the discussion and afterwards every member present joined in.

The fact that our local pharmacists are ignorant of this fight and of the work being done by our National Board of Pharmacy was developed—another line for individual work.

**M. S. Veal**, who was on program for a paper on, "The Early Diagnosis and Curative Treatment of Pulmonary Tuberculosis," was not present but his paper was in and the President instructed the Secretary to read same.

It was an interesting paper and followed out modern ideas. Among other things, he said that the physician will have been assisted to a great extent when he is invested with legal authority to make examinations in suspected cases of tuberculosis. He thinks the "laboratory habit" should not cause us to neglect physical examination. Considers loss of weight with continuous afternoon fever most important sign. Is highly enthusiastic about the curative treatment of these cases. He outlined the open air treatment and closed by saying that post mortem examinations prove, beyond a doubt that many cases of tuberculosis are cured and the patients have lived to die from other causes. The discussion was opened by W. B. Salin and then all in attendance took part.

On account of the absence of D. E. Lusby, who was on program to read a paper on "Infection of the Gall-bladder, Cystic and Common Ducts," this subject was not discussed, much to the regret of the society.

The program for the next meeting is as follows: "Rhinitis Hypertrophica," paper, W. B. Salin; discussion, K. S. McBee. "Broncho-Pneumonia," paper, Jas. A. Estes; discussion T. G. Connell. "Acute Chorea," paper, J. W. Botts, discussion, D. E. Lusby.

The meeting adjourned in order until 10 A. M.

Thursday, March 5th, 1908.

GEORGE PURDY, Secretary.

**Simpson**—The first meeting of the Simpson County Medical Society since January 7th was held March 3d at the office of W. H. Williams. The roll-call was responded to by nine old reliables with their dues. I have herein sent you a list of those who have paid their dues and those who have not. W. H. Williams reported a very interesting case, which I will attempt to state as he gave it to us: Miss H., age 28, had had la grippe; most pronounced symptom was sick stomach with vomiting, which is always a prominent symptom; temperature 101 deg., or less at all times; pulse 72, with increasing frequency until the end. She was constipated all the time from the beginning, anemic and pale. Her abdomen was tender all over with a thickening of the peritonium, and with some indication of effusion. The tenderness was not of an acute peritonitis, but of a general chronic condition. She lived six weeks.

The discussion on the case was of a very wide scope and it was with some difference of opinion that a diagnosis was reached in the case.

After the discussion of the above case, M. M. Moss read a paper on la grippe and the society contented itself in discussing the treatment only.

We hope at our next meeting to have a large attendance and cordially invite all members of the profession in the county to come and take part.

M. M. MOSS, Secretary.

**Warren**—The regular meeting of the Warren County Medical Society was held in the Doctor's Club Room Wednesday, February 26th, 1908, with the following members present: E. N. Hall, Rau, Briggs, Drake, Lewis, McCracken, McCormack, Souther and South.

In the absence of the President and Vice-President, the Secretary called the meeting to order. E. N. Hall was elected chairman. Minutes of the last meeting were read and approved.

The first subject on the programme was the "Therapeutic Action of Iron," by W. C. Simmons. Our former president being absent the secretary read a brief article on the subject.

This is the first meeting Dr. Simmons has missed during the year and the society earnestly hopes he will not start the precedent that retiring from office means retiring from active attendance.

E. N. Hall substituted for J. L. Neel who was to read a paper on "Treatment of Pernicious Anemia." Dr. Neel has not attended a meeting for over a year, however, the society is duly thankful he has paid his dues and also contributes toward retiring the indebtedness.

J. H. Souther in his usual live and enthusiastic manner spoke of the difficulty that country doctors had to overcome in order to attend the

meeting, some driving over muddy roads for 15 miles, then after their long and hazardous journey, only to find that those doctors who were on the program, some living in town failed to be present.

Some accused the society of being controlled by a clique. "Now," said Dr. Souther, "I am a true democrat and am down on rings, gangs or cliques which some accuse of dominating the society. I have been unable to find any such conditions. We have for our president a democrat and splitter Presbyterian, our vice president, a Republican and Baptist, for our secretary a woman, so I defy any member to say we are governed by a ring.

It was decided to have a mass meeting to discuss Tuberculosis, the secretary was instructed to send out letters to every member and non-member telling of the meeting and the program.

L. H. SOUTH, Secretary.

**Woodford**—The Woodford County Medical Society met in regular session on Tuesday, January 7th, 1908. Present S. M. Steadman, Parker, Holt, McCauley, Blackburn, Hart, Worthington, and Crenshaw. The secretary in the chair. A number paid their State and County dues. Dr. Arnold was not present to read his paper.

The society then elected its officers for the year 1908, as follows: S. M. Steadman, President; W. E. Riske, Vice President; J. W. Crenshaw, Secretary-Treasurer; W. E. Sleet, Delegate to State Society with Joseph P. Holt, Alternate.

S. M. Steadman was appointed a committee to see all the doctors of the county and obtain from them the names of such parties who can but don't pay their medical bills. Adjournment.

J. W. CRENSHAW, Secretary.

PURPERAL INFECTION.—(Continued from page 167)

The diagnosis by the general practitioner must be mainly based upon the symptomatology, as few are equipped to resort to culture tests. A persistent elevation above 100.5° in the puerperium should be taken as evidence of puerperal infection, unless it can be positively explained by some other condition. If the patient is suffering with malaria, then, if possible, the discovery of the plasmodium in the blood, or the therapeutic test should differentiate the condition.

Typhoid fever can now be definitely eliminated by the Widal reaction, using the test pump put up by the Parke Davis Co. It must be remembered that phthisis often manifests itself in the puerperium and accordingly the lungs should be examined carefully and the tubercle bacillus sought in the sputum. An intestinal toxæmia would be eliminated by the administration of a good purgative and if the elevation should be due to mastitis, then the pain in the breast should lead to a ready discovery of that condition.

## ABOUT THE HEALTH LEGISLATION.

To those conversant with the history of what occurred in regard to sanitary legislation at Frankfort during the recent session of the General Assembly there will always come mingled feelings of gratification and regret. The gratification came from the demonstration of the increased public confidence in our superb organization which was shown by the practically unanimous passage of every health and life-saving measure supported by it; the regret, that all of the unselfish labor of those interested in the public health was nullified by the perfidy of two traitors, one of them still claiming to be in our own ranks, through whose pernicious influence with the Governor they were enabled to secure the veto of all of the important health measures, except the Pure Food and Drug Bill and the one providing for the maintenance of privately owned tuberculosis sanitarium.

At the beginning of the session, the careful preparatory educational work done by the various county societies all over the State was evident on all sides. The really important Senators and Representatives, to whom the necessity for such legislation had been carefully explained by their home physicians, and county societies, never wavered for a moment in their active support of all of our measures. With but one negative vote in the Senate, not a single member of the House—Democrat or Republican—voted against any of them who had ever been heard of ten miles from his home before going to Frankfort. And this support was in spite of a campaign, under the guise of partisanship, characterized by every sort of malignancy and mendacity really designed to wrest control of the State Board of Health from the state medical associations, with the possibility of benefit to the parties to the conspiracy which they

could never hope to secure from an intelligent profession.

The Pure Food and Drug Bill, carrying an annual appropriation of \$30,000, probably the strongest and best law secured up to this time in any State, passed both houses by a practically unanimous vote, and was promptly signed by the Governor. The Vital Statistics Bill, the one appropriating \$25,000 annually to establish and maintain a State Laboratory and to carry on other public health work, the one to provide for an Annual School for County and City Health officers, and the almost model bill to define and punish criminal abortions, were submitted to and had the promise of the cordial support of every medical member in both houses. Up to this time all was smooth sailing, and it appeared that at this one session Kentucky was to be put in the front rank and its powerfully united profession made the most publicly useful and effective one in the United States.

As if by magic, all of this pleasant prospect disappeared. Bills were introduced in both houses to debauch the State Board of Health by making the appointment of its members political, to be selected by the Governor instead of by the respective State Associations, with the avowed purpose of packing it with those who would persistently oppose any further elevation of the standards of medical education. A member of the State administration, who as a medical man had secured the support of many physicians for the office he holds, but who has now frankly left our profession for a practical political career, and who thinks to strengthen himself by maligning and traducing his former associates, appeared as sponsor for this bill and in active opposition to all of our measures, but he was only an active mouthpiece, for back of him, poorly disguised, though stoutly denying it, was one of the leading medical teachers of Louisville, a man

whom the profession of Kentucky has honored with the highest offices in its gift, and who has always been loudest in his claims of friendship for the Board and medical laws.

These men, the leader and brains of the combination laboring under the disadvantage of an attempted disguise, displayed an activity worthy of a better cause, and no higher tribute could be paid to the profession of Kentucky than to state the fact that of the 4,100 physicians of every school of practice only two or three ever even wavered in their loyalty. As stated above they were even less successful in the General Assembly.

It was different after the bills reached the hands of the Governor. However well-intentioned he might have been, he was totally inexperienced in health affairs, and, being a layman, it was easier to mislead him, especially for medical men working in the dark, willing to spare no misrepresentation or falsehood to do so. In spite of the active support of all of the life-saving measures prepared by our Committee on Public Policy by the great leaders of his own party, and in spite of his intention to approve the measures, as evidenced not only by his statements to these gentlemen, but also to our committee and to his appointees on the State Board of Health, influenced, however unconsciously, by the malignant pressure brought to bear on him, at the last moment he vetoed not only the bill appropriating \$75,000 to acquire and \$30,000 per annum for the support of a State tuberculosis sanitarium, but also the bill increasing the appropriation for the State Board of Health from \$5,000 to \$25,000 a year and establishing a bacteriological laboratory\* and for other purposes, but, in addition, the model bill providing for an annual school for county and city health officers, already in force in more than a dozen States, and the bill punishing criminal abortionists. About this latter, it is only necessary to say that Kentucky is the last State in which abortion becomes a crime, only when the unfortunate woman upon whom it is committed dies.

The harmonious, united, active support of the profession, of every school and creed, and the demonstration of its power in securing legislation, probably gives honor enough for one year, and the treachery which prevented a complete triumph would not be mentioned but that it is an evident duty of this JOURNAL to its owners, the physicians of Kentucky; but it is with a feeling of profound shame that this duty is performed—shame that any man trained in our art, animated by petty spite or whatever ignoble motive, would be

a party to such perversion of known facts as would hinder the life saving work of the medical profession—the greatest, the most devoted, the most unselfish avocation amongst men, and yet our representatives were repeatedly told by the mouthpiece of this combination that their war would be continued at the next session and always unless they could capture and control the organization and dictate the appointments on the State Board of Health.

Our legislation was supported actively not only by every medical society of every school in Kentucky, not only by every health official in the State, but also by the State Farmers' Institute and a large number of County Institutes, the State Federation of Women's Clubs, the Kentucky Educational Association, the Kentucky Association of Charities and Correction, the State Press Association, the Louisville Board of Trade, the Louisville Commercial Club, the State Development Association, in fact every organized influence which has made any study of health conditions in the State. Formally and unanimously endorsed by the House of Delegates of our own Association, which represented 4,100 physicians, which appeared before the General Assembly by its duly elected Committee on Public Policy and by the full membership of its Council, as well as by the Homeopathic, Eclectic and Osteopathic Societies, is it not a little strange, to say the least, that any man should have been willing to place himself in such a false position with the Governor as to make him believe that he and not their duly elected and accredited representatives, was authorized to speak for the profession of Kentucky in its beneficent aims for the betterment of health conditions.

The lesson of all this is plain. Make our societies so much better that our position in public estimation will be higher month by month. Impress every public man with the importance of public health as an asset to the State. Let your patients understand how much easier and safer it would be for you to serve them—rich and poor alike—with all the aids of recent science, if, in addition to your own equipment, you could avail yourself of the services of a trained bacteriologist in a modern laboratory. Tell them of the 12,000 valuable lives uselessly sacrificed in our State every year by an ignorance and negligence that is criminal when the results are considered. Let them understand that men, women or children dead with preventible diseases are just as dead as if killed by "night riders" or other violent means. Let the great public know that money flows like water to keep soldiers in the field to protect property, and contrast with this the parsimony that counts the dollars for the lack of which human lives

\*For the text of the bill, see page 236.

are being sacrificed. In season and out of season let every medical man in Kentucky proclaim the accepted and oft reiterated maxim: *If every hope and aspiration of the doctors of Kentucky should be realized to-morrow, it would only mean a few more years of life to Kentuckians, and that those years should be years of health and happiness rather than of pain and decrepitude.*

Do these things, and before the legislatures and governors the position of the splendid medical profession of the Grand Old Commonwealth will be so impregnable that neither the shafts of envy nor of malice can find a weak place in its armor, so that our beloved State shall teem with a happy and contented people, unravaged by diseases *we now know how to prevent.*

### ON TO CHICAGO.

The largest and strongest delegation of physicians who ever left Kentucky at one time will go to Chicago June the first to the fifth for the annual meeting of the American Medical Association. From letters already received, our delegation will be more than twice as large as usual. The expense of attending the meeting will be so small, owing to low railroad rates and the reasonable hotel and restaurant charges of a great city like Chicago, that no practitioner can afford to miss this splendid opportunity for coming in personal contact with all that is best in American medicine. We are happy to inform our members that the Kentucky State Medical Association has made special arrangements with the Monon Route which will enable our members and their families to accept the cordial invitation of Mr. Thomas Taggart to be his guests at French Lick Springs on Sunday and Monday, May 31 and June 1, before the meeting. Our Association will be joined at Louisville by delegates from the county societies of the other Southern States, and we can all have a pleasant vacation of a couple of days at the greatest health resort in America without a penny's expense. Mr. Taggart is naturally anxious that physicians have a personal acquaintance with him and the springs. So if you intend going to Chicago, write as soon as possible to Mr. E. H. Bacon, D. P. A. Monon Route, Louisville, and he will tell you exactly what train to take and what your tickets will cost. There will not be one cent of extra charge for the two days you may spend at French Lick. Then write Dr. L. J. McArthur, No. 100 State street, Chicago, Ill., telling him exactly whether you will be alone, and, if not, how many people will go with you, and *how much you want to pay a day for room and board for each person.* You will get to Chicago Tuesday morning, June 2nd, at 7 a. m. You can get room

and board in Chicago from \$1 per day up. This whole trip is a rare opportunity and we trust that from 500 to 1,000 Kentucky doctors will take advantage of it. If possible arrange to take your wife along and give her the pleasure of the trip. Be sure to write Dr. McArthur and reserve rooms in Chicago just as soon as possible, as those who write first will get the best rooms.

### DR. CHARLES A. L. REED AND THE UNITED STATES SENATE.

An effort is being made to induce Dr. Charles A. L. Reed, of Cincinnati, to become a candidate for the seat now occupied by Hon. J. B. Foraker in the United States Senate.

It seems from recent publications in the Ohio newspapers, that the movement is not confined to the medical profession, which, of course, is a unit in Dr. Reed's favor, but that it is being prompted by many of the most influential leaders of the Republican party of that State.

And from a Republican party standpoint, the candidacy of Dr. Reed would certainly be very fortunate. He lives in the section of the State from which Senator Foraker's successor will naturally be selected. He is a life-long Republican, a student of public affairs and forceful writer on political, economic and social questions. He is a natural leader of men and a convincing speaker before popular audiences. He has long enjoyed a familiarity with public men and measures. He was a member of a State executive board under the late Gov. Bushnell. It has been his official duty for a number of years to appear before the various committees of Congress in the interest of measures of great public importance. In this connection, Senator Heyburn, the champion of the Pure Food and Drug Bill, stated in a published speech that it would have been impossible for him to have secured the passage of that measure if it had not been for Dr. Reed and the influence that he represented.

The Army Reorganization Bill that has just passed after a long struggle before three Congresses, is another testimonial to Dr. Reed's tireless industry in behalf of the public good—a service that he has rendered in these and numerous other instances, not only entirely without compensation from any source whatever, but at the expense of both time and money.

He has been commissioned at different times to represent the United States at several international congresses. It will be remembered, too, that a few years ago Dr. Reed was sent by President Roosevelt as a special commissioner to the Republic of Panama, and

that upon his return he presented a critical report which profoundly impressed both the Administration and the public. Every one of the numerous recommendations that he made was subsequently adopted, even to the extent of changing the personnel of the Isthmian Canal Commission and modifying essential features of the organization in the Canal Zone.

An example of Dr. Reed's thorough way of doing things was shown by the fact that, under his leadership, one hundred and five physicians went as members to the recent Ohio State Republican Convention, of which he was one of the officers. Their object was to secure a plank in the platform favoring the creation of a National Department of Public Health. It is needless to say that the plank is in the platform—the first time, we believe, that one of the great political parties has ever made a declaration on that question.

These facts are mentioned, and many more might be mentioned, to show that Dr. Reed, who has never been, and it would seem from the newspapers, is not now a seeker for office, is yet far from being a tyro in public affairs. They indicate, furthermore, that he has the solid backing of the 11,000 physicians of Ohio. This of itself is a political asset of great value, a fact which doubtless has been and is now being taken into account by the political leaders of Ohio who will do well if they can induce him to relinquish his large practice for a career in public life.

#### A ROLL OF HONOR.

Four physicians, members of the last General Assembly, should carry with them to their graves the esteem and gratitude of the medical profession of Kentucky: Drs. M. G. Watson, of Louisa; L. C. Nell, of Columbia; O. H. Hogan, of Williamstown, and J. O. Sloan, of Albany, introduced our bills for us, stood for us in the committees and were untiring in their support and in inducing others to support them. These gentlemen were equally divided between and leaders in the two political parties, but rose above parties in their advocacy of these life-saving measures. In like manner every physician in their respective sections or districts, regardless of politics, should consider it a privilege to assist them in any aspirations they may ever have, public or otherwise.

#### SENATE BILL NO 121.

Following is a copy of Senate Bill No. 121, which passed the Senate with but one dissenting vote, and the House by a two to one vote, and was then vetoed by the Governor:

AN ACT To amend Section 2054, Chapter 63

of the Kentucky Statutes, relating to the State Board of Health.

*Be it enacted by the General Assembly of the Commonwealth of Kentucky:*

SECTION 1. That Section 2054, Chapter 63, of the Kentucky Statutes, relating to the State Board of Health, be and is hereby amended by striking all of said section and inserting and re-enacting in lieu thereof such words that said section when so amended shall read as follows:

Section 2054. The sum of twenty-five thousand dollars per annum, or so much thereof as may be deemed necessary by the State Board of Health, is hereby appropriated for the following purposes:

1. To establish and equip a State Laboratory for the free examination of the products of tuberculosis, typhoid fever, diphtheria and other communicable diseases, with the view

2. To employ a skilled State Bacteriologist to their prevention.

and such assistants as may be found necessary for the proper conduct of this work.

3. To hold schools of instruction for county and city health officers and to provide teachers and demonstrators for the same.

4. To hold public health conventions annually in the various counties and districts in connection with farmers' and teachers' institutes or otherwise for oral instruction and demonstration of practical methods for the prevention of typhoid fever, consumption and other domestic pestilences.

5. To make a survey and investigation of the rivers, creeks, water sheds and other matters relating to the sources and character of the water supply in all sections of the State, with the view to the protection and purification of the same.

6. To pay the salary of the Secretary and such clerks, stenographers, sanitary inspectors and other employees as may be found necessary.

7. To pay the traveling and such contingent and other expenses of the Board as may be found necessary in the proper discharge of its duties.

These salaries and expenses shall be certified and paid in the same manner as is provided for the salary of the Secretary.

SECTION 2. This act shall take effect and be in force in accordance with the provisions of the constitution where no emergency is declared to exist.

#### HOW THEY VOTED.

From the list below you will see how your Representative voted on the State Board of Health Bill, published above:

The following members of the House voted yea—

- A. A. Alphin, of Carroll and Gallatin.  
 Robert H. Anderson, of Scott.  
 O. P. Applegate, of Campbell.  
 Louis W. Arnett, of Kenton.  
 Elliott B. Beard, of Shelby.  
 P. W. Berkshire, of Daviess.  
 O. Euston Brooks, of Graves.  
 Frank J. Brown, of Nelson.  
 J. T. Buford, of Franklin.  
 C. C. Chase, of Kenton.  
 J. Will Clay, of Montgomery.  
 H. K. Cole, of Daviess.  
 C. F. Crecelius, Pendleton.  
 John T. Davis, of Jefferson.  
 W. A. B. Davis, of Rockcastle and Laurel.  
 Henry H. Denham, of Metcalfe and Monroe.  
 Thurman B. Dixon, of Allen.  
 William E. Dowling, of Anderson.  
 John Feland, of Christian.  
 F. E. Graves, of McCracken.  
 Robert L. Harris, of Louisville.  
 W. W. Hopkins, of Floyd.  
 F. M. Hutcheson, Jr., of Henderson.  
 R. F. Hutchinson, of Carter and Elliott.  
 J. H. Jackson, of Owen.  
 W. J. Jackson, of Fulton and Hickman.  
 W. F. Klair, of Lexington.  
 W. C. McChord, of Washington.  
 Emanuel Meyer, of Louisville.  
 H. L. Myers, of Butler.  
 Duncan Milliken, of Bowling Green.  
 Garfield Moore, of Boyd and Lawrence.  
 Chris Mueller, of Louisville.  
 Jesse F. Nichols, of Ballard and Carlisle.  
 A. C. Oliver, of Morgan and Wolfe.  
 W. V. Perry, of Logan.  
 John C. Pirtle, of Hardin.  
 J. F. Porter, of Webster.  
 R. S. Rector, of Casey and Russell.  
 Gus W. Richardson, of Meade.  
 H. A. Schoberth, of Woodford.  
 W. H. Shanks, of Lincoln.  
 S. A. Shanklin, of Mason.  
 Robert C. Simmons, of Kenton.  
 J. A. Sloan, of Clinton and Wayne.  
 John L. Smith, of Lyon and Marshall.  
 John S. Steers, of Grant.  
 C. S. Templeman, of Nicholas and Robertson.  
 George C. Waggoner, of Henry.  
 John P. Wallace, of Louisville.  
 E. E. Wash, of Trigg.  
 George S. Wilson, of Union.  
 J. Hal Woodford, of Bourbon.

The following members of the House voted nay on the passage of the bill—

- J. W. Berkshire, of Boone.  
 F. Pierce Blair, of Bath and Rowan.  
 W. N. Brown, of Mercer.  
 Albert Butler, of Crittenden and Livingston.

- J. A. Duff, of Ohio.  
 W. F. Edmunds, of Barren.  
 Robert Enlow, of LaRue.  
 Thos. E. Finley, of Hopkins.  
 C. W. G. Hannah, of Greenup.  
 R. Dillard Hunter, of Clark.  
 W. Harrison Isaacs, of Pulaski.  
 T. C. Jackson, of Marion.  
 W. L. Kimbrough, of Todd.  
 Cleves G. Kinkead, of Louisville.  
 A. T. Knox, of Powell.  
 A. T. Lee, of McLean.  
 E. W. Lillard, of Boyle.  
 Jasper D. Lowder, of Lewis.  
 William S. Markolf, of Louisville.  
 J. B. Maynard, of Pike.  
 G. W. Parrott, of Green and Taylor.  
 C. C. Patrick, of Fayette.  
 G. L. Perryman, of Adair.  
 G. T. Reynolds, of Bracken.  
 Isaac G. Rice, of Johnson and Martin.  
 John T. Shanklin, of Fleming.  
 A. Sawyer Smith, of Knox.  
 J. W. Stump, of Harrison.  
 J. B. Swann, of Calloway.  
 Eugene W. Tandy, of Oldham and Trimble.  
 William M. Thompson, of Bullitt and Spencer.  
 W. C. Wym, of Garrard.

## OFFICIAL ANNOUNCEMENT.

### REPORT OF COMMITTEE ON MEDICAL DEFENSE.

#### LETTER OF TRANSMITTAL.

The Committee on Medical Defense, appointed at the last meeting of the Kentucky State Medical Society, realizing the great importance of their duties, have investigated the subject thoroughly and have the accompanying articles to offer the County Societies for their adoption.

In presenting this summary of their work, the committee desires to state that this matter was considered from three points, viz:

First—Will the formation of a defense union be beneficial to the physicians of Kentucky?

Second—Is such an Union practicable, and if so, what are the minimum rates necessary for good results?

Third—Can this Union have legal standing without coming within the regulations of the insurance laws?

The committee read carefully the reports of similar organizations of England, Canada and various parts of the United States, and found that malpractice suits had been greatly decreased in number in these countries and States, that satisfactory protection had

been given the members and that, in all cases, the benefits had been undoubted.

From this same research, the committee believe that the work can be properly carried on for the amounts mentioned, namely—\$5 for an entrance fee and \$1 per year from each member as dues.

As to the legal standing of the Union, the best lawyers in the State have been consulted and assurance has been given the committee that the articles now presented to the County Societies are in perfect accordance with the laws of Kentucky.

The various insurance companies charge \$15 for the protection which the Defense Union will give for \$1 (the entrance fee, \$5, being paid once only), and, therefore, the committee does not expect anything other than the unanimous adoption of their report by the County Societies.

Very respectfully submitted.

CUTHBERT THOMPSON, Chairman.

OSCAR E. BLOCH, Secretary.

Louisville, Ky., April 14, 1908.

#### PROPOSED CONSTITUTION.

I. The name of this Association shall be the Medical Defense branch of the Kentucky State Medical Association, and shall cooperate therewith as herein provided.

II. The object of this branch Association shall be the defense of its members against unjust suits for malpractice.

III. All members of the State Medical Association, and all future members on election, who wish to be members of this Defense Association shall pay an initiation fee of \$5, and yearly dues of \$1, to be collected by the Treasurer of the County Societies of the Kentucky State Medical Association, and forwarded by him to the Treasurer of this Defense Association.

IV. The officers of this Association shall be a Chairman, a Secretary-Treasurer and four other members (one of whom shall be the President of the State Medical Association) together forming an executive committee, and they shall have general charge of its affairs, who shall report at the yearly meeting of the State Association to the House of Delegates. The members of said committee shall be elected by the House of Delegates for ten years, except of those first appointed one shall serve ten years and one shall serve eight years and one shall serve six years and one shall serve four years and one shall serve two years.

V. The assistance in defense as herein provided shall be only of such members of the Kentucky State Medical Association as are in good standing, and who shall have paid the initiation fee and the yearly dues for this

special purpose. Neglect to pay the dues at the proper time shall forfeit all claim on this Association for any protection which it can afford and from membership in this Association. No doctor shall be defended for any action unless he was a member of the Protective Association and a resident of Kentucky during the time when the alleged malpractice was committed, and shall comply with the regulations herein and hereafter lawfully made.

VI. It shall be the duty of any member of this Association threatened with suit for malpractice to immediately notify the President of the County Society, who shall at once send him an application blank for names of witnesses, etc., and on receipt of this blank, properly filled in, the President shall immediately call his county committee and investigate.

VII. The President of the County Society in which the defendant resides, the Councilor of the Kentucky State Medical Association from the district, and a doctor (who must be a member of the Protective Association), chosen by the defendant, shall form a County Committee which shall investigate all cases of alleged malpractice. If for any reason the President or Councilor cannot act, the Secretary and Senior Delegate of the County Society shall act in his or their place in order. This committee shall examine the defendant and his witnesses, if necessary, under oath. If this committee agree that it is a case to be defended, it shall so report to the Chairman of the Defense Association, who shall immediately so notify the Executive Committee of this Association. If this County Committee should decide it is not a case to be defended, the defendant doctor can appeal to the Executive Committee of the Medical Protective Association of the Kentucky State Medical Association, and it shall in all cases have the final decision whether the case is to be defended or not. The findings of these committees, if unfavorable, are to be communicated to the defendant alone.

VIII. The only liability of the Medical Protective Association will be for the fee of the consultant lawyer which they have chosen, a reasonable fixed fee to be agreed to in advance of the local lawyer selected by the doctor, and the legally taxed court costs—all other expenses of the case to be borne by the defendant. Provided, however, that if the income of the Association for any one year has been exhausted by or appropriated for contracts, in defense of members, the Association shall have the right of apportioning dues to the expense of defense to be borne by it upon all cases subsequently arising until such dues shall again be sufficient to pay as before indicated; and, provided further, that

no officer or member of this Association shall be responsible individually for the whole or any part, or for any assessment upon any of the obligations which this Association, or its officers for it, are hereby authorized to assume.

IX. It shall be the duty of every member of this Association to aid the Association in every legitimate manner.

X. It shall be the duty of the Executive Committee to follow the case through any and all courts until a correct judgment be obtained, if in the opinion of the Council such a course should be judicious. *In no case will the Association compromise.*

XI. The Executive Committee may amend or change the rules and regulations during the year, but subject to revision by the House of Delegates at the next annual meeting of the Kentucky State Medical Association.

## SCIENTIFIC EDITORIALS.

### INFECTIONS OF THE BILIARY TRACT.

The attitude of the general profession toward the diseases of the biliary tract to-day has been compared, and not inaptly, to its attitude toward appendicitis some years ago. While at that time they insisted upon being able to demonstrate a certain group of so-called characteristic symptoms, which they to-day no longer regard as necessary to a diagnosis of appendicitis, so they to-day insist upon a symptom complex of given nature as essential to a diagnosis of "gall-stones," and which practice, in the light of modern knowledge, should be relegated to the past. The enormous amount of operative work done in recent years upon the biliary tract has shed such light upon the nature of the varied pathological changes found there, that we find the opinion of the surgical profession of to-day well expressed by Deaver, who says: "There is no doubt that cholelithiasis, cholecystitis, and all their results, near and remote, should be really classed as consequences of infection. The infection may not always be demonstrable in its results, the causative factor not always to be found when the damage has been done, yet in my opinion the inflammatory factor is the important one in all but the malignant diseases of the biliary tract." Nancrede in a recent article states his belief "that cholecystitis is an infective process which precedes the formation of calculi and that either with or without stone formation this disease of the gall-bladder implies certain potential dangers." Practically all workers in the surgery of the bile tract and laboratory investigators are agreed that stone formation is directly due to an infective

cholecystitis; the infection giving rise to calculi is mild in character, evidently caused by germs of attenuated virulence, while the suppurative, gangrenous, phlegmonous and perforating types of cholecystitis depend upon infection with active and virulent germs. Should virulent infective germs reach a chronically diseased gall bladder containing stones, suppuration, gangrene, and perforation with all of their possible consequences may rapidly result. The bacteria usually enter by way of the portal circulation, the common duct, and the systemic circulation; the germs usually encountered are the colon bacillus, the pyogenic cocci, and the typhoid bacilli. It is interesting to note that 28% of Deaver's cases gave a history of typhoid fever previous to the development of symptoms of cholelithiasis and in some of these cases the typhoid bacillus was obtained in pure culture from the gall-bladder and ducts years after the attack of fever, in one instance forty-one years after the attack. Nancrede also mentions instances where, seventeen and twenty years respectively, after the occurrence of the acute attack, typhoid bacilli were obtained in pure culture from the ducts and gall-bladder. They have been repeatedly found in the calculi themselves. Astley Paston Cooper Ashhurst recently reported two perforations of the gall bladder occurring in the course of typhoid fever with an analysis of twenty-one operations on the gall-bladder during typhoid fever due to a direct infection with the typhoid bacillus. These cases showed various stages of the inflammatory process, but were mostly of the suppurative and gangrenous types. As soon as we grasp the idea that all gall-bladder disease with the exception of malignancy depends upon varying types of inflammation, i. e., infection, and that gall-stones are not causative factors except in a mechanical way, but results of disease, we will begin to direct our efforts intelligently and logically to the recognition of a disease early in its course, before pericholecystitic, subhepatic collections of pus, crippling intestinal adhesions, or gastric dilatation due to involvement of the pylorus or duodenum in adhesions have placed beyond our control some of its results. We will recognize that if we wait for the classical symptoms of colic and jaundice we will overlook by far the majority of our cases; and further that the appearance of these symptoms does not always signify the presence of stones as has long been believed. The inflammatory process, if at all acute, will give rise to colic, and when not acute, the passage of plugs of mucus through the duct will occasion pain; the presence of jaundice, with or without chills and fever, may mean obstruction of duct or ducts with calculi, but most usu-

ally is an expression of the result of an infective cholangitis. The symptomatology of our text-books will have to be rewritten, based upon the pathological findings which an ever increasing operative experience has brought to light.

IRVIN ABELL.

### THE PATHOLOGY AND TREATMENT OF ALCOHOLIC DELIRIUM.

So much has been written by careless clinicians, and enthusiastic reformers on the effects of alcohol, that their opinions, correct though they were in the main, long obscured our exact knowledge of the subject; but in the past few years there has been such an accumulation of facts from the laboratory and autopsy room, that we are now as well informed in regard to the pathology of alcohol poisoning, as we are of that of almost any other disease condition. Lambert states that large doses of alcohol gradually lower the reflex excitability of the vaso-constrictor centers, dilating the capillaries and arteries of the splanchnic and peripheral areas, lowering the blood pressure, and acting directly on the heart muscle as a powerful depressant, weakening first the auricular and then the ventricular systole, causing more or less distension of both cavities, and gradual diminution in the output of blood. In large doses it paralyzes control of both the vessels and heart muscle. The sensation of warmth after the ingestion of alcohol, is due to the increased radiation of heat from the body through the dilated capillaries of the skin. The temperature of the body is thus lowered from one to three degrees F., while Shafer has reported temperature of 72.2, 76.4, 82.2, and 86 F. in drunkards exposed to cold, in all of which cases recovery occurred. In its effect on the brain, Schmiedeberg and Bunge hold that the apparent stimulation is a paralysis of the higher functions, and that alcohol depresses from the beginning. Kraepelin has shown that small doses diminish the ability and accuracy to add numbers and to memorize.

It is also noticeable that the tendency to erroneous judgment is increased. The subjects experimented upon believing that they had performed their reactions better under alcohol, when, as a matter of fact, the reactions were diminished in accuracy and rapidity. All the viscera are affected by chronic alcoholism, but in studying the lesions from it, one is struck by their great variations in intensity in the various organs of different individuals. In 125 autopsies on alcoholics at Bellevue Hospital, the liver was found to be diseased in every case. The enlarged cirrhotic liver being the most frequent. Chronic congestion and fibrosis are common in the spleen and pancreas, and the kidneys are practically

always diseased, chronic parenchymatous nephritis being first, and chronic interstitial nephritis second in point of frequency. In the heart, fatty degeneration is the most frequent lesion. The use of alcohol has a surprisingly slight effect upon the digestibility of food, but does produce acute and chronic gastritis in a vast majority of drinkers, thus destroying the digestive power of the stomach. As Lambert says, it has long been recognized that alcohol has a special affinity for the higher nerve centers. The lesions in the central nervous system seem to be brought about either from the degeneration of the cerebral arteries or from the direct action of alcohol on the nerve cells. In examination of given brains, it is often difficult, or even impossible to differentiate how much the changes are due to one or the other of these causes. But Berkley, who has probably done more original work on this point than any other American investigator, sums up a series of careful experiments on rabbits poisoned by ethyl alcohol in the proportion of their body weights that the usual amounts would be for man, in these words, "It was however in the muscular protoplasm of the arterial walls that the lesions were most marked, and there were indubitable indications that the cells were undergoing a retrogressive process. In the capillaries, as well as in the intermediary vessels, changes similar to those of the larger arteries were demonstrable." The cells showed the same departures from the normal in staining, and here and there in the lumen were plugs of white corpuscles, which, from their closely packed appearance must have entirely stopped the circulation of the blood in the vessels before death. The changes in the coats of the veins were similar to those seen in the arteries, but here aggregations of dying polynuclear leucocytes were more frequent, and were by far the most striking feature, both of their contents and of their surroundings. So vast were the collections in the perivascular spaces, that in some few cases the whole channel was filled, while backward pressure from the plugs, and compression of the vessels from the outside, had obtained to such a degree that in a number of instances the walls of the vein had ruptured." He goes on to describe a destruction of the leucocytes in and about the peri-vascular spaces, and concludes that these vascular and cellular degenerations give rise to those of the nerve elements and neuroglia which are also found. Oedema and congestions of the membranes are usually present, especially the former, and this ordinarily extends into the cerebral tissue itself. Microscopical examination of the cerebral tissues shows an intense degree of atheromatous degeneration of the minute vessels; of the cortex especially. The

changes found in the spinal cord are similar to those described of the cerebral tissues.

These findings have been further elaborated by various experimenters, notably Crittenden, and from the pathology we are acquiring a fund of medico-legal data of much practical value.

Accepting this newer pathology of alcohol, it is inevitable that we conclude that even the small and occasional use of alcohol produces permanent changes in cellular structures, particularly that of the nerves, and that the treatment of alcoholic insanity must be directed against lessened renal function, hepatic congestion, and beginning capillary inflammation, in addition to the special weaknesses of the particular patient. To this end the largest, yet most neglected gland of the human economy—the skin—should be stimulated by hot baths, massage, and vibration, to help take the strain off the over-burdened kidneys, to allay the irritation of poisoned nerve ends, and to equalize the disordered circulation. At the same time remembering that lowered nutrition, and vitality, with an auto-intoxication, due to both suspended functions and ingested poison, makes it an imperative duty to give large amounts of food, and without delay, while clearing the intestinal tract, stimulating the liver, and protecting the patient from overexertion.

Treated in this manner, cases of delirium tremens are shortened, and should recover in all instances where there are no organic complications.

GEO. P. SPRAGUE.

#### CEREBRO-SPINAL MENINGITIS.

The recent epidemic of cerebro-spinal meningitis which has been reported at Berea, naturally excites the fears and arouses the interest of physicians throughout the State.

*The Journal of Experimental Medicine*, for January, 1908, records the experiences and results of the serum treatment of this dreaded disease. In view of the possible incidence of this trouble in other sections of our State, it is of interest to record the results of the serum treatment of this dreaded disease, all other forms of treatment having proved so unreliable and so unsatisfactory. This method affords us at least some prospect of giving assistance to our patients and awakens our hopes for the future.

The serum is introduced into the cerebro-spinal canal, usually after the removal of a certain amount of the spinal fluid.

"The quantity of antiserum to be used at a single injection should not exceed, for the present, 30 cubic centimeters. It is desirable, although it would not appear to be essential, to withdraw from the spinal canal at least as much of the fluid as the amount of anti-

serum to be injected. The injection should be made slowly and carefully to avoid the production of symptoms due to increased pressure. This precaution should be exercised especially where the quantity of cerebro-spinal fluid withdrawn is less than the amount of antiserum to be injected.

"The injection of the antiserum should be repeated every twenty-four hours for three or four days or longer. Whether any advantage will be gained by more frequent or more numerous injections than here indicated, a wider experience must decide. As much as 120 cubic centimeters of the antiserum have been injected into the spinal canal in four days without causing unpleasant symptoms.

"The evidence at hand indicates that the earlier in the course of the disease the injections are made the better the results. Hence should the film preparation prepared from the first fluid obtained by spinal puncture show Gram-negative diplococci, some of which are within leucocytes, an injection of the antiserum should be made immediately and without waiting for the result of culture tests. Should the diagnosis be left in doubt or the disease prove later to be of another nature than epidemic meningitis, no harm will have been done by the injection of the antiserum.

"Although the best results have thus far been obtained where the antiserum has been injected early in the disease, yet the serum should be used in its later stages also, until our knowledge governing the value of the serum becomes more precise. The indications at present are that it is useless to employ the serum in the very late stages of the disease in which chronic hydrocephalus is already developed."

"In view of certain theoretical objections to the employment as curative agents of antisera developed for a microorganism whose toxic action is caused by endotoxin, Flexner dwelt on the encouraging circumstance that in epidemic meningitis the main pathological lesions can be brought directly under the influence of the antiserum by injecting the latter into the spinal canal; and he pointed out that while it is undoubtedly important to secure neutralization of the endotoxin yielded by the diplococcus on disintegration, the effect of restraint of growth and multiplication of the diplococcus may, at some period of the disease, be of even greater significance. There is experimental evidence for the view that the antiserum possesses a certain antitoxic value since it can neutralize the toxic substances contained in autolysates of the diplococcus. But its power to bring about rapid suppression of the diplococcus in infected guinea pigs and monkeys is considerable. In monkeys which have been injected with mixtures

of emulsions of the diplococcus and immune serum simultaneously, or first with the emulsion and next with the immune serum, the diplococcus is caused rapidly to diminish in numbers and to be more abundantly taken up by leucocytes. Since the facts at hand do not warrant us in concluding that any considerable multiplication of the diplococcus takes place in the experimental infections, the power of protection of the antiserum would appear to be dependent upon the restraint which it exercises over all multiplication and the increased tempo of phagocytic inclusion of the diplococcus which it brings about. It is probable that phagocytic digestion not only prevents further multiplication of the diplococcus but also that it detoxicates the endotoxin by reducing it to simpler and non-toxic or less toxic compounds. Still, in a few instances, in which the antiserum was injected into the spinal canal of monkeys infected with the diplococcus, the microorganisms disappeared without marked phagocytosis and more slowly than in the cases in which outpouring of leucocytes was considerable. The control of the pathological conditions in these instances appeared to depend less upon the phagocytes than upon the spinal fluid reinforced by the antiserum; and as the symptoms of intoxication were less than would have been present had the antiserum not been injected, a degree of antitoxic power must be ascribed to the antiserum."

The record of the results of treatment show that of 47 cases of epidemic meningitis treated with the antiserum, 34 recovered and 14 died, the percentage being 72.3, which was far lower than the percentage of deaths in the cases which were not treated with the antiserum.

It is also worthy of note that the cases which recovered under the use of the antiserum made perfect recoveries, except in one instance where there was some impairment of hearing. The question as to whether the injection of the antiserum subcutaneously would be of as great benefit as when injected within the spinal column has yet not been decided.

The probability is that the intradural injections by bringing the antiserum directly into contact with the infection will prove far the more reliable method of treatment. The serum exerts its influence apparently upon the bacteria and upon the acute inflammatory condition by reason of its effect upon the bacteria. It is not claimed that the serum will be of any advantage in the relief of obstructive lesions of the membranes the result of inflammatory processes.

"The dose of the serum employed thus far rests on an empirical basis. Whether the larger doses which have been used latterly are more efficient than the smaller ones used

at first, can be determined only by a wider experience than we have yet had. In test tube experiments degree of concentration of serum plays an important part in determining injury and disintegration of the diplococcus, since a high concentration of the serum is more effective than a low one. But the mechanism of test-tube bacteriologists and of intradural bactericidal effect may be and doubtless are widely different. Our knowledge of the manner of *intra vitam* disposal of the diplococcus after serum injection is very defective; but an important factor is doubtless the intracellular, phagocytic digestion for which we have evidence derived from the microscopical examination of the cerebrospinal exudate. While in active stages of the infection the intracellular diplococci present sharp outlines and appear vigorous, and the extracellular microorganisms are well preserved, after the serum injection the diplococci within the cells have lost sharpness of outline, stain indifferently, and strike one as degenerated, and those without cells are much reduced in numbers and staining power. Possibly it is this active and apparently accelerated intracellular digestion which prevents an increase in toxic effects following the serum injections such as might otherwise occur from the more rapidly liberated endotoxin. That the antiserum possesses certain direct antitoxic properties, which also tend to diminish the dangers of endotoxin-intoxication, would seem to be indicated by its power to neutralize *intra vitam* the toxic effects of an autolysate of the diplococcus."

The method of preparation of the Flexner antiserum is complicated and for the average physician too technical for practical value. That it is a wonderful advance in our treatment, even if not a specific for this dreaded disease, will be conceded.

PHILIP F. BARBOUR.

### NIHILISM AND DRUGS.\*

By A. JACOBI, M. D., LL. D., NEW YORK.

The mutations of therapeutical principles, or theories, or notions which have taken place in the course of consecutive centuries, mostly in their connections with mere empiricism, or gradually developing chemistry or philosophical systems, are so numerous as to preclude their consideration, except in a voluminous historical study. To-day, however, it is my object to claim your attention—important to men both scientific and practical—to the question of the value or uselessness

\*Address delivered before the Medical Society of the State of New York, January 28, 1908. Reprinted by permission from the New York State Journal of Medicine.

of drugs in the treatment of the sick.

In our own time it has been answered in contradictory ways, both by flippant arrogance and by men of honorable ambitions and great genius. The practitioner, relying on the consciousness of his purposes and guided by the necessities of his patient as well as by the confidence he places in the judgment of those in positions to experiment and to discriminate, and to teach, should not be blamed when now and then he wavers in his convictions and mistrusts his own observations.

On the foundation of the French school of pathological anatomy, the Vienna school of medicine was established about seventy years ago. Its main creators were Rokitsky, who claimed that pathological anatomy was the essence and sum total of medicine, and Joseph Skoda, who cared for the physical diagnosis of an organic anomaly but not for the patient. It was all care—such as it was—but no cure was seriously tried. Thus, in Vienna, the ideal patient was he who was satisfied with being auscultated and percussed by Skoda and autopsied by Rokitsky.

The callously scientific atmosphere of Vienna spread far and wide. In Craeow, Dietl, the professor of medicine, proclaimed as late as 1851, his and many leading men's convictions in the following words:

"Our practical work does not compare with the amount of our knowledge. Our ancestors laid much stress upon their success in the treatment of the sick; we, however, on the results of our investigations. Our tendency is purely scientific. The physician should be judged by the extent of his knowledge and not by the extent of his cures. It is the investigator, not the healer, that is to be appreciated in the physician. As long as medicine is art it will not be science. As long as there are successful physicians, so long are there no scientific physicians. Our power is in knowledge, not in deeds."

In the first years of his glorious and honorable career even Wunderlich shared these opinions, but in the first years only; while about the same time Oppolzer, as modest as he was—and is—famous, and as humane as learned, judged the doctor, according to the good he would do the sick through his knowledge and endeavors.

Under the influence of the icy atmosphere of Vienna science, Oliver Wendell Holmes said (1860), in his *Currents and Counter-currents*: "Throw out opium and a few specifics which our art did not discover and is hardly needed to apply, throw out wine which is a food, and the vapors which produce the miracle of anesthesia, and I firmly believe that if the whole materia medica,

as now used, could be sunk in the bottom of the sea, it would be better for mankind and all the worse for the fishes." This facetious outbreak of the great humorist, who was a popular teacher of anatomy and a studious observer of the contagiousness of puerperal fever as early as 1843—before Semmelweis laid the foundation of his immortality—but was no pharmacologist and no practitioner of medicine, has been quoted numberless times by men who thus believed they ranked with Holmes while imitating or adopting the grave mistakes of his scurrilous and sarcastic mood, and with Astley Cooper, who is quoted by Holmes on account of his remark that more harm than good is done by medication. If he be correct—let us assume it for the sake of argument—the only and simple thing to be done by him and by me, and by you, is to omit the harm and do all the good we can, and are expected to do, both by medication and otherwise.

After all, however, we meet with succour from our friend the adversary. With all the inconsistency of a poet's flights of imagination and instability of impressions, Holmes expresses himself as follows:

"It is not of the slightest interest to the patient to know whether three or three and a quarter cubic inches of his lungs are hepaticized. His mind is not occupied with thinking of the curious problems which are to be solved by his own autopsy—whether this or that strand of the spinal marrow is the seat of this or that form of degeneration. He wants something to relieve his pain, to mitigate his anguish or dyspnea, to bring back the motion and sensibility to the dead limb." You notice the poet takes wings and descends from his Olympian clouds to the earth inhabited by men and women and children, oppressed by human sufferings and looking for humane relief.

Dietl spoke in 1851, Holmes in 1860. The year 1907 brought us disquieting tidings from one of our brilliant, erudite, honorable and—alas—poetical clinicians, whom we shall always be proud of claiming as one of us, as an American. William Osler is charged by the telegraph and by the magazines with having said in an official address to London students:

"Be sceptical of the pharmacopoeia."

"He is the best doctor who knows the worthlessness of most medicines."

"Study your fellow men and fellow-women, and learn to manage them."

Within a day that message flew along the wires of the globe. Millions of practitioners were pained; people were startled.

The *Evening Post*, a lay journal, said of this array of categorical imperatives as follows: "Here we have three trump cards

placed squarely in the hands of the Barefoot, Sunshine, Barley-water, and other curists, the New-Thought health-givers, and the sufferers from various forms of religious mania." Dr. Osler probably used "sceptical" in its original sense of "examine and test," but we are pretty certain to have the dictum popularly translated—"the pharmacopoeia is a fake"; the "worthlessness of most medicines," will become "medicine is worthless," and "learn to manage men and women" will become the motto of the Pepper-Vanderbilt school. Besides, the Evening Post says: "Doctor Osler seems bent upon becoming the terrible infant of the profession."

We owe much knowledge and inspiration to his writings. Both by merit and accident he has reached a platform of his own where every word of his is greedily caught up by hosts of reporters and repeated by legions of pupils. Such a man should beware of any incautious expression which, having once passed over his lips, he may wish to recall but cannot. Nevertheless, however, he—unconscious of the intellectual havoc he has caused—turns to other audiences talking both fun and wisdom, and distributing earnest words and kindly smiles without being aware of having given recognition and food to the lazy and hypocritical. Imitators and followers he has in all classes—deservedly so. That is why I wish to clear him of a blame he merits as little as the obloquy he was exposed to a few years ago at the hands of a sensational reporter and a credulous public. Those who read his book are aware of the extent—large or otherwise—of his therapeutics.

We have always been anxious to secure to every individual practitioner the right to treat his patient according to his knowledge and conscience. That is appropriate in the case of the lowest of us, and must be conceded to those who walk on the summits, even though they reach the clouds.

What I read in his crisp sentences is this:

1. Be critical of the Pharmacopoeia as of everything else.
2. He is the best doctor who knows the worth and the worthlessness of medicines.
3. Study your fellow-men and fellow-women, and learn to serve them. "Therapy" means service.

I wish he had said that.

It has become popular to traduce the administration of drugs by calling it polypharmacy. Webster and Dorland define this word as "the administration of too many drugs together, or of too much medicine." The adverb "too" begs the question, so that the man who uses it against you should have no standing in court.

Even a very erudite and at the same time

practical man—I mean one of us, Dr. Gilman Thompson—makes the mistake of emphasizing self-evident things, and charging us with methods nobody must plead guilty of. In a late paper on "The Treatment of Pneumonia," he summarizes as follows: 1. "Good nursing and the exercise of constant watchfulness should outweigh polypharmacy and specifics." (2) "Do not crowd an overloaded heart with *too much* stimulation, and base the selection of the proper variety of cardiac stimulants on the existing balance between the conditions of vascular tone and the effort the heart is already making." (3) "Expectorants are useless, *as a rule*." (4) "Prescribe proper intervals of rest in which the patient is free from incessant efforts at medication."

This means, what? Do not wake a patient from a healthy sleep; do not insist upon too frequent examinations; do not be guided by the clock, but by your brains; do not be seduced by the excesses of a dosimetric quarter-hour medication theory, simply because it is absurd, and do not exhaust your patient. You always knew, that unless you give him the temporary rest required for restoration, you prepare him for the eternal rest. No rule will teach common sense to a doctor who has not learned enough to know he is no doctor and who should have become an undertaker. The word polypharmacy contains a reproach to which nobody will submit.

Even good journals like the *Boston Medical and Surgical* (vol. 155, p. 101) produce such commonplaces as these: "a healthy scepticism should take the place of excessive faith;" "medical practice is not confined to the administration of drugs;" "compound prescriptions are rarely desirable." The unsophisticated are easily impressed by such dicta, which are either unmeaning or self-evident. The inexperienced and lazy should rather be admonished to learn how to find indications and how to write a compound prescription when it is demanded, after his college has, like some others, neglected its duty to teach him. He should know the indications for the selection of drugs, as he is expected to know the rules for ordering diet, water, electricity, heat, cold, and massage—aye, even the placebos of consolation and hope. Surely I prefer them to the prediction of an imminent fatal termination, according to the dictates of our aggressively brilliant Richard (Cabot) the Lion-hearted, of a neighboring state. Unless the practitioner knows and does all that, he drives his patients to the manufacturers, the proprietary medicine vendor, the Christian scientist, and the rest of the quacks.

By the purists, among us, who are seldom practitioners, mostly philosophising platform reformers, polypharmacy is called even the

prescribing of more than one medicine at the same time. It is claimed by many as a principle that there must be only one drug in a prescription. One of the alleged reasons is that if there be two or three there may be incompatibility. I beg to suggest that drugs, when incompatible, should not be mixed; chemical decomposition must be avoided, and the practitioner should know—and mostly does know—how to take care of that patient of his. In most cases it is easy enough; in some it is not even necessary to be absolutely strict, for you know that, in spite of your schoolbook chemistry, morphine and lead, and morphine and gallic acid when mixed are still active. There is no ground for the pedantic demand that two medicines with similar action should not be prescribed together. Even though all your pharmacists were of perfect knowledge and accuracy, on the shelves of the very best of them drugs are liable to lose their efficacy. There is no digitalis, which though gathered in July and in England, and kept in an airtight vessel, will not deteriorate from month to month. That is why I recommend and frequently practice the combination of such drugs as tincture of digitalis, of strophanthus, and of adonis, or the solid extract of digitalis and of spartein sulphate, or of caffeine, on account of either their equal or similar effect. . . . What is your mixed treatment of mercury and iodides if not a transgression of the one drug rule—not found at the bedside but concocted on a classroom platform. They tell you that by mixing medicines you are liable to cloud your observation. Your observation on the several constituents of a mixture must be made before you approach your individual patient whom you are called to benefit. That is what the conscientious physician has been doing in his lifelong work. He claims no right to experiment on his patient or on any other human being.

There are three great classes of medical men—those whose domain it is to work in the pharmacological laboratory; those whose opportunity for rational experimentation is at the hospital bedside; and those more numerous and still more directly and practically useful than any of the rest. It is they who are to be the preservers of families, the saviors of individual lives, of trusting sufferers. Indeed, you will yet occasionally meet laboratory searchers who know and admit that the cream of the medical profession is the army of hardworking and conscientious general practitioners, and that the statesmen in the profession are found in the ranks of the general clinician.

You have been told that the one drug rule cannot be contested; surely not when you deal with a specific disease. A malaria fever must

not be treated with a plurality of medicines. Is not quinine its specific? Surely it is in most cases. But if you strike a case that is *not* simple, but of the cachectic type, complicated with anemia, with swelled spleen? with obstinate constipation? with chronic myocarditis? with valvular disease? those that come from Jersey, from South Brooklyn, from Russian Poland, from the shores of the Theiss? or those that exhibited all the traces of cachexia without ever a chill until the first big dose of quinine was administered. Does the one drug gospel object to giving arsenic with your quinine? or, when in old cases of neglected infection with enlarged spleens quinine and arsenic are not successful, to adding or temporarily substituting ergot?

These fifty years, taught by Dr. Francis Simrock, an assistant in the emigrant hospital at Ward's Island, I have thus utilized ergot in seemingly incurable cases. Or when you give quinine or arsenic, or both, and meet with a low hemoglobin percentage, will you dare to withhold iron? or a vegetable purgative in obstinate constipation? or digitalis in a complicating valvular disease? or caffeine or theobromin, as the case may be, in myocardial incompetency? Remember you treat no disease nor a Greek name, but a diseased man or woman.

There are those who dislike a prescription blank filled with three or four remedies, but there are also those who dislike the looks of a patient whose many ailments should not have to wait for the gradual and slowly conservative administration of drugs that could as well act simultaneously and conjointly, and better when conjointly. Indeed, when you treat adults they have, as a rule, more than one disease. It is infants and children only that yield a single uncomplicated diagnosis. The disease of an adult has a long anamnesis and the residue of previous illnesses. By insisting upon giving a single remedy, you may cure for and cure the last affection, and let your patient slip away from you under expectant treatment.

Only one drug! Are you also required to restrict physical treatment to one method? When you treat with a medicine anemia or feeble circulation? or constipation with cold water, or hot bathing, or massage, or electricity, will you *prescribe* one, a single one, and *proscribe* the rest? And indeed, when you mean to feed a man on 3,000 calories, you might just as well order a uniform single food, merely because it contains proteid and carbohydrates enough to suit your prejudiced pedantry. You know and do better; you change off and mix, you also know that the one drug demand is not a wise but a wisacre rule.

In connection with malaria I used the term "expectant treatment." Expectant treatment is called the method of waiting for urgent indications. It finds its justification or explanation in the fact that deaths are not frequent when compared with diseases. Indeed there is a death in 35 cases of illness, contrary to the syllabus of Dr. Sam. H. Dickson, of 1845, which teaches that the tendency of all disease is to death. Another alleged reason is the self-limitation of diseases, which in our country has been the teaching of Bigelow (1860). The same Bigelow, however, demands careful treatment as the first duty of the practitioner. He knew that a scarlet fever may last six weeks and run its self-limited course, but he knew also that death may step in at any period unless prevented by active treatment. A typhoid may run its three or its six weeks, perhaps no more; but a typhoid supinely left to itself may prove fatal from many causes. A whooping cough limits itself in three or five months, but it limits not only itself—it may also limit the child unless it be relieved as soon as possible by medication, the best of which is still—as it was fifty years ago—belladonna in ample doses. For every week's duration that could have been avoided is an opportunity for broncho-pneumonia, or a hemorrhage, or a convulsion. One child whose hourly convulsions I combated by chloroform for three successive days thirty years ago, is still alive with an unimpaired brain, waiting for his unknown death certificate at some future day. Let him wait; I don't care.

Expectant treatment is best elucidated in some of its phases by a few cases.

I saw a baby lately. She was ten months old, had a fairly normal intellect, two teeth, good bones and muscles, but the contractions of a spastic encephalitis. Her doctor had her examined by two of our justly famous physicians, so-called specialists. Treatment? "Let me see her again in six months." We stopped this expectant treatment. She was presented again after a regular iodide administration, and systematic bathing, and passive movements and scientific massage—markedly improved within six weeks.

A baby of six months was presented with his 15 pounds in weight, pale skin and conjunctivæ, flabby muscle, constipation, soft fat, placid though languid appearance, no trace of teeth, and low hemoglobin percentage. Treatment—expectant. I was told that the doctor had said all would be well after the teeth would come out. Expectant treatment is too often a compound of indolence and ignorance. The latter is exhibited in not knowing that the accumulated iron of the newly-born baby's blood decreases from month to month, that milk contains very little of it at

best, and that a human mother's milk may be more frequently defective than that of a less impressible animal. Actual treatment: add cereals and a daily dose of beef broth to the milk, the doses of which were reduced. Open windows by day and by night. A daily warm bath with lively friction to stimulate the cutaneous circulation and thereby the circulation in general, also drugs—strychnine  $\frac{1}{2}$  milligramme and iron 2 centigrammes daily. The actual treatment of a month proved superior to the persistent expectancy.

The waiting for the first teeth, procrastination until the seventh year, hope for changes about puberty, promise of improvement about the menopause—have you not met this expectant treatment, with all its pusillanimity and neglect? The underweight child of four or six years is not treated for his latent tuberculosis or his dormant syphilis; the girl with undersized heart and small arteries is permitted to glide into an incurable chlorosis, the woman of forty to totter along with her pernicious anemia and flabby myocardium. Expectant treatment! Verily, I tell you, it is malpractice, which should be punished on account of neglecting what nature and sound therapeutics furnish—the use of cold water and fresh air, and selected food—the cheapest is mostly the most effective—and cod liver oil, iodine, mercury, arsenic and strychnine. Expectant treatment is no treatment. It is the sin of omission, which not infrequently rises to the dignity of a crime. A woman of 46 years presented herself exactly four days ago. She had been under the care of her doctor these six weeks, and had taken medicine all the time. He boasted the medicines were mild, but had the great courage to tell her that if she did not become well soon he would make an examination of herself and her urine next week. The urine had not been examined. It consisted to a large degree of pus, rather fetid, with many renal epithelia. The abdomen, which she had complained of, had not been examined. She had a big tumor, a renal abscess of the size of a child's head. She has since taken her iron in the shape of a surgeon's knife, and is no longer under expectant maltreatment.

You may ask me why I refer to this case of criminal neglect. Firstly, because its like is frequent; secondly, because it shows to what extent—by false teaching, by the mere doctrine of the self-healing of disease and of the frequent incompetency of ill-selected medicines—the average man may be rendered callous, both in mind and in morals.

A few days ago there came a man of 39 years. Double heart murmur without increased impulse; murmur, posteriorly, faint only. No increase of size of the heart, but a liver reaching down to within 2 cm. above the um-

bilical level. You recognize in the last two symptoms a few characteristics of chronic myocarditis. Impossible to walk up a flight of stairs or three blocks on level ground. Expectant treatment! no medication, permission to drink his four cups of coffee and smoke four cigars a day. Actual treatment for the next month: rest in fresh air, a cold wash and brisk rubbing daily, no tobacco, no coffee, a mild saline purgative daily, trinitrin and codein in small doses. Probably I cannot change him into a Sampson, but I can render his life. Not without drugs, however, endurable and more useful. More expectant treatment: I need not say here that not every fever is beneficent through causing the formation of antibodies, and that an excess of bodily temperature is frequently a cause of dangerous disintegration of tissue—mainly of the heart—and in infants the origin of convulsions and of direct or indirect death. It is not necessary to teach here the indications or contra-indications of cold air, or of the administration of cold in ablutions, bathing or packs, or of warm bathing; none of them, however, is a panacea. In their place, or with them, a coal tar preparation—unless it be acetanilid, detestable, although it has been smuggled into the pharmacopoeia—with or without a cardiac stimulant, may be life-saving. Expectancy means loss of time and opportunity.

Expectant treatment in sepsis in general—in diphtheritic sepsis, in particular. Those of you who have seen it in bad epidemics remember its main features—the foul odor from nares and mouth, the colossal glandular swellings, bloody and serous nasal and pharyngeal discharges, erosions, petechiae or hemorrhages, unconsciousness or coma, and—unfortunately—no increase of temperature. You know that these are the cases that leave you and your antitoxin powerless, and the only possible salvation is in local antiseptics and energetic stimulation. They die, all of them, unless some are saved by a drug. That drug is alcohol. Bacilli and cocci and toxins do not engage in a playful game, they mean killing business. So you had better not play with your antidotes. No dose of alcohol—internal, subcutaneous, or rectal, administered intelligently, is too large. No dose will ever intoxicate, so long as the sepsis is not conquered by daily doses of five, ten, fifteen ounces of whiskey—properly diluted—given to a child of three or five years. Do not let up on whiskey before sepsis lets up on you. No matter how successful the most modern treatment with pyocyanase may prove in cases not reached by antitoxin, it appears that the alcohol treatment is still indispensable in the worst form of diphtheritic sepsis. For in his latest paper of November 5th

(*Munich Med. Woch.*), Rudolph Emmerich claims as one of the beneficial effects of pyocyanase—the result of bac. pyocyanus aureus—its power to reduce high temperatures. The saddest of diphtheritic forms, however, have a nearly normal or even decidedly sub-normal temperature.

Expectant treatment: A case of rheumatic polyarthritis—thousands of such cases all over the country. Your man had a number of such attacks, severe or slight, and more endocarditis with every one. Mount Clement is good for "rheumatism," so is Sharon or Richfield. Next summer you will go up and take treatment. Meanwhile what happens? the secondary cardiac enlargement and hypertrophy will grow, and anyhow there may be a new attack of rheumatism. Then my expectant doctor has a new job. When he is called or pays his visit a day or more have gone by and he prescribes salicylates. Maybe he knows salicylates as well as you and I, but he does not know what to do with it. Indeed, if two do the same thing, it is not always the same thing. When a patient has had rheumatic polyarthritis once, it will probably have him again. Such a patient must never be without his sodium salicylate on hand, ready to be taken without delay. He must take a few doses as soon as he feels the slightest sensitiveness in a joint, and stay in bed perhaps a single day only. That is the way to escape three or six weeks in bed and a new endocarditis; also to avoid the misuse of an honest drug—and the belief and its public expression in a poor innocent journal—not that you do not know how to employ a drug, but that the drug is useless.

How many cases of pneumonia have I lost in these fifty-four years? I might tell by counting death certificates. How many have I saved? You know I cannot tell, for I am not aware of how many would have got well without me; but when the feeble and arrhythmic pulse-beats rise in undue proportion to the number of respirations at an early date, you may feel sure the heart will give out before it is time for either crisis or lysis. Expectant treatment means neglect, and loses the game.

These endangered hearts demand help. Digitalis, strophanthus, spartein, camphor, caffeine, strychnine, ammonia, musk—they are required according to the indications, and by employing some of them, you may succeed in keeping your patient alive until he can get better.

Are there other things that may be required in a pneumonia? We are told often and by many that no opiates must be given. And why not, when sleeplessness and exhaustion are threatened by an incessant cough? A single dose of opium that provides a sleep of a

few hours may save the life of your patient and spare his doctor the self-reproach of expectant treatment permitted at an improper time. There are other cases in which drugs are positively life-saving—for instance: pneumonia of the second or third day, with vast infiltration, which exhibits cyanosis, beginning pulmonary edema, and dilation of the the right auricle and ventricle far beyond the right margin of the sternum. With or without a venesection you may save your patient by big doses of a drug. Apply ice, give a fluid extract of digitalis 10 to 12 minims in one dose, and repeat it once or twice within a few hours. Nihilism or drugs, you have your choice and your responsibility.

Great successes are not always dependent upon big doses. As small meals, well selected and repeated regularly, improve metabolism and nutrition, so small doses of digitalis continued indefinitely, strengthen the poorly innervated heart muscle, facilitate compensation in chronic valvular disease, improve, by its very effect on the arteries of the whole body, the heart muscle, and regulate visceral and universal circulation and nutrition. Small doses of digitalis, three to five grains every day, or their equivalents, may therefore be given in chronic anemia, chlorosis, and chronic tuberculosis—alone, or according to circumstances, with iron, arsenic, or nux. A treatment of that kind may be continued many months and years, uninterruptedly, without such cumulative effects as arrhythmia or vomiting. Its effect on the circulation in general is rather favorable on account of the improvement in gastric and hepatic circulation. They say we owe the knowledge of this beneficent method of employing digitalis in small and persistent doses, a few daily, to the Germans, like many other things which we are always glad to attribute to them. Indeed, it was Groedel who favored the method and mentioned it before the German Congress of Internal Medicine, in 1900. He was not at all applauded until one or two years afterwards Kussmaul and Naunyn reported a few favorable cases. Now it is called Groedel's method. It will reach America pretty soon. But after all it was not a product "made in Germany." If you want to learn all about it, both its theory and its application, and all the particulars, you will find them in the Transactions of the Medical Society of the State of New York, of 1884, in an article entitled, "Arsenic and Digitalis in Chronic Pulmonary Tuberculosis."

Which, as a general rule, are the doses of medicines? Nothing is easier than to be misguided. Minimum and maximum doses are forced upon you in text-books and pharmacopoeia with refreshing coolness. Hundreds of times I have been called up by a druggist

who informs me that he has been told the dose of spartein is one-quarter of a grain. I reply that may be the dose of the man who is to be drugged with a placebo, but that my patient requires his one-half or one grain dose six or eight times a day. The average dose of fluid extract of digitalis is set down as one minim; those cases which require ten may get well with ten, but surely die with one.

Dosage depends upon sex, age, body weight, the stage of sickness or convalescence, on high or low temperature, on the condition of the absorbing tissues on the locality of application, on the amount of blood circulating in the vessels, on the presence or absence of sepsis.

Age: The text-books tell us that a nursing must have a fifteenth or a twentieth of the dose of an adult in proportion to his body weight. I do not insist upon giving too large doses of drugs, but at least I do not gloat over big doses of expectancy. I try to give proper doses, for some instance, of corrosive sublimate in diphtheria and some other forms of sepsis. One thing I am sure of, as my experience in a thousand observed cases has taught me these thirty years—that a baby of six months will take from one-half to one milligramme of corrosive sublimate every hour, diluted in ten thousand times its quantity of water, and continue sixteen such doses daily for several days, and not be punished with stomatitis, gingivitis, gastritis, or enteritis. At that rate the baby will take one-fourth part of a grain of corrosive sublimate, or more, for several days in succession. The worst part of that practice is that now and then a man and brother will throw up his hands in horror. But I have met with horror, wonder, and acceptance successively, many times. Its best part is that it has helped me and many friends and pupils in curing many cases of diphtheria—particularly the laryngeal form.

Locality: A small dose of morphine administered under the skin just over a pleuritic or peritonitic pain acts much more quickly and effectively than the same dose in the arm. The latter locality is quite easy for a lazy doctor—I mean nurse—but for sound reasons an abomination to the patient. It acts five times more quickly and satisfactorily than when given internally, much better than in suppositories whose absorption depends on the condition of the rectum, filled with feces, beset with dysenteric or other ulcerations, or merely catarrhal. A soluble tablet of a tenth of a grain or a few drops of Magendie's solution, more or less, sucked down without water, are absorbed immediately in the pharynx, soothe racking attacks of cough; or when taken a few minutes before a meal, fa-

cilitates the gliding of food over an ulcerated tubercular throat, or prevents the vomiting of pregnancy.

During the first six weeks of his life the newly-born has an indolent nervous system. Its reflex actions are defective (Soltmann). That is why reflex convulsions recurring soon after birth are almost unheard of, while those depending on intracranial lesions and hemorrhages are very frequent; and why larger doses of strychnine are required for a spastic effect in the newly-born than later. Atropin, quinin, and nicotin are also required in comparatively large doses in the newly-born animal; and to the same extent opium. And still the books and essays that copy from each other, decade in and decade out, preach the prejudice that opium is incompatible with infancy. Nothing is a more untrue and curious statement. Opium is not to be a daily food, but in a majority of cases of enteritis a baby a year old may take one-thirtieth or one-fortieth of a grain every two hours. The relative dose given to an adult (15-20 times as much) would not be so well tolerated. We read of poison cases, it is true, but in fifty-four years of a New York practice I have not seen a single case of opium poisoning of my own making in ever so many thousands of cases of enteritis. Cases of death occur from carelessness or mistakes, very rarely from idiosyncrasy. Such occurrences there are, however. Once I sat up with a gigantic adult to whom I had given a single dose of five grains of iodide of potassium, nursing his pharyngeal and laryngeal edema. On the other hand, the same drug is given in daily doses of two drachms to a baby with tubercular meningitis, or the same or a double dose to a syphilitic adult.

As the dangers of opium in children's diseases are over-estimated, so the effect of belladonna is not obtained in daily practice on account of the smallness of the doses generally administered. Of the officinal extract of belladonna an adult may not take more than a grain daily without a dilatation of the pupils and dryness of the throat. A nightly dose of one-half of a grain, or a good deal more, however, is required and easily tolerated by a child of four years suffering from enuresis; and the effective dose in whooping cough of belladonna is measured by its flushing the cheek within half an hour, and not by any book.

The doses of strychnine are controlled by other nervous disturbances. When the splanchnic nerve is injured, or paralyzed by shock, the vast dilatation of the visceral blood vessels is controlled or obviated by large doses of strychnine only. In the paralysis of chronic poliomyelitis the internal administration of strychnine is useless; it will act

only in big doses and only when injected into a muscle once every day or two days.

The action of strychnine depends to a great extent on the condition of the blood, viz., anemia and sepsis. Experience teaches what experiments have demonstrated. The resistance of fishes to the action of curare was found (by Welker) to depend on the small quantity of their blood, which amounts to from 1-53d to 1-93d of their body weight; while in the child there is one weight of blood to nineteen, and in the adult one to thirteen parts of body weight. Ill fed, anemic, and septic persons, old or young, require big doses of strychnine, in accordance with experiments which prove that a depleted frog demands larger doses of strychnine than those not so depleted; and the depleted side of a frog more than the other side. It is mainly a slow convalescence in man, and thoroughly septic cases of scarlatina, diphtheria, typhoid and puerperal fever, that should be favored with large doses.

Why is it that the confidence in drugs may be easily shaken? Originally their effect was known empirically only. Thus even digitalis was removed from a place in the London Pharmacopoeia until Whithering restored it. The action of a deadly poison can be traced at the autopsy; that of a drug, either active or indifferent, is rarely amenable to that test. Moreover, a bad turn in a disease is readily ascribed to the drug; recovery, to the vigorous constitution of the patient. In the first case, the doctor was guilty; in the other, relieving the patient of his ailment and of his gratitude, he got no credit. Still, the drug is a chief reliance of the physician who moves among the people that have a right to expect to be cured or relieved, and for that end to be supplied with all the healing potencies furnished by nature. Many of them do not retain their reputation forever intact. New knowledge, new fashions, new experience, have altered our convictions regarding cold water, hot water, altitude, and electricity. On the other hand, scores of drugs, in spite of all the obloquy encountered by them, have preserved their standing. Purgatives, both saline and vegetable, exhibit their effects as of yore, and are credited with them. It is true our forefathers did not know indican, indol, and diacetic acid, and did not look proud, as we do when we spread ourselves with autointoxication and acidosis, but they knew and acted. *Qui bene purgat, bene curat.* Good purging is a good cure. Emetics also deal with us as with our ancient forefathers. We expect a full effect when we either take one or order one to be taken. We prefer the latter. The little girl who told the druggist she would return it if it did not work is still unique. Sulphur was known as

a disinfectant before Homer; Odysseus, when he had finished the crowd of would-be husbands of Penelope, told the old housekeeper to bring "purifying sulphur." Male fern has not lost its effect these 2,000 years. Aloe was extolled by Dioscorides and Pliny, podophyllum by the East Indians, rhubarb by the Arabs. Mercury was known to the pious crusaders, and we still bow to it. Poppy's fame has been sung in prose and verse; the glory of iodine, or of quinine, need not be told. The large number of alkaloids render drug treatment more positive and easier. The numerous cardiac and arterial stimulants, which I need not enumerate, and the artery dilators, which relieve the heart, the nitrites, iodides, and aconite have made us more sure of our footing, and our patients more comfortable and safer.

Antiseptic drugs, which have rendered surgical antiseptics and aseptics possible, and the anesthetics which cleared the sky of the wails of millions of human beings and aided the science of medicine and healing by rendering animals painless during experiments, demanded by the interests of mankind, have so fully accomplished their mission that they ceased to be a mere tale of wonderland. Well known old remedies have expanded their efficiency; for instance, Meltzer has demonstrated that the intraspinal injection of a sterile 25 per cent. solution of sulphate of magnesium—1 ccm. to 12 kilos body weight produces within 24 hours a paralysis and analgesia of the lower extremities and the pelvic region. The same amount for nine or ten kilos exhibits the same effect within one hour. In this way operations were made without any pain and tetanus was cured.

Sero- and organotherapy have not fulfilled all our expectations, simply because we expected too much, and in too brief a time. But diphtheria and tetanus, hydrophobia and plague tell wonderful stories of delighted mankind. Thyroid and adrenal substances belong to our surest aids. A case of acromegaly, now of nearly twenty years duration, has changed only imperceptibly these ten years since the woman, about 40 years old, took pituitary substance, with only a single increase of symptoms during half of the past year when she omitted the remedy.

A certain class of institutions has contributed much to the efficacy and the number of drugs. The German Universities, with their numerous pharmacological laboratories, the state institution presided over by Paul Ehrlich, of Frankfort, and the great manufactories of all countries, have contributed to our knowledge. Chloral hydrate, lanolin, cocaine, paraldehyde, sulphonal, veronal, trional antipyrin, phenacetin, pyramidon, etc., are the proofs after all that more good than harm

comes even from those places among us with which we have ample reason to find fault on account of the vast number of proprietary and quack medicines that swamp the market. But why offer rebuke there while the fault is ours? There are on this floor men good and true who are influenced by the wiles of drummers, by the outside elegance of their wares, by the alleged convenience of their administration, by the glowing praise bestowed on their action—to recommend them, aye, to prescribe them.

Some years ago Dr. Alfred Herzfeld of New York made it his business to look into this epidemic of quack medicine prescribing. He found amongst those of a prominent practitioner of the metropolis, "Remedium spontaneum Radway"—Radway's ready relief. He took the trouble to examine 50,000 prescriptions compounded in drug stores. Between 1850 and 1873 he met with no prescriptions of physicians that contained nostrums and machine-made tablets; in 1874, 1 in 1,500; between 1875 and 1880, 1 in 50; 1880-1890, 1 in 20; 1895, 12 per cent.; 1898, 15 per cent.; 1902-1903, from 20 to 25 per cent. Personally I have looked over the register of a large drug store in New York. Of 100 prescriptions of doctors in good standing, 70 contained nostrums from all countries.

It is interesting to perceive that Germany, the very land which raised nihilism into power, furnished, without losing its grip on scientific medicine, the vast majority of what is both good and evil in pharmacy and therapeutics, from a proprietary article which has proved life saving and epoch-making, like diphtheria antitoxin, to other patented compounds, which prove to be downright quackery. Nor is it the trade alone that indulges in distasteful commercial methods, but the medical profession also. In spite of its scientific ambition and achievements, the ethical standard of the German profession is low. Advertisements of themselves, of their specialties, of the manufacturers' wares, are commonly found in the columns of newspapers and the bulky medical magazines. What we meet with occasionally amongst us here, viz.: paid so-called original essays, laudatory of new chemical productions, seems to have been promoted into a system amongst our transatlantic brethren. Indeed it seems to take the democratic spirit and the civic pride of a democratic community to condemn it. After all, it appears Plutarch was right when he said, that though death kills everything, superstition will survive it.

I might go on at some length exhibiting a list of drugs that are meant to save, to relieve, to increase your patient's power of resistance, to prolong life and to make it bearable. While for instance, biologists here and

elsewhere try to discover the etiology of carcinoma as the foundation of a causal therapy, the knife has added to its many triumphs in curing it. Nor is the apparent helplessness of a great many inoperable cases left to its inevitable fate. Von Mosevig, of Vienna, and Willy Meyer, of New York, injected pyoktanin into the cancerous tissue; neither continued the treatment long. I caused great pain in the small number of cases in which I followed their methods since 1891 and 1893. In the year 1897 (*Journal of the A. M. A.*, June 26th), Dr. Henry R. Slack, of La Grange, Ga., published a few rather favorable cases. The torture, however, to which I exposed my patients made me change my procedure. Since 1892 I have given methylene blue—methylthionin hydro-chloride—internally in hundreds of cases of inoperable cancer with such fair results as I have discussed at the Boston meeting of the American Medical Association (*Journal of the A. M. A.*, Nov. 6, 1906).

Nor should I be silent in reference to the drug therapy of chronic tuberculosis. Nearly twenty years, since the late Dr. Schüller's first communication concerning guaiacol, have I employed it in at least 5,000 cases of tuberculosis. What I am getting more sure of from year to year, and have published repeatedly, is its reliability, no matter whether it is caused by its beneficent action on digestion, or what I prefer to believe, its direct influence on a probable toxin formed by the tubercle bacillus. While engaged in preaching with a thousand others the gospel of air, and water, and rest, and food, and sanitarium, I cannot withhold my constant exhortation that no private, and no sanitarium, and no hospital and dispensary treatment of chronic tuberculosis should be carried on without some preparation of guaiacol.

To prove the uselessness of drugs, they tell you that the older a doctor gets the less medicines he will give. There are, however, old doctors and old doctors. Old doctors have no right to be senile. As soon as they become senile they are doctors never more. Advancing years, should add to their diagnostic powers, to their success in finding proper indications, and to their knowledge of the action of drugs. Their own experience should be, and is supplemented and matured by that of their brethren, by the teaching of the laboratories, the clinical hospitals, the writings of their peers and betters. That is valid for the so-called old and the so-called young. For let no man rely solely on his own doings and findings. There are those both old and young who make the same mistakes year in and year out, and call it experience. Let the young and the old men beware. White hair and scores of years are not wisdom by them-

selves. It is certainly true that in our times, when the means of diagnosing have grown to a wonderful extent, a young man of 30 or 35, bright, open-eyed, erudite, with an appreciation of all that is new and a recognition of the value of what made our fathers—Sydenham, Boerhaave, Peter Frank, Trousseau, Watson, Clark, and Flint—great physicians should be a mature and experienced practitioner at the time when arterio-sclerosis makes its first gentle appearance. When you meet an old doctor who tells you that he gives no drug, or a young one who was born old, who uses no cold water, no massage—on account of their alleged uselessness—he belongs to the class which remained in the rear away from the battlefield of the army of explorers and fighters, or that unlucky class whose brain was first in falling victim to insidious atheromatosis. We are human and all are subject to the laws of nature which is indifferent to whether she preserves full manhood in one and makes an object of pity of the other. They say we are wonderfully and fearfully made. Some 'wonderfully, some fearfully.

A wise man, one of our profession, Peter Frank, confessed a hundred years ago: "When I was young, the sick feared me, since I got old, I fear the sick." But while fearing them, he never ceased to love the sick and place at their disposal what a ripe empiricism and vast experience taught him. What Bigelow proclaimed as the "leading idea" of the doctor, viz. therapy, was inscribed in Frank's conscience. He appreciated that nature only can heal, but also that by recognizing her power and ministering under her, we master her. That is why we learn that and why nihilism is as conceited as it is impotent; and why we are convinced of the truth of what Robert Bartholow said in 1876 in an address delivered before the medical and surgical faculty of Maryland: "He who despises his art, can never become a great artist. Good practitioners are always found to be men entertaining the greatest confidence in the powers of medicines." Medicine is more than pure science. It is science in the service of mankind. We live in the era of therapy; therapy "in political, social and individual life."

### SOME PERTINENT FACTS IN THE HISTORY OF THE STATE BOARD OF HEALTH.

By J. N. McCORMACK, M. D.

The State Board of Health was created to meet the emergency of an epidemic of yellow fever, the act creating it was approved by

Gov. McCreary March 16th, 1878, and Drs. Pinckney Thompson, Henderson; W. B. Rodman, Frankfort; R. W. Dunlap, Danville; James Shackelford, Maysville; Richard C. Thomas, Bowling Green, and Lunsford P. Yandell, Louisville, were appointed as its first members. The Board was organized at Frankfort on April 3d, following, by the election of Dr. Pinckney Thompson as President and Dr. N. J. Sawyer, Frankfort, as Secretary. Dr. Yandell resigned at the close of the first meeting, and at a later date Dr. James W. Holland, Louisville, was appointed to succeed him.

As showing the rapid changes which occur in the personnel of the profession, although all of the members of this first Board were comparatively young men, not one of them is now living. Dr. Thomas died suddenly December 28th, 1879, and the writer of this was appointed as his successor. Since that time there have served on the Board Drs. J. M. Poyntz, Richmond; John J. Speed, Louisville; J. O. McReynolds, Elkton; W. L. Breyfogle, Louisville; J. A. Lucy, Lexington; Robert Walker, Scottville; George Beeler, Clinton; Arch Dixon, Henderson; J. H. Samuel, Maysville; J. H. Letcher, Henderson; L. L. Robertson, Middlesboro; I. A. Shirley, Winchester; J. B. Kinnaird, Lancaster, and Chester Mayer, Louisville, besides the present members: Drs. William Bailey, Louisville, who has served continuously for twenty years, J. M. Mathews, Louisville, for sixteen years, Geo. T. Fuller, Mayfield, for ten years, and W. A. Quinn, Henderson; K. W. Coffman, Owensboro, serving their first terms, and H. S. Keller and John G. South, both of Frankfort, recently appointed.

The Board has never had but two Presidents. Dr. Thompson served continuously in that capacity from its creation in 1878 to 1893, and Dr. Mathews from the latter date until the present time. There have been three Secretaries: Dr. Sawyer, Frankfort, served from April 3, 1878, until January 15, 1880; Dr. Speed, Louisville, from May 10, 1880, until October 1883, and the writer continuously since that time, although he only accepted the position temporarily until a suitable man could be found to fill it, and his resignation has always been at the disposal of the Board if an acceptable man can be found who will take the work.

From 1878 to 1900, a period of 22 years, the annual appropriation for the Board, to enable it to protect the life and health interests of the people of the entire State, was only \$2,500, but it soon became one of the most active and useful branches of the administration. One of the most disastrous epidemics of yellow fever which ever prevailed in this country broke out in the South shortly after

the Board was organized, and the disease soon made its appearance at Hickman, Bowling Green, Louisville and other points in Kentucky. With funds furnished upon their personal credit, Drs. Thompson and Thomas at once took the field, induced Drs. Blackburn, Cook and Lester to go to Hickman and assist them elsewhere, put inspectors on all the lines of travel from the infected districts, and from that day to this the Board has been an active, aggressive power whenever pestilence threatened our people from any source. To appreciate the unselfishness of this work it should be known that no member of the Board ever received one dollar of compensation for his services, except the Secretary, and, as will be shown later, that his salary has been little more than nominal during most of the time.

Taking the broadest view of the danger to our State from exotic pestilence, and realizing the impossibility of protecting our extensive border without funds, as soon as I was put in charge of the work, an organization of all of the State Boards of the Union was effected for the purpose of mutual improvement through an interchange of views and plans, but still more to hold the other States as bulwarks between us and the Gulf, Atlantic and Pacific coasts. I was Secretary of this organization for the first two years, its President continuously for eight years and constantly on the quarantine commissions for inspecting and building up our defenses at all of the seaports.

In 1886 pleuro-pneumonia having appeared in the State, and the entire cattle industry being paralyzed by a rigid quarantine, a comprehensive law was passed placing the diseases of all domestic animals under the control of the Board, and appropriating \$6,000 for the eradication of the disease in question. Within a week we exterminated the pestilence and freed the State from quarantine, drawing only \$3,000 of the appropriation for the purpose, and covering \$568 of this back into the State Treasury after the work was accomplished. To appreciate what this means, it is only necessary to say that most of the States where this disease gained a foothold spent hundreds of thousands of dollars in getting rid of it, Connecticut, the State next lowest to ours, expending over \$76,000 in doing so.

Dr. Sawyer, the first Secretary, was required to do only routine clerical work, and was paid a salary of \$1,000, with an office furnished him. This was increased to \$1,200 for Dr. Speed, with an office, fuel, lights and janitor. For seventeen years I served for a salary of \$1,200, going over the State during epidemics and in organizing the profession, and spending much of my time at Frankfort

during each session of the General Assembly looking after health and medical legislation and practicing medicine as best I could in the meantime to support my family. I was often offered the entire appropriation, less the actual expenses, but could not accept it without crippling a work to which I had consecrated my life. In all these years, as now, I furnished the State an office, fuel, lights, and janitor free of expense, as there was no money to pay for them, and my wife and son made themselves proficient and served as my typewriters, so that the work could be carried on until it was appreciated. When the appropriation was increased to \$5,000, the Board asked me to devote my entire time to the work and offered an additional compensation of \$1,800 for duties outside of the Secretaryship, and I gave up a practice worth far more than the entire appropriation to do so. During all these years my son, even when a student, was on the danger line with me whenever yellow fever, small-pox or other pestilence threatened our people, and often, protected only by our overalls, we carried women and children to the ambulances and buried the dead from these loathsome diseases until we were covered with virus. The work has grown upon us so in recent years that my son has given up a large part of his practice to aid me, serving absolutely without compensation, until the Board at its last meeting decided to give him the extra compensation it had formerly paid to me. During all these years I have vouchers, arranged and numbered year by year, for every dollar appropriated for the Board, and its official quietus, after examination of the same by the auditing committee each year is of record.

The administration of the medical law was placed in the hands of the Board in 1893. At that time quackery flourished in Kentucky, as it does in most other States at the present time. Medical Institutes and fake concerns of every kind abounded and their advertisements filled the papers in Louisville, and their representatives were heralded as monthly visitors to most country towns, while clog dancing medical companies robbed the people and insulted and made sport of the medical profession. In less than a year's time, with no money except that raised voluntarily by an aroused and outraged profession, and with no power except that back of the Board, quackery was swept from the State and for fifteen years we have not had an itinerant or advertising doctor within our borders, the only State in the Union and the only country in the world of which this is true. At one time, in bringing all this about, I had 2,500 diplomas stacked up in my residence with only my wife and son to pack and repack, sort out and

classify, and issue certificates to the worthy. In this connection the constant unselfish assistance of the medical referees in each county deserves especial mention. Many of them have served continuously since the passage of the first law. No one of them ever received any compensation, and the eradication of quackery would have been impossible without them.

The development of our local health service has involved even more of labor and self-sacrifice. We have now 950 members of county and municipal boards, backed in most instances by the best system of county societies and the most devoted profession in the world. Much has already been accomplished in the prevention of small-pox, and only the lack of financial support from the State and local fiscal authorities prevents the practical restriction or entire prevention of tuberculosis, typhoid fever, diphtheria, scarlet fever, cholera infantum and other domestic pestilences which levy such a heavy tax upon our people every year. If we continue true to ourselves and to the humane cause in which we have enlisted it is only a question of time until we will be recognized as one of the most useful and important departments of the government.

#### CONGENITAL DISLOCATION OF HIP.\*

By JOHN B. RICHARDSON, JR., LOUISVILLE.

Having been assigned this subject and having read a paper of the same title four years ago, I will have to ask you to pardon frequent reference to and quotation from that paper. During the time that has elapsed since writing this paper, I have had no experience with any method for reduction and have seen only two dislocated hips. The reason for this is evident from the stand I took at that time. I have seen no good reason for a change of view since then. I shall try and cut as much as I can from my first paper and add what is new and what points I have been able to gain from correspondence with gentlemen, who are still doing Lorenz' operation.

For some unaccounted reason, this condition is found much more frequently in the female sex. Lorenz reports 671 cases, of which number 87.6% were girls and 12.2% were males. Reports from the Ruptured and Crippled Hospital of 500 cases show about the same proportion of females and males. 82.6% being found in the female sex and 17.4% in the male. Of these 500 cases 64.4% were unilateral and in 36.6% both hips were implicated.

In considering the pathology found in these hips, I will first describe the bony and then the soft structures. The acetabulum is

\* Read before the Kentucky State Medical Association, Louisville, October, 1907.

usually least affected. It may be normal in size and depth. This is the usual finding in infants, who have not subjected the joint to any strain. However, even in infants, the acetabulum may be undeveloped. In older children, where walking has been indulged in, the chances are more marked. The acetabulum is relatively smaller and there is formed a new depression to take the place of the old acetabulum. This is never sufficient to form any support for the femur. The head of the femur is usually flattened, the neck shortened and the angle lessened, producing a *coxa vera*. These changes become more marked the longer the joint has borne weight. There are also accommodative changes in the other bones of the pelvis, as there are in the spinal column. There is lordosis and lateral curving of the spine. In bilateral cases the lordosis is increased and the sacrum is dislocated downward and forward, causing a change both in the inlet and outlet of the pelvis. This seems to have no marked effect on the expulsion of the foetus, as these women have no great difficulty during labor. The muscular changes are due to misplacement of the femur and to disuse. The adductors and psoas and iliacus are shortened. The glutei, obturators and gemelli are lengthened and changed in direction.

The cause of the dislocation is not known. Many theories have been advanced but that they occur so much more frequently in the female sex causes them to be of no great importance. The most frequently accepted theory is the defective development of the acetabulum. This has been disproven. In the new born the acetabulum covers only one-third of the head of the femur while later one-half is covered. This may have some causing influence. Heredity plays some part as instances are reported of several cases occurring in the same families. Dupuytren reports three families in which several children were affected; Whitman reports a family in which three children had this dislocation, the order being the third, eighth and ninth child.

The diagnosis is not usually made until the child begins to walk. In unilateral cases the limp is noticed very readily. The body lurches forward in a characteristic manner, due to the shortened limb becoming still shorter when the weight of the body is brought to bear on the elastic capsule. The limp becomes more marked as the patient continues to bear weight. The shortening in young children may be from one-half to one inch. After long use it may be as much as two inches. The trochanter is prominent and above Nelaton's line. Motion is more free than normal and the trochanter can be pulled up and down with slight manipulation. The head can be rolled under the finger when ro-

tation inward and outward is practiced. Pain in the joint is not usually complained of although these patients are more prone to injuries from falls, etc. They are usually tired more readily than normal children. These symptoms often increase during growth, but in adult life are apt to become less troublesome, due to the head having formed a new but insecure acetabulum. The muscles of the affected side are somewhat atrophied, but the general condition is usually good. In bilateral dislocation, the limp is replaced by a waddle, known as the "sailor gait". The hollow of the back is increased and the belly protrudes. The thighs are separated abnormally.

There are three dislocations: posterior, anterior, and supracotyloid. The posterior is most frequent. The anterior is the "anterior reposition" of Lorenz, and is considered by him the position to be desired when a true anatomic reposition cannot be maintained. Remembering the symptoms the diagnosis is not difficult. The X-ray gives a good picture of the condition in most instances.

In 1890, Hoffa first used the open method for reduction. Later came the method of Lorenz, which caused such a stir in our lay papers several years ago. Lorenz endeavors to replace the head into the acetabulum by manipulation. A full description of the method may be found in any work on Orthopedics. The bloodless method consists first of traction drawing the head down to the acetabulum. The thigh is then flexed to a right angle with the body. The adductors are then broken down by forcible manipulation. The thigh is now forced in abduction to the plane of the body. The third step consists in overcoming the resistant tissues on the back of the joint by flexing the femur until the toes are made to touch the face. Then by hyperextension the anterior resistance is overcome. Now the pelvis is fixed by one or two assistants, and the thigh is abducted over a wedge of wood, covered by a suitable padding. This abduction is continued until the head is forced over the posterior rim of the acetabulum. If, on abduction, the head can be easily slipped out of the acetabulum, the prognosis for a perfect result is said to be bad. A plaster of paris spica is applied in this forced abduction and the child allowed to walk as soon as it is able. This spica is allowed to remain for six months. A high shoe is placed on the foot of the dislocated side. At the end of six months the plaster is removed and the thigh brought to a position nearer normal. Another spica is applied. This is worn for three or four months longer. If the spica has been applied correctly there is practically no discomfort from it. The patient usually becomes used to the

position and no complaint is made. Magendie's solution or codeine is always needed to control pain.

This is a hurried description of the so-called bloodless method of Lorenz. It is beyond me to describe the force required to go through these different steps. You may have some idea of it when I say, without exaggeration, that it requires the combined effort of the operator, most frequently two and always one assistant and two nurses. Perhaps you may better appreciate this point when I give you some examples of the accidents occurring during this bloodless method.

I have seen four fractures of the femur, one of the upper third during the first operation, was put up in a spica, and the child placed in bed to await the "knitting of the bone." No doubt a second trial was had at this unfortunate, who had been enjoying life as much as a perfectly sound one, before Lorenz visited us. On two occasions, at the second operation, when the abduction was lessened, the thigh was broken, one in the lower and the other in the middle third. In still another case when the outward rotation was too great, the femur was fractured in the lower third in an attempt to overcome this rotation. No account, of course is taken of the rupture of a few small blood vessels in these fractures when the term "bloodless" is applied.

The outward rotation is as much as 60° in many cases. Careful massage will reduce this, however, if continued as indicated.

Paralysis of the anterior muscles of the leg is sometimes seen. This most often clears up, although I have seen several cases where a persistent "drop foot" was noted.

In one case a subcutaneous extravasation of blood occurred, extending from the mammary region above to the knee below. This must have been an injury to an artery of some size for the blood to have found its way to a point so distant from the injury. This hip was reduced.

The most serious accident that I am aware of was when rupture of the femoral vein occurred. This was quickly followed by gangrene, amputation, and death.

These points cannot be overlooked when one is considering the advisability of operating on these cases.

When the dislocation has been reduced the head should be prominent and the femoral pulse felt under it.

Whitman, in his *Orthopedic Surgery* says this condition should be found. He also says, "The first indication of failure is a slight lateral displacement of the head to the outer side of the artery."

In the *Journal of the American Medical Association* of February, 27, 1904, is an arti-

cle by Harry M. Sherman of San Francisco, entitled, "Report of Two Children Operated on by Lorenz." In this article the writer describes the findings at an open operation done about six months after Lorenz had operated. His description in part is as follows:

"The femoral artery could not be compressed between the finger and the femoral head, as is normally the case; but the head was recognized external to the artery, and more superficially placed than usual in a position beneath the anterior superior spine." This would seem to be the anterior reposition of Lorenz. He continues by saying, "A longitudinal incision was made, internal to the teno-vaginae-femoris, and directly down to the head. Around the head was a thin fibrous layer, which I first took to be the joint capsule, but which proved to be only a layer of laminated fibrous tissue, an adventitious capsule. The cartilage of the femoral head, now exposed, was found to be eroded, as if by some absorptive process. The pit for the ligamentum teres was obvious, but there was no ligament. Usually, at this stage of the operation for reduction by arthrotomy, I am able by flexing the hip to a right angle, to thrust my finger down to, sometimes through, the constricted part of the capsule, but in this case it was impossible. There was no such open path. Further dissection showed a band of capsule coming from the lower part of the acetabulum, and twisted around and behind the neck; but partial section of this did not open up the way to the acetabulum. Finally the rim of the acetabulum was found and the capsule opened there. It was found that the manipulation in November, 1902, had torn the capsule, had thrust the head through the opening, and left it among the muscles at the outer part of Scarpa's triangle and just beneath the fascia lata, while the trochanter had been crowded into a position internal and posterior to the head, and very nearly into the acetabulum. The acetabulum, once exposed was found to be very shallow, but the head was easily put into it, or on it, by an inward rotation movement. Very little capsule, however, was left in front of the head, and this was a serious loss."

In most of the cases I have examined, after the first dressing was removed, the head was found on the outer side of the artery. It would be logical to suppose that the same condition existed in these cases that was found by Sherman in his. As is pointed out in this article an intact capsule could bear weight better than one that is torn, and also there appeared nothing which could be counted on to hold the head in its new position. So it would seem that the operation had done more harm than it had done good.

In 1903, V. P. Gibney, of New York, in his

report to the Board of Directors of the Ruptured and Crippled Hospital, prefaced his remarks upon congenital dislocation of the hip as follows:

"Let it be understood that it is not the time to give final results." He then recounts 33 patients operated upon. Some were double dislocations. Of this number 18 were under 7 years, 11 between 8 and 10, 4 between 10 and 12. He reported 3 as cured, 3 ended in good results, 8 were reported as in a favorable condition, another 8 were improved, 5 were still in the first dressing, 1 death. This showed 9% cures. 3% deaths was shown.

In a recent communication from him he has the following to say: "I believe in the bloodless operation of Lorenz for a great many cases of congenital dislocation of the hip. I have found a good many failures, that is anatomically speaking. The head does not slip out into the anterior position. I saw this summer at Berck-sur-mer France. Dr. Calot treating some of these cases, and by his method, it is claimed that there are very few anterior displacements. His method he thinks differs from that of Dr. Lorenz, but really the only difference seems to be the thoroughness with which Calot brings down the head to the bottom of the acetabulum and rather back of it putting up in extreme inward rotation as well as abduction.

Our practice at the Hospital for Ruptured and Crippled is a resort to the Lorenz method in the majority of cases, but when we fail, we do not hesitate to employ the open method, which is practically an arthrotomy, not a gouging out of the acetabulum for deepening it."

Dr. W. L. Townsend, of New York, writes: "The patients operated on in New York by Lorenz method, the perfect cure probably will not exceed 25% but a very large number are markedly improved in every way by the operation. A small percentage cannot be reduced and require an operation. The operation is certainly one of great value and to be recommended in suitable cases."

In 1903 Whitman considered 40% cure resulting upon the operation. In a recent conversation with him, although refusing to write a letter to that effect, he said he thought 50% were cured.

These New York gentlemen are all close observers and are thoroughly honest in their expression of the operation but during a years' service in the Ruptured and Crippled Hospital where there were cases which had been operated on as long as 18 months previously I failed to see but one case that I thought cured. I not only saw many cases which were not cured but some who had not taken a step during all of this time. One

which was in bed and unable to even be in a wheel chair. The one point which impressed me so forcibly during my visit this summer to the Ruptured and Crippled Hospital was the complete absence of all these Lorenz cases. In 1903 they were the first to be shown to any and to all visitors. This summer, try as I did, I failed to see a single case cured or uncured.

"In 1903 Ridlon, of Chicago, gave 10% cures as his experience, with 20 to 30% of failures, the remaining 60 or 70% being classed as improvements. In a most interesting letter from Dr. Ridlon received in August he gives perfect results in 25% and good results in at least 70% leaving only 5% for failures. These results are far above those reported by the New York surgeons, and may be accounted for when we see this statement in his letter to me: "And now nearly everyone who has performed many bloodless replacements has some little trick or maneuver which he believes to be an improvement on the older method." Perhaps Dr. Ridlon has struck some little method by which he is able to hold the hip in position.

Dr. Chas. F. Eikenbary, of Spokane, Wash., whose opinion I value very highly, in an answer to a request for his present opinion of the bloodless method, replies as follows: "I am not and never have been a very firm believer in the Lorenz operation. *I have seen too many children made worse.*" He then states that he believes in one trial at the bloodless method and if that failed the open method should be used. Dr. Eikenbary had a years' service at the Ruptured and Crippled Hospital in New York and was Ridlon's assistant in Chicago for several years. For this reason I feel his opinion is of great weight and his statement that "too many children made worse," bears out my own observations.

In conclusion I wish to say that when we are considering this operation, we must bear in mind the following points:

1st. At the outside 25% cures.

2nd. Three per cent. deaths.

3rd. An operation which produces more trauma and consequent shock than any I have ever witnessed.

4th. In spite of the term "bloodless" a large amount of hemorrhage, which we are unable to deal with.

When this is done, my advice is to let the Lorenz or any other so-called bloodless method alone and if any treatment is adopted to use the open method, where we are able to see what we are doing and where we can deal with our hemorrhage.

The cases of adult congenital hip which I have seen get about very nicely. In several married women children had been born and

attention to household duties had been performed to the satisfaction of all concerned.

A case coming to me for advice would be told to let the child strictly alone, to apply no braces or to employ no operative measures, to allow the child to grow and not, above all things, to reduce its chance in this life by the attempting of the Lorenz procedure.

### TRAINING, A PROPHYLAXIS FOR NERVOUSNESS.\*

BY EDGAR DUFF BURNETT, LOUISVILLE, KY.

There come with the twentieth century broad and inviting fields for woman leading her away from the marriage vow and quiet retreats of home life. We find the commercial world of the metropolitan cities teeming with its once beautiful clerks, book-keepers, and stenographers. Taking a glance into the professional world we see woman striving with man in the delivery of seathing invectives or merciless philippics at the bar; doing major surgery or treating fevers; most of all we see her, care-worn and anxious, crowding the portals of our American bulwark, even the public school by which the youth is led to work, act and think systematically.

Again we see her after midnight hovering about the dissipation of the social hall or tarrying at the festal board. And so from this strenuous pace with all its attendant conditions and circumstances we see her roses fade; her eyes lose their brightness and the rhytm and mirth of her laugh are gone. Now what does the physician see? A sad, disappointed, care-worn nervous young woman that has grown suddenly old.

None the less can be said of man. In the mighty push and grab of our too fast age we find men swallowed up by the surging maelstrom of greed for gain and mad desire for position and recognition. How the soul of man seems to yearn for the "flesh pots of Egypt!" and how reckless his methods of graft and his death grip as he reaches out for filthy lucre!

We see him speeding to the music of "chough," "chough," "chough" in his concentrated business efforts, or reveling with Bacchus in his social opportunities. The professional man in the great demands upon his physical economy, has no time for sleep, consequently he must needs add the lash of the stimulating "hypo" or imbibe a bit of the distilled that sparkles. In the critical hour of the ward healer and frenzied finance it doth seem that "brain storms" and nervous collapse are all too frequent—truly "De-

mentia Americana" is making rapid strides and great onslaught.

How shall we meet the exigencies of the hour?

To have your structure as strong as adamant that it may withstand the storms of time you must dig deep and make your foundation sure and steadfast.

We must go back to man's primary state and fortify his tender life in his earliest hours. Some one has said that to train a child properly you must begin with the grandparents. The wisest man in all the earth admonishes us in the careful training and discipline of the child.

The home, the first and mightiest kingdom of this earth, must be the puissant factor in moulding the child into an adult, strong, robust and self-possessed.

Study to know thyself. How few men and women have been trained to understand themselves and know their limitations. The history of practically every nervous breakdown is one that outlines lack of early training and failure to appreciate the individual's horizon.

If we would see strong and stable men and women, those who manifest self-control, we must train and discipline the infant and child with untiring assiduity.

The immaturity, rapid growth and relatively large size of the brain and spinal cord during early life make them peculiarly sensitive to impressions and disease. Because of the instability of the nervous centres and the greater irritability of the motor, sensory and vaso-motor nerves, apparently trivial causes are enough to produce quite profound nervous impressions. Errors in diet and disturbances in nutrition add greatly to nervous phenomena in the small child.

How very necessary that the habits of taking nourishment, sleeping, bathing, evacuating the bowels and bladder and of receiving an abundance of exercise and fresh air become a fixed counterpart of every infant. The attention of devoted kins-people and friends in playing with or tossing and jumping a baby is most likely to render it unstable, irritable and nervous. Every baby should be supplied with a separate crib without rockers and a quiet and warm but well ventilated nursery. A dry napkin, a satisfied appetite and a warm bed are all that are needed to produce sleep—consequently, fairy tales, lullabys, and rocking should never be indulged in for facilitating sleep. All undue excitement and stimulation to the point of shrieks of delight are positively harmful.

The rapid growth of the brain during the first two years places a very grave responsibility upon the nurse, and this should be the mother the greater part of the time. The

\*Read before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

mother alone is the one pre-eminently fitted for fostering and training this tender mind. As early as three months the infant recognizes the tender or stern tone of the mother's voice. How interesting to note the rapid developments of sensation, emotion, volition and intellect. An eminent authority says, "In my opinion, a child of ten months who does not weep or cry at least four or five times a day, who is not amused, and who is not irritated, like a savage, or a young animal, by a mere trifle is lacking in sensibility and in intelligence, and will, no doubt, be lacking in character—bury him; he is dead. It is necessary to surround the cradle with an atmosphere of sweet serenity, but it is not always necessary to hide anger. Just anger should be shown, but with moderation."

Volition in the small child should receive special training and education in developing self-control.

"Let a child grow as a tree grows, according to its own sweet will." The exuberant spirit of the child must not be suppressed. The little prince and princess of nature have innate propensities for communion with the great outside world. David Harum says, "A certain amount of flees is good for any dog, it may keep him from worrying over being a dog" even so a certain amount of dust and freckles is good for any child. A stick horse and a stone bruise comprehend the transient joy and sorrow of the boy quite as much as the broken doll and the mud pie do for the girl.

"Like begets like," is a law unalterable, and in the same degree the child must love his playmate and develop the natural tendencies of his young years. While his life must be one of schooling and discipline, he needs must have sunshine, plenty of exercise and ozone.

During the malleable period the greatest opportunity is afforded for instilling the strong principles of obedience, self-denial and patience. The child's mind is so very plastic that the teacher is able to mould it *ad libitum*. Papal authorities claim that if they have the child under their training and tuition for the first seven years, they have no fear of losing him. Moses, the mighty leader and law giver, although he was taught all the wisdom and military skill of the Egyptian court, adhered to the burning principles that his mother sowed in his heart and mind during his first years.

The child is a great imitator, conforming to the lives and actions of his seniors. How very important that he develop strength of mind, body and character that he may meet the obligations, responsibilities and reverses of life with sanguine hope and so not become a victim of nervous collapse. The scepter of

the home and school-room seal his future. Perseverence, sympathy, love and decision should characterize the influence of parent and teacher. Universal kindness should pervade his daily life; however, it seems expedient occasionally to infuse an ounce of the fluid extract of birch-wood into his physical economy. This acts as a stimulant to the tardy loiterer, and furthermore has the effect of a counter-irritant; promotes a flow of ideas, giving a feeling of well-being; is a sedative, and has the properties of an eliminant acting on the incorrigible.

Sam Jones used often, in his life time, deliver a lecture entitled, "More Taffy and Less Epitaffy." I truly believe in the Gospel of sunshine and hope to our patients and their families. A splendid theme for the doctor would be, "More Strap Oil and Less Cod-liver Oil." If in youth the individual be controlled and stimulated to full development and strength the physician would have small need for his nutrients and restoratives.

"Where the brook and river meet."

With the development of the sexual organs and the transition from childhood to adult life every parent should acquaint his offspring. Let us notice the fair daughter. She is slipping out of childhood's land of dreams and fantasy into the realm of the practical which is woman's kingdom. She has her own peculiar and individual questions to settle and her own environment is a matter of no slight importance. What she is now forecasts what she may be, what indeed she will be twenty years hence, when her life with its broad opportunities and its insistent obligations has made her its own. She stands to-day where the little limpid brook with its narrow, silvery thread and flower-bordered banks meets the brimming river. It is impossible not to love her, not to be wistful for her. Winsome and clever, or thoughtful and brooding, merry or quiet, according to her temperament she is in some phases a problem to her mother and in many ways a puzzle to herself. Chameleon-like she takes on the coloring of her associates and environment. She expresses herself in superlatives, and exaggerates both likes and dislikes. How very easy for this spirited young life to be led into excesses that forecast a physical and moral break-down. It is far more important that a girl at this formative stage of her being shall be thrown with high-minded and gracious mannered persons, than that she shall be drilled in Latin and Mathematics, though this too is a worth while thing.

At this age the anxious hour is upon the boy even more than upon the girl, because of the stronger latent sexual instinct that is being awakened. The nature of our bodies, the function of the reproductive organs and the

great law of the propagation of human life should be taught the young in their innocence and confidence. The subject ought to wear an aspect not only negatively innocent but positively beautiful. I am confident, in spite of current belief and of the blundering of many generations, that there is nothing in a normally constituted child's mind which refuses to take in the subject from this point of view, provided that the right presentation of it be the first.

Because of foolish reserve on the part of parents this subject is omitted in the child's training and discipline. So the boy's craft is embarked without a sail, drifts from the influence of the home and is likely to become stranded on the rock of puberty. The time must come when the child silently discards the fables and myths with which his questions earlier in life were satisfied. Observation will generally tell us when he begins to feel a curiosity about the fact of birth. At this receptive age the grand facts of maternity and generation are eagerly absorbed and can be firmly stamped upon his mind.

It is appalling when we reflect on the tone in which the chance instructors of our children handle these sacred themes—dirty-minded school-boys, street urchins or foul-mouthed adults, anyone, in short, who at an early age may be sufficiently defiled and sufficiently reckless to talk to them. No matter what palliatives may be applied or antidotes given later on, the poison thus imbibed never quite leaves the system. Because of such wanton negligence on the part of parents we see the inevitable tendency to indecency, morbid self-desire, temporary insanity—to say nothing of deceptiveness, dishonesty, arson, homicide and suicide. Is it not time for the family physician to raise his voice in admonition and awaken the parent from his lethargy on this vital question?

The profoundest respect for virtue, chastity and the rights of others should be the burning principle that guides the young as well as their seniors away from the shoals of the "social evil."

The daughter should be none the less instructed that she may develop into a strong, well-poised woman. Granting that she may be comparatively immune from temptation, should not something be said when the time of possible matrimony is at hand to prevent a young woman from surrendering herself to a husband in ignorance of the full meaning of marriage?

"Earth's noblest thing, a woman perfected."

The marriage vows are very binding, and should be held in great sacredness. "Many waters can not quench love, neither can the floods drown it." It is the one abiding thing

in a world of shifting shadows. Truly now is coming the hour of her crowning prerogative. We note in her great changes physically and as regards her daily life. She is becoming more quiet, gentle and serene; her entire anatomical make-up is undergoing a complete evolution; her motherly instincts are growing more perceptive and her nature is developing into one of true mellowness. With the expectation and advent of motherhood she is peculiarly prepared in body and heart to foster and love, beyond the ken of man, her offspring. Before the babe comes, during the quiet months of waiting for its arrival, the mother's heart should be as a cloister, hallowed and pure. No storm of passion should sweep it, no fretful reluctance should mar its peace.

A babe seems a mere waif on the stream of eternity, but in its little hand may lie the destinies of nations. Great men and great women, too, have had great mothers. Lincoln said, "All that I am, all that I hope to be, I owe to my angel mother." As we watch the hallowed life and career of that peer in statesmanship and military tactics, George Washington, we see the finished moulding of a mother's hand and heart. The office of the mother is the greatest and most responsible under high heaven. A mean, petty, selfish, nervous, vain and egotistical mother will impress those traits on her child; he will draw them in with the milk that feeds his early life. For the sake of the child and his physical and moral stamina let the mother be noble and strong. The home does not exist for selfish gratifications. It has debts to the community and duties to society. It is the foundation of the church and state. It is the great training school where character is moulded and the foundation for right living and good citizenship is laid. When nations fall into ruin and decay it is because manhood has lost its prestige and bartered its birthright for some mess of pottage. Back of every man stands his home.

The true mother trains the child to obey, lovingly and continually not by penalty and severity. By her unbroken self-control she offers shelter and refuge to her child. Her authority is expressed and felt by constant firmness and tender calmness rather than by threats and harshness.

My fellow confreres, we must look to the intelligent and faithful mothers for a stable posterity and for a human race with well-established nerve force and equilibrium.

Then let us so teach all womankind and admonish them:

"And say to mothers what a holy charge  
Is theirs—with what a kingly power their  
love

Might rule the fountains of the new-born

mind.

Warn them to wake at early dawn, and sow  
Good seed before the world has sown its  
tares."

## THE NEW PURE FOOD AND DRUG LAW.

An act for preventing the manufacture and sale of adulterated or misbranded foods, drugs, medicines and liquors, and providing penalties for violations thereof.

Be it enacted by the General Assembly of the Commonwealth of Kentucky:

Section 1. That it shall be unlawful for any person, persons, firm or corporation within this State to manufacture for sale, produce for sale, expose for sale, have in his or their possession for sale or to sell any article of food or drug which is adulterated or misbranded within the meaning of this act; and any person or persons, firm or corporation who shall manufacture for sale, expose for sale, have in his or their possession for sale or sell any article of food or drug which is adulterated or misbranded within the meaning of this act, shall be fined not less than ten dollars nor more than one hundred dollars, or be imprisoned not to exceed fifty days or both such fine and imprisonment. Provided, that no article of food or drug shall be deemed misbranded or adulterated within the provisions of this act when intended for shipment to any other State or Country, when such article is not adulterated or misbranded in conflict with the laws of the United States: but if said article shall be in fact sold or offered for sale for domestic use or consumption within this state, then this proviso shall not exempt said article from the operations of any of the other provisions of this act.

Section Two. That the term food, as used in this act, shall include every article used for or entering into the composition of food or drink for men or domestic animals, including all liquors.

Section Three. For the purpose of this act, an article of food shall be deemed misbranded:

First. If the package or label shall bear any statement purporting to name any ingredient or substance as not being contained in such article, which statement shall not be true in any part; or any statement purporting to name the substance of which such article is made, which statement shall not give fully the name or names of all substances contained in any measurable quantity.

Second. If it is labeled or branded in imitation of or sold under the name of another article, or is an imitation either in package or label of another substance of a previously

established name; or if it be labeled or branded so as to deceive or mislead the purchaser or consumer with respect to where the article was made or as to its true nature and substance or as to any identifying term whatsoever whereby the purchaser or consumer might suppose the article to possess any property or degree of purity or quality which the article does not possess.

Third. If in the case of certified milk, it be sold as or labeled "certified milk," and it has not been so certified under rules and regulations by any County medical society, or if when so certified it is not up to that degree of purity and quality necessary for infant feeding.

Fourth. If it be misrepresented as to weight or measure or, if where the length of time the product has been ripened, aged or stored, or if where the length of time it has been kept in tin or other receptacle tends to render the article unwholesome, the facts of such excessive storage, ripening, aging or packing are not plainly made known to the purchaser and to the consumer.

Fifth. If the package containing it or its label shall bear any statement, design, or device regarding the ingredients or the substances contained therein, which statement, design or device shall be false or misleading in any particular. Provided, That articles of liquor which do not contain any added poisonous or deleterious ingredients shall not be deemed to be adulterated or misbranded within the provisions of this act, in the case of articles labeled, branded or tagged so as to plainly indicate that they are compounds, imitations, or blends, and the word "compound," "imitation," or "blend," as the case may be is plainly stated on the package in which it is offered for sale. Provided, That the term blend as used herein shall be construed to mean a mixture of like substances, not excluding harmless coloring and flavoring ingredients used for the purpose of coloring and flavoring only.

Section Four. For the purpose of this act, an article of food shall be deemed to be adulterated: First. If any substance or substances be mixed or packed with it so as to reduce, lower or injuriously affect its quality or strength. Second. If any substance be substituted wholly or in part for the article. Third. If any valuable constituent of the article has been wholly or in part abstracted; or if the product is below that standard of quality represented to the purchaser or consumer. Fourth. If it is mixed, colored, coated, polished, powdered, or stained whereby damage is concealed, or if it is made to appear better or of greater value than it is, or if it is colored or flavored in imitation of the genuine color or flavor of another substance

of a previously established name. Fifth. If it contains added poisonous ingredient which may render such article injurious to health, or if it contains any antiseptic or preservative which may render such article injurious to health or any other antiseptic or preservative not evident or not plainly stated on the main label of the package. Sixth. If it consists of or is manufactured from in whole or in part of a diseased, contaminated, filthy or decomposed substance, either animal or vegetable, unfit for food, or an animal or vegetable substance produced, stored, transported or kept in a condition that would render the article, diseased, contaminated or unwholesome, or if it is any part the product of a diseased animal, or the product of an animal that has died otherwise than by slaughter or that had been fed upon the offal from a slaughter house, or if it is the milk from an animal fed upon a substance unfit for food for dairy animals or from an animal kept and milked in a filthy or a contaminated stable or in surroundings that would render the milk contaminated. Provided, That any article of food which may be adulterated and not misbranded within the meaning of this act, and which does not contain any added poisonous or deleterious ingredient and which is not otherwise adulterated within the meaning of paragraphs four, five and six of section four of this act, or which does not contain any filler or ingredient which debases without adding food value, can be manufactured or sold, if the same be labeled, branded or tagged so as to show the exact character thereof. And all such labels and all labeling of packages provided for in any provisions of this act shall be on the main label of each package and in such position and character of type and terms as will be plainly seen, read and understood by the purchaser or consumer. Provided further, That nothing in this act shall be construed as requiring or compelling the proprietors, manufacturers or sellers of proprietary foods which contain no unwholesome substances or ingredients to disclose their trade formulas except in so far as the provisions of this require to secure freedom from adulteration, imitation, or misbranding. But in the case of baking powders, every can or other package shall be labeled so as to show clearly the name of the acid salt which shall be plainly stated in the face of the label to show whether such salt is cream of tartar, phosphate or alum. Provided further, That nothing in this act shall be construed to prohibit the manufacture or sale of oleomargarine, butterine, or kindred compounds in a separate and distinct form, and in such manner as will advise the consumer of the real character, free from coloration or ingredient that

causes it to look like butter.

Section 5. That the term drug, as used in this act, shall include all medicines and preparations recognized in the latest revisions of the United States Pharmacopoeia or National Formulary for internal or external use and any substance intended to be used for the cure, mitigation or prevention of diseases, either of man or other animal, and shall include paris green and all other insecticides and fungicides.

Section 6. That for the purpose of this act, an article of drug shall be deemed to be adulterated: First. If when a drug is sold under or by the name recognized in the United States Pharmacopoeia or National Formulary, it differs from the standard of strength, quality or purity, as determined by the test laid down in the United States Pharmacopoeia or National Formulary official at the time of investigation. Provided, That no drug defined in the United States Pharmacopoeia or National Formulary shall be deemed to be adulterated under this provision if the standard of strength, quality, or purity be plainly stated upon the bottle, box, or other container thereof, although the standard may differ from that made by the test laid down in the United States Pharmacopoeia or National Formulary. Second. If the strength or purity fall below the professed standard or quality under which it is sold. Third. If in putting up any drug, medicine or preparation, proprietary or otherwise, used in medical practice, or if in making up a prescription or filling an order for drugs, medicines or preparations, proprietary or otherwise, one article is substituted or dispensed for a different article for or in lieu of the article prescribed, ordered and demanded, or if a greater or less quantity of any ingredient specified in such prescription, order or demand, is used than that prescribed, ordered or demanded, or if it deviates from the terms of the prescription, order or demand by substituting one drug for another. Provided, That except in the case of physician's prescriptions nothing herein shall be deemed or construed to prevent or impair or in any manner affect the right of the druggist or pharmacist, or other person to recommend the purchase of an article other than that ordered, required or demanded, but of a similar nature, or to sell such article in lieu of an article ordered, required or demanded, with the knowledge and consent of the customer.

Section 7. For the purpose of this act, an article of drug shall be deemed to be misbranded: First, If the package or label bears any statement, design or device regarding such article of drug or regarding any ingredient or substance contained therein

which shall be false or misleading in any particular, or if it is falsely branded as to State territory or country in which it is manufactured or produced. Second. If it be an imitation of or offered for sale under the name of another article, or if it be labeled, branded or in any way represented or sold so as to deceive or mislead the purchaser or consumer as to the quality, purity or medicinal value. Third. If the contents of the package as originally put up, or the contents of the package, box, bottle, phial, can or other container, sold or exposed for sale, delivered, given away shipped or offered for shipment, shall have been removed in whole or in part, and other contents shall have been placed in such package or box, phial, can or other container, or if when a package or container has been once emptied and new contents placed therein all original labels, marks, brands and identifying marks are not entirely removed or effaced and new labels, marks and brands truthfully describing the new products affixed. Provided, That such new contents shall not be like or similar to said original contents. Fourth, If the package, box, bottle, phial, can or other container shall fail to bear a statement on the label of the quantity or proportion of any alcohol, morphine, opium, cocaine, heroin, alpha or beta eucaine, chloroform, cannabis, india, chloral hydrate or acetanilid or any derivative, or any preparation of any such substances contained therein. Provided, That nothing in this paragraph shall be construed to apply to the dispensing of prescriptions written by a regularly licensed practicing physician, veterinary surgeon or dentist and kept on file by the dispensing pharmacist or to such drugs as are recognized in the United States Pharmacopoeia and the National Formulary, and which are sold under the name by which they are recognized; and provided further, that this provision shall not be construed as repealing or in conflict with any statute which prohibits the sale of certain drugs except upon a prescription of a physician; and provided further, That nothing in this act shall be construed as repealing any acts regulating the practices of medicine or pharmacy not in conflict herewith: Provided further, That no prescription shall be knowingly refilled except for the person for whom it was written.

Section 8. It shall be the duty of the Director of the Kentucky Agricultural Experiment Station, or under his direction, the head of the Division of Food Inspection of the said station, to make or cause to be made examinations of samples of food and drugs manufactured or on sale in Kentucky at such time and place and to such extent as he may determine. He shall also make, or cause to be made, analysis of any sample of food or

drug which the State Board of Health or the State Board of Pharmacy, may suspect of being adulterated or misbranded, and of any sample of food or drug furnished by any Commonwealth's, County or City Attorney of this State. And the said Director may appoint such agent or agents as he may deem necessary, who shall have free access at all reasonable hours for the purpose of examining into places wherein any food or drug product is being produced, manufactured, prepared, kept or offered for sale, for the purpose of determining as to whether or not any of the provisions of this act are being violated, and such agent or agents upon tendering the market price of any article may take from any person, firm or other corporation a sample of any article desired for examination. The Director of said Experiment Station is hereby empowered to adopt and fix the methods by which the samples taken under the provisions of this act shall be analyzed or examined, and to adopt and fix standards of purity, quality or strength, when such standards are necessary or are not specified or fixed herein or by Statute. Provided, That such standards shall be published for the information and guidance of the trade. Provided further, That for the purpose of uniformity, when such standards so fixed differ from the legally adopted standards of the United States Department of Agriculture, the Director of said Station shall arrange for a conference between the proper food control representatives of the United States Department of Agriculture and the Director of said Station and the representatives of the trade to be affected, for the purpose or arriving, if possible, at a uniform State and National Standard. Provided, further, That in the case of final dispute the validity of such standard adopted by the Director of said Station shall be determined by the Courts under the rules of evidence. And provided further, That when the standard or nomenclature for any food or food product has been determined by the Supreme Court of the United States, such standard or nomenclature shall govern in the enforcement of the provisions of this act. Provided further, that all rulings pertaining to the sanitation under this act shall be collaborated in connection with the State Board of Health. And Provided further, That at the regular annual meetings of the Kentucky Pharmaceutical Association and the Kentucky State Medical Association each of said Associations shall elect one representative, which representatives, together with the Director of said station shall make and establish all rules and regulations for the governing and carrying out of the provisions of this act relating to drugs.

Section 9.—Whenever any article shall

have been examined and found to be adulterated or misbranded in violation of this act, the Director shall certify the facts to the Commonwealth's Attorney of the District or to the County Attorney of the county, or to the City Attorney of any City or town in which the said adulterated or misbranded food or drug product was found, together with a statement of the results of the examination of said article of food or drug duly authenticated by the analyst under oath and taken before some officer of this Commonwealth authorized to administer an oath having a seal. And it shall be the duty of every Commonwealth's Attorney, County Attorney and City Attorney to whom the Director of said station shall report any violation of this act or to whom the State Board of Health, or the State Board of Pharmacy, or to whom the Chief Health officer of any county, city or town shall report any such violations, to cause proceedings to be commenced against the party so violating the act, and the same prosecuted in manner as required by law. Provided, however, That in case of the first charge or finding the manufacturer or dealer shall be notified of the findings and be given a hearing within fifteen days before a report is made to the Commonwealth's, County or City Attorney as herein provided. Provided, further, That where more than one sample of the same brand of product has been taken and examined the first finding or charge shall be construed to apply to all samples so taken, and notice and hearing shall apply to all such samples.

Section 10. Said Station shall make an annual report to the Governor upon adulterated food or drug products in addition to the reports required by law which shall not exceed one hundred and fifty pages, and such annual report shall be submitted to the General Assembly at its regular session, and said station may issue from time to time a bulletin giving the results of the inspection and of all analyses or samples taken or submitted for examination under this act together with the names of the parties from whom the samples were taken, or where the inspections were made, and as far as possible the name of the manufacturer, the number of samples found to be adulterated, the number found not adulterated, and other information which may be of interest to the manufacturers or dealers in food or drug products or to the consumers. Provided, however, that before such publication is made, the manufacturer of the article and the dealer shall be furnished a true copy of the facts to be published regarding the article at least thirty days before the publication and hearing given the dealer and manufacturer, and any statements or explanations made by such manufacturer

shall be included in the same place and along with the publication made regarding the article. And Provided further, That if at the hearing of the manufacturer or dealer, as provided by section nine hereof said manufacturer shall produce the affidavit of a competent analytical chemist controverting the finding of said station or its director or chemist, as the case may be, and affirmatively showing that there is neither adulteration or misbranding of such article under the provisions of this act, then there shall be no publication of either the name of the manufacturer or dealer or of the name of the brand of the article until after a trial and a verdict of guilty as herein provided. And Provided further, That where prosecution is made for violation of any of the provisions of this act, no official publication shall be made of the result of the inspection and analysis until the matter has been finally adjudicated, and in case of appeal, by the Court of last resort.

Section 11. Said Experiment Station shall receive Seven Dollars and Fifty Cents for the analysis or examination of any sample of food or drug taken or submitted in accordance with this act, and expenses for procuring samples of food and drugs and in making inspections into the condition of and wholesomeness and purity of the food produced, manufactured or sold in food factories, grocery stores, bakeries, slaughtering houses, dairies, milk depots or creameries and all other places where foods are produced, prepared, stored, kept or offered for sale; for studying the problems connected with the production, preparation and sale of foods, for expert witnesses attending grand juries and courts; clerk hire and all other expenses necessary for carrying out the provisions of this act. Provided, The total expense from all sources shall not exceed in any one year thirty thousand dollars. The Board of Control of said Experiment Station shall furnish to the Auditor of Public Accounts an itemized statement of the expenditures of money under this act. The expenditures reported to the Auditor shall be paid by the Commonwealth to the Treasurer of the Experiment Station upon the written request of the Board of Control of said experiment station, and the Auditor for the payment of the same is directed to draw his warrant upon the Treasurer as in all other claims against the Commonwealth.

Section 12. When any manufacturer shall offer any article of food or drug for sale in the State, he shall file with the Director of the said Station, when requested by him, the name of the brand, the name of the product, the place of its manufacture or preparation, and a true copy of all the labeling used thereupon. Failure to so file within thirty

days shall be punished as provided in Section one of this act.

Section 13. In all prosecutions under this act, the Courts shall admit as evidence a guaranty which has been made to the holder of the guaranty by any manufacturer or wholesaler residing in this State, to the effect that the product complained of is not adulterated or misbranded within the provisions of this act. And said guaranty, properly signed by the wholesaler, jobber or manufacturer or other party residing within this State from whom the holder of the guaranty may have purchased the article or articles complained of, and containing the full name and address of the party or parties making the sale of such article to the holder of the guaranty, and in the absence of any proof that article or articles complained of were adulterated or misbranded after they had been received by the holder of the guaranty, shall be a bar to prosecution of the holder of such guaranty under the provisions of this act.

Section 14. All acts or parts of acts inconsistent herewith are hereby repealed, but this said act shall not be construed to repeal Chapter forty-eight of the acts of the General Assembly of nineteen hundred and six entitled, "An Act to regulate the sale of concentrated commercial feedings stuffs, defining same and fixing penalties for violations thereof." So much of this act as relates to drugs and liquors shall not take effect until on and after January first, nineteen hundred and nine.

W. J. GOOCH,

Speaker of the House of Representatives.

WM. H. COX,

President of the Senate.

Approved March Thirteenth, Nineteen  
Hundred and Eight.

AUGUSTUS E. WILLSON,  
Governor of Kentucky.

## COUNTY SOCIETY REPORTS.

**Anderson**—The Anderson County Medical Society met with Dr. Paynter on Monday afternoon, April 6th. Those present were:—C. W. Kavanaugh, Paynter, Lillard, Milton, Gilbert, Gibbs, Shoemaker, Pindar, Simpson and Murdock.

**J. R. Murdock**, owing to absence of Dr. Adams, read a paper on "Puerperal Septicaemia." In his paper he gave a description of the various kinds of fever that arise after confinement, and the different diagnosis between these and puerperal septicaemia. After a description of the symptoms the treatment was entered into and thoroughly discussed. Lysol solution was preferred to Alphozone, Creolin, Bichloride, etc. Use iodoform gauze as pack and place bicloride gauze pad over the vulva. Beef

tea or malted milk to keep up strength; veratrum v., aconite and byronia are used and sometimes gelseminia. Give plenty of cold water to drink. Use enemata for constipation. Open up abdomen for evacuation of any pockets of pus as last resort.

**C. M. Paynter**: A retained piece of placenta attached will give rise to continuous hemorrhage. If it is not attached you will have the bad odor, but no hemorrhage. Extreme caution should be used in handling of subsequent labor cases.

**C. W. Kavanaugh**: We must always keep in mind the distinguishing features between septicaemia and septicaemia. Thorough irrigation is about all that is necessary in septicaemia. In septicaemia it is generally a question of the resisting power of the patient against the ravages of the disease. Where surgical interference is necessary for accumulation of pus, it is nearly always advisable to remove entirely the uterus and appendages. There is no lochia present in septicaemia, as the fever dries it up. About all the treatment you can use is the judicious use of iron, quinine, and whiskey.

**G. D. Lillard**: The majority of the cases of puerperal septicaemia die. It is not a good idea to use the curette even in sapremia. Use the finger to remove any offending material when possible. There is no way of telling when the uterus is absolutely clean.

**O. F. Shoemaker**: Don't use curette but very little, especially after the poison has already been absorbed into the system.

**R. F. Milton**: A great many cases of so-called septicaemia are cases of sapraemia. Five to ten drops or even one dram of oil of cinnamon in one quart of water is an excellent antiseptic wash. Be careful in use of *Veratrum viride*, *Byronia* and *Aconite*, as they differ a great deal in their action. *Veratrum v.* is indicated where there is a red streak down the middle of the tongue. *Echinacea* is an excellent remedy.

**Sidney Simpson**: Reported a case of septicaemia which he had treated. This case got up ten days after labor and was taken sick on the twelfth day. Death followed on the twenty-ninth day after high delirium and other typical symptoms of puerperal septicaemia.

**L. O. Pindar**: Some cases of labor which I have attended leads me to believe that there is such thing as immunity from the disease. Bad surroundings, etc., make everything favorable to infection, but I have not seen a case.

**J. R. Murdock** closed the discussion. He advocated the use of a uterine sound bent at one end and covered with gauze as a curette.

**C. M. Paynter** read a paper on Circumcision, in which he described several methods of operating, especially that of J. M. Ross, which he highly recommended.

There was some difference of opinion in the society as to the amount of immunity obtained

by circumcision from syphilis.

The society passed unanimously a resolution thanking our representative, Judge Dowling, for his support of the measure before the last House in the interest of public health and the medical profession. The society adjourned to meet with Dr. Kavanaugh on first Monday in May.

J. W. GILBERT, Secretary

**Bath**—The Bath County Medical Society met Saturday, March 14th in J. H. Taulbee's office, with the following present: Walden, Taulbee, J. W. Jones, Robbins, Corneilson and Daily.

**B. Corneilson** reported a very interesting case. Woman 60 years old, came to him suffering with her bladder, was very weak and nervous; after treatment for several weeks she passed a tooth-like structure which was about the size of a large pea. This caused considerable pain, and the doctor assisted her by catching it with forceps and removing it. Three days later there was dribbling of urine, and she had no control of it. On the fifth day after the passing of the tooth, the doctor discovered a bunch of hair protruding from the urethra and removed it by the aid of a pair of forceps and found a nest containing a small bone almost an inch long.

She has now recovered and passes urine normally. Her youngest child is 25 years old.

**J. H. Taulbee** said that it was a dermoid cyst which had attached itself to the bladder and then ruptured and emptied its contents into the bladder.

**A. W. Walden** reported a case of a child 9 years old contracting tuberculosis from her great grand-mother with whom she slept.

**H. J. Daily** reported a case of ptomain poisoning in child 18 months old from eating canned salmon.

The petition of C. L. Cook, of Salt Lick, was received and referred to the Board of Censors. The board recommended him for membership. The By-Laws were suspended by unanimous vote, and he was elected to membership.

As our delegate, R. E. Evans, had moved out of the State, a motion was made and seconded that we go into the election of a delegate. Motion was carried, and J. H. Taulbee, of Owingsville was duly elected.

The society adjourned to meet Monday, April 14th, at 10 A. M., in J. H. Taulbee's office.

H. J. DAILY, Secretary.

**Barren**—The Barren County Medical Society met at Glasgow, April 14, 1908, J. Morgan Taylor in the chair. Members present, W. T. Britt, A. E. Ferguson, C. W. Froedge, R. E. Garnett, J. G. Siddens, A. T. Botts, S. T. Botts, J. M. Taylor and R. S. Plumlee.

**W. T. Britt** reported a case of hydrocephalus.

**A. T. Botts** reported a similar case. Child lived 24 hours, having convulsions every few

hours during the time. **R. E. Garnett** had never seen but one case. Had a midwife for 12 hours. Called a physician, and he another physician. They worked 12 hours and delivered a body, but head still in pelvis. Head was perforated, water drained away and head delivered.

**R. S. Plumlee** had seen one case which had been in care of another physician. Woman in labor 24 hours. The attending physician was unable to make a definite diagnosis. Finally diagnosed as hydrocephalus. Attempted to deliver with forceps. No avail. Perforation, relieving head of an immense amount of water. Head being greatly elongated, collapsed, and was easily delivered by aid of placental forceps.

**S. T. Botts** reported a case of ascites of foetus. Attempt was made to deliver with forceps, and head was severed from the body. Then the bag of waters could be felt through the opening into the abdomen of foetus. Perforated with a pair of scissors, draining the water away, after which delivery was easily accomplished.

A general discussion followed as to time and manner of delivering the placenta.

**S. T. Botts** delivers by the bimanual method as soon as the cord is severed. Others favored waiting till tone is restored to the uterus and deliver by Crede's method.

**J. G. Siddens** makes gentle traction on the cord.

**A. T. Botts** suggested that if the placenta could be removed without introducing the hand, there is one chance less that the mother is infected.

**A. E. Ferguson** presented a clinical case as follows:—Man 35, married, sick two months, previous health good; over a year ago had a small tumor removed from ear with Yandell's paste. Height 6 ft., weight 125. Temperature 100 to 102 degrees, pulse 90 to 110. Has coughed and expectorated a little for a few days owing to fresh cold. Began with pain in small of back, followed by small hard knots the size of quail eggs seemingly in fascia of back. Has pain in stomach and soreness under ribs. Indigestion, loss of appetite, and has been constipated for three months. Loss of flesh and strength. Mother died at 63 of tuberculosis. Father died at 79 of dropsy. Heart, lungs, and kidneys normal. Oedema of lower limbs, liver twice normal size. Diagnosis:—Multiple Sarcoma. Treatment:—Nil.

The chairman suggests that each member have a case ready to report at each meeting. Have it arranged logically.

R. E. Garnett, Froedge, and Plumlee were appointed as a committee on resolutions on the death of J. B. Honeycutt, and reported as follows:

Whereas. It hath pleased Providence on the 14th day of December, 1907, to remove from among us by death J. B. Honeycutt.

Resolved, That this society has lost one of its most useful members, the medical profession one of its most efficient physicians and surgeons, the community a valued citizen, and the wife and children a gallant husband and tender father.

That the society tenders its sympathy to the bereaved family.

That these resolutions be spread on the minutes of the society, published in the **State Medical Journal**, and a copy be furnished the family of the deceased.

R. E. GARNETT,  
C. W. FROEDGE,  
R. S. PLUMLEE,

Committee.

**J. M. Taylor** read a paper entitled:—"The relation of the Medical Society to the Laity."

Motion carried to submit the paper to the **State Journal** and local papers for publication.

The chair appointed R. E. Garnett to prepare a paper for the next meeting on How to Prevent Piracy Among the Members of the Medical Profession, and C. W. Froedge to prepare one on Rheumatism.

No further business appearing the meeting adjourned to meet May 12, 1908.

R. S. PLUMLEE, Secretary.

**Casey**—The Casey County Medical Society met in Judge M. L. Sharp's office at Liberty, on the 26th day of March, with J. M. Haney in the chair.

The first thing on the program was a paper by D. S. Floyd on "The Etiology and Pathology of Tuberculosis." The paper was a good one, and relished by all present. It was discussed by all present.

**C. B. Creech** then read a paper on "Bacteriology," which was a splendid paper, and discussed by J. T. Wesley.

**J. M. Haney** then read a paper on "La Grippe" which was discussed by all present.

The Committee on Program reported the following: Immunity, C. B. Creech; Summer Diarrhoea, Pierce Martin; Puerperal Eclampsia, L. F. Hammond; Diagnosis and Treatment of Tuberculosis, D. S. Floyd.

The society then adjourned to meet in Liberty on the 23rd day of April, 1908.

L. F. HAMMOND, Secretary.

**Christian**—The Christian County Medical Society met in regular session in the City Courtroom, President Stites being in the chair and the following present: House, Woodard, Wright, Keith, Rice, Erkiletian, Ketchum, Sandbach, Harned, Broaddus, Backus, Allen, Blakey, Young, Jackson, and Beazley. On a call for report of cases **R. L. Woodard** reported a case of aneurism below politeal space. The history of the case was that the tumor appeared first

in politeal space, and afterward gravitated to present position.

**J. H. Rice** reported a case in a child of 13 years, with following history:—Morning temperature of 100° to 100.5° and evening temperature of 100.5° to 101°, ranging as high as 104.5° and continuing for a week before becoming normal. Then on resumption of food the symptoms were repeated for two successive times. A chronic constipation through the entire attack, patient jaundiced, cornea infected with bile pigment. Nausea and emesis and irregular intervals. Tenderness over Glisson's capsule and lower right quadrant of abdomen.

This case elicited quite a discussion, the question being raised as to the correct diagnosis, whether catarrhal cholecystitis, mild typhoid, or some affection of appendix.

**J. W. Harned** read a paper entitled "A Sketch on Hystero Epilepsy, and on Angina Pectoris," with a report of case of each.

**H. C. Beazley** read a paper on "The Malevolent Influences of Adenoid Degenerations."

These papers were discussed by J. H. Rice, Erkiletian, House, Woodard, Wright, Young, Blakey, Stites.

A motion was passed to secure a permanent place of meeting. President Stites appointed Young, Blakey, and Keith to attend to the matter. There being no further business to come before the society it adjourned, to meet again the third Tuesday in April.

J. PAUL KEITH, Secretary.

**Carter**—The Carter County Medical Society met in regular session in the office of Stovall & Stovall in Grayson, April 14, 1908, with officers present J. Watts Stovall, pres. pro tem.; D. B. Wilcox, secretary; members present, J. Q. Stovall, W. A. Horton, C. L. Hudgins, Geo. H. Buek, G. B. O'Roark, and Geo. S. Wilcox. Jno. D. Mutters, of Kilgore and a member of Boyd County Medical Society was also present.

Minutes of the three previous meetings read and adopted.

Having money in the treasury it was decided to collect no dues for 1908.

A vote of thanks was ordered sent our member of the Legislature, Hon. Robt. L. Hutchinson, for his action in a just cause toward important medical or health legislation during the past session of that honorable body at Frankfort.

**G. B. O'Roark** read an interesting paper on "Sarcoma."

**D. B. Wilcox** read a paper on "Connective Tissue."

**J. Q. Stovall** read a paper on Pott's Fracture, which was discussed by W. A. Horton, G. B. O'Roark, and John D. Mutters.

**Jno. D. Mutters**, when the subject of buying a microscope was taken up strongly emphasized

its use and if he had to do without it or a clinical thermometer, would certainly dispose of the latter.

**G. B. O'Roark, Geo. S. Wilcox, J. Watts Stovall and D. B. Wilcox** were assigned subjects on the several portions of the skull, and **M. W. Armstrong** on "Colles Fracture" for our next meeting at Olive Hill, May 12th, 1908.

Our meetings are proving more interesting each month.

**H. B. Fraley**, a very successful physician of Willard, Ky., was elected a member of the society and is entitled to your valuable **Journal** and to membership in the Association.

Very respectfully,

D. B. WILCOX, Secretary.

**Davies**—The Daviess County Medical Society met at the city hall, Owensboro, on March 17th, with thirty-seven members present.

**E. D. Turner**, of Sorgho, presented a transfer card from the Barren County Medical Society, and was admitted to membership by a unanimous vote.

Our State President, **D. M. Griffith**, gave an account of his work at Frankfort during the session of the Legislature, which was much appreciated. His report made us feel proud of the State Society. He said the Committee on Legislation of the State Society had worked hard at a great personal sacrifice, and had accomplished a great deal. He suggested that a vote of thanks was due that committee. It was given with a vim.

The society instructed its secretary to write Governor Willson, asking him to sign Senate bill No. 121, if it came to him.

The society paid the expenses of **D. M. Griffith** to Frankfort to work in the interest of the exemption bill.

**P. D. Gillim** read a paper on "The Etiology and Pathology of Chronic and Acute Rheumatism."

**Ed Barr** read a paper on "Acute Articular Rheumatism."

**W. L. Taylor** read a paper on "Chronic Articular Rheumatism."

The papers were all complimented very highly and were discussed by **W. E. Irvin**, who said that baths at Hot Springs, Arkansas were the best treatment for chronic rheumatism. He quoted from Dr. Martin, of that place, who claimed that the waters were radio active.

**C. H. Todd** thought more could be done by clothing, diet, and hot baths at home.

**J. W. Ellis** said the papers were excellent, and on every-day diseases, and coming from the very youngest members of the society were much appreciated. The old theory was that there was hyperacidity of the blood, and to neutralize that the alkalies were given. I give them yet on the same theory. I also give alteratives in chronic

rheumatism, the best of which is iodide of potash.

**H. K. Orsburn** thought that while it was not proven that rheumatism was a germ disease, he so considered it. Had a patient with rheumatism in hand and fingers. Had the nurse to rub with liniment. Later the nurse had rheumatism in her hands. I think it is contagious. I have never had any good results in treating tonsillitis locally, but have cured it with large doses of salicylate of soda. Never got any benefit in rheumatism from using alkalies. Think the Hot Springs baths do good by elimination, enabling the patient to take more medicine.

**A. McKinney**: In treating rheumatism we are at sea without a compass. Lactic acid has been given, and produced rheumatism. We have hyperacidity; when alkalies are not used we have more heart complications. I always use them with that in view. Have given as much as 190 grains of salicylate of soda in 24 hours. Must treat symptomatically. Must relieve pain, even if morphine has to be given. Eliminate pains as much as possible. I think counter irritation does good, think when we quit blistering we condemned one of our best remedies."

**D. M. Griffith**: "Pyemia is a suppurative condition; in rheumatism we have a serous exudate. **H. K. Orsburn** said one-third of tonsillitis is rheumatism. That is correct. A man who has tonsillitis due to rheumatism has more attacks of rheumatism. His tonsils should be taken out. When they are, it is my experience that he has no more rheumatism. Such tonsils ought to be excised as a prophylaxis."

**P. D. Gillim**: "This discussion has been very instructive. **Dr. Griffith's** remarks surely give us food for thought. Do not believe lactic acid is the cause. The germ is the cause of the acid."

**Ed Barr**: "I am very thankful for the discussion."

**W. L. Taylor**: "The discussion has benefited me very much. The text books gave me no information on the treatment of chronic articular rheumatism. I do not think the iodide of potash does any good."

The society took dinner at the dining-room of the Methodist Memorial church as the guests of the Owensboro Medical Society.

The afternoon was devoted to the reports of cases.

Next meeting will be at Rome on June 16th.

J. J. RODMAN, Secretary.

**Elliott**—The regular meeting of the Elliott County Medical Society was held in Dr. Maggard's dental office Monday, the 6th day of April, 1908. The following members were present:—Maggard, Harper, Hunter, Lyon, and Sparks.

**E. H. Maggard** reported a case of puerperal

anemia, which was discussed by all of the members present.

**J. L. Lyon** read a very interesting paper on Bronchial Pneumonia, which was commented upon by the members present. I was unable to secure the paper for publication.

J. C. SPARKS, Secretary.

**Fulton**—The Fulton County Medical Society met in regular session in the office of John W. Naylor, in Cayce, April 9th, 1908, and was called to order by S. W. Luten. The following members were present:—H. Luten, J. M. Hubbard, Lon Naylor, S. W. Luten, Jno. B. Mahan, J. R. Luten, J. A. Phelps, C. A. Wright, C. M. Blackford, J. W. Naylor, J. M. Alexander, S. Cohn, John Yates, and L. P. Baltzer. Owing to the rain and muddy roads several members were prevented from attending.

The following resolution was introduced, read and adopted:

Resolved, That this society condemn all druggists guilty of counter-prescribing and refilling prescriptions that bear the words "Do not refill" unless authorized to do so by a written order from the prescribing physician.

Resolved, That while regretting the necessity of being forced to take this step, and appreciating the fact that the majority of druggists will unhesitatingly co-operate with us in this movement, we ask that all druggists kindly take notice and protect us in what is just and right, when viewed from a fair and impartial standpoint, and if they have been guilty of this mistake in the past that they kindly desist, thereby preserving the friendly relations that should exist between them and their friends, the doctors, and prescription authors.

Resolved, That in event any druggist, after having been informed, still persists in this violation, that this society take proper steps to stop same.

**J. R. Luten** reported a case of Ulceration around the mouth of the urethra in a female. It was an interesting case and was discussed by J. M. Hubbard, Yates, Alexander, Cohn, and Baltzer.

**John Yates** reported a case of Tubercular Adenitis.

The next discussion was on Typhoid Fever, and all present had quite a lot to say in regard to its treatment.

Five new members were added to our society, viz: John A. Naylor, Lon Naylor, J. R. Luten, C. M. Blackford, and P. B. Curlin.

**H. E. Prather** transferred his membership to the Jefferson County Medical Society, in Louisville.

There being no further business, on motion the society adjourned, to meet in Cayce on Thursday, June 4th, 1908.

L. P. BALTZER, Secretary.

**Garrard**—Dear Doctor:—I am just from Lancaster, where I met the Garrard County Medical Society. The doctors in Lancaster are all friendly, in a good humor, they are neat in appearance and I think as nearly antiseptic as doctors usually are; they all have nice homes and offices, and all of them appear to have "patience" enough to make them feel pleasant.

The greatest trouble with the doctors in the rural towns and the country is, they are so busy and prosperous, and are surrounded so pleasantly with good roads and good paying patrons that they don't believe it will justify them to quit business and pleasure long enough to attend a medical meeting.

I understand that Wm. McElliott, of Bryantsville, has recently bought a \$30,000.00 farm near Lancaster, and must needs go and see it. One of our Buck eye doctors "had bought five yokes of oxen, and must go and prove them," and Bascom C. Rose "was contemplating matrimony; therefore he could not come." But, William L. Carman, of Paint Lick, and the doctors of Lancaster were present, and we had a very interesting meeting.

The doctors of Garrard County are good men and good doctors, and when we can get them enthused a little they will have a good society.

I am, very truly,

J. T. WESLEY.

Councilor 7th Dist.

**Henry**—The Henry County Medical Society met in the Court House in New Castle on March 30, 1908. Meeting called to order by Geo. M. Jessee, president. Present, J. P. Nuttall, Webb Suter, Everett Morris, Alfred Wainseott, Fred Garvey, R. W. Porter, Isaac Kelley, W. L. Nuttall, O. P. Chapman, O. B. Humston, Joe Morris, Vernon R. Jones, E. E. Bickers, and Owen Carroll.

A letter from the Kentucky State Medical Association, commending the action of Rev. Geo. C. Waggoner, representative from Henry County in his efforts to further medical legislation during the past session of the Legislature, was read by the secretary. The society ordered the secretary to have said letter printed in the Henry County local paper and to write a letter of thanks from the society to Rev. Geo. C. Waggoner.

**A. P. Dowden** read a paper on Acute Parenchymatous Nephritis.

**J. P. Nuttall** on Chronic Parenchymatous Nephritis.

**Everett Morris** on Prophylaxis.

The papers were discussed by all present and much enjoyed.

**Vernon P. Jones** and **J. Fred Garvey** were elected members.

Meeting closed to meet again on next regular meeting day. OWEN CARROLL, Secretary.

**Jefferson—Proceedings** of the Jefferson County Medical Society, the president, B. F. Zimmerman presiding.

At this meeting, in addition to routine business, plans were laid before the society to inaugurate a vigorous campaign for an increase in membership. The city has been divided in sections, committees selected for the respective sections, each of which were supplied with the names of the non-members in each district and April 13 set apart as "Field Day."

An appropriation of \$130.00 was made to the support of the Jefferson County Medical Library.

An invitation was extended the society to hear Willard H. Hutchings, of Detroit, address the Academy of Medicine on the Opsonic Index.

The editor of the *Journal* honored us with his presence and voice at this meeting.

Announcement was made that at the next meeting, March 23, **Henry L. Coit**, of Newark, N. J., president of the American Association of Medical Milk Commissioners and **Otto P. Geier**, Cincinnati, O., secretary of the American Association of Medical Milk Commissions, would be our guests and read essays on the milk problem with reference to a certified product.

#### A CASE OF ACNE WITH SEBORRHEA OLEASA.

By M. L. RAVITCH.

Mr. Ben B., age 22, presented himself to my office two months ago. He was suffering from an aggravated case of Acne, accompanied by Seborrhea Oleasa. Family history good. Denied ever having specific disease. Habits excellent. Health good. The disease started with a Seborrhea of the scalp and excessive secretion of sebaceous matter on the face. Skin later became dirty and greasy; an excessive crop of indurated pimples followed which covered almost every inch of his face and neck.

Domestic remedies and remedies suggested by several physicians were tried with negative results. There is not a physician who would like to tackle a case of Acne, and why not? The therapy of Acne has not changed for the last 50 years. Consult your text books for the last 50, nay, for the last 100 years, and you will find the same or a little made-over formulæ for Acne. The only thing for you to do is to stuff your Acne patients with Arsenic and tonics of iron,—new and old; use your smearing preparations, old and new. Stop up your patient from inside and outside and you think you have done something; but let me tell you, gentlemen, you may oil and soften a harsh and dry skin; you may cover and conceal a blotchy skin; but do you really know what you are doing. If you cannot improve his or her skin, you advise him or her to get married.

To my mind all your salves, proprietary or

non-proprietary, all your creams are fakes in their conception and failures in their action. To treat a case of Acne is not so easy, as you may think. To treat it successfully you have to seek for the real cause. In this case I had to deal with two conditions: with hyper-secretion of sebaceous glands and also obstruction of same. Hyper-secretion of the sebaceous glands produced these dirty and greasy patches and obstruction-comedones and indurated pimples. In the treatment of such a case, the best results are obtained by means which may be termed dynamic rather than chemical. This includes, antiseptic soaps, use of instruments and above all X-ray. The last remedy is the peer of all of them. Since the X-Ray has been proven to possess bactericidal action, it should be, then, more effective since it has been definitely established by Gilchrist that bacillus Aenes is the primary cause of Acne. I think Gilchrist was right when he said: "It has occurred to me whether we are not taking a wrong view in considering the anemia, constipation, headache, coated tongue, etc.; as always predisposing causes of Acne Vulgaris, whereas, these symptoms may be the result of continued absorption of toxin from the number of bacilli present in all the lesions. As far as the principle is concerned, the disease can be compared with erysipelas. In erysipelas the streptococcus pyogenes invade the skin, an acute local inflammatory process is set up and the toxin is absorbed rapidly into the blood, which causes the constitutional symptoms, viz: fever, headache, coated tongue, constipation, loss of appetite, etc. We do not say that these symptoms are the predisposing cause of erysipelas, but that they are the result of the disease. So from analogy, although we are dealing with a much more chronic disease in Acne Vulgaris, it is not too much to infer that the accompanying symptoms may result from the continued absorption of toxin produced by the innumerable number of bacilli present in the Acne lesions.

One more point about this patient. Since childhood he had a dislocated nasal septum, which caused a deformity in the nose. To correct this deformity is not a very difficult piece of plastic surgery. Any good surgeon could accomplish it to perfection. I invite the surgeons to discuss the last point.

#### DISCUSSION.

**Curran Pope**—Dr. Ravitch has reported a very interesting case. I would like to say that, in using the X-Ray in the treatment of acne, he is likely to find that there will be a recurrence of the trouble at certain points on the face, and that he will have to repeat the treatment from time to time. The reason for this is that the glands cannot all be destroyed; furthermore, we

would not want to take the chance of destroying all the glands in twelve sittings, even if we could do so. In treating any trouble on the face with the X-Ray we must bear in mind that we not only have to get the stimulating effect that come from the irritation caused by the X-Ray, but we must carry it to the point where the gland itself is actually destroyed. The advantage of the X-Ray in this condition is that it destroys the bacteria and, at the same time, destroys the glandular tissue.

Another fact should be borne in mind by those who use the X-Ray on the face, and that is the danger of setting up an intense dermatitis. However, this can be easily overcome by applying a high-frequency current, or by applying the red light, using a heavy red cloth.

**Dr. Ravitch (closing):** I have nothing to add except to say that I do not believe the high-frequency current amounts to anything. We can get the same result from static electricity. I have not seen a case where the high-frequency current has done any good.

**W. B. Pusey:** At a recent meeting of this society, when a symposium of papers was read on the subject of mastoiditis. I made the statement that there were certain cases in which it was not necessary to go into the bone to effect a cure. I have three patients here to-night who have fully recovered from this trouble, and the bone was not gone into. I would like for those who so desire to examine these patients.

**A. O. Pfingst:** These cases of mastoiditis are always interesting to me. We sometimes see cases which respond to treatment less radical than that which we are in the habit of employing. The patients whom Dr. Pusey has brought here to-night have been treated by simple incision through the periosteum, which has resulted, as we see, in very good cures. I can cite a case which I saw recently which recovered without either incision or operation. This patient refused to be operated on. Suddenly the discharge through the ear canal became more copious than usual and in a week or ten days the swelling over the mastoid disappeared.

What influence incision has upon these cases is hard to determine, and I am inclined to believe that Dr. Pusey's patients would have gotten well even without the incision, with free drainage through the canal and the nose. The incision has nothing to do with the cure other than letting out the pus that had formed under the periosteum. I think that, in the adult, there is very little chance of making the condition worse by undertaking the more radical operation. We can do no harm in exploring the bone, even if we do no especial good. The small opening in the bone will heal by primary intention. If we do not find pus, the opening soon closes up. Cases that do not heal in this way

are few and far between.

Dr. Pusey is to be congratulated; I had been rather skeptical as to the benefit obtained by simple incision.

**M. F. Coomes:** I have been greatly interested in the patients presented by Dr. Pusey. I think most of you received a little booklet a few days ago, in which the statement is made that many of these cases will get well by simply cutting down to the bone.

I remember one case in the person of a man from a neighboring town, who came here with an enormous abscess which had not opened. He stated that he was not able to go to a hospital. I opened the abscess and let out a great amount of pus. The whole temporal bone was denuded. That man went back home and made a good recovery.

I believe that in many of these cases, where there is no suppuration (and we do certainly have mastoid periostitis without suppuration), where the bone undergoes congestion, if I may use the expression, we may effect a cure by making free incision, going down through the periosteum, and establishing free drainage. However, in all mastoid cases, where we have an infectious pus, we must let that pus out before the patient will get well.

Every now and then we see a case in which there is a discharge which looks like pus, but which is, in reality, nothing more than lymph cells. I believe we may have lymph cells there as we do in the eye. I remember two or three years ago, in making a cataract extraction, and in thirty-six hours that man's eye had been eviscerated by the excessive flow of white blood cells into the eye. The man complained of pain and at the end of twelve hours I unbandaged the eye and found it apparently bathed in pus. I had the secretion examined under the microscope and found that it was not pus, but lymph cells. It is possible that we may sometimes have excessive flow of lymph cells into the mastoid, and I can understand how we might get rid of them, but I do not see how we can get rid of infectious pus without opening the bone.

I have a baby here to-night on whom I did the Brophy operation for closure of the hard palate five weeks ago. I brought the child here in order that you may see what has been done and the condition of the mouth five weeks after the operation. On the right side the septum and palate are together and on the left side the palate is loose, and I had to wire the two sides together.

## SYMPOSIUM ON ABORTION AND MISCARRIAGE.

ETIOLOGY AND SYMPTOMATOLOGY OF ABORTION AND MISCARRIAGE.

BY OSCAR W. DOYLE.

At the start I wish to state that in cover-

ing the subject for this evening, I have not made any attempt to make a differentiation between abortion and miscarriage, there being a wide difference of opinion considering a separation of these two conditions; if they indeed be separate and distinct. The facts contained in this paper are not new by any means, and are used simply as a ground-work to lead up to the more serious proposition as it will be presented in the two papers which are to follow.

The etiological factors of abortion and miscarriage depend in the first place to a great extent on the previous "personal history" of the patient, it being very essential to know if there be any history of previous constitutional diseases. Having obtained a personal history of the patient, the causes may be divided into the predisposing and exciting. Any constitutional disease such as syphilis, which is one of the most frequent causes, will give rise to either abortion or a miscarriage. Tuberculosis, chronic kidney lesions, chronic pernicious anemias are etiological factors. In the acute kidney involvements where we have albuminuria, the toxine will produce these conditions. The albuminuria that occurs during the course of pregnancy has often been blamed for a miscarriage, while a so-called "undetermined toxine," the result of pregnancy, which may have produced the albuminuria may have been of sufficient virulence to have produced miscarriage. The toxins of any of the acute fevers may produce it. Chronic and obstinate constipation; excessive vomiting have produced it. Improper habits and diets, too frequent use of alcohol and drugs are other causes. Improper exercise resulting in violent exertion and over-muscular stimulation have produced many cases. Diseases of the nervous system, and marked reflex nervous stimulation—the result of sudden frights or sudden emotions, and marked mental depressions have been other causes. Too frequent nursing of children where pregnancy has occurred during lactation has been a frequent producer of these conditions, especially in women who lead "loose lives." Gonorrhoea is said to be a frequent producer of either. Any of the diseases of the pelvic organs, especially those of an inflammatory nature are extremely apt to produce these conditions. Mal-formations, and mal-positions of the generative organs, especially retroflexion of the uterus are frequent producers of these conditions. Women who have borne a number of children are said to be especially predisposed to miscarriage, and especially after they have had one miscarriage.

Previous miscarriages seems to render the patient especially liable to miscarriage in any

subsequent pregnancy. The death of the foetus, especially for an undeterminable cause is a very powerful predisposing cause. The death of the foetus nearly always insures miscarriage, either normal (so called), or induced. Any injuries such as falls, direct violence to the abdomen are powerful producers of either condition.

Abortion has been produced mechanically both legitimately and criminally. Sorry to say criminal abortion seems to be on the increase. How anyone can so far forget their self-respect as to be guilty of producing criminal abortion, I cannot understand. Criminal abortion "is done" not only by "the professional (?) abortionist", but is said to be performed by some so-called (?) ethical men under the cover of supposed necessity and important surgical currettments. Legitimate abortion is such only when the life of the mother can be saved by the delivery of the foetus, and by no other means.

*Symptoms:* Abortion or miscarriages may be complete or incomplete, dependent on whether the foetus is expelled or retained. One of the earliest symptoms is hemorrhage. The hemorrhage may be slight or it may be copious, or of an intermediate degree. It may be continual or recurrent. When a pregnant woman in the early stages begins to exhibit signs of hemorrhage, it is at the least a sign of a so-called "threatened abortion." The sensation of chilliness and shivering may be the first symptoms. These may be caused entirely by nervousness or the involvement of the nervous system by the impending shock, or they may be the result of hemorrhage. The patient frequently complains of hot and cold flashes. These, however, are absent in a large number of cases. Pains in the lower portion of the abdomen accompanied by "a sense of bearing down" may accompany the hemorrhage or may occur after the hemorrhage has been noticed for some time, and they do occur in cases where hemorrhage is absent until almost time when the foetus is expelled. These pains are a constant factor when the morbid process has once been fully established.

During the fullest period of abortion or miscarriage, the symptoms are identical with those of normal labor. Frequently the foetus is expelled first and the secundines may be delayed from several hours to several days before being expelled; hence, it is extremely important that in all cases of abortion or miscarriage that it be determined that not only the foetus, but that the secundines have been expelled from the uterus. Retention of any of the uterine contents may give rise to secondary hemorrhages or septicaemia. Any serious complication may lead to death.

## PROPHYLAXIS AND MEDICAL TREATMENT.

BY WILLIAM B. DOHERTY.

I regret to offer an apology. When I received a telephone message to address the society I thought it meant to discuss a paper rather than to read one. However, I shall offer a few remarks on the prophylaxis and medical treatment of abortion.

Dr. Doyle has covered the ground very nicely and well in regard to the causes of abortion.

It is a good idea to assume that the uterus has a temperament. It may have an apathetic, an agreeable or an irritable temperament, so that the contents of the gravid uterus may be expelled on the least provocation, or it may be subjected to almost any amount of violence by traumatism and drugs, without an abortion having been produced. We all have known instances of pregnant women having fallen from a horse, or down stairs, or taken the most powerful oxytocics without any effect on the contractility of the uterus.

We have the preventable, or so-called "threatened," abortion, the inevitable, the complete, and the incomplete. There are two words that I believe are so unscientific in their meaning, and savor so strongly of rank quackery, that they should not appear in a medical book, or journal, or be used by a physician; these are "threatened" and "cure."

The treatment of preventable abortion may be summed up in one word *rest*: rest for the woman in bed and uterine rest, by sedatives.

A hypodermic injection of morphia to be followed later by opium and hyoseyamus by the mouth or rectum and keeping the woman in bed and free from excitement until all the symptoms have disappeared are the best measures for the prevention of abortion. If there be any underlying cause, such as syphilis, or dislocation of the uterus that should be treated. If the fundus is jammed under the promontory of the sacrum, and cannot rise over the pubes at the end of the third month, the woman is bound to abort if the retroversion is not corrected.

It is difficult to draw the line between the preventable and inevitable abortion. Even should we have pain and hemorrhage and dilatation of the cervix our duty is to prevent the abortion if possible. There are many instances in which there have been sufficient dilatation of the cervix to admit the index finger and contraction of the cervix took place without the expulsion of the ovum, and gestation went on to full term.

Hence the importance of the continuance of rest for several days after the symptoms on abortion have subsided, and the administration of *Tr. Viburnum Prunifolium* in teaspoonful doses three times daily for weeks af-

terwards. Cold applications, vaginal tamponade, and ergot are contraindicated when the object is to prevent the abortion.

With the protrusion of the membranes or copious hemorrhage, the abortion becomes inevitable and the mode of procedure is then quite different.

*The bladder and rectum should be emptied.* (This I would emphasize,) the vagina washed with sterile water, or weakly carbolized or lysolized water, the woman placed across the bed, her hips raised, the fundus grasped and pressed down, and the finger used as a curette introduced, and an effort made to remove the membranes. Should we be unsuccessful a vaginal tamponade of sterile gauze should be used, pressed against the cervix and left in the vagina for six or eight hours and a few doses of ergot administered. There is a strong probability that the ovum has been expelled in the meantime, or if not the cervix has become more patulous under the influence of uterine contractions produced by the ergot and tampon. After the removal of the tampon, the vagina is again washed and another attempt made to remove the membranes with the finger. If our effort should be again unsuccessful another tampon, higher up, a cervico-vaginal tampon should be introduced and left there for some hours.

It is indeed exceedingly rare that the uterus cannot be safely emptied if those rational means are adopted.

I am aware that many believe that instrumental curettement offers the best means of relief, and should not be delayed owing to the dangers of hemorrhage, sepsis and an endometritis following. I do not concur in this opinion. An abortion to me is a miniature labor with its stages not so well defined. We do not employ surgical interference in cases of labor unless some condition exists which calls for it. I don't see why an inevitable abortion should not be allowed to proceed, and a good chance given the uterus to expel the foetus and membranes without surgical interference.

The truth of the matter is that I fear that is too much curettement done for show, and often by inexperienced men. It is more difficult to perform instrumental curettement than to amputate a limb. Why should we use an instrument, when we can accomplish the same end with the finger.

It is said that the membranes should be removed to lessen the danger of sepsis, and that to curette the uterus when sepsis exists by postponing the operation, curetting then involves enormous danger. I am convinced there is greater danger from too active surgical interference than from lack of surgery.

Instrumental curettagé in exceptional cases is judicious—but I believe it should never be

used without persistent efforts having been properly made to remove the membranes with the finger.

SURGICAL TREATMENT OF ABORTION AND MISCARRIAGE.

BY H. A. DAVIDSON.

Not every case of abortion or miscarriage should be treated surgically, but it is my firm belief that if the large majority of such cases were treated by surgical methods we would have fewer sequelae such as endometritis, subinvolution, displacements, sepsis, anemia, sterility, neuroses, and recurrences.

Since abortion and miscarriage are both pathological and not natural physiological processes, we cannot expect nature unaided to restore the affected organs to their normal conditions.

Embryology teaches us that the decidua serotina and the chorion frondosum have developed sufficiently at the end of the twelfth week or third lunar month to form the placenta, and this the landmark to distinguish between abortions and miscarriages, the twenty-eighth week being the terminal period for miscarriages.

The treatment of threatened or preventable abortion is entirely medical and it is not in the scope of this paper to take up that phase of the question.

Inevitable, incomplete, complete, concealed and missed abortions, however, should be dealt with in an active manner.

It is often a difficult question to decide when an abortion is inevitable. Persistent hemorrhage containing clots and fragments of the ovum mixed with amniotic fluid, severe and increasing pains and uterine contractions, an os dilated sufficiently to admit the examining finger which palpates the ovum within the cervix, when these conditions are present then we may in nearly every case consider the abortion inevitable.

The fact should not be overlooked that abortion has been prevented even after considerable hemorrhage and dilatation of the os sufficient to admit two fingers.

In any case of abortion, after we are satisfied that it is not preventable, three plans of treatment are open to us—the one of inaction called the expectant plan, the other which calls for active surgical interference, and the third plan which calls for inaction until some complication requires active interference.

Adherents of each plan of treatment may be found in every body of physicians, and not until a large number of statistical records prove conclusively that one plan yields better results than the others will the treatment be established upon a firm foundation.

I believe that the majority of those who have tried all methods of treatment will agree

that the active surgical method is more satisfactory to both patient and physician. Edgar gives us the statistics of 242 cases treated by him, and they show a decided advantage in favor of the surgical method of treatment.

The several varieties of abortion require different methods of treatment. Since most abortions occur at the third month, we will describe the treatment of such a case. All methods preventing abortion having failed and having determined that it is inevitable, then our treatment becomes the opposite of that which has been used to prevent the abortion.

The patient should be placed in dorsal position, upon a suitable table upon which is placed a Kelly pad, the legs flexed and held by a Robb leg holder. The external genitals should be thoroughly scrubbed with green soap and a one per cent. lysol solution and then irrigated with a bichloride solution. The vagina should be treated in a similar manner, using gauze with which to scrub its epidermal-like surface.

Instruments and operator having been thoroughly sterilized, a weighted Sims speculum is introduced into the vagina, the anterior lip of the cervix is grasped by a double volsellum forceps and dilatation of the cervix is begun with the Godell steel dilator. The cervix is dilated slowly in all diameters until two fingers can be introduced into the uterine cavity. With the index and the middle fingers of the right hand in the uterus and the left hand on the abdomen over the fundus to make counter pressure the product of conception can be loosened from the uterine wall by insinuating the finger between the recently formed placenta and the wall of the uterus. A broad, dull, irrigating curette is scraped over the entire inner surface of the uterus to remove any portions of the decidua that may have been left by the fingers. The uterine cavity is then irrigated with a half gallon of hot sterile saline solution which washes out clots and loosens decidua and causes a firm contraction of the uterine muscles.

It is not necessary to pack the uterus with gauze for drainage purposes, because it would do more harm than good. Neither is it necessary to pack the vagina, because the natural drainage is excellent. After cleansing and drying the external genitals, the patient is put to bed and involution of the uterus is aided by half drachm doses of fluid extract of ergot three or four times daily or a combination of ergotin gr. i and strychnine gr. 1-30 may be given for the same purpose. Vaginal douches of bichloride 1-4000 may be given each day and on the fifth or sixth day the patient may sit up.

The above is the treatment for an ordinary non-septic, inevitable abortion. The most important part of the whole procedure is the digital curettage, because without the finger in the uterine cavity to palpate the whole interior you can never be sure the cavity is empty. The dull and even the sharp curette will often leave behind secundines which will cause hemorrhage during the puerperal stage.

The treatment of incomplete abortion, non-septic, is the same as the above for inevitable abortion. In so-called complete abortion it is always wise to make a digital exploration of the uterine cavity to be sure it is complete, because hemorrhage has often been known to follow such complete abortions.

As soon as the diagnosis of concealed or missed abortion has been established, the uterus should be emptied by the same procedure employed for inevitable abortion.

In septic abortions the treatment is somewhat different and there should be as little traumatism to the inside of the uterus as possible. The fingers should be relied upon almost entirely. The dull curette may be used occasionally, but the sharp curette should never be used because of the danger of breaking down the granulation barrier formed by nature and scattering broadcast in the circulation the infective germs.

In the early months of pregnancy before the placenta is formed, complete abortions are common, but after the third or fourth month they are rare, because the placenta is firmly adherent to the uterine wall and this fact constitutes one of the chief differences between abortion and miscarriage.

As we approach nearer the seventh month the process is more and more like labor, and it is often wise to wait until the uterus has expelled as much of the product of conception as possible and then aid it by a digital curettage.

In all cases of abortion and miscarriage, where hemorrhage is profuse, it is a good plan to pack tightly the vagina with twenty-five or thirty-five yards of sterile or iodoform gauze, wrung out of hot water. This not only prevents the hemorrhage but aids in the dilatation of the cervix while preparations are being made for the proper surgical treatment.

#### DISCUSSION.

**Edward Speidel:** I wish to thank the essayists for the very excellent papers that have been presented.

In spite of the fact that the text books disagree as to when the terms abortion and miscarriage should be used, I believe it is necessary to make a definite distinction. By one authority the period of gestation is divided into ten lunar

months. An interruption occurring during the first three months is called an abortion; during the second three months, a miscarriage, and after that a premature labor. This authority also subdivides the first period into early and late abortions; if during the first month, an early abortion, after that a late abortion.

In regard to the etiology of abortion, it is generally conceded that in all cases an endometritis must be present to bring about an abortion; that a woman with a perfectly healthy endometrium will retain the ovum in spite of all efforts to expel it. This may explain why a woman, under certain circumstances, may take the strongest emmenagogues without effect, while in other cases a very trivial accident may produce an abortion.

The most important point in the treatment of threatened abortion is complete rest, in bed. We should insist upon the patient maintaining a recumbent position, not even rising to evacuate the bowels or kidneys. If the patient is allowed to get up at all, it defeats the purpose for which she is put to bed.

Another important point is to give the stomach and intestines as much rest as possible, preventing intestinal peristalsis by letting the stomach alone. The administration of medicine should be per rectum and, in cases where the patient is particularly desirous of retaining the product of conception, rectal feeding should be resorted to.

The treatment of the condition depends, to a large extent upon the time the abortion or miscarriage occurs. If during the first month, and the ovum is expelled, then surgical procedure is not always necessary, provided there is no elevation of temperature. In such cases nature will take care of the decidua that has formed.

If the abortion occurs during the second or third months, the ovum being expelled and the decidua retained, the latter must be removed manually as soon as possible. For that purpose the best thing to use is the finger. If it cannot be done successfully with the finger, then a sharp curette should be used.

The treatment of septic cases is, of course, entirely different. In these cases the cervix should be dilated and the interior of the uterus palpated with the finger and anything that is present in the uterus should be removed. However, under no circumstances should any instrument be introduced into the infected uterus. The patient has a better chance if the uterus is left alone.

Miscarriages occurring during the fifth and sixth months of gestation deserve some especial consideration, for the reason that there is apt to be severe post-partem hemorrhage. In such cases there should be no interference, in order that the bag of waters may not be ruptured.

**W. B. Gossett:** I would like to quote one or two extracts from a paper upon "Miscarriage

and Its Treatment" which I read in August, 1901:

"A miscarriage is an expulsion of the contents of the gravid uterus before the foetus is at a viable age, and when the expulsion is not produced by criminal measures. If the expulsion is due to criminal procedure, then the term abortion should be used instead of miscarriage.

"The degree of development of the ovum makes a difference in the phenomena of the miscarriage. A miscarriage at the first or second month is not similar to one of the fifth or sixth month. During the fifth or sixth month a miscarriage is very much like a labor at full term. At the first month it is similar to a painful menstruation. During the second month the pains come with some regularity, and at the third month, this is more marked and continued to become more marked as the pregnancy advances."

You will see from this that I believe the term abortion should be dropped except in cases of criminal procedure.

We all know that the trouble in miscarriage is, not in passing the little foetus, but in getting rid of the placenta. The expulsion of the foetus is very simple, but portions of the placenta are frequently left behind. If you can remove the placenta with the finger, do so, but it frequently happens that you can remove only a portion of it with the finger, and it is then necessary to use the curette. I have here one form of curette which I like better than anything I have ever tried, and which I can use without the placental forceps. With this instrument I can go up into the cervix, get beneath the portions of the placenta and take them out without injuring the uterus in any way. With a sharp curette there is danger of puncturing the uterus. I formerly used the sharp curette, but I have abandoned it in favor of this instrument. As to the use of Bichloride, I don't use it.

I have used lysol for a number of years and I know of nothing to equal it where a post-partum douche is necessary.

I wish to emphasize that when a curettement is done that as great care should be exercised as in doing an abdominal section.

**W. H. Wathen:** I am not now practicing obstetrics or treating abortions, but in consultation work and in my work in previous years, I have had a very extensive experience in these cases.

It is a question what is meant by surgical treatment of abortion. If it means the use of instruments, then I say that it is seldom, if ever, indicated immediately after the abortion occurs, and not until some complication resulting from sepsis develops. The best curette and the best dilator that I have ever found is my finger.

When, twenty-five years ago, I advocated (and but few then agreed with me) that the secundine should always be promptly removed after every abortion, I was told that this treatment was not

good, on the ground that, if tampons were used in the vagina, the membranes would be expelled and no after treatment would be necessary; and, further, that it was impossible to remove the membranes from the cavity with the finger. I want to say that, in twenty-five years, I have not seen a case where, if called promptly, I was not able to dilate the uterus sufficiently well with my finger or fingers, and, by placing the woman in an exaggerated lithotomy position and giving her anesthesia, to push the womb down and remove with my finger every particle of decidua structure. In some cases you may not be able to get all of these structures away, but you will have, as a rule, completely separated them, and then, if the cervix is tightly contracted around your finger, you may with forceps or blunt curette pull the membranes away.

I have recently been called in consultation in a number of cases, and in only two did I use anything but my finger, and those were cases in which the abortion had occurred two days before I saw the patients, and contraction had so far progressed that I could not successfully use my finger, but with a plain curette I separated the membrane and pulled them all away with a forceps.

In another case where the woman had a fibroid tumor and aborted at three and one-half months, I simply separated the membranes with my finger and pulled them away with the placental forceps.

**Chas. Hibbitt:** I believe it is a good rule to never put anything into the uterus if we can avoid it. I do not even carry the finger into the uterus if its contents can be gotten out without the aid of it.

There is only one other point I wish to speak of; that is, with reference to curettage. We can sometimes carry a pair of forceps into the uterus, attach it to the placenta and remove it without any trouble; at other times, we have to loosen up the placenta and little particles are left behind attached to the walls of the uterus. Dr. Gossett stated that it is here we must use the curette. I differ with him. I have adopted the plan of grasping an ordinary gauze sponge with a pair of common forceps and carry it through the cervix into the uterus and sweep it around the walls of the uterus. The rough surface of the sponge or gauze will detach or brush off the particles on the inside of the uterus, and they can be swept out with another sponge. I use no irrigation after this procedure. This plan eliminates the use of a curette, sharp or dull, or any other instrument.

**B. J. O'Connor:** There is one thing which, if insisted upon and carried out in the management of these cases, would bring better results, and that is asepsis. I think a great many of us are prone to be a little careless, even in examining a case of abortion. If we were as careful

in making these examinations as are the surgeons in operating, a great many of the complications following abortion would be avoided. Another thing, we should practice asepsis rather than use antiseptics, such as bichloride of mercury, which does as much to bring on infection as it does to prevent it.

**A. T. McCormack:** I have listened to the papers and discussion with a great deal of pleasure. The question of abortion is a very interesting one to every practitioner.

I agree with my friend Dr. Doherty that inevitable abortion should be so denominated by us only when the membranes or the foetus are presenting at the os. It is extremely rare, except when the abortion occurs during the first few weeks of pregnancy, that I find it necessary to use any dilator other than my finger.

The State Board of Health has adopted a definition of criminal abortion which is at once simple and comprehensive. It is, if I remember correctly, "emptying, or attempting to empty, the uterus at any time during the period of pregnancy, except it be the only means of saving the life of the mother." We cannot get this too firmly fixed in our minds; that, whenever the uterus is emptied unnecessarily, a murder is committed, and that the man who brings it about is a murderer none the less because his victim is guilty only of "unborn innocence."

**Oscar W. Doyle (closing):** I have enjoyed the discussion very much. I want to endorse the point made by Dr. Gossett that we should make some differentiation between the terms abortion and miscarriage. The laity accepts the term "abortion" as criminal in all cases, where this word is used.

I also wish to endorse Dr. McCormack's remarks to the effect that abortion is legitimate only when brought about in order to save the life of the mother.

Another thing I wish to indorse is the finger as a curette as brought out by Dr. Wathen and others.

**Wm. B. Doherty (closing):** I was particularly glad to hear my friend Dr. Wathen endorse the finger as a curette in these cases.

When I used the word antiseptics rather than asepsis, of course I meant cleanliness. I discarded bichloride of mercury years ago and do not believe it should be used any time without using sterile water afterwards.

I was delighted to hear the finger indorsed, as I rather expected a good many of the gentlemen to take issue with me, because I thought most of the men in this city who do surgical work preferred instrumental curettement to the finger.

**H. A. Davidson (closing):** I do not believe any antiseptic should be used in the uterus. In my paper I recommended the use of saline solution. I can see no objection to using any ordinary antiseptics for vaginal douches.

Dr. Wathen said that he did not find it necessary to use a dilator in any case of abortion, yet in the past three months I have seen a number of cases of abortion in which it was impossible, no matter in what position the patient was placed, to introduce the finger into the cervix. In those cases a dilator should be used. In late abortions, where the cervix is easily dilated, of course a dilator is unnecessary.

I want to reiterate that it is absolutely necessary to introduce the finger into the uterus, because I do not believe any instrument will clean out the uterine cavity perfectly, nor can we be sure that it is clean unless we palpate with the finger. It is only when we cannot remove every portion of membrane and decidua with the finger that the curette should be used, and then a dull curette is all that is necessary and there is no danger of injury to the uterus.

V. E. SIMPSON, Secretary.

Proceedings of Jefferson County Medical Society, the president, B. F. Zimmerman presiding, March 23, 1908.

The transfer card of Hugh E. Prather, from the Fulton County Medical Society was presented and accepted.

A committee was appointed consisting of Wm. Jenkins, Jno. G. Cecil, and B. C. Frazier to investigate the feasibility of securing permanent quarters for the society in the Atherton Building. The society is sorely in need of such provision and its membership has now reached such proportions that it is felt that such end may be accomplished.

The preliminary reports of the various "Field Day" committees are very satisfactory. Our members are enthusiastic and those not belonging are coming to realize the importance of the post-graduate work such an organization provides and the necessity of medical organization for economic reasons.

Henry L. Coit, Newark, N. J., and Otto P. Geier were the guests of the society, and read instructive and timely papers on the milk questions now attracting the attention of the profession throughout the country. A rising vote of thanks was extended the gentlemen.

The committee in charge of the "Registration of Nurses," consisting of O. E. Bloch, G. S. Harris and D. C. Morton made a report to the effect that plans were now being worked out that they believed would render the nurse service more satisfactory, as a Nurses' Directory was being created which would be official, thus removing much of the annoyance at present experienced by physicians in securing nurses.

OUR EXPERIENCES WITH CERTIFIED MILK IN CINCINNATI.

By OTTO P. GEIER, Cincinnati, O., Secretary American Association of Medical Milk Commissions.

It was while demonstrating the impure and

dangerous milk supply of Cincinnati, before the Academy of Medicine, that Dr. W. H. Crane died most suddenly and tragically on May 5th, 1906. A vigorous, keen, intellectual, broad-minded physician, filled with humanity, passing out/in this tragic way, left a deep impression upon the medical fraternity of our city. One month later the formation of a Milk Commission was proposed and the President of the Academy appointed the same. Two personal friends of Dr. Crane's took their places on this Commission and whatever they may have been able to accomplish in this work reflects but his unselfish devotion in the same direction.

In August, 1906, the "Certified" milk appeared in the Cincinnati market. Some few months later "Inspected" milk, then "Inspected Bulk" for hospitals, and the further history of this Commission does not differ much from that of earlier Commissions. They placed both a clinical and a household milk in the market, educated themselves, as well as the physicians, on this topic and used their influence to raise the standard and quality of the general supply of their city.

A few months after the organization of this Commission, it addressed a serial of twenty-five questions, covering every phase of milk commission activity, to the twelve commissions then known. An exhaustive tabulation of these replies formed part of a report to the Academy of Medicine November 12th, 1906. It showed that there was considerable diversity in the supervision of working methods, bacteriological and chemical standards, etc., and the prediction was made that at some date in the near future all these commissions would be called together in conference to harmonize their requirements and unify their standards of purity.

On February 25th, 1907, an invitation was issued by the Cincinnati commission to hold such a conference, either in Cincinnati or elsewhere, as the majority might determine. An enthusiastic response was received from most of the commissions, but unfortunately no reply was received from Dr. Coit, of the Newark, N. J. commission. It was like playing Hamlet without Hamlet. An imperative telegram referring him to our invitation, brought back an acceptance in a forty-word message.

From that time things moved quickly. A temporary organization was formulated, which mapped out a program and decided that the meeting should be held at Atlantic City, June 3, 1907, one day previous to the American Medical Association. To give some idea of the labors of this temporary organization, it can be said that some one hundred and fifty letters alone were issued from the Secretary's office relative to this conference.

Even the most optimistic were surprised at the size of the meeting and the character of the men that came to attend from near and far. Members of commissions from New York to Oakland, Cal., elbowed with the leading scientists and hygienists who had been devoting themselves to some particular phase of the pure milk crusade. During the session twelve commissions reported their methods and results. Dr. Coit traced the early history and development of the milk commission idea in his paper, while other papers were presented on the more general topic.

It was an inspiration to see with what devotion, regularity and close attention these sessions were attended, to the number of about one hundred and twenty-five men.

A permanent organization known as the American Association of Medical Milk Commissions was formed. A President, Secretary and Treasurer, along with five other members comprising the Council of this association, were duly elected. The executive officers are to be elected each year, while the five remaining members of the Council were elected for one, two, three, four and five years, respectively. The terms of office expire in the succeeding five years, and so one member of the Council will be elected at each annual meeting. The following standing committees were appointed: Medical Examination of Employees; Chemical Standards; Bacteriological Standards; Veterinary Inspections; Protection vs. Tuberculosis.

One clause in the Constitution of this Association gives the keynote of its life: "The purpose of this Association shall be to federate and to bring into one compact association the Medical Milk Commission of the United States; to exchange views and to adopt uniform methods of procedure in the work of Medical Milk Commissions; to fix chemical and bacteriological standards; to determine the scope of veterinary inspections, and to foster and to encourage the establishment of Medical Milk Commissions in other cities." The conference agreed that a crusade for pure milk in any section could be best advanced by the establishment of a Medical Milk Commission appointed by the County Medical Society.

It was determined likewise that the Secretary should edit and have printed for distribution, the proceedings of the annual meetings. The report of this meeting will soon appear. The next Annual Meeting is to be held in Chicago, Monday, June 1, 1908, one day previous to the American Medical Association.

It will be recalled that we had knowledge at the time of the first conference, of some twenty-two Commissions. The Secretary of the Association has been in correspondence since

June, 1907, with fourteen other cities, who have organized or who are contemplating the formation of a Medical Milk Commission. This has brought with it the writing of some one hundred and fifty letters along with the distribution of such printed matter as the Secretary had at his command and which would assist in the proper conception of this work.

Out of this experience has come the realization of both the present limitations of this Association, as well as its tremendous possibilities under more favorable circumstances. One cannot conceive of any organization capable of doing more good than this, had it sufficient funds to print and distribute a concise working manual covering every phase of Milk Commission activity, as well as to do the heavy clerical work and correspondence that naturally follows the request for and from all quarters.

The A. A. M. C. should be in position to put into the field a representative, who would visit one county medical society after another in our larger cities, giving a stereopticon lecture on this subject. The address should be held under the auspices of the county medical societies, who would invite representative business men and charitably inclined citizens. His demonstrations should cover bacterial and chemical analysis of their own city's milk supply and that of hospitals and institutions. Pictures of their best and worst dairies should be shown on the screen. All facts bearing on the urgent necessity for an intelligent and concerted study of their milk supply by a disinterested, unselfish set of men organized into a Medical Milk Commission would be advanced.

At such very meeting, funds could be raised with which to begin the work. The literature and the working manual of the Association would be distributed and thus at once a broad interest created as well as a demand for a clean supply of milk. Once established, each Milk Commission becomes a potent factor in the community, not only in supervising the production of a limited supply of clinical milk such as "CERTIFIED," but their activity and study of the milk problem will stimulate the efforts of the local Board of Health and thus naturally affect and eventually raise the quality of the total supply of that city. Dr. Goler shows a lowering of mortality in children under five, from 33% to 15% by such a crusade in Rochester. The general mortality of civilized communities has been steadily lowered while that of infants under one year remained about the same. Gastro-intestinal diseases, which are the largest single factor of this latter, is due chiefly to improper feeding and causes an enormous loss of potential wealth to our nation.

Mr. Nathan Strauss, of New York City, has

had his name heralded from coast to coast, as a benefactor of mankind for the heated milk supplied to New York City's poor. Stripped of all fancy, his pasturization nearly kills a certain percentage of the bacteria in a dirty milk, possibly leaving the toxins that have already been elaborated by their growth. This method tends likewise to create false sense of security as to its keeping quality, while it actually lowers the germicidal power of milk. Pure milk is better than purified milk. It is not the purpose of this paper to minimize or depreciate the good he has done, but rather to hold in contract the efforts and possible results by Medical Milk Commissions. Mr. Strauss works with a product from an unknown source and of unknown quality.

The Medical Milk Commission starts out at the dairy with healthy cattle, free from tuberculosis. It insists upon modern sanitary rules throughout the process of milking. It cools the milk, bottles it in a clean state (practically free from bacteria), and retards their increase by keeping the milk cold until delivery to the consumer.

In other words, the A. A. M. C. stands for clean, cold milk produced by healthy cattle and free from pathogenic bacteria and speedy delivery. That does not seem like an unreasonable demand, yet few cities, *comparatively*, can claim such product.

Mr. Nathan Strauss, in his philanthropy we assume, receives one dollar's worth of return for every dollar spent in his pasteurizing plants. The man who spends one dollar in the furtherance of the Milk Commission idea would see it increase a thousand-fold in its effectiveness.

This is no tale of an Aladdin lamp, but one in fact. Let us marshal the proof and show how this is provable.

The history of any well organized medical Milk Commission is that of careful study of the local problem by the leading physicians of a community—one or more model dairies are soon established—a demand for their product is created by educating the physicians of that community to the value of such a clean supply. We then find that the laity begin to demand milk of a better quality and are educated to pay a higher price for same. The demand for any article soon creates a supply and we find that dairymen try to produce the quality of milk for which there is a demand, especially since it is sold at a premium.

Philanthropy usually steps in at this point and supplies this clean, safe milk to the babies of the poor through milk dispensaries. With the publicity that naturally follows, there comes the demand that the local Health Board improve the general supply and through this many links in the chain, the masses are finally reached.

All over this great land of ours, the men of great means and generous hearts are seeking some avenue of well-doing. Could they know the tremendous possibilities for good that lie in this work; could they see how far-reaching their philanthropy could be made through the establishment of hundreds of Medical Milk Commissions in as many cities; could they appreciate how quickly these results would become national in extent and help solve the most serious economic and social problem of all people in all lands; then would our Association be embarrassed by the riches that would flow in to do this work. And what better trusteeship for such a fund than the A. A. M. C., made up of the leading physicians and hygienists of the country, who have given their best thought to the solution of this very vital subject of pure milk—and all come of unselfish devotion and a broad humanity.

CLEAN MILK IN ITS ECONOMIC AND MEDICAL RELATIONS WITH SPECIAL REFERENCE TO  
"CERTIFIED MILK."

BY HENRY L. COIT, M. D.,  
Newark, N. J.

The professional purpose of trying to save human life makes all the medical world akin. The relations of clean milk to this altruistic work have now become very important and touch it at many vital points. In accepting your invitation to speak on these relations before this splendid gathering of Kentucky physicians, I am greatly honored.

Milk is the most important link connecting the present with the past. It is with this vital fluid that the foundations of human life are laid. It is by the initial use of milk that all men and women become links in the chain which makes them units in the human race.

Upon the kind of milk employed will depend the physical character of the human unit, and this is determined during the milk period of infancy. Since material lactation is a rapidly disappearing function it is the most urgent question before mankind to-day.

How to get pure milk is a vital economic question. The present enormous infant mortality among the industrial class and a declining birth rate are looked upon with apprehension by all political economists.

In Europe where infant mortality is already a menace to the integrity of nations, will be found crowned heads with their ministers eagerly trying to solve the problem of depopulation.

In France where material sterility is coupled with a high infant mortality the situation is acute and every means is invoked to stem the tide of decadence. The Paris Statistical Department reports a shortage of 400-

000 births a year to keep them level with the proportionate increase of other countries. They now have three births to a family—they need four.

The only available means to prevent this state of things is by successful artificial feeding to cut down the death rate in the milk period of infancy, whether in Berlin or Brussels, New York or New Orleans is about 30% of the number of yearlings who are born alive.

How to get pure milk is a great medical question, since it constitutes almost the exclusive diet of the entire sick population. It is also the only food available for the nourishment of infants who must be fed artificially.

How to get pure milk is a serious public question, because milk being a delicate organic fluid easily spoils unless it receives great care. It thus becomes the cause of disease by its decomposition, and is also the carrier of contagion in many of the most fatal epidemics.

How to get pure milk is a crying social question expressed in the bitter wail of the tenement house child. This is a sociologic problem of great magnitude and would be a field for the philanthropic activities of many millionaires. More lives are saved and more pauperism prevented through the distribution of pure milk at infant milk depots first in Europe and then in this country than by all other agencies combined. The widespread morbidity in infants caused by bad milk is proven by the marvelous results of the work of these institutions with good milk. Knox in Baltimore reports a reduction in the death rate of dispensary fed babies to ten percent.

How to get pure milk is an urgent family question. Death comes to the home too early, it robs the child of its birth right to live. When parents realize that milk and mortality are inter-dependent and that milk is the causal factor, then desirable legislation will be forthcoming and we shall have adequate protection for the people.

NECESSITY FOR THE PURE MILK MOVEMENT.

It is the duty of every citizen to champion this cause and be a bulwark against undesirable legislation and thus help to disseminate a knowledge of the importance of pure food.

The greatest danger of impure milk is the insidious approach of tuberculosis. The ravages of this disease are unchecked because of popular ignorance and indifference, commercial greed and municipal failure. With the recent report of the Royal English Tuberculosis commission, the profession has deserted one leader for another so that to-day the consensus of opinion points to milk as the probable carrier of most of the tuberculosis to children.

Behrings theory of ingestion tuberculosis during infancy is gaining ground and there are many facts which indicate its probability. Park and Ravenel both furnish strong proof that bacilli may traverse the intestinal wall without damage to either and establish infection in bronchial gland or serous cavity. A very large proportion of tuberculosis in children is surgical and is acquired by primary glandular infection.

It would be strange if the cow upon whom humanity is such a parasite did not find some way to communicate her besetting disease to man. I saw in Belgium on the border of Holland, two hundred cows in quarantine, coming from the open and healthful dyke lands. The officer in charge told me that on test, from 35 to 50 per cent would be rejected and sent back to Holland as tuberculous. Tuberculosis is so prevalent and so insidious in the cow, used so completely for human food, that it would be strange if some avenue of approach was not found. In Japan they have cows and they have tuberculosis but it is chiefly among adults who eat rare meat. The Japanese infants rarely use artificial food but are nursed and thus escape.

Almost everywhere else a large proportion of young children are given raw milk. Meat is not the natural food for infants, so that the infection must be derived from the forty quarts of milk per month filtered through the baby's intestine and which contains bacilli from the faeces in the stable or the vascular udder.

#### DEFECTS OF ORDINARY METHODS OF MILK PRODUCTION.

Every ordinary method thus far employed for producing and distributing milk on a large scale, reveals serious defects and cannot be trusted to yield a product suitable for use in the sick room or for the diet of the young infant.

Gathered milk, so-called, represents the larger portion of milk brought to the cities.

This is mostly milk of a low grade and in many cities needs only to pass the casual view of the milk inspector at the railroad station in order to fulfill the scanty municipal regulations.

Much of the gathered milk collected and distributed by dealers is brought to the creamery by the small farmer in forty-quart cans. It is drawn the night before from the cow, herself unclean, in a dusty barn, in an open pail. The cow's hide is soiled, by the bedding wet with manure, the milking is done with unwashed hands, grimy with the farm work, the milk is aerated in an odoriferous barn, perhaps cooled in a well, then dragged through the sun to the creamery, mixed with a hundred such units, bottled by machinery, transported from fifty to one

hundred miles by railroad to the city and sold with a profit to the farmer, a profit to the creamery, a profit to the railroad, a profit to the middleman, a profit to the small dealer, and all accomplished within thirty-six to sixty hours after it is drawn.

Legislation has heretofore been trusted to regulate this matter, but neither State legislation nor the ordinances of municipal boards of health can secure for us what we require. These influences are too remote from the thing desired, the scope of their demands too limited, and their standards too low. They cannot be indentified very closely with actual dairy work, except through paid officers, who, as employees of the law, act as policemen, and do not stimulate the best efforts of those to whom we must look for what we need.

Furthermore, it will probably always be true that legislation cannot easily regulate the details of special kinds of work. An ordinance in its letter may require market milk to be clean, but how it shall be made clean it cannot define. The law may fix a standard of cleanliness and purity, but it cannot determine the exact methods whereby this standard may be attained.

In order that the law may be a means to this end, it must determine by a code what constitutes a clean hand, clean udder, a clean pail, a sterile container; what constitutes a healthy cow, a safe workman, a good feed and fodder or suitable bedding or proper housing—these the law never has and probably never will obtain for us.

#### POSSIBLE METHODS OF CONTROL.

There are three possible methods of control for the milk supply.

First—Commercial control which is in vogue in many cities and is largely employed in Europe. It consists of a license to collectors and distributors of milk, with no proper or efficient inspection. This is true of Pittsburg, with 600,000 inhabitants, where most of the supply is brought on the railroads from points one to two hundred miles distant. It is inefficient and great harm is thus wrought through sickness and death.

Second—Municipal control, which involves official inspection of farms, supervision of transportation and milk shops. In this the score-card has recently been employed. Copenhagen, New York City and Rochester are types of this method. In Rochester the remarkable results are due to the brilliant and efficient work of the health officer. In every large city the control of by far the greater part of the milk supply must fall on the health department, therefore very great importance is to be attached to an investigating commission of physicians, which may make recommendations; thus, in New York,

the Health Commissioner recently obtained \$175,000 to increase the efficiency of his department. New York consumes daily one million six hundred thousand quarts of milk and it is obtained from thirty thousand sources of supply.

Third—Medical or professional control.

This method does not supersede the municipal machinery of the health department employed in large cities to look after the general milk supply. It attempts to obtain special milk or clinical milk suitable for the sick and young infants. This product is so far above the requirements of the law that it is not strictly under the law at all. The method provides for the voluntary unpaid services of a commission of physicians, who combine under their control a dairyman, a chemist, a bacteriologist, a veterinarian and a medical inspector of employees, who render to the commission information upon which, if their requirements and standards are met, designate the product "Certified Milk."

The method includes (a) contract control of production, (b) automatic advance of requirements as time goes on, (c) safeguards applied with the most advanced scientific knowledge obtainable.

#### THE BEST SUPERVISION OF MILK PRODUCTION.

In order to obtain pure and clean milk for his purposes, the physician faces a problem which taxes all his resources.

It is difficult to harmonize the facts in the realm of preventive medicine that the physician is under obligation not only to discover the means to prevent disease, but finds it necessary himself to institute and conduct the crusade against evils which menace human life.

This results from two conditions, namely, a public lax and indifference with reference to vital interests of their health, and legislative bodies apparently helpless when their dictum runs counter to powerful commercial institutions.

The physician is the best supervisor of milk production, because of his ability to apprehend danger, because he is more generally informed concerning the origin, nature and sources of those conditions inimical to human life. As touching his duty, there can be no question, he is the proper custodian and the best judge of matters affecting the public health, and his knowledge equips him with the most effective means of warfare against evils of this class.

I desire to call your attention to a brief history of a plan to procure cow's milk designed for clinical purposes.

"Certified Milk" is a term employed to designate cow's milk of a particular grade of purity. It was coined by the writer and

first used in connection with a plan brought to the attention of physicians, and finally put in operation in Essex county, New Jersey, in 1893.

The plan had its origin two years prior to this in 1889, when, coincident with the introduction of the more scientific methods of infant feeding, the great difficulty of obtaining cow's milk of a uniform high standard was brought forcibly to the attention of the writer.

An effort was made at this time through the medical society of New Jersey to obtain relief by legislative enactment which would correct the current injurious practices at the sources of milk supply, but after two years of diligent labor very little was accomplished except to awaken a general interest in the subject and to establish the conviction that the profession had an important duty to perform.

It was found that the clinical aspects of this question appealed so strongly to physicians that their co-operation in any properly organized effort for reform was assured. Accordingly in January, 1893, a plan was presented to the Practitioner's Club, a leading medical society in Newark, which met with their endorsement. The plan was without precedent known to its author, and was at once submitted for approval to Prof. T. Mitchell Prudden, the late Prof. Albert R. Leeds and Dr. Rowland G. Freeman, all of whom were later identified with its development.

It provided for a commission of medical men, who, with the support of physicians generally, should by voluntary supervision, paid expert inspection and final certification, endeavor to influence a supply of milk produced under regulations imposed by themselves.

It was considered essential to success that the commercial interests of the dairyman should not be ignored in the attempt to secure the purely scientific objects of the commission. It was proposed that an approved dairyman, possessing honor, financial ability and dairy facilities be induced, by reason of promised medical support and the increased price of the milk, to conduct his dairy in conformity with a contract made with the commission in due legal form.

The plan provided that the commission establish correct clinical standards of purity of cow's milk; become responsible for a periodical inspection of the dairy under its patronage; provide for the bi-monthly examinations of the product by a chemist and bacteriologist; for medical supervision of the health of the employees and likewise for frequent scrutiny of the stock by competent veterinarians.

By the employment of well-known experts in these four departments a reliable safeguard is established against the common dangers of contaminated and impoverished milk.

The commission proceeds on the supposition that the combination of a purely commercial institution with one whose objects are purely scientific is not impossible. Its purpose is chiefly to influence the production and proper handling of milk intended for clinical purposes, which it seeks to accomplish by a rigid legal supervision of methods imposed upon a reliable dairyman.

The legal requirements are stringent and binding. The code includes ample sureties for its fulfillment, necessary forfeiture clauses, a territorial limit for the sale of the product, and provision for the compensation of the experts employed by the commission.

It controls the character of the land used for pasturage and the cultivation of fodder; determines the construction, location, ventilation and drainage of buildings; provides for an abundant and pure water supply, and prevents the use of water from wells or springs holding surface drainage.

It requires in the stable cleanliness and order, and disallows the keeping of any live stock, except the cow, within 300 yards of the dairy buildings.

It regulates the assortment of the herd with reference to uniform results, as well as the health, the breed, and the temperament of the animals.

It excludes any that are tuberculous or are found in a state of health prejudicial to the herd. It provides for proper housing and shelter of the animals together with their grooming, their treatment and the prompt removal of their waste from the stable.

It regulates the feeding with reference to uniformity in the chemical composition of the product, and restrains the use of all questionable or exhausted materials for food. It governs the collection and handling of the milk by insisting upon a proper regard for cleanliness as viewed by the bacteriologist in its relation to the animal, her surroundings, the milkers' hands, the vessels and the association of persons handling the milk with immediate or remote sources of infection.

It controls by minute specified requirements every step in the cooling of the milk and its preparation for shipment, and adds to the product every detail of care necessary to promote its keeping qualities or favor its safe transportation.

The motives of the commission are disinterested and its members forbid to themselves any pecuniary rewards. The experts are employed by the commission and paid

by the dairymen. The bimonthly reports of these officers to the commission are the basis of its approval of the product, which, in the form of a certificate, is issued to the dairyman.

#### DISTINCTIVE FEATURES OF THE PLAN TO CERTIFY MILK.

The meetings of the commission are held bimonthly at a stated time and place. The quorum is small to insure the transaction of business and the issue of the certificates if the reports of the experts are satisfactory. The reports of the bacteriologist, the chemist, the veterinarian, the dairy physician and the visiting section of the commission are read and discussed. The dairyman and veterinarian attend the meetings. The chemist's report includes the results of complete bi-monthly quantitative analyses of the milk. The bacteriologist's report includes the numerical findings of bimonthly examinations of milk. The dairy physician reports on the condition of health of every employee of the plant.

The following are some of the questions asked of the dairyman:

What improvements in dairy facilities since last meeting? What improvements in the methods of transportation and delivery? To what extent is the sterilizing plant for infected bottles used? At what temperature are contagious bottles sterilized? Total daily product of milk? Daily product of certified milk? Rations given to animals in certified herd? Sources and quality of the water supply for all purposes?

The following are some of the questions asked of the veterinarian:

Number of cows in hospital? Their condition and treatment? Number in quarantine under inspection? Number in recruiting herd? Number in certified herd? Number tuberculinized since last meeting? Number rejected because of reaction? The physical condition of the animals? The sanitary condition of the stables and surroundings.

It will be found necessary for milk commissions to exercise patience in realizing many of their plans. Educational influences are always slow, and in this matter the installment of new methods for obtaining results must often wait upon increased business to warrant the outlay.

The price of the product determined by the commission is not an insignificant factor in the success of the enterprise. Expensive requirements may call for the expenditure of large sums, such as installing an ice plant or electric light and power. Experience demonstrates that while no milk fit for domestic use can be produced with profit to the dairyman for less than five or six cents as first cost, milk of a suitable grade for clini-

cal purposes cannot be sold at a profit for less than fifteen cents per quart.

#### CLINICAL STANDARDS FOR COW'S MILK.

In order to meet the clinical requirements of cows' milk in the present state of our knowledge, three conditions of purity must be fulfilled. These requirements were formulated in 1892 by the writer in connection with the organization of the foregoing plan. They need only to be stated in this connection:

'First—An absence of large numbers of micro-organisms and the entire freedom of the milk from the pathogenic varieties.

'Second—Unvarying resistance to early fermentative changes in the milk, so that it may be kept under ordinary conditions without extraordinary care.

'Third—A constant nutritive value of known chemical composition and a uniform relation between the percentage of the fats, proteids, and the carbohydrates.'

#### RESULTS OF THE PLAN TO CERTIFY MILK.

These are scientific or professional and commercial. It has been found possible to combine two widely diverse interests to effect a public good, and that a purely professional scheme may work harmoniously with and influence a commercial institution.

The influence of this single initial effort upon milk production in general cannot be gainsaid. This high-grade object lesson not only had the effect of revolutionizing methods in its immediate neighborhood, but has unquestionably influenced many important efforts to obtain pure milk throughout the country.

A most gratifying result has been the universal confidence of the profession in the gratuitous and disinterested work of the commission and in the character of the product, almost the entire output of the plant being employed by physicians in their work.

The clinical standards adopted by the commission have in the main been realized. Though not entirely fulfilled, they cannot be, because they represent requirements which automatically advance beyond any possible improvement.

The periodical examination of the milk by a bacteriologist has been both instructive and advantageous, and has done more than any other feature of the supervision to improve the milk.

It is found that the reduction of bacterial contaminations which determine the changes in milk is the most difficult problem to solve. More species of bacteria are indigenous to the dairy barn than any other place known, and no medium is so favorable to their growth as fresh, warm milk. There are many conditions which make it difficult to protect milk against their approach, and the vicissi-

tudes through which it passes on the way to the consumers are many, and all favorable to the multiplication of these organisms.

It is my conviction after an experience of fifteen years in observing the work on a large plant, that a maximum of 10,000 bacteria per cubic centimeter can be maintained throughout the year if the man in charge of the milking is experienced in his work, understands fully and is in sympathy with every detail of the requirements of the contract, and is familiar with the principles and practice of cleanliness. This class of overseer has yet to be trained for his work.

It has been our policy from the first not to publish the numerical findings of bacteria, and this has been on the advice of our bacteriologist, Dr. Rowland G. Freeman, whose experience in milk work should make his judgment final. This policy has also been influenced by the fact the history of efforts to make germ-free milk is too short to enable us to determine the sources of milk germs so exactly that we can with precision adopt effective measures to prevent them.

The result of frequent chemical analyses of the milk shows its relative food values and has been helpful to those who use the product for accurate percentage-feeding of the young.

The close supervision of the health of the workmen on the plant by a qualified physician has shown it possible not to have had a single case of communicable disease on a plant producing over 6,000 quarts daily, during a period of fifteen years.

The veterinary inspections have been far-reaching in their results; this officer, like the others, being amenable to the commission, is stimulated to vigilant watchfulness over the health of the herd. It has been found that by inspection and tuberculinization of the animals before they are brought to the plant, by the application of the tuberculin test periodically, to every animal in the herd, by the rejection of those which react, and by the prompt isolation of every animal in ill health, it is possible to keep a herd of milk cows continuously free from conditions which would jeopardize the milk.

The keeping qualities of certified milk are remarkable in view of the fact that with our present limited knowledge large numbers of bacteria in milk are still unavoidable.

The keeping qualities of clean milk are improved in proportion as the bacteria are kept out of the milk and its immediate reduction to a temperature which retards or prevents their growth. Certified milk can be taken on transatlantic voyages and kept sweet throughout, which is now frequently done. It may be shipped to foreign ports in cold storage for use on return voyages. Members of our commission several years ago carried a supply to

the continent of Europe which remained sweet for many days. It has been taken from New Jersey through four express transfers to the woods of northeastern Maine and kept sweet for one week after its arrival. It was regularly shipped to Paris during the exposition, and maintained such a reputation throughout that the dairyman, Mr. Stephen Francisco, received two gold medal awards. I have received milk in New York, having been shipped to Liverpool on a trial trip twenty-one days before, and sending one quart to the bacteriologist and one to the chemist, found that the chemist kept his quart eleven days unimpaired, and on the thirtieth day found my own supply still sweet. On another occasion certified milk was kept on ice forty-five days before it precipitated its casein. One hundred quarts were taken in cold storage on a private yachting cruise through the West Indies, from which was taken the daily supply and which exceeded the needs of the party, who brought back sweet milk at the end of six weeks.

It would be manifestly one-sided to fail to mention some of the advantages which have accrued to the dairyman who has been largely instrumental in these results. The business growth in fifteen years would seem to be a temptation to anyone who could command the experience and facilities. The Essex county plant owned by Mr. Francisco had fifteen years ago 100 cows, and produced 800 quarts of milk; it now houses 700 cows, and yields an output of 6,500 quarts daily, with lands including about one thousand acres.

Certified milk, being designed for clinical purposes, is subject to the following restriction in its sale, namely, that when at any time the demand exceeds the supply and the milk is required by a physician, the holder of a physician's order is a preferred purchaser. Thus far this work has been largely educational and experimental, and yet it has not been without large measure of practical results as respects the superior quality of the milk obtained, the approximation to the standards adopted, and the benefits derived from its use in the dietetic management of the sick.

It is highly desirable that this work should be done in every large center of population, and that there should be some uniformity of requirements for certified milk, because it is chiefly designed for accurate medical and dietetic purposes.

The speaker who follows me, Dr. Geier, will outline before you the organization and work of the American Association of the Medical Milk Commissions. This is a federation of the medical commissions following the foregoing plan, and there are now thirty in the United States. There should be some State and Fed-

eral recognition of this work and an important means of promoting its philanthropic objects would be for each State to establish the legal status of the Medical Milk Commission, and then, as has been done in two States already, limit the use of the term "Certified Milk" to milk produced under the direction and control of a Medical Milk Commission.

There is but one principal involved in obtaining "Certified Milk", namely, that of initial cleanliness.

The principle of initial cleanliness is illustrated very well by the methods of the Holland housewife, who keeps dirt out rather than sweep it out; it is primary and preventive and it requires to effect it, scrubbing, scouring and scalding. First it must be in the thought and then it will find practical expression in the environment through eternal diligence.

#### TREATMENT OF FRACTURE OF THE SPINE.

BY J. T. DUNN.

For convenience let us divide Fractures of the Spine into two groups, first, fractures which *do not* produce paraplegia; second, fractures which *do* produce paraplegia, with paralysis of bladder and bowel.

It is not the purpose of this paper to deal with that class of cord injuries produced by uncomplicated dislocation or hemorrhage.

Considering the *first group*, fractures which do not produce any form of paraplegia must of necessity be a fracture which does not disturb the lumen of the natural canal (fracture of spinous process or of laminae without depression.) This form of fracture is rare and usually involves only the spinous process. Occasionally, however, the laminae may be fractured and the blow, which produced the fracture, not sufficient to produce depression or narrowing of the lumen of the canal. The treatment of such a case, or in any case where we have no paralysis to deal with, is quite easily disposed of as compared with a fracture of such a nature as to cripple the chord by narrowing the spinal canal. In simple cases where we have no fracture of the spinous process, or of the laminae with no displacement, rest in bed upon a hard mattress, union will take place in from six to eight weeks. Such a condition may be treated by the application of a plaster of Paris jacket, just as in the treatment of Pott's disease.

Our *second division* cannot be disposed of so readily, for here we come face to face with the all-important question, that of "to operate" or "not to operate." We are dealing with a class of fractures that encroach upon the cord in various degrees (fracture of laminae, or body, or fracture of body with dislocation) which produce pressure from that of slight extent, to the most severe form in which

the cord has been completely severed, as is the case with many of the so-called fracture-dislocations.

The neural canal may be broken anteriorly or posteriorly. Of two, the anterior, usually accompanied by anterior displacement, is much more serious than the posterior, and operation offers considerably less encouragement. Fractures involving the posterior aspects of the neural arch implicate only the laminae, and on account of lying posterior to the canal are easily reached through a posterior incision. Not so, however, when the canal is damaged on its anterior surface, for in such instances the surgeon is unable to give relief from pressure without more or less disturbance of the cord. The blow which causes fractures of the laminae is usually sufficient to drive the fragments into the lumen of the canal, thus impinging upon the cord and paraplegia is the result. The degree of compression may in a measure be judged by the amount of paraplegia below the point of injury and the loss of control of the bladder and bowels. A life of catheterization, purgatives, enemas, bed sores and constant attention of friends or nurse confront the surgeon when damage has been done to the neural arch sufficient to damage the cord.

I can conceive of a fracture involving the body and even the neural arch, without sufficient displacement to cause the least paralysis, except the temporary paralysis due to concussion or that caused by hemorrhage. Such a condition, however, is rare, and the real nature of the injury would never be disclosed and would possibly be treated as a sprain and result in perfect recovery.

If, after receiving a spinal injury, paraplegia does not occur immediately, but soon follows, the surgeon is enabled to make a diagnosis of pressure due to hemorrhage or to inflammatory products. If all goes well, however, absorption will take place, not only of the blood but of the inflammatory deposits, and the paraplegia will slowly disappear. On the other hand such a favorable result may not ensue and the blood clot or the inflammatory deposit may undergo suppuration, in which instance operative interference would be the only means of correcting the condition.

That class of cases, however, in which the laminae are driven into the cord, and that class known as fracture-dislocation, are the most serious, especially the latter, for the prognosis of fracture of the spine are like those of the skull, they depend upon the amount of damage done to the inclosed nervous tissue, and on this depends the plan of treatment.

Fractures of the body are rare, but fractures of the body with dislocation of the upper fragment forward and in front of the low-

er fragment is common, especially in the lower cervical, dorso-lumbar and sacro-coccygeal. The scissors-like action of the upper fragment slipping down over the lower fragment so nearly severs the cord in many instances that recovery is impossible, even though the fragments be replaced at once.

There are two methods of handling fracture of the spine complicated with injury of the cord: *Non-operative and operative*. The non-operative method consists in placing the patient flat on the back upon a hard mattress and after shock has disappeared an anaesthetic is administered, by means of extension and counter-extension, the surgeon makes a conservative attempt at reduction by judicious manipulation. The advocates of this plan bones are replaced much good has been done, claim that no harm can result and that if the even though the cord is completely severed by unpinning the nerve ends, thus relieving great suffering. If the cord is not crushed the paraplegia will be benefited by this procedure. Failure may result, however, on account of the interlocking of the articular processes, or on account of the fracture being of the impacted variety.

Following the manipulation above described, the patient is placed in bed in a dorsal position, and if necessary maintained in that position by the use of sand-bag, especially if the injury is in the cervical region. In the course of six or eight weeks union will have taken place and the patient may be allowed to go about encased in a plaster of Paris jacket, if the injury has been in a dorsal or lumbar location, and with the head suspended in a mechanical device resting upon the shoulders, if the fracture is in the cervical region.

The operative treatment of fracture of the spine, enumerated in our second group in this day of asepsis should be done as fearlessly as the abdominal surgeon would open the abdomen.

I am surprised at the statement made on page 154, Sajou's Analytical Cyclopaedia of Practical Medicine, Vol. 3, which says: "The results of operation have been so unsatisfactory even at the hands of its most earnest advocates, and the effect of traction and the plaster jacket so manifestly advantageous, that the mechanical method is the treatment of election even though the operation has occasionally disclosed and remedied pathological conditions upon which no manipulation could have exercised a beneficial influence."

To my mind prompt removal of compressions is essential here as in skull injuries, hence every case with compression should be operated on at once, unless it be due to hemorrhage in which instance delay sufficient to allow absorption is advisable. The operation is not

difficult nor hazardous. Laminectomy relieves pressure and allows inspection and palpation of the cord as well as the anterior portion of the neural canal.

The non-operative treatment of the fracture of coccyx consists of rest in bed, massage, electricity and liquid stools.

The operative treatment of fracture of coccyx consists of the removal of bone in its entirety or in part through an incision made from the tip of the coccyx up to its base and the bone carefully dissected out, while the rectum is guarded by one finger placed in close relation with the anterior surface of the coccyx. After the bone is removed the dead space is closed by pressure on the posterior rectal wall while a series of interrupted stitches are applied externally.

Operative treatment gives best results in the following conditions: First, fracture of neural arch with depression; second, fracture of neural arch with extravasation of blood; third, when a fracture is located in the lumbar region below the cord; fourth, fracture of the coccyx.

The first three of this group are relieved by laminectomy alone. In the fifth and most troublesome condition, that known as fracture dislocation, laminectomy may be supplemented by removing the transverse processes to enable the surgeon to replace the dislocated fragments. The operation of laminectomy is done as follows: A median vertical incision is made through the skin about six or eight inches long, the center of which lies over the injured vertebrae. Some advise a large horse-shoe incision, with the integumentary flap turned either upward or downward, claiming as an advantage that the spinous processes are not subsequently covered by a line of incision, the horse-shoe incision crossing between the two spinous processes. The incision having been made, the muscles are detached by a vertical incision on each side of the spines.

When the neural arch has been exposed, the laminae is divided by Hey's saw or Rongeur Forceps, some preferring the chisel, the detached muscles being held out of the way by retracters. It is advisable to remove the spinous processes of three or four vertebrae before endeavoring to make your incision through the laminae. The laminae having been severed or having been freed by line of fracture is lifted from the bottom of the wound, thus exposing the neural canal with its cord. If the cord is healthy no evidence of injury or hemorrhage will be visible. On the other hand, if damage has been done to the cord it will readily be determined not only by inspection but by palpation.

If the theca is tense and discolored an incision should be made and the blood or pus al-

lowed to escape. If there is no further damage, the wound should be closed without drainage unless pus is present.

In dealing with a fracture dislocation, the surgeon has not done his whole duty until after removing the laminae, the cord is retracted to one side and a careful digital examination made along the anterior wall of the canal which will be found broken at a given point. It would be necessary under such circumstances to remove the transverse processes of the two adjoining vertebrae at the point of dislocation in order to allow the fragments to pass by while extension and counter-extension is being made while the patient is still under the anaesthetic. The fragments having been placed in position, the wound should be closed without drainage, unless there is pus or considerable blood. Should drainage be necessary, horse-hair capillary drainage should be used instead of rubber tubing.

#### DISCUSSION.

**G. A. Hendon:** The presentation of Dr. Dugan's case brings to mind a similar one which I had under observation some six or eight years ago, in which a woman, weighing about 160 lbs., fell out of a third-story window and, in addition to fracturing the fourth cervical vertebrae, also sustained a fracture of the forearm. After about a week had elapsed she suffered complete paralysis, both motor and sensual, from the first or second rib down. At the end of the second week I made a laminectomy and found the fragments of crushed bone pressing in on the cord. These were lifted up and removed, and the patient lived for about six weeks.

One feature I particularly wish to mention was the rapidity with which union occurred in the fractured forearm, perfect union resulting with a natural amount of callus. However, gangrenous areas developed in the extremities, and on all parts of the body exposed to the slightest pressure. The woman finally died about six weeks after the operation, the immediate cause of death being meningitis and inflammation of the spinal cord.

**Jno. R. Wathen:** I wish to mention only one point in these cases, and that is how hopeful we become after operation. I remember a patient who was brought to me from the mountain district of Kentucky some years ago. The fracture was at the junction of the last dorsal and first lumbar vertebrae and he had complete paralysis from the waist down. I operated on this man, and, immediately after the operation, he began to complain of burning pains through his legs, indicating that the sense of feeling had returned in those members. In twenty-four hours we could move the sartorius muscle and had sensation down as far as the knee, and later he could straighten out his foot. He continued to gradually improve until the paralysis of the bladder

and rectum had been apparently overcome, and was then sent home. However, six months later, degeneration occurred and he died of gangrene of the bladder and intestines and at all pressure points on the body.

**Dr. Dugan** (closing): I believe in operating in the majority of these cases unless we have pressure symptoms, in which event it is best to treat them on the expectant plan, rest, etc. Even in those cases where we have total paralysis coming on immediately, indicating that the cord is entirely severed, I believe we should open them up because there is no set of symptoms which will enable us to say positively that the cord is completely severed.

I remember a case which I saw recently and in which I felt sure that the cord was cut in two; all sensation of pain, as well as the reflexes, were gone. I gave a very unfavorable prognosis, telling the family that I did not believe operation would result in much benefit. Fortunately, in this case it proved to be due to pressure of the bone, which was relieved and the patient got well.

In all cases where the bone has been driven in by direct force, or in gun-shot wounds, I think we should operate. I recently saw a patient who was brought here from Tennessee, who had been shot some months before. He came with bed-sore, with retention of urine and paralysis of the rectum. I operated on him and found a large amount of lamina driven down. This patient improved considerably, returned home and is now able to control his urine. He is not able to walk or use the lower portion of his body, but the improvement has been sufficient to justify the operation.

VIRGIL E. SIMPSON, Secretary.

**Metcalfe**—The Metcalfe County Medical Society met in J. A. Yates' office on the above date with the following members present: — Yates, York, Edwards, and Vanzant.

The society was called to order by the president, J. A. Yates. The minutes of the previous meeting were read and adopted.

No clinical cases reported, but **S. R. York**, of Centre, read a paper on "The Difficult Experience of the Early Diagnosis of Typhoid Fever by the Country Doctor," which was a very able paper and was discussed by the members present. A motion was made by S. R. York, and seconded, to hold four regular meetings at Edmonton a year—March 7th, June 6th, Sept. 5th, and December 5th, 1908, and to hold one or two meetings at Sulphur Well, and one annual meeting at Summer Shade, at P. W. Bushong's Sanitarium at the date hereafter named.

A motion was made and seconded to amend the By-Laws so that we meet as above. Dr. Edwards was appointed to read a paper at our next meeting on "Osteo Myelitis," and U. G.

McPherson a paper on "Broncho Pneumonia." P. W. Bushong a paper on "Diphtheria," J. H. Owens, a paper on "The Diagnosis and Treatment of Placenta Previa." There being no further business the society then adjourned to meet March 7th, 1908.

H. R. VANZANT, Secretary.

**Nelson**—The Nelson County Medical Society met in the office of the secretary at 11 A. M., April 1st, with nine members present and W. E. Crume, of Washington County, and B. A. Muster, of LaRue County as guests.

The society was called to order by President Heizer.

**J. C. Smith** reported two cases of puerperal convulsions, which were freely discussed.

**W. Lucien Heizer** read an interesting and instructive paper on "Surgical Cleanliness" which was well received and freely discussed.

**S. B. Crume** read an exhaustive paper on "Erysipelas," which was discussed by all present and all in all was an instructive paper and discussion.

**Hugh D. Rodman** read a paper on "Acute Nephritis," which elicited general and full discussion.

Society adjourned to meet the first Wednesday (6th day) in May, at which meeting three or four papers on obstetrics will be read, embracing several of its phases. Our society has now 15 members and we will most surely report 3 or 4 more in a few days, making 18 or 19 out of 23 who are eligible to membership.

HUGH D. RODMAN, Secretary.

**Owen**—The Owen County Medical Society met in regular monthly session in its rooms in Owenton on Thursday, April 2, 1908, with J. H. Chrisman in the chair. Minutes of the last meeting read and adopted. The roll call showed the attendance small. Those answering present:—W. B. Salin, J. A. Estes, W. E. Foster, J. H. Chrisman, and George Purdy.

On account of the small attendance the regular program was not followed, but informal talks for the good of the society were made by all present.

The society extended a unanimous vote of thanks to the Hon. J. H. Jackson, Representative from Owen county, for his faithful and efficient assistance to all sanitary and medical legislation in the recent session of the Kentucky Legislature.

After the regular business was finished, W. E. Foster made some interesting remarks on the subject which had been assigned him, "Hysteria." Later several present took up the discussion and the time was very pleasantly and profitably spent.

The next meeting is expected to be one of

the most interesting in the history of the society. The program will be a "Symposium" on "Normal Labor" and is as follows:

"First Stage," paper: J. C. B. Foster; discussion, W. B. Salin.

"Second Stage," paper: George Purdy; discussion, J. A. Estes.

"Third Stage," paper: J. H. Chrisman; discussion, J. W. Botts.

The meeting will be held at 10 A. M., Thursday, May 7, 1908.

GEORGE PURDY, Secretary.

**Taylor**—A meeting of the Taylor County Medical Society was held at Campbellsville on April 9th, 1908. Present, C. V. Hiestand, president; J. L. Atkinson, S. H. Kelsey, E. L. Gowdy, O. R. Reesor, H. G. Sanders, B. T. Black, Benj. Vaughn, O. M. Kelsey, and J. B. Buchanan.

As the society had failed to meet on stated appointments, there were few papers for this meeting.

**J. L. Atkinson** reported a case of mucous diarrhoea. Female, 38, in which mucous casts of the colon were passed off. The length of the casts were, in some instances twenty inches, and the quantity passed as much as two pints. There existed nausea and vomiting mucoid substance.

**O. R. Reesor** reported a case of catarrhal condition of bowel which simulated obstruction, in which high enema brought away a large quantity of mucus and relieved the apparent obstruction.

**C. V. Hiestand** read a paper on Pathology and Symptoms of Lobar Pneumonia, Acute, which was well discussed by the society.

**S. H. Kelsey** presented a paper on Acute Bronchitis, Pathology and Symptoms, which was discussed by Atkinson, and Vaughn.

The session was then closed and meeting of the Post-Graduate Club opened. We are meeting regularly in our post-graduate class, and, notwithstanding our number is small, are deriving much benefit from this course of study. The members of the county society have promised a better and more regular attendance in future, and I hope to report more interesting meetings.

The next meeting will be held at Campbellsville, Thursday, May 7, 4 P. M., 1908.

J. B. BUCHANAN, Secretary.

**Trimble**—After a lapse of several months the Trimble County Medical Society met at Bedford in Dr. Hancock's office on Monday, March 16th. Present: F. W. Hancock, Fix, McMahan, Harwood, Contri, Rand.

The officers for the current year were elected as follows:—President, F. W. Hancock, vice-president, C. C. Fix; secretary, L. G. Contri; delegate, L. G. Contri; censors, C. C. Fix, and C. P. Harwood.

On motion from Dr. Harwood the society

will substitute a subject to be discussed by the whole of the society instead of reading papers. The subject to be discussed at the next meeting will be "Pneumonia."

B. O. Rand withdrew from the society for reasons best known to himself.

Society adjourned to Monday, April 20, 1908.

L. G. CONTRI, Secretary.

**Trimble**—After a slumber of several months the Trimble County Medical Society met in Bedford last Monday (March 16th). Slumber was the outcome of the misinterpretation and misrepresentation caused by certain rules adopted by the society at a meeting in November, 1906. Now that this society is revived I think that it behooves us to enlighten the censoring and ever faultfinding portion of our misinformed community, and impress the mind of the public that the object of a medical society is not to extort from the people, our patrons, but instead to protect them from diseases, from charlatanism as far as possible and practicable protect our citizens from contracting diseases. The county society has for its object a continuous school of medicine, in which each member can contribute to the common treasury of knowledge, ideas and methods, and can receive abundantly therefrom without demerit of the store. Besides this great advantage, freely available to all, what each member brings to it will be increased in value to the donor. No one can have a fair knowledge of any medical subject, unless he has written upon it for others, or helped in its discussion at an assembly of physicians for their consideration. It is the essential nature of our knowledge that we should submit to an organized body of our fellows that we may see it through other eyes than our own and from viewpoints differing from ours; to the end that it may be broadened and modified into a better adaptability to the needs of those who confide to our keeping the most valued possession of their lives.

We are by nature social beings, and the physician who acts alone, outside of medical society, does himself an irreparable injury, deprives medicine of its just rights at his hands, and at best gives second-rate service to those who need and have a right to the best that is in him. A physician who keeps aloof from medical societies in order not to displease the community where he resides should be looked on with suspicious eye. He ought to think that the medical society helps to make of its members good citizens, gentlemen, scientific and safe practitioners. A medical society is a power for social, political, moral and religious stability. Membership is a precious privilege; it is also a stern duty. "Take therefore from him his one talent and give it to him who hath ten talents." It ever will be. "From him that

hath not shall that be taken even away." A simple statement of inexorable truth. Gain or lose what you have. Outside of generous fellowship there is no gain. The county society is a conservator of patriotism and worthy citizenship.

Hereafter in accordance with the suggestion of Dr. McCormack, Organizer of the American Medical Society, the Trimble Medical Society will be open to the public. We invite all to attend. Following are the officers elected for the ensuing year:—W. F. Hancock, president; C. C. Fix, vice-president; L. G. Contri, secretary and treasurer; C. C. Fix and C. P. Harwood, censors.

L. G. CONTRI, Secretary.

**Washington**—The Washington County Medical Society met in its room at the court house, April 13th, being the regular monthly meeting. The president, W. W. Ray was in the chair. Those present:—W. W. Ray, M. W. Hyatt, J.N. Shehan, J. C. Mudd, S. J. Smock, and J. M. Spaulding.

S. J. Smock read a paper on "Measles," which was a very interesting paper. It was discussed by M. W. Hyatt and W. W. Ray.

Drs. Barnett and Crume failed to be present with their papers.

S. J. Smock brought before the society a very interesting clinical case.

It was unanimously voted that the secretary congratulate Hon. W. C. McChord for the interest taken in the passing of medical laws, a notice of each meeting be handed to the local papers for publication until further notice.

Crume, Barnett, and Shehan to bring papers next meeting.

No further business, it was moved and seconded to adjourn to meet again at the next regular meeting, May 11th, 1908.

JNO. M. SPAULDING, Secretary.

**Warren**—Under the auspices of the Warren County Medical Society an Anti-Tuberculosis meeting was held at the State Normal, Wednesday, March 25, at 1 P. M.

The following were present:—J. H. South-er, Stone, Rutherford, Townsend, McCracken, Grider, White, Freeman, Keen, Blackburn, Rau, Lewis, Ramsey, Dowell, Briggs, Porter, H. P. Cartwright, F. D. Cartwright, Campbell, South.

More than 600 people were present during the entire session.

**Program.**

- 1. Historic Review . . . . Dr. W. C. Simmons
- 2. Tuberculosis a Transmissible Disease . . . . . Dr. T. W. Stone
- 3. The Economics of the Tuberculosis Problem . . . . . Hon. T. W. Thomas
- 4. The Public School and the Tuberculosis Question . . . . . Supt. E. H. White

- 5. Spitting . . . . . Mrs. J. A. Mitchell (Woman's Federated Clubs.)
- 6. Tuberculosis a Preventable Disease . . . . . Dr. E. N. Hall (President of the County Board of Health.)
- 7. The Legal Control of Tuberculosis . . . . . Hon. R. C. P. Thomas
- 8. Tuberculosis a Curable Disease . . . . . Dr. J. H. Blackburn
- 9. The Solution of the Problem . . . . . Prof. F. D. Mutchler
- Early Recognition . . . . . H. P. Cartwright

The meeting was called to order by the chairman of the Program Committee.

T. W. Stone, the president of the society opened the meeting and told of the work the county society was doing and its aim and purpose to make better physicians and facilitate methods of preventing diseases.

He spoke of the contagiousness of tuberculosis, and how it was transmitted by infected milk, sputum, and meat.

Hon. T. W. Thomas, in discussing the Economics of Tuberculosis, told of the great death rate of this disease, not only in this country, but the entire world, its cost to a community, not only in dollars, but in the long-lingering suffering of the individual and the probability of infecting others.

Supt. E. H. White said this subject comes into the work of every school teacher, and it is in the school-room where the subject must be taught. Crowded, poorly-ventilated school-houses harbor the disease. This subject must be combatted by publicity as to its cause, and methods of preventions.

W. H. McCracken: The greatest danger comes from living in infected houses. People often move into houses formerly occupied by consumptives and do not fumigate, consequently are liable to contract the disease.

Promiscuous kissing of babies causes the spread of the disease.

Poor ventilation in school-rooms and sleeping-rooms increase the prevalence of tuberculosis.

H. P. Cartwright: The most valuable aid to the war against tuberculosis is to train the student and the physician to recognize it in the early stage, when it can be cured and its contagion prevented. Physical signs must be learned and depended upon, as the bacteria cannot be found early.

J. H. Blackburn: Recent statistics show that tuberculosis is curable or at least can be "arrested" in many cases. Patient should always be under the care of an intelligent physician, with a properly trained nurse when possible. Treatment consists of (1) fresh air and sunshine, (2) rest, physical and mental, (3) dietetics, (4) medicinal treatment. Patient should avoid (1) the doctor who can "cure" him with medicines

for a stipulated sum, (2) "patent medicines" which are advertised as a sure cure.

Hon. R. C. P. Thomas spoke on the "Legal Control." A law must be backed up by healthy public sentiment. We cannot breathe life into a law unless the people are willing, and it is in harmony with public opinion. It is a right of the State to reach out a protecting arm against diseases and pass reasonable regulations in regard to public health. The legal control of tuberculosis rests on the medical profession, and their ideas can be crystalized into reasonable laws.

Prof. F. D. Mutchler said:

"Suppose it were perfectly certain that the life and fortune of every one of us would, one day or other, depend on his winning or losing a game of chess. Don't you think that we all should consider it to be a primary duty to learn at least the names and moves of the pieces; to have a notion of a gambit, and a keen eye for all the means of giving and getting out of check? Do you not think that we should look with a disapprobation amounting to scorn upon a father who allowed his son, or the State which allowed its members, to grow up without knowing a pawn from a knight?"

"Yet it is a very plain and elementary truth, that the life, the fortune and the happiness of every one of us, and, more or less, of those who are connected with us, to depend upon our knowing something of the rules of a game infinitely more difficult and complicated than chess. It is a game which has been played for untold ages. Every man and woman of us being one of the two players in a game of his or her own. The chess-board is the world, the pieces are the phenomena of the universe, the rules of the game are what we call the laws of nature. The player on the other side is hidden from us. We know that his play is always fair, just and patient. But also we know, to our cost, that he never overlooks a mistake, or makes the smallest allowance for ignorance. To the man who plays well, the highest stakes are paid, with that sort of overflowing generosity with which the strong shows delight in strength. And one who plays ill is check-mated—without haste, but without remorse."

Huxley wrote this splendid paragraph in 1868, at a time when he was one of the most practical teachers that the world has ever known. I am convinced from his writings that he considers the laws of health and disease to be primary rules of the game. Therefore, as a teacher, before this body of laymen and teachers, I want to submit for serious consideration the proposition that it is the school teacher's first duty and the school patron's first duty to co-operate with the medical profession in order to prosecute a strenu-

ous campaign against tuberculosis and any other preventable diseases. The speakers preceding me on this program have told you of the nature of the disease, its curability and its contraction, etc.

It remains for us to wrestle with "the solution of the problem," the working out of which can only be done through education.

We have come to believe that matters of health and disease should be given more consideration in the common school course of study. It seems to me that no one would ever think of questioning the validity and appropriateness of spending time enough in the school—say in the physiology class—to learn at least the conditions as they are to-day relative to the tuberculosis problem. When we recall the mortality due to this preventable disease, and the suffering and loss to the State on its account, and reflect that practically nothing is said about it in any of our teachers' meetings—and no knowledge of it is required of those who instruct in the schools—the situation seems appalling. This condition becomes manifestly worse when we recall that physiology is required by law to be taught in order that the individual and general health may be improved thereby. Health and disease considerations are not given in the public schools. Our system of education has for its primary purpose that of *training for efficiency in living*. Something is fundamentally wrong with the system just so long as we neglect the teaching of the tuberculosis problem and the problems presented by other common preventable diseases. One of the primary factors, therefore, in the solution of this problem is the public school teacher. Let him join hands with the physician and the result will be manifest. Let the physician and the layman demand of the teacher that he fulfill the full measure of his duty, and let the teacher get the physician's co-operation and the "solution of the problem" will be well begun. I know of nothing that will yield such immediate and such practical results as will teaching in the public schools of the State the things that have been discussed here to-day and are being discussed in similar meetings throughout the country.

#### IN MEMORIAM.

Dr. J. A. Reed, born May 9th, 1845, died January 25th, 1908. He graduated from the University of Pennsylvania in 1866, and was a member of the Mason County Medical Society, American Medical Association, Maysville Academy of Medicine and Surgery, local surgeon of the C. & O. Railroad. He died after a lingering illness of cirrhosis of the liver, at Maysville.

## DOCTORS AND DRUGGISTS.

The discussion of the relation between the doctors and the druggists at a recent meeting of the Jefferson County Medical Society was both timely and valuable. As a practical matter, partly the fault of our own profession, partly due to the insidious workings of the purely commercial pharmaceutical manufacturers the tendency in the drug business has been to lower it to a mere trade rather than retain it on a higher professional plane. Notable exceptions to this tendency—survivals of the real pharmacist exist in almost every county, but it is difficult to get the tyro in a drug store to do the really difficult work necessary to make of him a capable prescriber when it is so much easier to pour the contents of a few bottles together according to more or less general directions from some distant manufacturer. The real pharmacist deserves, and generally receives the support and assistance, of self-respecting physicians. The imprudent pretenders to the art who run "cut rate" stores in our cities, who announce, in the papers and on the fences in glaring headlines "cure-alls" for all incurable diseases and abortives for the self-limited, merit the contempt they receive from intelligent people, and it is this class which threaten the time honored relation between the physician and the pharmacist. On the other hand, the medical man just graduated from a medical college, untaught in materia medica or pharmacology, his college too shortsighted to furnish a competent teacher—in many instances giving absolutely no instruction—in the branch which is only second to diagnosis in the practical work, is an easy prey to the ready-made mixtures, whose chief—and often only—value is their palatability furnished *ad libitum*—may we not say *ad nauseam*—by the manufacturing chemists, or, in his ignorance and self-conceit, if he be venal, readily grabs at a secret partner-

ship with some one of the more nefarious manufacturers who stand ready to furnish him with an optimistic system of therapeutics all ready made to supply the void left by his lack of proper training in school. Of such sort are the doctors who in their turn vilify and denounce all druggists. No one of our readers but knows some men ashamed to write a prescription at all lest it betrays their ignorance.

Surely the intelligence of both professions can steer between such a Scylla and such a Charybdis—between the lazy or the venal druggist whose only care is the easiest dollar in sight and the untaught or the doctor who would not think out a prescription if he could and could not, however much he would.

As a practical matter let us be doing something. Talk the matter over with the best druggist in your vicinage. If you do not understand enough pharmacology to write a prescription get some recent work on the subject and the U. S. P. and the N. F. and you and your pharmacist put in your odd hours studying together that you may the better cooperate in doing good work. Explain to your druggist why he ought not to treat or mistreat diseases. Let him once understand that it is not because we fear his competition, but because we know how hard it is to treat a sick person correctly when we have been especially trained in diagnosis, and we know it is impossible for him to do it by guess-work. Concrete instances will occur to every man. Only recently a good woman, about 60, went into a Louisville drugstore—one of the "cut-rate" variety, and they usually "cut" quality more than prices in such places—and told a clerk she had a pain in her rectum. She said it did not hurt all the time but that the pains were very sharp when it did hurt. She reckoned she had the piles. He told her he guessed she had the piles and

that the Pyramid Pile Cure was the best thing she could use—that it almost never failed. She purchased several boxes from time to time and six months had passed away before she was examined to find a hopeless because neglected cancer of the rectum. It was not because of the few dimes profit realized by this druggist that physicians would feel outraged over this recital, but because between the bungling of the poor victim and the druggist—utterly unqualified for diagnosis—valuable time was wasted and another case of cancer passes to the hopeless class because seen too late. In like manner economists estimate that a majority of venereal diseases are treated in drugstores by boy clerks who make a joke of the nasty diseases they pretend to cure. Physicians know how difficult it is to treat gonorrhoea, how few cases are even cured by the most scientific methods. Gynecologists tell us that between 90 and 96% of the surgical operations on women are caused by gonorrhoea contracted from incurred husbands, that two-thirds of the childless marriages come from this neglected disease. Tell your druggist these things and if he be capable of honesty at all he will help you as you can and should help him. The two professions of right ought to be allied. Only "blind leaders of the blind" will further estrange them. If we will get together as they did the other night in Louisville and reason the matter out, we will find that the competent physicians and the honest pharmacists will finally "leaven the whole loaf." We would be glad to publish the views of our readers on this subject.

#### THE TELEPHONE QUESTION.

The telephone question is much the same in every city and every county in Kentucky. The Cumberland, East Tennessee and Bell systems were the original companies formed in response to popular demand for thoroughly organized long distance service. First in the field these systems by means of their enormous capital and practical business management, have gradually extended their wires until they have reached not only every village but almost every farm house in the State. Such rapid growth along entirely new lines naturally developed structural weaknesses that only time, good sense and plenty of money could remedy. A more improved service in one city would dissatisfy patrons in another where the company could not yet install the improvement. Shrewd franchise grabbers were not slow to take advantage of the situation. A lawyer or two, a few of the "boss" element in politics, a Yankee with a fat purse and the knowledge of the promoters' methods and the deed was done. Some northern trust company furnished that

part of the funds which could not be placed among the citizens of the victimized town and the flotation was complete of a new and independent telephone. Many community lines in country districts were planned to fill emergencies and these have usually done good service, but it is unquestioned that most of the so-called "home" lines in the cities have been built by rank outsiders, the money furnished by capitalists, not with the idea of running a telephone exchange at all but in order to unload stock and securities on the various local markets.

In the meantime the older companies with cold-blooded practical business men at their head have expanded to meet this hard class of competition with a wonderful rapidity earning dividends and furnishing a better and better service in marked contrast with bankruptcy and failure amongst their rivals.

Cognizant of this history many of the physicians of Warren county protested against the issuance of a charter to an independent company in Bowling Green. It was issued, however, and like doctors elsewhere, they have had the annoyance and expense of two telephones in offices and homes. In a town like Bowling Green this is a considerable amount each year—enough easily to support one physician. After thinking over and digesting these facts for some several years, a meeting of the profession was called and it was voted to use only the Cumberland or East Tennessee system on account of the long distance connections which are of such importance to physicians not only to receive calls and other important messages but also to place emergency orders. Of course a minority retained both phones. There are always some whose judgment is superior to the body of their fellows, but such men in the long run only harm themselves. In most places they are excellent men, members and officers of their societies and as the idea of community of interest in the material welfare of the profession extends and becomes more deeply rooted, these will be the very men who will be most active in all such work. Innovation—especially those which save money—create objectors, but time will soften and remove the objections and all will get together on this and many other things which are at present little thought of as fields for professional activity. It is always well to remember, "United we stand; Divided we fall!"

#### ATTACKS.

Scurrilous attacks by misanthropes, the smaller fry of politicians, the patent medicine press and the hirelings of the New York Life Insurance Company on not only the officers of this Association but on railroad surgeons, medical insurance examiners who

feel that they are of enough value to receive the \$5.00 fee, which is the minimum fee accepted by any reputable physician in this State, on the Kentucky insurance companies in general, have been mailed as circular letters as well as published in the newspapers and in that class of medical journals owned or controlled by the patent medicine people. This class of warfare does not appeal to the medical profession of Kentucky. It is far easier to attack the profession or the men who are working for it than to do work. The business of this Association is conducted by a House of Delegates composed of at least one delegate from each county society in the State. Any man who attacks this splendid body of representative physicians injures himself far more than those attacked. The officers of this association need no defense to the doctors of Kentucky and no defenders except them.

---

#### NIHILISM AND DRUGS.

This JOURNAL has published many articles of real value to the profession of Kentucky, but we feel that it is no invidious distinction to say that the masterly address of Dr. Jacobi delivered before the New York State Association which we published in our May issue by his special permission is the most practically useful message which has come to the general practitioner in a decade. Many of our readers write that they have read it over time after time to find new points each time. Our medical schools have neglected materia medica. Most of us know too little of our armamentarium. The giving of drugs is only one of the important things physicians use in the treatment of disease, but if he does not know their physiological action and therapeutic indication he is powerless at the bedside in cases of real illness even if he knows all the rest.

---

#### OUR INSURANCE COMPANIES.

A peculiarly cowardly attack on Kentucky insurance companies has been mailed to many of the physicians of the State under the guise of a personal attack on the Secretary of the State Board of Health. In this letter, among other falsehoods, and there is no material statement in the entire letter which is true, it is said that one of the Kentucky companies is "absolutely insolvent." As there are four life insurance companies in Kentucky such an attack involves all of them. In order to allay any doubt in the matter the JOURNAL addressed an inquiry to the Insurance Commissioner's office in regard to the matter.

The attached letter from Commissioner Bell will reassure medical examiners and oth-

ers as to the stability of our home companies.

State of Kentucky—Office of Insurance Commissioner, Frankfort, Ky., May 9, 1908.—My Dear Sir:—Replying to yours of the 4th inst., I beg to advise that it is my best judgment that the rumor as to the insolvency of one of the Louisville insurance companies, is entirely without foundation. If this Department had even a suspicion that any company authorized to do business in this State was insolvent, an examination would be made at once and the public would receive notification.

It is the policy of this Department to furnish the fullest protection to the policyholders, and that can be done only by the most rigid supervision of all companies, both domestic and foreign.

Very truly,

CHAS. W. BELL,  
Insurance Commissioner.

This effectively disposes of the only statement in this circular letter which deserves attention.

##### THE TREATMENT OF PUERPERAL INFECTION.

Before considering the treatment of this condition it is well to remember that under ordinary circumstances there should be no mortality in sapraemia. There are cases on record, in which the entire placenta has been left in the uterus and the patients recovered nevertheless in six months or more.

Even in septicemia if the uterus is left alone, the patient is more apt to escape the serious complications which so often follow upon injudicious and meddling interference. The keynote of treatment therefore, is not to meddle with the uterus, unless there is a definite indication for it.

Prevention is better than cure and so the prophylactic treatment should command fully as much attention as the curative. It is definitely established that patients suffering with toxæmia during pregnancy, are liable to infection in the puerperium. Hence the necessity for a constant supervision of the woman from the onset of pregnancy to the end of gestation.

That this is impractical in the ordinary labor case, with the low fees paid for obstetrical work is self evident. It is to be hoped, that in time the laity will be educated up to the necessity for such care of the pregnant woman and will be willing to pay properly for it.

The conduct of labor cases should be made

as simple as is compatible with the safety of the patient. It is improbable that the physician will resort to the elaborate Halstead method of disinfecting his hands in conducting a labor case in a private house. As is well known, this method of hand disinfection calls for a scrubbing of the hands and finger nails in hot water, cleansing the nails, again scrubbing in hot water, then immersion in a hot solution of Potassium Permanganate, Oxalic Acid and then in Bichloride Solution.

Let the requirements be so simple that no physician can find an excuse for not complying with them. If thoroughly done, a careful scrubbing of the hands and finger nails with soap and hot water, cleaning the nails, again scrubbing the hands in hot water and then immersing them in 1-2000 Bichloride should answer every purpose. If the physician has been dressing suppurating wounds, or treating infectious diseases, then no method of hand disinfection will suffice and he must use sterile rubber gloves throughout the labor.

No lubricants should be used on the fingers in making vaginal examinations. If the hands are immersed in the bichloride solution and the fingers kept wet, the examination is readily made and no micro-organisms, imbedded in vasaline are firmly planted in the upper fornices of the vagina.

Women must be educated up to the necessity of having vaginal examinations made by the open method. No one at the present day would catheterize a woman under the bed sheet and she is subjected to even greater risk if a vaginal examination is made in labor in that manner. If the legs are draped with a sheet and the vulva covered with a sterile towel as is done in the up to date vaginal examination, then the patient is only subjected to exposure in the short time that is necessary to introduce the fingers by the sense of sight. Where the patient refuses to submit to this method for the vaginal examination and the delivery, then the physician to be absolutely safe has no alternative except to depend entirely upon abdominal palpation and auscultation of the foetal heart sound for his diagnosis of position and progress of the case and must deliver the patient in the left lateral position. There is a tendency at present to do away with vaginal examinations as much as possible in labor, as even under ideal circumstances, infection may be carried up into the vagina from the vulva.

The only knowledge gained by the examination, is the extent of dilatation of the cervix and as one becomes expert, more information can be derived by abdominal palpation, than by internal examination.

Neither ante partem nor post partem va-

ginal douches should be used, unless especially indicated. The only indication for an ante partem vaginal douche, is a pathological vaginal discharge especially gonorrhoeal and in such instances it is given principally to limit if possible an infection of the baby's eyes whilst passing through the vaginal canal.

In most instances it cannot prevent a gonorrhoeal infection of the uterus in the puerperium, because the uterus is generally infected from the latent gonococci that lie deep in the cervical glands.

Whether or not we accept the statement, that the normal vaginal secretion is sterile, statistics prove that it is the woman's greatest safeguard against infection.

Ahlfeld who is one of the most earnest advocates of the statement, that the vaginal secretion contains pathogenic bacteria and who has ante partem douches administered accordingly in his Maternity, has 38% of infections in his cases whilst those not using the vaginal douche have a much smaller morbidity. The post partem douche ordinarily is unnecessary and will often give rise to infection from particles forced into the uterus from the vagina.

The physician should repair all lacerations of the perineum and any abrasions of the vaginal mucosa, too slight for operative interference, should be painted with Tr. Iodine. The curative treatment is both medical and operative and whilst there is no absolute specific for the condition, the following course of treatment has given me and some of my colleagues who have tried it, excellent results in very grave cases.

It is safest under all circumstances to consider an elevation of temperature in the puerperium, as due to infection. If one is absolutely certain that the placenta and membranes have been removed and there is no infected blood clot, then a diagnosis of septic infection may be made. A good dose of calomel, followed by two ounces of castor oil should first be given to eliminate intestinal toxæmia and to stimulate those eliminating organs. Then quinine should be administered in five grain doses every three hours for twenty-four hours. At the end of that time if the temperature has not disappeared, then it cannot be ascribed to malarial infection, a condition to which the puerperal woman in this locality is very subject. In the meantime, a hot vaginal douche has been given, followed by an intra-uterine douche of normal saline solution T. 115°. Neither bichloride or lysol solutions should be used in the uterine cavity, as they may be followed by systemic poisoning. If the patient is not very much improved after twenty-four hours, then she should be anesthetized and under rigid asepsis, the uterus should be di-

lated manually and anything found therein should be carefully removed by the fingers. This is again followed by a hot intra uterine douche of normal saline solution.

The patient is kept upon a light diet by preference butter milk. Strychnine and ergot are administered hypodermically alternating every three hours. The ergot causes a firm contraction of the uterus, thus preventing a spread of the contagion from that organ, whilst at the same time it is a cardiac stimulant even more effective than strychnine.

In addition to this, the patient receives a daily injection of 1-2 oz. of nuclein solution by means of a large antitoxin syringe. I am in the habit of injecting the nuclein into the side of the abdomen in the right and left hypochondriac region and if ordinary asepsis is practiced, no harm can result.

It is known that the power of the blood cells, to destroy pathogenic organisms is due to nuclein which it contains and it is but rational therefore in condition in which the body is so satiated with septic bacteria that the nuclein in the blood cannot combat them to aid nature by the administration of that substance.

If the disease does not show a ready response to the nuclein then I use collargol in conjunction with it. I have had a number of cases of puerperal infection recover with the nuclein medication alone. I have had some very grave cases recover when collargol was used in conjunction with the nuclein solution, but I have never depended upon collargol alone.

As to collargol, it has been introduced and highly recommended by Crede, of Dresden, who claims that the colloidal silver which it contains inhibits bacterial growth, and so directly combats septic infection. It cannot however, affect collections of pus that are encapsulated.

Collargol should be introduced into the system per rectum. It is used in the dose of 7 1-2 grs. dissolved in 2 oz. of water twice daily. A rectal enema of one pint of warm water is first given, and a half hour later the collargol solution is introduced by pouring it into a small funnel in the end of an ordinary rectal tube which has been inserted into the patient's bowel for eight or ten inches, the patient lying in the left lateral position with the hips elevated so that the solution may be retained as long as possible. Precautions must be taken to catch the solution as it escapes, in the bed-pan or upon a pad, as it will stain the bed clothing badly. The injections must be continued twice daily for fourteen days and combined with the nuclein injections, have resulted in the recovery of a number of my patients who, I am sure, would

have succumbed without a resort to these measures.

I have used the anti-streptococcic serum in a number of cases but without results, and this seems to be the general opinion. It is a question, however, whether the unfavorable reports made in regards to its action may not be greatly due to a faulty impression as to the effect and use of the serum.

Attention should be called to the fact that the serum is antitoxic; that is, it has the power to neutralize the toxins produced by the streptococci, but it has no influence upon micro-organisms themselves. If this is properly understood, then it follows that the serum injections must be repeated daily in order to combat the toxins as they are produced and until the streptococci exhaust themselves.

Furthermore, if a serum is going to be effective in a given case, then it should show results in twenty-four or thirty-six hours. If it does not, then a different make of serum must be tried, for it is known that there are different forms of streptococci, and a serum made from a pure culture of one form will not affect an infection from another. Finally, it must be remembered that it cannot influence a mixed infection.

EDWARD SPEIDEL.

#### RELATION OF BOVINE TO HUMAN TUBERCULOSIS.

The dogmatic denial by Koch that tuberculosis in the human and in the cow was intercommunicable served to arouse the attention of investigators and has resulted in a far more exact knowledge of the tubercle bacillus. The English bacteriologists and sanitarians have shown conclusively that the bovine tubercle bacillus can produce in the human being all the symptoms of the human tubercle bacillus, and by them the disease is considered intercommunicable.

It has been a question also for discussion, as to whether the tuberculous cow could contaminate the milk, unless there were specific tuberculous lesions in the udder. It was believed by many that if there were distinct lesions from the tubercle bacilli in the lungs, that this did not necessarily mean a tubercular infection of the milk.

A recent experimental study of this subject has resulted in the establishment of the very important fact; namely: that the infection of the milk with the tubercle bacilli from the tubercle cow, occurs most frequently not through the udder, but through the feces of the sick cow.

An examination of a number of samples of city milk showed a sediment in 70 per cent. of the cases, and this sediment was formed in part of the feces of the cow. In the next

place, it was shown that the feces of cows suffering from tuberculous infection, contain the tubercle bacilli, and lastly, the feces from cows suffering from tuberculosis was mixed with milk, and other foods, and fed to young animals, resulting in the production of tuberculosis in these animals, so that the chain of evidence is practically completed.

The great majority of bacilli can be recovered from the milk, either in the cream which means tuberculous infection also of butter, or in the centrifuged slime but skim milk and buttermilk have been shown to contain tubercle bacilli, and in this medium they will retain their virulence for a long time.

The percentage of cases of tuberculosis in dairy cows has been estimated at from 10 to 90 per cent. The use of the tuberculin test has shown that a large number of cows have tuberculosis, although there is no other evidence of the disease, yet even these apparently beginning cases would expel the tubercle bacilli from the bowels.

"Dr. Albin Burkhardt after the examination of 1452 human cadavers, found that 91 per cent. showed lesions of tuberculosis irrespective of the cause of death. Nageli, from the examination of 500 cadavers, places the figure at 96 per cent. and Sch'enker, from 100, make it 66 per cent."

From these facts it must be conceded that there is great reason to agree with the theory of Baumgarten and of Behring that tuberculosis is most frequently acquired in childhood, and that it is only at about puberty that it begins to present its severe symptoms. It is believed that the tubercle bacillus may lie latent in a lymphatic gland for many years, waiting for a favorable opportunity to develop. This latency of tuberculous infection makes many feel less alarmed over the tuberculous infection in the milk of cows, but the duty stands out preeminently with all those having the care of the young babies, that they shall secure a milk that is absolutely free from infection with the tubercle bacilli.

PHILIP F. BARBOUR.

## OFFICIAL ANNOUNCEMENT.

(REPRINTED FROM MAY JOURNAL)

### REPORT OF COMMITTEE ON MEDICAL DEFENSE.

#### LETTER OF TRANSMITTAL.

The Committee on Medical Defense, appointed at the last meeting of the Kentucky State Medical Society, realizing the great importance of their duties, have investigated the subject thoroughly and have the accompanying articles to offer the County Societies for their adoption.

In presenting this summary of their work,

the committee desires to state that this matter was considered from three points, viz:

First—Will the formation of a defense union be beneficial to the physicians of Kentucky?

Second—Is such an Union practicable, and if so, what are the minimum rates necessary for good results?

Third—Can this Union have legal standing without coming within the regulations of the insurance laws?

The committee read carefully the reports of similar organizations of England, Canada and various parts of the United States, and found that malpractice suits had been greatly decreased in number in these countries and States, that satisfactory protection had been given the members and that, in all cases, the benefits had been undoubted.

From this same research, the committee believe that the work can be properly carried on for the amounts mentioned, namely—\$5 for an entrance fee and \$1 per year from each member as dues.

As to the legal standing of the Union, the best lawyers in the State have been consulted and assurance has been given the committee that the articles now presented to the County Societies are in perfect accordance with the laws of Kentucky.

The various insurance companies charge \$15 for the protection which the Defense Union will give for \$1 (the entrance fee, \$5, being paid once only), and, therefore, the committee does not expect anything other than the unanimous adoption of their report by the County Societies.

Very respectfully submitted,

CUTHBERT THOMPSON, Chairman.

OSCAR E. BLOCH, Secretary.

Louisville, Ky., April 14, 1908.

#### PROPOSED CONSTITUTION.

I. The name of this Association shall be the Medical Defense branch of the Kentucky State Medical Association, and shall co-operate therewith as herein provided.

II. The object of this branch Association shall be the defense of its members against unjust suits for malpractice.

III. All members of the State Medical Association, and all future members on election, who wish to be members of this Defense Association shall pay an initiation fee of \$5, and yearly dues of \$1, to be collected by the Treasurer of the County Societies of the Kentucky State Medical Association, and forwarded by him to the Treasurer of this Defense Association.

IV. The officers of this Association shall be a Chairman, a Secretary-Treasurer and four other members (one of whom shall be the President of the State Medical Associa-

tion) together forming an executive committee, and they shall have general charge of its affairs, who shall report at the yearly meeting of the State Association to the House of Delegates. The members of said committee shall be elected by the House of Delegates for ten years, except of those first appointed one shall serve ten years and one shall serve eight years and one shall serve six years and one shall serve four years and one shall serve two years.

V. The assistance in defense as herein provided shall be only of such members of the Kentucky State Medical Association as are in good standing, and who shall have paid the initiation fee and the yearly dues for this special purpose. Neglect to pay the dues at the proper time shall forfeit all claim on this Association for any protection which it can afford and from membership in this Association. No doctor shall be defended for any action unless he was a member of the Protective Association and a resident of Kentucky during the time when the alleged malpractice was committed, and shall comply with the regulations herein and hereafter lawfully made.

VI. It shall be the duty of any member of this Association threatened with suit for malpractice to immediately notify the President of the County Society, who shall at once send him an application blank for names of witnesses, etc., and on receipt of this blank, properly filled in, the President shall immediately call his county committee and investigate.

VII. The President of the County Society in which the defendant resides, the Councilor of the Kentucky State Medical Association from the district, and a doctor (who must be a member of the Protective Association), chosen by the defendant, shall form a County Committee which shall investigate all cases of alleged malpractice. If for any reason the President or Councilor cannot act, the Secretary and Senior Delegate of the County Society shall act in his or their place in order. This committee shall examine the defendant and his witnesses, if necessary, under oath. If this committee agree that it is a case to be defended, it shall so report to the Chairman of the Defense Association, who shall immediately so notify the Executive Committee of this Association. If this County Committee should decide it is not a case to be defended, the defendant doctor can appeal to the Executive Committee of the Medical Protective Association of the Kentucky State Medical Association, and it shall in all cases have the final decision whether the case is to be defended or not. The findings of these committees, if unfavorable, are to be communicated to the defendant alone.

VIII. The only liability of the Medical Protective Association will be for the fee of the consultant lawyer which they have chosen, a reasonable fixed fee to be agreed to in advance of the local lawyer selected by the doctor, and the legally taxed court costs—all other expenses of the case to be borne by the defendant. Provided, however, that if the income of the Association for any one year has been exhausted by or appropriated for contracts, in defense of members, the Association shall have the right of apportioning dues to the expense of defense to be borne by it upon all cases subsequently arising until such dues shall again be sufficient to pay as before indicated; and, provided further, that no officer or member of this Association shall be responsible individually for the whole or any part, or for any assessment upon any of the obligations which this Association, or its officers for it, are hereby authorized to assume.

IX. It shall be the duty of every member of this Association to aid the Association in every legitimate manner.

X. It shall be the duty of the Executive Committee to follow the case through any and all courts until a correct judgment be obtained, if in the opinion of the Council such a course should be judicious. *In no case will the Association compromise.*

XI. The Executive Committee may amend or change the rules and regulations during the year, but subject to revision by the House of Delegates at the next annual meeting of the Kentucky State Medical Association.

## ORIGINAL ARTICLES.

### SYMPOSIUM ON TYPHOID FEVER.

#### COMPLICATIONS, PROPHYLAXIS, PROGNOSIS AND TREATMENT.\*

BY J. C. McCREARY, CAVE CITY.

I will assume that the case has been clearly diagnosed as typhoid fever, and will proceed at once with the complications in the order I have most frequently found them to occur in my practice. You will bear in mind that my experience has been of that in the country and small towns, where I have not always had the advantage of trained nurses and other hospital conveniences.

*Renal:* Acute nephritis may develop, the urine being diminished in quantity, and scanty, may have retention. I have frequently had to relieve my patient with the catheter; this trouble may occur early, or late in the course of the disease, most frequently late. If you examine the urine at this time

\* Read before the Kentucky State Medical Association, Louisville, October 16, 1907.

you will find it to contain albumin, casts, blood and epithelium. Uremic symptoms may appear at this time, making the prognosis grave. In one case, I had a vesical catarrh come up, which I attributed to the frequent use of the catheter in relieving the retention.

*Hemorrhage:* Hemorrhage occurs in about six per cent. of our cases, and most generally takes place in the latter part of the second or third week, and is caused by the opening of the blood vessels of the bowels during the ulcerative process; the bleeding may occur from the edges of the ulcers; if it shows in the early part of the disease, it may be due to the hyperemia of the lymph follicles. The hemorrhage may be so small as to be almost undiscernable to the eye, or may be much as three pints, as in one case I will mention; Mr. W., who was near the end of the second week, when I was called hurriedly one morning about daybreak to come as quick as possible, upon my arrival I found my patient in apparent condition of shock, and upon looking into the commode, to my surprise, found at least three pints of blood and yet this patient made an uneventful recovery. The significance of a hemorrhage, however small, is always grave, but recovery is possible, though the hemorrhage may have been copious and frequent. Death occurs in thirty to forty per cent. of cases with hemorrhage. If the hemorrhage be profuse death may occur at once; sometimes a hemorrhage may exert a favorable influence, if the patient be in a state of stupor and delirious, he may quickly change to that of consciousness.

*Perforation:* Is a complication that occurs only occasionally, but almost always brings up a fatal diffuse peritonitis, and which is to be most dreaded; fortunately I have never encountered this complication but am always on the lookout for it and have my course outlined should it appear.

In perforation I would expect to find a collapsed condition of the circulatory system, and evidently by vomiting, small frequent pulse, and may detect fluctuation. I can think of no other complication which I would so much dread as peritonitis especially if due to perforation. I would expect to find either a general peritonitis or localized.

*Catarrhal irritation of the pharynx:* In my first experience in treating typhoid, many of my cases were affected with a thrush which extended over the mouth and throat, and often reaching the esophagus; tongue heavily coated with a yellowish fur, sometimes extending through Stenson duct to the parotid gland; also through the duct leading to the middle ear setting up a suppurating otitis media. Profiting by my experience, I have been more careful to insist on a frequent and thorough cleansing and disinfecting of the

mouth, and as a result, have no further trouble of this kind.

*Bronchitis, Lobar Pneumonia:* These we are more apt to meet with in the aged. The first mentioned however may be found in a mild degree in most all cases, but the cough is usually slight and not troublesome, but if not given some attention the bronchial secretions may accumulate to such an extent as to give rise to a more serious condition.

Lobar pneumonia as I stated is more apt to be found in the aged, and coming up as a late complication, accompanied by the usual symptoms, rigor, cough, intense chest pains, rusty expectorations, etc.

*Stomach:* The stomach seldom offers any unusual complication beyond the anorexia, nausea and vomiting, the latter if appearing during the decline is probably due to, or excited by some gastric ulceration or errors in diet, irritating medicines.

*Spleen:* In most of my cases the spleen was found enlarged sufficiently to be palpated below the margin of the ribs and gradually increased in size up to the third week.

*Liver:* In a few cases, have had a congestion of the liver, with jaundice.

*Venous Thrombosis:* It generally comes up during convalescence, manifesting itself along the course of the femoral by swelling edema and tenderness along the course of the vein, soreness in thighs and calves, fever of irregular type lasting two or three weeks, after which the swollen member can be brought to its natural size, however I can but always have some uneasiness for fear an emboli may become detached and bring about sudden death. In my practice of five years I have only encountered this trouble in two of my cases, and they giving me but little trouble.

*Nervous system:* Delirium is very frequent in the severer cases, and is most marked at night or at a time when the patient is alone. Picking at the bedclothes is a condition I never like to see in a patient, I look on it as an unfavorable symptom. The motor nerves seem at times unusually affected, a twitching of the muscles of the face and extremities are quite common. Often have neuralgia affecting the occipital and other cranial nerves. Paralysis, seems to be the chief among the nervous complications. I have had one case of hemiplegia occur at the end of the third week, coming up very suddenly, at a time when the patient seemed comparatively out of all danger and on the road to recovery.

*Post-typhoid insanity:* This is mentioned by many as some times coming up as a complication, but I have never had it in a patient of mine.

*Relapses:* They occur in about three per

cent. of cases, and do not differ from the true disease except in duration, which is of a much shorter course.

*Prognosis—Severity of infection:* When the temperature rises suddenly at first and remains high for a number of days, with persistent vomiting, delirium, complete prostration, indicating a severe infection, the prognosis is grave.

*Condition of the patient:* If the patient has been a strong drinker, or of loose habits, prognosis not good.

*Complications:* Each complication arising renders the case more grave and uncertain.

*Age:* The younger the patient the more favorable the prognosis, while typhoid fever as a rule is not severe before the age of puberty, yet after that age the gravity increases with age, you have the added liability of pulmonary and cardiac complications.

*Puerperal state:* When typhoid occurs during childbed the prognosis is grave, fifty per cent. of them dying.

*General conditions:* If the patient is fleshy we should give a guarded prognosis, as it is in these that we are confronted with collapse.

Should the patient be suffering with Bright's disease, weak heart or any other chronic troubles, it would of course make it more grave.

Before leaving prognosis I wish to add just a few more lines that should have come under the head of "Severity of infection;" to-wit:

A high temperature is usually considered a serious case, a temperature of 105 or 106 and maintained for several days is most surely to terminate fatally. To the contrary it has been only a short time since I had a case in which the temperature never at any time passed 102, and yet terminated fatally at the end of the second week; so we must not consider a low temperature always favorable. If the temperature be 104 or 104 1-2 and heart in good condition, pulse not exceeding 110 or 115 and no intermissions, I would not consider the case unfavorable, but if the pulse reached 130 or 140 and weak, it is then unfavorable.

*PROPHYLAXIS:* The patient should be isolated as far as possible, this is necessary for many reasons. No persons should be allowed in the room save the nurse and the patients immediate family and they only occasionally.

*The nurse:* Those attending a case of typhoid fever may convey the bacilli by handling the food and drink, which is intended for other persons of the household. The nurse should be very careful to disinfect her hands before handling food to be eaten by other members of the family, or to permit

the knives or forks used by the patient, to be used or placed on the family table. If the nurses hands or linen should become soiled she must thoroughly disinfect them before leaving the room.

*Excreta:* If scrupulous care is not taken, in handling and disinfecting the excreta, it may become dried and form a dust and scattered throughout the entire house, lighting on milk, meat, or other food, and thereby conveyed. The excreta should be received into a vessel for this purpose and thoroughly disinfect before emptying into the closet or burying. For a disinfectant, I use chloride of lime, six ounces to the gallon of water, and then pouring about six ounces of this solution into the vessel after each movement of the bowels, or kidneys, letting it stand three hours before emptying. It is then taken and poured into a hole dug three feet deep and dirt pulled in on top. I have used copperas one pound to the gallon of water, but do not consider it as good as the chloride of lime.

*Patient's linen:* The patient's linen should be changed daily or oftener if soiled, after they are removed they should be boiled for at least thirty minutes. The bed linen should be changed daily and disinfected in the same way. When the patient leaves the room the bed should be fumigated and aired daily for a week.

*TREATMENT—Isolation:* The patient should be placed in a well ventilated room preferably an upper room, in which only the physician, nurse and occasionally the members of the family are permitted to enter. If the patient be of a nervous temperament, I consider company a serious objection; it being the custom for them to go into all the details of every severe case of typhoid fever that they have ever heard of, and often telling the patient that they are affected exactly in the same way. Visitors very often make such remarks as, "You look so much worse than I expected to see you, etc."

*General treatment:* You should put your patient to bed just as soon as the general symptoms point to this disease, and provide the very best nursing that their circumstances can secure. Place the patient on a mattress in a room, with a sunny exposure if possible, well ventilated, but free from drafts. I have a rubber cloth spread over the mattress under the sheet, and kept smooth to prevent bedsores. The patient should be kept in a recumbent position; using the bedpan for evacuations.

The body should be sponged two or three times daily with dilute alcohol, a good plan is to occasionally use alum water on the back, to prevent bedsores. The nightdress and sheets should be changed every morning, all soiled clothing to be removed at once. The

patient should be kept as quiet as possible, and his wants attended to promptly.

A typhoid patient should never be left alone while in the delirious stage, since we so often hear of cases, in the short space of time, have left their bed and jumped from the window or done themselves other bodily harm.

Cold fluids should be given freely, especially water; I most frequently give it in the form of lemonade, and give it whether called for or not, this produces free diuresis, and in this way rids the system of much poisons.

I have the temperature taken three or four times daily and placed on a chart prepared for the purpose, and in this way, I can glance over the chart at each visit and note the progress or changes made from day to day.

After the fever has subsided, I have the sponging continued and followed with gentle massage. When I can not have the assistance of a trained nurse I write out very explicit directions to be followed, as to time for giving medicines, disinfecting of the discharges, bed linen, etc.

*Diet:* The digestive powers being very much lessened, it is useless and harmful as well, to give food which will pass through into the intestines without the proper change in the stomach, and there act as an irritant to the mucous membrane and undergo fermentation, creating gas in the intestines and thereby producing toxins to be taken up in the circulation. My experience has been that milk forms the best diet for typhoid patients, and with the majority have found buttermilk to be the ideal food, yet in a few cases, sweet milk agrees best, but in giving this I always dilute it with linewater to prevent curdling in the stomach.

I give them milk every two or three hours, using three to five pints during the twenty-four hours. Raw eggs, broths, milk with the white of egg, Horlicks, malted milk, meat juice, etc.

In convalescence I give cooked rice (cooked for at least three hours) egg, egg custard; withholding all solid food until the temperature has remained normal throughout the day, for a period of ten to twelve days. I pass from a liquid to a semi-solid, then gradually up to the solid diet.

*Stimulants:* In the third and fourth week the majority of typhoid patients need a stimulant. I do not approve of the time honored method of giving alcohol to every patient, believe it should be condemned.

In the mild form of typhoid fever, I believe the patient will do much better without alcohol, but in a few selected cases it seems to be beneficial, but I never give it until I have first tried other stimulants.

If the patient has been a drinking man, or

is old and feeble, alcohol given in moderate quantities, commencing in the latter part of the second week, after the headache has ceased, does much good. If collapse is threatened I give, say one-half ounce every hour, and strychnine one-twentieth to one-fifteenth hypodermically every three hours until the depression has been overcome, and then continue the strychnine in one-thirtieth grain every four hours. I have also had good results from other stimulants as digitalis, ether, caffeine and strophanthus.

*Hydrotherapy:* Water given internally and applied externally does much to lessen the effects of the toxemia. In deliriums, restlessness, twitchings, I have found nothing to mitigate those symptoms, equal to cold spongings. It has never been my pleasure to be so situated as to use the Brand method; but I use as a substitute the nearest to it, that the patients' circumstances will permit. The sponge bath has been the one applicable to most of my patients, cold water, or what I think better still, equal parts of water and alcohol. If I can not get the alcohol I tell them to use vinegar in its stead. I have the patient sponged every three hours when the temperature is 102° or over, and continue the sponging until the temperature is reduced one to two degrees.

I find the cold baths will not do in children, old people and the nervous, the shock being too great for them; in such cases I use the alcohol and water, letting it be tepid instead of cold.

In connection with the bath, I find great efficacy in using the ice-cap at the same time. In one case where I failed to get the desired results from the cold spongings, I secured the happiest effects from rolling the patient in a wet sheet wrung from water at a temperature of 80 degrees, and around this place a dry blanket, producing a free perspiration thereby speedily lowering the temperature two or more degrees.

*Internal antipyretics:* Acetanilid, phenacetin and antipyrin are the principal ones used, but I must say that I use them just as seldom as possible. I consider them dangerous drugs to employ, owing to their depressing effect on the heart. If in spite of the sponging, the fever continues high, with nervousness, I may give a five grain dose of phenacetin and repeat this in four hours if necessary, at the same time the heart should always be guarded by a stimulant.

*Medicinal treatment:* In my treatment I rely chiefly on the intestinal antiseptics, not from the idea of destroying the bacilli, but to render the intestinal tract in a condition not susceptible to their propagation, thereby, rendering it only necessary to rid the system of the existing germs. My preference is the

eliminating treatment. I begin with calomel, podophyllum and guaiacol carbonate every two hours for the first forty-eight hours, being governed however by the condition of the bowels, my idea is to secure four to five actions per day. I then leave off the calomel, if there should still be a tendency towards constipation, I give small doses of salts or Pluto water. I continue the podophyllum, guaiacol carbonate adding menthol, a few days longer, when I drop the podophyllum. I now take two tablespoonfuls of epsom salts add to an ordinary glass of water, and have a tablespoonful of this given every three hours, this to be kept up throughout the treatment.

I contrive to change my antiseptics frequently, using salol, zinc sulphocarbonate, copper arsenite if there should be a tendency to diarrhea.

The following are a few of my favorite prescriptions:

R  
 Guaiacol carbonate .....5i  
 Zinc sulphocarbonate .....5ss  
 Lactopeptin .....5i

M—fiat chart No. xii

Sig.—One every three hours.

R  
 Guaiacol carbonate .....5ss  
 Salol .....5i  
 Zinc sulphocarbonate. grs xii

M—fiat chart No. xii.

Sig.—One every three hours.

R  
 Guaiacol carbonate .....5ss  
 Cupri arsenitis .....gr. 1-100  
 Zinc sulphocarbonate .....5ss  
 Strychnine sulphate ....gr 1-4

M—fiat caps No. xvi.

Sig.—One every three hours.

TREATMENT OF SPECIAL SYMPTOMS.

*Headache:* The headache coming on in the first week of typhoid fever should be relieved by rest and cold to the head, if this fails, had better give a three grain dose of phenacetin, or ten to fifteen grains of sodium bromide.

*Insomnia:* This is best relieved by the baths, when not, I have had good effects from a dose of chloralamid, or a small dose, say one eighth grain of morphine hypodermically, and that without any constipating effect.

*Delirium:* For this I have gotten the best results by placing ice to the head, if of hysterical origin, I give valerian and assafoetida.

*Vomiting:* This is rarely troublesome, if so, a little chipped ice or minute doses of calomel generally relieves promptly.

*Tympanites:* If of moderate degree will need no treatment, but if excessive, use tur-

pentine stupes over the bowels, also a few drops internally, I have also had good results from assafoetida.

*Diarrhea:* I do not consider it diarrhea unless there are more than four movements per day, if they should exceed this number, try to locate the cause and correct. It is very often due to some little indiscretion in the diet, but if not relieved in this way, I give a dose or two of acetate of lead and opium.

*Constipation:* If you have used the salts throughout the treatment as mentioned above you will not be troubled with constipation.

*Hemorrhage:* Hemorrhage calls for complete rest; if severe the movements must be passed onto the drawsheet, place an ice bag to the right iliac region and give ice by the mouth, withhold all stimulants, and give morphine hypodermically, restrict the food for the next twenty-four hours.

*Bedsore:* The smallest bedsore demands active treatment, they should first be cleansed by a weak antiseptic solution, then dusted with boric acid, calomel and bismuth. If they seem to be stubborn about yielding to treatment, we can often bring about happy results by applying Peruvian balsam with castor oil one to thirty-two.

*Perforation:* This demands an immediate operation, if early diagnosed, the medicinal treatment, is the administration of morphine or opium, ice may be given for the dryness of the throat, and all food should, for a time be withdrawn.

*Thrombosis of the femoral vein:* The best treatment I have ever found for this trouble is to elevate the limb and keep at perfect rest, applying the following ointment along the course of the vein:

R  
 Ichthyol  
 Lanolin aa .....5ii  
 Ung Bellad q. s. ....5i  
 M—fiat Ung.

Sig.—Apply along the course of the vein three times daily.

I also have them wear an elastic stocking when on their feet for some time.

*Convalescence:* I never allow a patient to get out of bed until they are sufficiently able to make the change with safety. I first have them sit up in bed changing their positions often, this is done two or three days previous to their sitting in the chair.

Dressing often fatigues them, and to prevent this, I have them wear only a dressing gown. Their strength returns slowly, and a reerudescence with a slight rise of fever may be expected, which soon subsides, and is best treated with laxatives and enemas. In seasons of favorable weather, gentle exercise in

the open air, mental excitement must be avoided.

The diarrhea sometimes persists, due to the calonic ulcerations and should be treated by restricting the diet to milk and other light forms of food.

Now is your time to commence giving your tonics, iron, quinine and strychnine, etc.

SUMMARY OF MY EXPERIENCE WITH TYPHOID FEVER AND COMPLICATIONS.\*

BY D. H. ERKILETIAN, HOPKINSVILLE.

The horrors of last years' visitation of yellow fever is but too fresh in the minds of thoughtful physicians to interest them in the movement to check the prevalence of epidemic diseases. There has been marvelous improvements made in the sanitary condition of our civilized commonwealth to prevent the possible outbreak of an epidemic of typhoid fever which is at present a thing of the past. But the true honor of this great achievement is solely and wholly needs to be bestowed on the medical profession. Indeed a great field for philanthropy of the highest order was opened and it was happily exercised by the science of medicine in a manner most creditable to the human heart. A tribute of highest order I can confer on the profession of medicine just for the purpose of enlightening the minds of those who have been looking on our profession as mere shadow in an imaginary type and that medicine actually did not achieve anything worthy of notice—by declaring that the modern medical science in all its various fields of labor has distinguished itself above that of the preceding ages by its knowledge and intimate acquaintance to the etiologic factors producing the disease. Furthermore the increasing interest taken in the development and growth of biological chemistry and the discoveries in the field of pathology and bacteriology has put the therapy upon a rocky foundation.

Even confining myself to the treatment of this most complex malady, (requested by our kind secretary) a complete and exhaustive presentation of full details will not be practical. I may omit problems which are of distinct recognized importance to you all, which points I leave for your consideration.

The disease in view has its remarkable qualifications, has its unthought of complications, has its uncertain and sometimes diverting pathways, has its various centres of radiation and in some instances has its sudden and uncalled for fatal ends.

It is a disease which will ever refrain in taking advantage of a physician's easy slumber. Fortunate is the sick, suffering with

typhoid fever who did not experience the horrors of a complicated stormy sea. But even under the most favorable circumstances, in the hours never thought of as when there seems to have not even the least symptoms pointing to a trouble, the onset of grave complications is not a case of rare occurrence. A physician cannot be too certain about the course of typhoid fever. He must never claim the sick out of danger until he takes him over the hurdle of convalescence, and even then he must hold the reins tight.

In treating the typhoid fever an early and rigid diagnosis has its incomparable value. I admit that in some instances the disease presents itself in very puzzling, and in fact, abnormal manner, but after an exhaustive inquiry as to the symptomatology and bacteriologic examinations, to a practical eye the detection of the presence of typhoid fever is a matter of little time. It is not necessary for all the symptoms to present themselves before we realize the existence of typhoid fever. There is a peculiar impulse on the part of the physician which makes him realize he is dealing with certain disease. Especially is this true in typhoid fever.

The study of arterial tension is a very valuable diagnostic point. It shows more or less important variations under the influence of the disease. At the commencement as a rule it is diminished or increased at the second or third weeks. To the diagnostician it has a decided value in revealing complications. Do not fail to regularly auscultate and to keep a good record of the pulse with its various characteristics while the patient is under the influence of the disease. Furthermore the application of Diazo reaction in the urine and the Widal test of the blood, as early as possible, are two leading diagnostic means we possess. The Widal test is more trustworthy occurring in 98% of typhoid cases. All but 16 out of my 113 cases of typhoid fever have been examined through these processes before a definite diagnosis is concluded upon. The addition of these researches to what have already been acquired enables the physician to diagnose his case more correctly and dissolves the doubt.

There are instances in which the onset is very sudden. They are so uncharacteristic of that regular typhoid of gradual onset. This fact can be easily demonstrated by the fact that the bacilli developed in the organism without showing any clinical aspect until it is well developed.

Malaria is not a clear factor of the disease per se, though may complicate the beginning or the end of the disease. However we live in malaria plasmodium malaria germs while in typhoid fever we have Eberth's bacilli to

\* Read before the Kentucky State Medical Association, Louisville, October 17, 1907.

investigate. In both instances the application of Widal test will clear the situation.

It has been my experience among children that it is difficult to diagnose a typhoid fever correctly until the second week, even though Widal test and Diazo reaction is under our command.

Experience teaches us that the conservative conduct of typhoid fever has its many-sided advantages. In order to reap a definite success let that calm, and yet a resolute determination, accompany a vigorous campaign. Indeed it is equally important to know how to avoid the complications as to know how to treat them. The whole force of a practitioner's armamentarium must be concentrated not alone on the treatment of the conditions on hand but also such precautions be taken as to guard the patient against the probable onset of serious complications.

Typhoid fever is not a disease that can be potted upon at the expense of the patient. Neither is it a malady which can be dragged and waited upon for further symptoms to point themselves. But should an early and clear diagnosis accompany a rigorous treatment, not alone can a great many complications be avoided, but mortality be reduced to a minimum.

It is impossible to lay a definite rule for the treatment of all cases of typhoid fever, but there is a similarity of trend in all typhoid cases and each case is characterized by individual peculiarities. So that it is feasible that every case be treated broadly upon the general principles and yet each be treated according to present indications.

Carefully selected and detailed directions must be carried into effect. Select a well ventilated and light room and clear it to its utmost simplicity. From the very beginning of the disease acquaint the patient and the family with the disinfectants to be used and also with the mode of their application. If possible isolate the patient entirely from the family. The stricter a physician is in seeing that his orders have been carried out to perfection the better results he will get and the more they will appreciate him.

An upright, painstaking and intelligent nurse is a Good Samaritan in the hours of agony of the patient, and a true help in the struggles of the attending physician. I wish the time was near at hand when our schools for nurses or hospitals would graduate plain, more efficient, competent and faithful nurses instead of training them in a most limited haphazard manner in some branches of medicine, thus causing them to neglect the true nature of their calling.

Furthermore, medicinal treatment of typhoid fever has its leading prestige over all other treatments. In the face of a natural

tendency in the medical profession to discard the use of medicament based upon the training of some schools and also opinions of some of our learned authors, it is my humble belief based upon my careful observation in 113 cases of typhoid fever in the last three years that medicinal agencies are the faithful standby of a physician and in some instances they serve as a deadly weapon in defending the nature. I admit also the fact that the drugs in the hands of an infamous and careless practitioner are dangerous articles. The physician is called in to safeguard the interests of the sick and to omit any of the means to effect a cure, is sin against the profession of medicine and deserves to be punished by its councils.

The three drugs I administer from the very day I make up my mind I am treating a typhoid fever until convalescence sets in are turpentine, as an agent which possibly will prevent intestinal hemorrhage; iron, as an agent which promotes digestion and improves the blood; sulpho-carbolate of zinc, as a reliable intestinal antiseptic.

These drugs were never used freely or carelessly but in small doses and also in combination with other drugs. Under the continual use of iron the patient comes out strong and well and bears well the train of the disease so peculiar to typhoid fever.

Goister and also Kayser proved by scientific investigations that gall bladder is a favorite seat for typhoid bacilli, even years after the recovery of the patient the bacilli multiply there. Therefore it is advisable to bring out a copious flow of bile to wash out the bacteria.

In calomel we have an efficient disinfectant. It stimulates the secretory system and relieves engorgement. It is laxative in grain doses and an efficient diuretic. As all these valuable qualities can be found in one drug and which is much needed in typhoid fever, our judicious use of calomel, even to German Specific, is justifiable.

Pyrexia is a symptom which is second to none in importance. In the combination quinine sulph., salol, Dover's powder, salicin and occasional addition of potassi nitras I have found an efficient antipyretic. We all know quinine sulph. is a powerful antiseptic, checking abnormal fermentation. It serves as an antipyretic. While salol passes through the stomach unchanged and the parts freed in the intestinal canal acts as an antipyretic and antiseptic, and also checks excessive diarrhea. The small amount of opium in Dover's powder has quieting effect over the intestinal peristalsis. Salicin has its antipyretic, anti-ferment and antiseptic qualities and also is destructive to lower organisms and nitrate potassium and efficient diuretic (serve) de-

creasing the uric acid and increasing the urinary water thus alkalinizing the blood and the urine. After a short period an application of antipyretic if I fail in reducing the fever below 102° F. I resort to hydrotherapy in company with internal medicines. The external application of cold or tepid water abstracts the heat from the patient, calms restlessness, favors assimilation.

Currie's method of bathing increases the flow of urine and lessens toxicity and clears the system of a large quantity of toxins. It has its beneficial action upon the nerve centers thus promoting sleep. I think it is a great mistake on the part of some of our learned practitioners to discard the use of hydrotherapy in typhoid fever when it is indicated. Time and again I have observed the beneficial effects and happy results of hydrotherapy and never will cease to use it unless otherwise convinced. In the absence of a nurse great precautions needs to be taken in the use of hydrotherapy. The internal application of cold water is just as important as its external application. It allays the thirst, increases the secretion of saliva, bile and pancreatic juice. Encourages the flow of urine and perspiration. It must be given freely in the shape most suitable to the patient. We must never forget the fact that there is a danger of an overdose of antipyretics and injudicious use of hydrotherapy but when nature is battling against the disease be sure that we be a helpmate and not a hinderance to her cause.

Aconite and veratrum viride, once so freely administered in typhoid fever, is contraindicated.

On account of its cardiac tonic, vascular stimulant and diuretic qualities digitalis holds among the first rank of drugs in typhoid fever, but its action must be carefully watched. It is very important for the physician treating a typhoid fever case to concentrate his whole energy to the weakest point.

The sounds of the heart should be incessantly watched during the course of the disease. When the impending heart failure is shown by cyanosed extremities, pulmonary edema and weakened blood circulation, digitalis hypodermically may be used. If the heart and pulse flag, which will be visible in the second and third weeks, we must reinforce alcohol with strychnine, ether or camphor. Camphor is an excellent stimulant, both to the heart and nervous system.

Several years ago my attention was drawn, through an article in a medical journal to the possible occurrence of hepatic abscess in typhoid fever. I am well convinced of such an occurrence and I think it most advisable to have a thorough and repeated examination of the liver. Enlarged and tender liver, jaun-

dice, signs of septic infection and severe peritoneal pain are the leading symptoms pointing to a hepatic abscess. It must be remembered that the operation of any hepatic abscess is very badly borne by a typhoid patient, but if an operation, done successfully, prognosis as a rule is favorable. During the intestinal complication, when they present themselves in diverting and complex manner, the battle needs to be fought in a very cold-blooded manner. The protesting stomach causes a great deal of delay and is sometimes detrimental to the good interests of the patient. In that case apply mustard plaster on the epigastric region, suspend the diet, internally administer drop doses of carbolic acid, cracked ice and lime water. Dilute hydrochloric acid is well recommended. In intestinal complications the use of high enema is highly beneficial. It cleanses and flushes the lower bowels, removing the hardened deposits and also cools the intestinal heat, but it is wise for the physician himself or a competent nurse to attend to this part of the work. Intestinal antiseptics are of great value in relieving diarrhea and in checking putrefaction. Sulpho-carbolate of zinc, lime and soda is a very reliable antiseptic, also guaiacol carbonate is an efficient one; also tracol and eucalyptus oil is highly recommended.

In case of persistent diarrhea the administration of a combination of bismuth, tannic acid and opium may be resorted to. Da Costa recommends sulphate of copper and opium. Tannalbin and ichthoform have their ardent admirers. The meteorism which is the forerunner of hemorrhage and perforation in the majority of instances, can easily be treated by a combination of camphor and charcoal, and also by emptying the gas by passing a rectal tube.

A sudden drop of temperature to or below normal is quite a reliable symptom of hemorrhage. Hemorrhage and perforation do not meet each other so often. It is a physiological fact that the blood vessels of the intestinal tract contract very rapidly under the direct stimulation of splanchnic nerves. Such drugs as ergot, digitalis and strophanthus, each cause the contraction of arteries in that region. The administration of these drugs has its value in checking the hemorrhage.

Turpentine oil is an excellent vascular stimulant, an antipyretic and diuretic, it restrains the hemorrhage and invigorates the heart. It can be given from 1-4 drams, even more. Hot water enema, and hot foot bath, ice bags on the abdomen and elevation of the lower extremities of the patient are the methods that must not be neglected in case of hemorrhage. The adrenalin chloride solution, 1-1000 every two hours has its happy results.

Coleinm-chloride, gelatin and suprarenals have their advocates. In taking into consideration the complication of perforation, such symptoms as ablation of liver dullness, and sweating and dull expression, changes in the rate and character of the pulse and change of temperature, paroxysmal pain, abdominal rigidity, tenderness and distention will be invariably present, but among all other symptoms, mere suspicion of the rigidity of the right side at the lower rectus muscle, in company with severe paroxysmal pain should be enough to lead us into an immediate operation.

Operation in the hands of a skillful surgeon, when called upon at a very favorable time, is much safer and less dangerous than the complications, themselves. Indeed, it is much safer to treat the prospective perforation than to wait for full development of the symptoms. Do not wait too long for the diagnosis of perforation. Call in a surgeon at the moment a suspicion appears, nothing can be gained by waiting. Beware also of the fact that perforation occurs in such a time when all the normal powers of the patient are weakened by the long standing sickness. But between the two I will risk my patient to an operation. Not even 5% recover without an operation and if the operation is done within six hours after the onset of perforation 50% may recover.

One happy consolation is that in nearly all cases the diagnosis of perforation can be easily made without the slightest doubt, and even if it takes all our energies to open the abdominal parieties while the patient is in such a state of complete breakdown, yet undoubtedly we can accomplish some good in closing up that highly inflamed hole in the intestines.

In the course of typhoid fever the development of pneumonia is a very unhappy accident. The continued attack of these two most wasting diseases makes our prognosis very doubtful. Under the circumstances helpful means for the aid of nature should be employed. Supportive treatment is the most successful at the end.

Among the nervous symptoms, insomnia can be treated with trional; delirium and nervousness would be overcome by chloral. Such diseases as paralysis, insanity, pleurisy, Bright's disease, tuberculosis, etc., are some of the serious sequella which may present themselves in some cases of typhoid fever.

It is a happy thought to think that the tendency of typhoid fever among children is towards recovery. The intestinal canal during typhoid fever is the seat of many troubles and dangers. The restriction of medication and irrigation and hydrotherapeutic measures will best suit the children.

The question of feeding has been the subject of controversy among the practitioners. Every physician has his choice bill of fare to offer to his patient, but the importance of pure food has been repeatedly overlooked. For this reason I would rather treat a typhoid case in the country than in the city.

"I love the city, but country the best.

If so you wish, I leave for you to test,

Pure air, pure water, don't forget pure food,

The gifts of Nature ne'er cease to do good. Disease will find no solace, refuge there

Where pure milk, eggs and buttermilk ain't rare."

In order that the patient may be able to withstand the ravages of the disease, he must be kept in the best possible condition. In the majority of instances we starve them. Milk has a leading rank, while acute symptoms last. It is better given with pepsin or hydrochloric acid or with both. Buttermilk is well-liked by all and can be given freely. Barley or rice water, or eggnog may be used as substitutes for milk. After the subsidence of more acute symptoms, such diets as gruels and broths, beef tea, rice, soft boiled eggs, etc., may be given. It should be insisted upon that the patient take as much as a quart of water every twenty-four hours. Alcoholics furnish a food which supplies the loss which is produced by the fever and exhaustion from combustion of tissues. But give them while they are benefiting the patient. If stimulants increase the delirium and nervousness it is better to restrict their use.

The typhoid patient has an unusually delicate taste and very sensitive feeling. A fly in the soup for a healthy stomach, is a matter of accident, but for the sick it sounds like an insult and produces a disgust for that particular diet, never to be forgotten. Indeed it is highly important for our nurses to know how to feed, what to feed, and also how to prepare the food to suit the patient.

As soon as the convalescence sets in withdraw all the medicines from the sight of the patient thus convincing him of the safety of his condition.

Among the tonics to be allowed I have found happy results in the combination of dil. phosphoric acid, tinct. nux vomic., tinct. ferri chlor. and syr. pruri virg. to be given after meals.

As I said before the patient is not safe until we are over the hurdle of convalescence with him and even then hold the reins tight. The duty of the physician does not cease until he instructs the family and the patient about the extreme importance of carrying out the rules laid out for convalescence. During this period the least of uncalled for disturb-

ances must be avoided, both mental and physical. A happy and cheerful atmosphere must surround the patient.

In conclusion, I wish to emphasize the fact that typhoid fever is not a disease which runs its course unmoved from any medicinal agencies. Indeed it requires the attention of a studious, calm, clear-headed captain of common sense to lead his ship in safety to the harbor of convalescence. No definite rule can be set aside for all individuals alike but every case should be studied by itself and each be conducted as it presents itself. It is a disease in which every hour has equal value as to the treatment. A neglect, even the most unthought of insignificant point, may bear serious results.

If I may be allowed to trespass temporarily the rules of etiquette I will conclude my discourse with this happy message that during the entire period of my practice I have not experienced a single death from typhoid fever, and hope and trust the same will be by good fortune in the remainder of my active practice.

#### TYPHOID FEVER.\*

BY W. F. HICKLE, HUBBLE.

Typhoid fever is an acute febrile condition, it runs its course from 14 to 70 days. The majority of cases reaching convalescence at the end of the third week. A fever like typhoid was recognized by Hippocrates as early as 450 B. C.

In the writings of Galen, 130 B. C., a fever is described which is undoubtedly typhoid.

Coming nearer our own time in the early part of the Seventeenth century, Adrainus Spigelius writes on this fever and a little later in the same century Thomas Willis, F. Hoffman and Thomas Sydenham all give very good descriptions of this fever. In the Eighteenth century E. Gilchrist, Jno. Huxham, J. C. Reidel and Mannigham recognize and write on this same fever. But to Dr. Louis, a French physician, is due the credit for a fuller description and naming it typhoid. Dr. Louis published a treatise on typhoid in 1829, which gave him an international reputation.

For a long time there had been no differential diagnosis between typhus and typhoid fevers. The first to point the difference between the two diseases were American pupils of Louis's. These pupils were W. W. Gerhard and C. W. Pennock.

Among others who were making some notoriety in these distinctions may be men-

tioned Alfred Stille, George C. S. Shattnek, Sir Wm. Jenner and A. P. Stewart.

*Etiology:* The etiology of typhoid fever is conceded to be the bacillus of Eberth—discovered by him in 1880 and soon confirmed by Klebs, Koch and Friedlander.

They are found most numerous in the intestinal canal but are also found in the lymphatic system, in the glands of the mesentery, in the liver, in the spleen and in the kidneys. They are found also in the marrow of the bones, in the blood, in the bile, in the urine and in the spots of Louis.

That these bacilli have a tenacity to life that few others possess has been abundantly proven. It requires a temperature of 156° F. to destroy them, two-tenths per cent. carbolic acid is without effect on their growth in a culture medium. In the upper layers of the soil they retain their vitality for five or six months. They live on soiled linens from 50 to 70 days and freezing and thawing has no effect upon them.

Of all natural destroyers sunlight is the best as they lose their vitality in from one to five days owing to time of year and the amount of heat derived from the sun. Typhoid fever is disseminated by a careless disposal of the urine and alvine discharges. The water and milk supply being the most frequent sources of infection. Sometimes by the breath as it is my opinion that I have seen one case so produced by the two sleeping in the same bed during the prodromal symptoms of the first.

In the excretions of the white cook mentioned this summer in the Journal of the American Medical Association she proved to be a walking laboratory for the dissemination of typhoid fever though it had been six years since she had been ill of that disease.

For these reasons we should be very positive in our instructions in the disposal of the excretions.

A free use of chloride of lime, carbolic acid, boiling water and the burying of the discharges, so as not to contaminate a water supply, a garden or be carried by the ever present fly, should be well drilled into our clientele.

This lack of knowledge on the part of the laity has been the cause of many being infected with typhoid bacilli, therefore we should not be neglectful of our duty of so important knowledge.

*Pathology:* The principal lesions in typhoid fever are in the small intestines and may extend into the large bowel. Peyer's patches and the solitary follicles at autopsy show that they have borne the brunt of the battle. That the other viscera may be involved has been mentioned, due probably to general toxemia: some claiming however that

\* Read by title before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

it is due alone to the bacillus typhosus which has been carried by the blood current to these other organs.

Peyer's patches and the solitary follicles go through three stages, infiltration, ulceration and cicatrization.

The floor of the ulcer is most frequently the submucosa or the muscular coat though it may be the peritoneum. Through this extremely thin membrane is where perforation takes place resulting in fatal peritonitis.

The spleen and the liver usually become very tender on percussion and may assume twice or thrice their normal size due to the stasis which may accompany any continued fever.

Hypostatic pneumonia sometimes occurs in those cases which have remained in one position too long.

*Symptoms:* Symptoms of typhoid fever have been enumerated so often that they have become a hackneyed subject.

The majority of my cases complain of great lassitude, of being wonderfully sleepy and of terrible dreams. The headache in typhoid is usually occipital though it may be general, I do not recall a case that did not have headache during the prodromes. The patient has an aversion for all kinds of food for a week or two before consulting a physician.

The diarrhea when present is of dark brown color and of the classical pea soup consistency, the evacuations number from three to fifteen per day with a most intense odor which is quite characteristic, the epistaxis mentioned so often in the text books I meet very infrequently.

The swelling in the right iliac is very common and for the first few days the gurgling is quite noticeable.

The rose colored spots of Louis make their appearance on the abdomen about the eighth day and are of great diagnostic value, they resemble a flea bit and are just a little elevated, they appear in crops run a course of three or four days and then desquamate a light bran-like desquamation from the crater of each spot. I call especial attention to the elevation and desquamation as I have never seen either mentioned in literature, to be able to see both most easily one must look for them on the level of the abdomen.

The temperature in typhoid is an important symptom.

Some diagnosticians claim that they can make a diagnosis alone from the morning fall and the evening rise, that this diurnal wave is true of all continued fevers I think we all agree and is therefore not peculiar to typhoid. The appearance of the tongue in typhoid is a heavy brown or yellow coat and its extraordinary red tip and edge. The point of the

tongue has a tremor, when extended, peculiarly its own. When the tongue is turned up or down the point still trembles but not so much as when it is extended. In other digestive disturbances the tongue may have a tremor but when the point is turned up or down the patient can then control the tremor, as just stated this is not true of the typhoid tongue. The coat begins to give way at the end of the second or third week under a proper regime and medication, it clears rapidly unless the patient is improperly fed or omits his medication when it will quickly fur again but this time the epithelium will not be so long and not so brown but fully as dry if the fever is high which it usually is.

The heart as a rule is not exceedingly rapid not usually over 100 in my cases, a soft quick pulse is a very unfavorable symptom and shows that something is seriously wrong which requires immediate attention.

In delicate patients the pulse and temperature fluctuate easily, exertion, excitement, talking or reading near the patient or even in an adjoining room will send both temperature and pulse up appreciably. If the patient is interrogated will complain of being very tired from this extra strain on the nervous system, most typhoid patients are very sensitive to noise: I have known them to be irritable from the lowing of a cow, the crowing of a rooster or from the monotonous sound of a sewing machine.

The respiration is not usually rapid and is usually in keeping with temperature and pulse.

The diarrhoea in typhoid is not usually troublesome and in most cases is really beneficial as it is nature's remedy in eliminating the toxins. It is an index for castor oil, calomel in minute doses or the salines to flush out the decomposed material which is acting as an irritant and by the absorption of the toxins is producing a general toxemia. If you are wary of undue peristalsis a 1-12 gr. of morphia may be given per orem or hypodermatically to correct this feature that not being enough to lock the bowel. The idea being to splint the bowel just enough to allay undue peristalsis and to prevent griping. Constipation which is so marked in some cases should be corrected by dram doses of castor oil with ten drops of turpentine repeated every 6 to 12 hours until it acts together with plain warm water enema as indicated. If no symptom of hemorrhage supervenes the oil should be continued as indicated throughout the disease. One good evacuation every 48 hours will suffice though one every 24 hours is better.

*Complications:* Complications of typhoid are not many though the patient may have two diseases at the same time.

I wish the profession would quit using the term typho-malaria as indicating a single disease, it is either typhoid or it is malaria or the patient may have both diseases at the same time though it is rare, when we meet both in the same patient let us so denominate it and explain it.

Nephritis is to be thought of in all severe cases especially if much turpentine is being administered, test urine frequently that you may not be found sleeping.

Phlegmasia alba dolens usually in the left leg often complicates convalescence.

Mastoditis sometimes complicates and the differential diagnosis is sometimes difficult.

Cardiac complications though rare are myocarditis, endocarditis, and pericarditis, the former may cause sudden death.

As typhoid fever predisposes to tuberculous it is well to bear this in mind and that many mistakes are made in the differential diagnosis of typhoid fever and miliary tuberculosis is not to be forgotten.

*Diagnosis:* If the diagnosis of typhoid was as easy as many of the text books would have us believe the diagnosis would be made at the first visit and consultation for this purpose would be rarely needed, I think the cardinal diagnostic symptoms are: the prolonged prodromes, loss of appetite, diarrhoea with its characteristic odor referred to in the early part of this paper, occipital headache, furred tongue, red tipped and trembling, tympanites, and gurgling and the spots of Louis are conclusive symptoms, the epitaxis when present is also conclusive when associated with other strong symptoms.

Some forms of malaria are sometimes difficult to differentiate from typhoid though the microscope would settle that in a few days though most of us take the other plan when in doubt that is administer quinine though contraindicated in typhoid.

Some cases of deep abscess are also difficult to differentiate though in case of abscess the temperature remains high. The differential diagnosis of pneumonia is not as a rule difficult though we must bear in mind that hypostatic pneumonia may occur in typhoid due to one position maintained in bed too long.

*Treatment:* This brings us to the treatment where the profession usually part company. The treatment as laid down in many of our text books is really a disappointment to read, if two or three of the leading text books were submitted to a jury of twelve well informed men, not doctors they would be compelled to bring in a verdict that the profession knew but little of the treatment of typhoid fever and according to the teachings laid down in the books the patient need not employ a physician and that he need not take

any drugs, that he might eat and drink anything which he might choose.

A decision like the above would be inevitable from the evidence submitted. I contend that there is a rational treatment for typhoid fever.

The rapid strides in the past two decades in surgery are almost beyond comprehension, the wonderful achievements in this branch of medicine are due to our knowledge of bacteriology, asepsis and antiseptics, uncounted thousands of lives have been saved in surgery from this knowledge of infection; the same might be said of internal medicine if more attention was directed to its merits. For a long time I have advocated the internal administration of antiseptic measures for the amelioration of typhoid fever.

If typhoid is produced by a germ why not combat it as the surgeon does the germs that may infect his field of operation.

Some contend that the bacilli are buried out of reach in the infiltrated tissues of the intestine that they are in the blood, the liver, the kidneys, the spleen and even in the marrow of the bones. For this reason antiseptics they say will do no good. It is for this very reason that antiseptics should be administered. Some of these same ones contend that so many agents have been manufactured for this purpose that that is evidence of their uselessness. Not at all. It is because the ones that are efficient, (and they are many), have not been properly administered. Therefore a mechanical cleansing of the canal is indicated frequently not only to sweep out the typhoid bacilli but many others as well whose combined effect, if left in the tract, will produce a general toxemia. After the tract has been thoroughly cleansed with any of the eliminants then the antiseptics administered with a free hand will soon show their efficiency by destroying that terrible odor from the feces which is quite characteristic. There are many agents which are efficient which I will not mention as they are well known, as stated above if administered liberally they will sweeten the contents of the bowel and of the bladder as well. By inhibiting the growth of bacteria in the economy not only of the bacilli typhosus but numerous others as well whose combined effect produce a general toxemia and whose combined local effect frequently cause perforation in Peyer's patches. Therefore like the surgeon I argue to keep these wounds as clean as is possible both chemically and mechanically and thereby greatly lessen the danger of the fatal issue.

There are many antiseptic drugs which are used in the treatment of typhoid all of which are more or less useful but some of which have objections as being too toxic to the patient or nauseating or too irritating to the

kidneys and so the profession has almost quit the use of drugs in typhoid. The reason for this failure they were not properly administered or the bowel was not properly prepared for their reception, it being more difficult to get antiseptic effect in the presence of a bowel full of decomposing material loaded with all kinds of bacteria.

For sometime I have been doing a little laboratory experimenting seeking for a drug non-toxic, non-irritating and highly antiseptic. I am not going to spring a new drug on the profession nor a proprietary with a new and fanciful name but one with which we are perfectly familiar "boracic acid." This together with salol has filled my wants. The boracic in saturated solution will preserve milk, cider, wine, etc., for a long time after the untreated product has become acid.

It being practically non-toxic and non-irritating it can be administered in much larger doses than any other drug with which I am familiar. It should be pushed after elimination is well established until the feces lose their terrible odor, the tongue becomes moist, the fever drops frequently to less than a 101° and the patient expresses himself as feeling very well except weak. I do not give more than five grains of salol every four hours but the boracic solution may be pushed to effect without any deleterious effects.

It is impossible to prescribe dosage in any disease but the attending physician must be able to know when he gets an effect which is desired. I get better effects from this drug therapy than any which I have tried but I also get results from the other antiseptics, but the objections are sometimes troublesome.

*Feeding:* The buttermilk diet is the ideal diet as it leaves no casein curds in which bacteria may develop or act as foreign bodies to irritate the ulcers about which so much is said. From three to six ounces of buttermilk every four hours is usually sufficient though this too must be regulated by the attending physician.

As any antiseptic which will inhibit the growth of pathogenic bacteria will also inhibit the physiological enzymes it is best not to administer the antiseptics within an half hour before or an hour after feeding so as to not retard digestion and to get the full antiseptic effect of the drug at a point where it is needed.

I rarely have any occasion to use febrifuges or antipyretics.

When required the cold sponging answering all purposes.

The treatment for hemorrhage I have nothing not in the text books.

## THE NECESSARY FACTS FOR A COMPLETE INSURANCE EXAMINATION.

BERNARD J. O'CONNOR, LOUISVILLE.

After we have obtained all the necessary facts from an applicant concerning his personal and family history, made the physical examination and urinalysis, and filled in all the blank spaces of the examination form correctly, it is perfectly natural to feel that our examination is complete. But have we ever thought of the many letters which we have received from the medical director requesting us to secure additional information concerning some of the facts that we have recorded and how much time, trouble and possibly money we may have saved ourselves, our company, the applicant and the agent if we had anticipated such matters at the time of the examination? In about 25 per cent. of all the examinations that we turned in to the home office letters must be written, or the examination itself must be returned to the examiner for corrections, completion or additional information. Such conditions would not arise in more than 2 or 3 per cent. of all cases if examiners were careful and well trained.

Since carelessness and sins of omission are the greatest factor in the necessity of so much correspondence, it is essential that we lay most stress on their prevention. If the examiner would make a copy of each examination he would find it perhaps of great value in later years and it would draw his attention to many omissions in his report. Or, if he would simply allow his examination to lie aside for a short time and before mailing it, would critically review his work as the medical director does, forgetting as far as possible that he himself made the examination, we would see very few of these mistakes. It must be admitted that the arrangement of the examination forms, especially when the examiner is called upon by various companies, is responsible to some extent for our shortcomings. Insurance companies will never agree on a perfectly uniform blank but they should all agree on putting their questions in the same manner, so that the same reply can always be given in negative cases. What explanation can be offered for one company wanting to know, for example, whether albumin is present in the urine, while another asks if it is absent?

Promptness in answering correspondence, etc., is a prominent characteristic of a good examiner. If the necessary information can not be obtained within two days, the examiner should acknowledge the receipt of the letter, explain his delay and inform the company when he will be able to answer the letter in full. If it is ever necessary to hold

over an examination longer than forty-eight hours to secure any additional information concerning the family history, the condition of the urine, etc., or perhaps on account of some slight indisposition of the applicant at the time of the examination, we should always communicate our reasons to the home office.

While the services rendered in the physical examination, etc., of the applicant is the chief feature in our examination for which we are paid by insurance companies, I will limit my observations solely to the clerical part of our work. To bring home the importance of the physical experience at the hands of three local examiners will suffice. This applicant first appeared before an elderly examiner, who stripped him to the waist and made a very thorough physical examination, even to the testing of all his reflexes. Unfortunately, however, this examiner regarding the urinalysis of a man thirty years of age in apparently perfect health as unnecessary did not request a specimen of his urine. This man soon applied for insurance in another company. Their examiner, after completing the clerical portion of his labor, simply brought his ear in proximity to the applicant's chest and without even listening to a single heart sound, he said, "Oh! you're all right. That's all that is necessary." He entirely omitted the most important part of the examination for which he was paid a fee of \$5.00 by the company. A short time later under the hypnotic influence of an agent of another company, he appeared before a third examiner who made a complete examination and found an albuminuria.

Reviewing briefly some of the questions that prove to be the more common stumbling blocks for the examiner, let us recall the fact that when we receive a positive answer to a question that the answer is usually incomplete. Even before writing the "Yes" it is always best to first ascertain whether the applicant's answer is reliable or correct, and then secure the necessary details. Should there be any doubt as to exact nature of the illness, especially if it is of recent date, or any features thereof, concerning which the applicant may be ignorant, it is wise to secure data of the illness from the attending physician before mailing our report. In some instances it may even be necessary to have the applicant examined by a surgeon, or a specialist to secure necessary information. Such information should be obtained without any extra expense to the company, and at the time of the examination rather than later.

In regard to the applicant's habits respecting the use of alcohol, the examiner without any fault of his own often records many distorted statements. Our companies always

want to know the average number, or amount, and the kind of drink taken per diem. If we are led to believe from the applicant's answer that he is anyway near the insurance limit, it is advisable to ask whether the applicant takes a drink before breakfast, as this is not only a suspicious sign but also a dangerous custom. If the applicant is honest enough to acknowledge that he has ever been intoxicated we should in a diplomatic and indirect manner learn the frequency and duration of such conditions and the date of the last. If the applicant has been a teetotaler for a short time we must not forget to elicit a history of his previous habits, as he may be a periodic or spree drinker. We should also make inquiry, if the applicant's habits are anyway suspicious, as to whether he has ever had delirium tremens, or has taken a "cure," as both classes are dangerous. It is perhaps best not to record any history of alcoholic abuse in the applicant's presence as it will quickly terminate any further information that he might render to you personally.

When an applicant has had appendicitis or has had an operation therefor it is important that, in addition to the ordinary details, we should record not only the date of the operation but also whether the appendix was removed, whether an abscess was simply drained or whether there was primary union.

Asthma is only a symptom of a disease and it is essential to learn the cause or the true nature of the disease. It is prima facie evidence that any physician who classes every form of dyspnoea as asthma or pneumonia is not only a poor examiner but a dangerous doctor. Asthma due to hay fever or to some trivial nasal irritation does not necessarily debar the applicant from insurance.

Blindness in one eye does not always prevent the issuance of insurance but the medical director must always be informed as to the cause and date of the blindness and the condition of both eyes before he can take any action.

A history of cancer or malignant growth is usually sufficient to reject an applicant, but in justice to the applicant we should always make inquiry from the surgeon as to whether his diagnosis was the same after the operation, etc. As a rule surgeons are not as willing to acknowledge their mistakes particularly to their patients. A simple epithelioma without glandular involvement which has been removed five or ten years previous and in which no evidence of recurrence has been noted, will not prevent the applicant from securing insurance if we can get a statement of the facts from the surgeon.

Cough, clearing of the throat and hoarseness are symptoms that may not be acknowl-

edged by an applicant but are often observed by a careful examiner. They are more or less of significance and should never be omitted from our report. It may even be advisable to secure a statement from a competent specialist after we have carefully excluded pulmonary or cardiac diseases so that we can eliminate for our medical director the possibility of a laryngeal tuberculosis, syphilis or tumor. Such symptoms on the other hand may be due to habit, occupation, or, as in case of Jews over forty years of age, it may be a racial characteristic.

Discharges from the ear or perforation of the tympanum no matter how innocent beyond the ordinary details calls for a statement as to the condition of hearing, the condition of the ear after exposure or colds. A statement from a competent aurist as to the location of a perforation, the presence or absence of granulation tissue, or caries of the bones and the extent of impairment of the hearing is essential if such a condition exists.

If there is a history of fistula the medical director wants to know not only the location, date, duration and cause, but also whether we can eliminate tuberculosis particularly as a factor.

In gout in addition to the ordinary facts we should record any family tendency to the disease, or its allied disorders such as lithaemia, arterio-sclerosis, interstitial nephritis, apoplexy. Note must also be made as to the presence or absence of gouty deposits, or tophi, in the points, hands or ears and as to the urinary symptoms during and between attacks.

When an applicant acknowledges an attack of gonorrhoea a good examiner will always take note and record the presence or absence of shreds in the urine voided.

Hernia when present demands an actual examination to establish the variety, extent and the efficiency of the truss worn.

Indigestion, dyspepsia, colic, no matter how trivial or apparently insignificant the symptoms, are often of grave import. Should the applicant be a light weight let us look closely to his family history and personal condition for tuberculosis. We should moreover always eliminate even in the most trivial cases of indigestion, cramps or any abdominal trouble the possibility of biliary or renal calculi, appendicitis, aneurysm, tumors, intestinal ulceration, etc.

Insanity is a disorder that is seldom acknowledged in either personal or family history but if we alter the question slightly and ask if any member of his family was ever slightly deranged or mentally unbalanced we would receive more positive answers to this question.

In recording the history of an injury, wound or scar we must not forget to state the cause, extent, severity and the disability resulting therefrom and more particularly the information as to whether it was due to accident, or was self-inflicted, or was the result of combat.

Over and underweight applicants close to the acceptable limits should always be actually weighed and measured at the time. It is ordinarily justifiable perhaps to remove the coat and vest of a heavy applicant and to pull the tape snugly around his abdomen and to avoid including his trousers in our measurement. In both over and underweights we should forward information as to the age and approximate weight and height of the other members of the family. To determine more accurately how much a person has actually gained or lost in weight in a certain period it is well to ask him before placing him on the scales how much he thinks he weighs, and how much he weighed the last time that he was on the scales. In connection with the subject of weight, it may be remarked that the best evidence that the medical director can have that an applicant has perfectly recovered from any illness is the statement that he has fully recovered his weight.

Paralysis from cerebral or spinal disease is an entirely different matter from a prognostic standpoint than that due to a peripheral disorder. If causes of serious consequence such as alcohol, lead, syphilis can be excluded for the latter, your applicant may be fully entitled to insurance. Infantile paralysis, if the deformity or crippling is not extensive, should not debar from insurance. If the examiner cannot differentiate these forms it is a matter of justice both to the company and the applicant that the opinion of a competent neurologist be secured.

Rheumatism is not only a commonly abused term but one that has caused considerable unfairness to many an applicant through the examiner's readiness to record everything that the applicant states without further investigation of its correctness or reliability. It is a good rule never to jot down a "Yes" in answer to this question until we have found out how long his rheumatism kept him in bed or away from his business.

Stricture of the urethra, like other conditions, may be due to false conception on the part of the applicant and it is advisable to have him describe the operation as he may depict a simple meatotomy or sounding instead of a urethrotomy. If the stricture was operated on several years previous to the examination, ascertain from the specialists the after-results and particularly the size of the sound passed at the last sitting. Under this head we must remember that all cystitis in

applicants of forty or over is not due to stricture or hypertrophied prostate, but such facts must be made clear to your medical director before your applicant can secure insurance.

Syphilis is acknowledged after making certain as to the reliability of the diagnosis and detailing the date of the initial lesion, the extent, nature and duration of the secondary symptoms, it is essential to record the presence or absence of tertiary symptoms and render a full account of the time, extent and method of treatment.

Varicose veins, when present, must be examined and their cause, location, duration, secondary changes like ulceration due to them and size compared with that of a lead pencil, must be recorded in our report.

Vertigo, dizziness and fainting are manifestations of such varied significance that we must not only give the ordinary details as to etiology, frequency, etc., but must also inform the medical department whether the applicant actually fell during the attack or had to grasp objects to prevent his falling.

In obtaining the family history, particularly if there has been any early or suspicious deaths, we should never accept a "don't know" if there is any member of the family alive who can furnish the desired information. If there have been any deaths from tuberculosis in an applicant's family, his association with such relatives during their illness must be investigated and recorded. A complete, careful and accurate report upon family history is always good evidence of a careful examiner. The examiner who overlooks the instructions concerning family history and who accepts off-hand all of the applicant's statements without further investigation, is a dangerous man for an insurance company.

The urinalysis is the last feature to be presented. If an examiner finds either albumin or sugar, or a specific gravity above or below the limits, it is usually advisable to secure a second and possibly a third specimen, to report the findings of each specimen and to forward to the home office a specimen of the urine. If the applicant gives a history of such a condition the same method of procedure is advisable.

Such specimens should be vouched for as authentic and it is wise to add information concerning the time voided, possibly the diet and amount of exercise, and as to the preservatives employed, a one per cent. formalin solution being perhaps the best. If the urine, however, is voided directly into a bottle that has been sterilized by boiling, or germicidal solutions, the addition of preservatives is scarcely necessary except in hot weather or for long distances. If the specific gravity of the urine is persistently low we should have

the applicant abstain from beverages and obtain a specimen after a dry meal, and we should examine carefully every specimen for albumin and for sugar if the gravity be high. If there is any probability of a diabetes or nephritis, it is more advisable to secure a specimen of urine voided in the afternoon, rather than that of the morning. Above all, let the examiner remember that any freshly voided specimen of urine which is cloudy and does not clear up perfectly on the addition of acetic acid and boiling, even though the cloudiness does not increase on boiling, that he is dealing with some form of albumin which is more or less an evidence of disease.

#### REPORT OF A CASE OF GUNSHOT WOUND OF THE ABDOMEN\*.

By W. S. LITTLE, OWENSBORO.

Man, 28 years old, shot with a 38-calibre revolver in the right inguinal region, half inch to the right and a little below McBurney's point, the bullet ranging downward, backward and inward. There were six punctures of the intestine, four complete and two in which the mucosa and sub-mucosa were clipped from the inner side of the gut. In these I split the peritoneum and closed as in the complete, with a continuous suture of No. 1 silk. After closing each perforation I sutured the peritoneum about a quarter of an inch on either side, drawing it over the primary suture. After making a hurried search for the ball the patient not doing well under the anesthetic, I closed the incision after stitching the peritoneum with heavy silk, which in my opinion is the very worst material we have for that purpose. There was some trouble with the wound, no doubt caused by infection along with the silk ligature, but it healed in a reasonable time. At the end of four weeks the patient began to run a temperature of 102° to 103°, with sweats and all the symptoms of pus absorption. He was removed to J. J. Rodman's office and the accompanying skiograph taken. The photographer who developed it has unfortunately printed it from the wrong side, which shows the bullet very distinctly in front of the lesser sacro-sciatic ligament. Another position located the bullet about three-quarters of an inch in front of the opening.

In operating for the removal of the bullet, I made an incision through the skin about an inch above and two and a-half inches inward from the head of the femur, and by blunt dissection with the handle of my knife worked my way through the muscles, divided the

\* Read before the Daviess County Medical Society, March 17th, 1908.

ligaments and so reached the pus cavity, which was in direct contact with the peritoneum. I removed the ball, which I found split into two parts, inserted a drainage tube. Patient recovered in a short time.

## CHLOROSIS, SECONDARY AND PERNICIOUS ANAEMIA\*.

By VERNON BLYTHE, PADUCAH.

*Anaemia*—Means a deterioration in the quality of blood, which may affect red cells or hemoglobin or both, manifested by numerous symptoms: Extreme pallor of lips or conjunctiva, low specific gravity and diminution in rouleau formation.

*Chlorosis or Green Sickness*—Typical abnormal red cells; normoblast are nucleated red cells of normal size; microcytes are very small red cells, stained deeply, seen in severe anaemias, nonnucleated.

*Etiology*—Young women and girls, sometimes older persons, tailors, more common in blonde types, insufficient nourishment and ill ventilation, overwork, constipation, homesickness, sustained and repeated emotions.

*Symptoms*—A yellowish green pallor of the skin, more often girls from sixteen to twenty, irregular menstruation, no particular emaciation, but weakness, short breath, vertigo, capricious appetite, cold extremities, palpitation of the heart.

*Microscopic Changes*—The red cells are moderately reduced. Hemoglobin markedly reduced. Microcytes are very prominent. Poikilocytes are red cells with variation in shape; they are very frequent. Crenation is very apt to occur. Normoblast are met with in lighter stages, granular degeneration of red cells is quite frequent. Leucocytes are the same as in normal blood.

*Secondary Anaemias*—Typical abnormal red cells; macrocytes or large nonnucleated red cells and microcytes or small nonnucleated red cells.

*Etiology*—Insufficient nutriment; bad food and air, chronic gastritis and cancers of the pylorus. Excessive demands of the blood forming organs; chronic diarrhea; hemorrhages.

*Toxic*—Lead, syphilis, malaria, suppuration, tumors, uremia.

*Intestinal Parasites*—Bothriocephalus Latus, Worm or Egyptian Chlorosis or Uncinaria Dnodenale.

*Hemorrhages*—The severity depends upon rapidity of the loss and upon the long continuation. The red cells may in ten hours be decreased to 900,000. The recovery depends on the amount lost and the general

health of the patient. Often taking several weeks or months.

Hemoglobin recover the specific gravity slower than the red cells.

*Microscopical Appearance*—The red cells have very much the appearance as seen in chlorosis. Normoblast are apt to be present. Basophiles are more numerous, the granular degeneration and chromatin net work is more abundant, leucocytes are slightly increased.

*Bad Hygienic conditions*—The red cells are often reduced to 500,000 proportional with the hemoglobin, due to the lack of food and iron.

*General Diseases*—Suppuration, this process destroys the blood and lowers the powers of the blood producing organs. The red cells fall at times to 20%.

Acute infectious fevers are followed by great reduction of red cells and hemoglobin and the presence of macrocytes and microcytes.

Diseases of gastro-intestinal system are followed by marked inanition and loss of blood plasma.

*Toxic Agent—Syphilis*—In its first stage has slight anaemia, becoming more marked in the second stage and in the third stage closely resembling pernicious anaemia with megaloblastic red cells and a great lowering of the hemoglobin.

*Malaria Fever*—There is a great reduction of the red cells, as low as 500,000 and granular degeneration brought about by direct destruction of the red cell.

*Uremia*—There is a marked reduction in red cells and hemoglobin.

*Lead Poisoning*—Granular degeneration is very prominent and polychromatophilia, which is a diffused or regular stained red cell by basic dyes. Normoblast are seen in advanced cases.

*Arsenic*—There is a moderate granular degeneration and severe anaemia, due to reduction of red cells.

*Acetanilid—Case Notes*—The red cells were reduced to 2,100,000 hemoglobin to 35%. Urine shows granular cast and albumin.

*Malignant Tumors—Carcinoma of Stomach*—Case reported: The red cells had lost possibly 50% of hemoglobin with marked variation in the shape of the red cells, several normoblast were seen, and several nucleated red cells, a prominence of polymuclear leucocytes.

The situation of the tumors have a great deal to do with the amount of anaemia produced. Bone tumors, especially the small, round cell sarcoma produces rapid anaemia.

*Intestinal Parasites*—Cause a great reduction of the red cells, nucleated red cells are present in many cases, especially the megaloblast, poikilocytes and granular degeneration.

\* Read before the Post-graduate course of the McCracken County Medical Society.

*Idiopathic or Pernicious Anaemia*—It is an anaemia in which red cells are remarkably reduced along with the hemoglobin and is obscure in origin, characterized by large nucleated red cells and very small nucleated red cells.

*Etiology, Obscure*—Severe hemorrhages, long continued, malaria, syphilis parasites, middle age.

*Pathologic Anatomy*—The skin takes on a dead yellowish hue or jaundice. At first there is little emaciation, the heart muscles have a fatty degeneration, the liver cells have a peculiar deposit of iron in them and itself is often enlarged and fatty, sometimes iron is found in the spleen, the spleen is increased in size with an increase of iron pigment, the marrow of the bone is dark and the fatty substances are absent, nucleated red cells are numerous, there is atrophy of the secreting tubules of the stomach. Lymphoid cells are very much increased.

*Symptoms*—The onset is insidious, there is a progressive bodily weakness and torpor, a yellowish hue to the skin, mucous membrane of the mouth and gums are blanched, respiratory symptoms show shallow breathing, circulatory symptoms are large, soft, jerky pulse, haemic murmurs may be heard in region of the heart. There are often retinal changes and cutaneous hemorrhages.

The digestive symptoms are anorexia, nausea and vomiting, diarrhea and a reduction of gastric juice. Nervous symptoms are numbness, languor and sometimes slight paralysis. There may be moderate fever. The urine shows cast and urobilin.

*Blood Changes—Early Case*—There is an increase in the amount of hemoglobin of each cell.

Change of shape and size of red cells a marked feature.

Polychromatophilia and basophilic granules are fairly abundant.

Leucocytes are normal, but there may be a slight increase of lymphocytes.

Specific gravity greatly reduced. Blood plates and fibrin are scanty. The red cells have a central depression, staining with eosin and carbo-fuchsin.

*Advanced Case*—Poikilocytes and microcytosis are abundant. Megaloblast and megalocytes are very numerous. Polychromatophilia and basophilic are numerous. Hemoglobin is not reduced in proportion as much as the red cell.

## LACERATIONS OF THE VAGINAL OUTLET.\*

BY FRANK H. BEARD, SHELBYVILLE.

This subject has practically been exhausted, if not forgotten, by most of you, and yet is coming up every day in the practice of all general practitioners, and every gynecologist, and of course specially belongs to the obstetrician, for if he and the general practitioners do their work well there rarely will be any need for the second operation.

It would be better to style this paper "wounds of the vaginal outlet," for by that we would understand an injury, a separation of healthy tissues, a laceration of the parts, or an incision done with a blunt instrument, as it were, for very often they are in appearance, even as if done with a knife. We then would understand the importance of attention to these wounded parts and not regard this accident as merely a physiological consequence, hence should be let alone, no it should be no more let alone than a large incised wound of the arm or leg for these structures are of vast importance to the woman and upon their reparation depend her health and happiness.

Causes are predisposing and exciting. Predisposing are the age of the patient, a large fetal ovoid (whether physiological or hydrocephalic) breech presentation, prolapse of funis, precipitated labor, a general oedema of the parts, small vaginal outlet and dry labor. Exciting causes are forceps delivery, quick labor, or any emergency that calls for quick delivery.

Knowing these causes should always suggest the idea of looking for laceration. In fact a very careful inspection should be made even after every delivery.

Divisions of lacerations are very difficult of description. We always in the primipara have a laceration of the fourchette, or a very slight laceration of the vaginal mucous membrane. We may divide them, however, into a partial laceration of the perineum, complete laceration of the perineum with or without tearing of the vaginal wall, complete laceration of the recto-vaginal septum, with or without tear, or both or either, rectal and vaginal wall. This covers practically all of the different forms of lacerations. Some have divided them into internal and external, etc. The sooner we learn that the skin has nothing in the world to do with the functions of these muscles the better it is for ourselves and patients. The perineal body is a collection of insertions of a number of muscles and some or all of these may be lacerated. This being the case they should be re-

\* Read before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

paired when wounded the same as any other structure in the human body. The repair of these lacerated wounds is either primary or secondary, but of course like all other wounds should be repaired primarily if possible. The early primary operation is the one of necessity and can be done by almost any physician. A doctor that can let down a rail fence and go through the gap put it up again can repair a lacerated perineum, and should always do it even though he may leave the rail fence down. If he has repaired the wounded structure and there is failure he should advise the secondary operation on all such cases for they demand it. The reason it is not done, it is overlooked purposely by physicians, and a great many of them do not want the patient to know that there was a laceration. The old obstetric idea that it was a disgrace to have a laceration has been exploded long ago, and if a woman is searching for a doctor that never had a laceration in his practice she can find him if she selects one that never had an obstetrical case. I have heard doctors say they have had forty or fifty cases and never had a laceration. Easy enough of explanation, they never looked to see, because I believe the old way as taught about supporting the perineum is practically worthless and I know of no new ones.

The primary operation is simple and consists in putting the wounded surfaces like they were before the injury and retaining them by sutures as you would any other wound. The sutures used are anything that has ever been or not been used for suture material, of course done under strict aseptic precautions. I prefer chromicized cat-gut, have used some fine silk worm gut or silk.

The primary operation should be done on all cases. Partial lacerations or complete lacerations of the perineum proper give, of course, the best results. In complete lacerations of the recto-vaginal septum we have a very much more serious operation, especially with tear of rectal and vaginal walls, but even these structures can be repaired with very little trouble and pain to the patient, and may be done even without an anesthetic but I think in these cases it is better to use the anesthetic and do the operation under the strictest aseptic precautions and have a table and a nurse and plenty of assistance and do a very thorough operation.

I herewith append the report of a few cases of primary operation:

Case 1. Primipara, age 29, was confined in August 1900, dry labor, forceps applied but removed before head was delivered through perineum, complete laceration of the perineum, repaired immediately with silk worm gut, union perfect. Confined her again in 1903, forceps delivery again, found the perineum

in good shape and this time no laceration.

Case 2. Primipara, age 22, confined in August 1900, complete laceration of perineum, repaired the next morning with chromicized cat-gut, recovery complete. Delivered her again in September 1901, no laceration. Delivered her again in October 1907, child very large with no laceration.

Case 3. Primipara, age 22, confined in March 1905, complete laceration of the perineum, repaired the next day with chromicized cat-gut, patient able to take a trip in three weeks, perfect union. Confined her again in August 1907, slight laceration of the perineum which was repaired with chromicized cat-gut at the request of the patient, union perfect.

Case 4. Primipara, age 38, forceps delivery, complete laceration of the recto-vaginal septum, repaired with chromicized cat-gut, union perfect.

Case 5. Primipara, age 26, confined in May 1906, complete laceration of the perineal body, repaired immediately using silk worm gut, recovery and union were complete. The stitches were removed the twelfth day.

Case 6. Primipara, age 28, hard and dry labor, complete laceration of the perineum, sutured with silk worm gut, union perfect.

If we have failed in any of the primary operations, or if for any reason the primary operation was not done, the secondary operation should be advised. This operation is quite a different thing and calls for more surgical ingenuity than most any other procedure. There have been so many operations advised that the young surgeon looks around for one to select from and perform upon his patient and right there meets with his first obstacle. He reads all the operations from Marion Simms to Howard Kelly and finds himself more mystified than ever. I do not believe there is a single operation that applies to two cases. Every case is a law unto itself. Howard Kelley does Simms operation and Waldo does Kelley's operation in some cases and Simms, if he were living to-day, I venture to say would do Thomas A. Emmett's operation in some cases. So we see in the selection of the kind of operation we are often baffled right at the start, by reason of the fact that there are so many different ways of doing the same thing we would naturally expect that it is not an easy matter in every case. It is best not to do anybody's operation if you are in doubt, but just repair the perineal structures before you.

This secondary operation is more difficult and should only be attempted by one who is reasonably prepared for it. I think in the home it can be done, but preferably in an institution for such things. The preparation of

the patient is very important, and upon this largely depends the success of the operation. She should even be prepared more carefully than for abdominal section. The attention to the minute details, and the after treatment of the patient have more to do with the success than any kind of operation you may perform. The operation depends upon the character of the laceration. A partial laceration of the perineum is simple enough, a complete laceration of the perineum is not difficult, but the laceration of the recto-vaginal section is a very difficult one in some cases. I have no special operation to advise, but after the patient has been prepared for the operation, and anesthetized we can then best determine the procedure to bring about the repair of the lacerated structures that will restore the functions of the muscles.

In the selection of sutures I would advise the old silver wire. They should be left in from four to six weeks, chromicized cat-gut is used by a great many, silk and silk worm gut are used. A very careful and thorough dissection is often required in a great many cases. I believe that the different forms of curved scissors are the best means of doing this, some use the knife with good success.

The thorough coaptation of the parts is of prime importance. The after treatment of the patient should be rest in bed, quiet and catheterization every six hours for several days. The patient should be kept in bed from three to six weeks.

The diet should be the same as after an abdominal section. The bowels should be moved after the third or fourth day. Too much stress can not be laid on the after-treatment and nursing of these important cases.

Report of two cases of secondary operation.

Case 1. Mrs. A., age 60 years, was confined 37 1-2 years ago and had a complete laceration of the perineum which was not repaired and has not borne any children since. Six months before operating for the laceration she was operated upon for appendicitis, she did not seem to be able to get up and suffered all the time, after the appendicitis operation there was a general relaxation of the entire system, and I found upon examination both a cystocele and rectocele and advised the operation of perineorrhaphy, she was operated upon at the King's Daughters Hospital on March 30, 1907. A thorough dissection and the parts sutured together with silver wire was done. The sutures were left in for four weeks and she made a complete recovery and is going around everywhere with comfort to-day.

Case 2. Mrs. B., age 27, mother of three children, baby one year old, was confined first in 1901, with no laceration, and again in 1903 with a very slight laceration, was con-

finied again in 1906 in Bath county, Kentucky, the child being delivered before the doctor arrived. There was a complete laceration of the recto-vaginal septum. The doctor repaired the wounded structures at that time but failed of union and I found her one year afterwards suffering with bearing down pains incontinence of feces, and mitral murmur of the heart following an attack of rheumatism and phlebitis that lasted for several weeks. She was a perfect picture of despair, not being able to go anywhere, her mental faculties were below par as the result of this deplorable condition of affairs, hence I determined upon the operation in spite of the fact that there was an organic heart murmur and marked anaemia. She was operated upon at the Kings Daughters' Hospital July 7, 1907. Ether was used as the anesthetic. Used the silver wire suture and left them in for three weeks. The function of the bowels was entirely restored; her mental condition became normal and she seemed a different woman for her recovery was complete.

#### DRAINAGE OF THE GALL BLADDER.\*

By G. B. O'ROARK, GRAYSON.

I report this case, not that there is anything new about the operation, but that it might add encouragement to other country doctors.

I had a series of typhoid in one family which in itself is not commendable, but in spite of all precautions, they continued to be infected. I asked them if they were still using water from a certain well and found that they were nearly two months after I had warned them against it.

But to the point—two weeks after I had pronounced all convalescent, I was called to see one of the typhoid patients, a boy six years old. They said the boy had been complaining for 4 or 5 days of a pain in his abdomen. On examination I found his temperature 99°, pulse 96, slightly jaundiced.

The abdomen slightly distended, bowels were open. By palpation I located a tumor about two and one-half inches below and to the right of the ensiform cartilage, very sensitive, the right rectus muscle rigid. The family stated he had had considerable fever two days before. Knowing the case to have been typhoid, I diagnosed probable abscess. I explained to the family that, if an abscess, there was great danger in delay and advised immediate consultation. I sent a runner after Drs. Gilbert and Horton, and told them to come prepared to do an abdominal section, being six miles from town they did not arrive

\* Read before the Carter County Medical Society, January-14, 1908.

till 3 P. M. In consultation we agreed that it was either an abscess or an occluded gall duct, either of which necessitated an immediate operation.

Expecting what their decision would be I had previously prepared patient, had plenty of hot water, etc. After making up our minds, gave patient chloroform, made him ready and after making field as aseptic as possible, at a poor farmer's house, assisted by Dr. Gilbert, Dr. Horton being the anesthetist, I made an incision about three inches long to the right of median line over area of greatest prominence. After carefully going through the peritoneum, we came to a mass of inflamed omentum, finally locating the tumor in region of gall bladder, after breaking up the adhesions as much as possible we were enabled to bring it up in the wound and found that it was the gall bladder greatly distended; after passing 2 ligatures through the upper and lower borders we walled off the viscera by means of sterile gauze, and proceeded to open. We obtained from 6 to 8 ounces of muco-purulent fluid, inodorous, no trace of bile, but five small, round calcium stones, after evacuating thoroughly and finding no more stones, we proceeded to close the wound, by first making fast all sides of the opening in the gall bladder to the wall of the abdomen and then by three rows of sutures closing the wound around a drainage tube. Then draining with gauzes held in place by the many tailed bandage, boy rallied without nausea, in twelve hours no trace of fever, pain ceased, four days after operation bile began to flow freely, wound healed by first intention, and now twenty days after the operation boy is sitting up in bed, playing with his toys and calling for more to eat.

#### ADENOIDS.\*

By H. C. BEASLEY, HOPKINSVILLE.

No obstruction of the upper air passages is so typical in its chain of malevolent influences as adenoid hypertrophy. So it is to this subject in the general category of obstructions that your attention is called in this paper.

This has now become an old subject to the profession. It has been elucidated and elaborated until originality of expression concerning it has become almost as impossible as originality of ideas; yet cases are still unrecognized or untreated as they pass daily before us often bearing the stamp of a degeneracy of mind and body on their faces.

In order to concisely demonstrate and analyze the influences of adenoid vegetations, it becomes necessary to study briefly the anat-

omy of the pharynx, which is a tub flattened antero-posteriorly. Its roof being continuous with the roof of the nasal chambers. Its main tunie is fascia lined with mucous membrane. It has no real anterior wall although the soft palate and uvula hang as a curtain before it. Two folds of mucous membrane extend from the posterior palate border, the pillars of the fauces between which lie the faucial tonsils. These are normally flat cushions of adenoid tissue. Across the tongue a line of adenoid tissue stretches from one faucial tonsil to the other, this ring is completed by another line of adenoid tissue in the mucous membrane of the pharynx above the soft palate and behind the chonae called adenoids, the pharyngeal tonsil, Luse tonsil or adenoid vegetations. The lining of the pharynx is exceedingly vascular, the ascending pharynx artery supplying it mainly; the carotid artery and internal jugular vein, however, being only separated from it by its layer of fascia. The secretions of the mucous membrane of the pharynx when irritated are very viscid. Beneath its lateral walls extend the Eustachian tubes conveying air and serving as a ventilator to the middle ear, these tubes passing downward on either side cause a bulging of the pharyngeal wall in front of which we find the eustachian orifices.

It is to an hypertrophy of this normal pharyngeal tonsil, which is composed of lymphatic tissue situated in the naso pharynx between the orifices of the Eustachian tubes that we wish to devote particular attention.

The first symptom which we may find in adenoid hypertrophy is obstruction of nasal breathing, being proportionate to the dimensions of the pharynx and to the size of the new growth which is subject to variations on account of its vascularity. This is exaggerated during a coryza which is the causal factor in the production of the growth.

In this case a repetition of the congestions causing a hyperplasia of the lymphatic tissue.

This obstruction to nasal breathing necessitates mouth breathing with all of its evil sequellae, namely, the inspired air is not sufficiently warmed nor filtered nor does it contain the required amount of moisture, so that the adult who has had hypertrophied adenoids in childhood although they usually become atrophied near puberty, may suffer with their sequellae post-nasal pharyngitis with dropping of mucus into the throat producing hoarseness and congestion of the vocal cords or it may take the other form of pharyngitis sicca or dry catarrh of the pharynx.

The pharyngeal obstruction by adenoids is also one of the most potent causes of that lack of resonance in the voice which we usu-

\* Read before the Christian County Medical Society.

ally call, "talking through the nose but which is really caused by not talking through the nose, the acoustic properties of the open nasal chambers being necessary to perfect the quality of the tones.

We will now notice the effect of adenoids upon the shape and configuration of the face, maxillae and nose. Mouth breathing necessitated for so much of the time by the presence of adenoids causes a thickening of the lips, a sinking in of the sides of the nose, a vascular fullness of the eyelids which imparts to these patients a characteristic expression.

The patient often snores when sleeping, the mouth being almost constantly open when lying down. The effort made to breathe through the obstructed nasal passages invites congestion by creating a partial vacuum or rarefaction of air in the naso-pharynx so that the nasal mucous membrane becomes chronically inflamed and there is turgescence of the posterior ends of the turbinates and an engorgement of blood around the Eustachian orifices which may close the tubes or produce by continuity of tissue a catarrh of the middle ear, either purulent serous or plastic. Indeed three fourths of all the cases of ear inflammations and deafness originate from some disease of the nose and throat and adenoid degeneration is the most prevalent and serious factor in the production of these nose and throat cases.

The hard palate is elevated by the pressure of air, nearly all these cases having a high pitched palate, the upward pressure of the palate often causing a deviation of the septum. These deviations of the septum are rare, however, before the seventh year and before second dentition. The septum serves as a prop to the upper maxilla according to Deboon and pushes it apart from the base of the skull and being crowded upward by the hard palate until it can no longer resist the pressure gives way and the deflection results. Kerner and Waldo recognized two degrees of configuration of the maxillae namely before and after second dentition, with adenoids present for any length of time the palate becomes dome-shaped, the lateral axis is shortened, lengthening the antero-posterior axis; the alveola process becomes cleftic, but no angle is formed and the teeth are in normal position until after second dentition. After second dentition if the adenoids remain the deformities are greatly exaggerated, the anterior portion of the alveola inclines forward, an angle is formed, the median incisors are turned in their axes and the upper maxilla becomes V-shaped. The position of all the teeth are more or less changed in typical cases.

The teeth do not approximate anteriorly. These malformations are very disfiguring

and are caused by the necessary mouth breathing when the growths are present, for when the mouth is closed, the tongue filling the buccal cavity exerts pressure against the lateral part of the maxilla; and with the mouth open, this pressure is removed and the cheeks press inward forcing the alveola nerve together, and the influx of blood during second dentition causing the maxilla to become softer at the time produces the deformity.

Again frequently anemia is produced by the failure of the patient to get sufficient air in his efforts at nasal respiration. An insufficient amount of oxygen is taken in to properly supply the blood in this way causing the impoverishment.

These patients are dull mentally, in many cases their minds are sluggish and their expression slow. Numerous nervous symptoms may accompany adenoids which to properly enumerate would require a paper unto itself. The influences however enumerated herein are sufficiently malevolent to invite the investigation of the general practitioner as well as the specialist. In all of these cases an early diagnosis and removal of the growths is imperative in order to prevent the many complications and disfigurements which may accompany it. It lies within the province of the physician to educate the people in these matters and I trust that the time may soon come when no ill that human flesh is heir to, which can be prevented or cured in its incipency, can owe its origin or evil influence to a lack of parental education in these things due from the members of the medical profession to whom they look for the preservation of their corporal welfare and their lives.

## SCARLET FEVER.

By J. B. R. COOPER, SHIVELY.

Some writers who have contributed articles on scarlet fever, claim that the disease is of ancient origin.

The description left us by these old authorities are rather obscure, and critics fail to find clear clinical evidence of the disease until the last four or five centuries.

Sydenham studied it in the Seventeenth century. In the same century a diagnosis was made differentiating scarlet fever from measles but during the last 200 years the first mentioned has been the theme of many writers.

It has long been regarded as one of the most fatal maladies both from its frequency and great mortality, and was introduced into the Western hemisphere by European navigators about the year 1735.

The five cases I am reporting are taken from a recent epidemic occurring in my prac-

tice, and in the report have selected such cases as will show both the severe and mild forms of the disease.

Case 1. Clara R., age 6, was called to see her Dec. 25, 1907, found her suffering from scarlet fever and diphtheria. Rash was rather light, glands of neck moderately swollen, some diphtheritic membrane on right tonsil, left tonsil covered with scarlet fever membrane which to me had the appearance of follicular tonsillitis.

Administered 3000 units of antitoxine Dec. 25.

Throat was sprayed every two hours with equal parts Dobell's solution and peroxide of hydrogen.

The enlarged glands were treated with a 50% ichthyol ointment and syr. iodide of iron, 8 minims every six hours.

She was given a milk diet from the first, consuming one-half pint every three or four hours.

Infusion digitalis also given, 30 minims every three or four hours, according to the amount of urine passed.

Her temperature ran rather a peculiar course some mornings registering 103 1-5, again 100 1-5, in the evening 103 4-5, again 100 3-5.

As her fever declined it ran a regular typhoid fever curve. In the forenoon she would be free from fever, in the afternoon her temperature would rise to 100 1-5, again 102 2-5.

This child had two brothers and one sister. All were given 300 units of antitoxin the same day, (Dec. 25, 1907) it was given to Clara.

As soon as the diagnosis of scarlet fever and diphtheria were made in this case the patient was placed in the front part of the house, with a room between the sick and the one occupied by the other members of the family, none of the family were permitted in the sick room for the first 18 days. This child recovered without having the least trouble with either speech or hearing.

Case 2. Lizzie K., age 14 years. This case came under my observation at a rather late date in the disease—about the 6th or 8th day. She was very weak both from not having had the proper nourishment and the effect of scarlet fever. Found her with glands on left side of neck badly swollen, temperature 104°, pulse 140, tongue coated, bowels constipated, kidney secreting but half the normal quantity, and face showing great suffering. Gave her infusion digitalis 60 minims every three hours, and calomel followed by Crab Orchard salts. On fourth day opened her neck on

left side. About one pint of pus was discharged. Packed cavity with carbolated gauze, discharge continued for some days. The evening of the fourth day her temperature was 103 4-5, pulse rapid and weak. The second day after opening abscess her pulse and temperature were normal. This girl's recovery was slow, owing to her having been neglected in the early stages of the disease.

Case 3. Casper S., age 7 years. Called January 11, 1908. Rash covered entire body, pulse 150, temperature 104° and the child was delirious at times. Throat full of membrane but could not decide as to diphtheritic complications. Gave infusion digitalis 30 minims every three hours. Syr. iodide iron, 10 minims every 6 hours, 50% ichthyol ointment for swollen glands on right side of neck.

On morning of second day made positive diagnosis as to the diphtheria, and gave 4000 units of antitoxine. Had throat sprayed every two hours with equal parts of Dobell's solution and peroxide of hydrogen. The first night he slept but little and was very restless. Second night slept better. Temperature second night was 102 3-5°, pulse 130. The morning of the third day the membrane was almost as large as before the antitoxin was given, and injected 3000 units more. The membrane did not disappear until the morning of the eighth day. During this time the boy's temperature gradually declined until it became normal. Pulse followed almost the same course but was rather weak. Strychnine was given until 9th or 10th day. At times membrane in Casper's throat would come away in pieces almost as large a nickle but would form again during the night.

About the 8th day his kidneys gave some trouble, secretions almost ceased. Hot baths were given, with slightly increased doses of digitalis and his condition became as near normal as it had been before the kidneys refused to work. This patient was confined to his bed over two weeks.

Cases Nos. 4 & 5. John K., age 6, Christ K., age 8. Called January 6, 1908. Found both with slight sore throats. Glands of neck enlarged but little. Temperature 100°, pulse 110, rash so light as to cause some doubt in diagnosis. Temperature and pulse both normal on fifth day. These cases were treated very much like Case No. 1.

The children were isolated and the mother cared for them. An older sister with an eight-months-old baby and two older brothers of the sick boys, were in no way affected by the disease. The patients made a quick and easy recovery.

## CHOLECYSTECTOMY.\*

By A. H. BARKLEY, LEXINGTON.

In accepting an invitation to read a paper before this society, I did so without thinking how difficult it would be to find some subject that would be of interest to you, however I have selected Cholecystectomy.

A few remarks upon this phase of a subject so large as surgery of the biliary passages may not be amiss at this time. It must not be understood from what will follow that the writer believes Cholecystectomy is to be preferred in all cases to Cholecystotomy. This is far from the object of this paper, but it is the desire of the writer to impress upon you that in well selected cases Cholecystectomy when rapidly and properly performed gives as good result and as low mortality as Cholecystotomy.

This operation is by no means an old one as it was first practiced by Langenbuch in July 1882. He reported 12 cases of which number two died, one dying from ulceration of the bile duct caused by the presence of a stone which he did not detect at time of operation, the cause of death in the second case not given. Following Langenbuch Courvoisier, Tillman, Depage, Monnyhan and others have employed this operation with more or less success.

Depage collected 22 cases of removal of the gall bladder with two deaths.

Martig was able to collect 87 operations of Cholecystectomy with 12 deaths.

*Indications and Need of the Operation.*—While Cholecystectomy has been performed by many surgeons throughout the country it was not until Monnyhan wrote his excellent article and reported his brilliant results with this operation, that surgeons generally began to look upon it with favor or were willing to accord it a stable place in surgery of the gall bladder and biliary tracts.

The need for an operation of this kind becomes apparent at once to those of you who have done much work along this line. Its employment is largely determined by the condition found when the abdomen is opened and also depends on the condition of the patient at the time of the operation.

The one great principle in surgery of the gall bladder and biliary tracts is drainage. When drainage has been established in a given case or when we have performed an operation in such a manner as to remove the cause for drainage, we have accomplished perhaps the most important thing for which the operation was intended.

It is a well known fact that cholecystitis and cholangitis arise from the presence of

stones usually in the bladder and that operative interference is demanded chiefly for the inflammatory trouble caused by their presence.

As has been said that drainage is the principle aim if the operation generally undertaken upon the bile tracts, so it is, but with the employment of cholecystectomy you at once do away with the need of drainage except in exceptional cases, such as gangrene, septic cholangitis, etc., in simple uncomplicated cases it has been thought best by many surgeons to insert a small cigarette drain down to the point of ligation to be removed in 24 or 48 hours. This is hardly necessary unless there was some chance for the peritoneum to have become soiled. If drainage of the biliary tracts is demanded it can be accomplished by inserting a tube in the hepatic duct.

What do we accomplish in removing the gall bladder besides dispensing with drainage? We have removed a sack, if I may be permitted to so speak, as it is nothing more than a store house for bile as it does not play any part in the functions of the human economy as has been proven time and again by its complete removal. We have removed the possibility of any future inflammatory trouble arising from the presence of stones therein.

It might also be urged that if the operation is done early malignancy of the gall bladder may be forestalled. On this point there still exists in the minds of surgeons and pathologists some doubt as to whether or not gall stones form in the bladder as the result of malignancy—certainly not in all cases—or whether malignancy is the result of irritation from stones. In order to give weight to the operation of Cholecystectomy as a means of preventing cancer of the gall bladder it will be necessary as Monnyhan has said to prove that cancer forms in the gall bladder after stones have been removed. Now while this is not definitely settled there seems to be some ground for this belief as Monnyhan records two cases where cancer appeared in the gall bladder some months after Cholecystotomy.

I can do no better than quote what Monnyhan and others think constitute valid reasons why the gall bladder should be removed.

First. Traumatism, rupture, etc.

Second. Gangrene, phlegmonous and membranous cholecystitis.

Third. Chronic inflammations with dense thickening of the wall of the gall bladder and cystic duct with or without stenosis of the latter, also in cases where the gall bladder is intimately adherent to adjacent structures. In such cases the gall bladder is no longer of use as a receptacle for bile.

Fourth. In hydrops or empyema due to

\* Read by title before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

blockage of the cystic duct by stone, stricture, growth or external inflammatory deposits or in cases of mucous fistula following operation for these conditions.

Fifth. In cases of fistula between the gall bladder or cystic duct on the one hand and the stomach, duodenum or colon on the other.

Sixth. Ulceration of gall bladder or cystic duct by stones that have found their way through into the liver substance, and in primary carcinoma of the gall bladder.

Primary cholecystectomy has not been approved by the majority of surgeons. It has been urged that it is a more dangerous operation than cholecystotomy or choledochotomy. I think all of you who have had much experience along this line of work will agree that in suppurative and atrophic conditions the better operation is total removal of the bladder at once if the patient's condition will permit, than to drain and then later be compelled to remove it because of a recurrence of the primary trouble.

In simple cases and by simple cases I mean cases where stones are present without any active inflammation I believe, from my own experience and that of other surgeons whom I have had the pleasure of seeing do work along this line, that it is just as simple an operation and does not consume any more time and whose mortality will, I think, compare favorably with cholecystotomy.

Richardson in the Medical News of May, 1903, states what he thinks are very serious objections to cholecystectomy. They are as follows:

1st. There is great danger in the operation.

2nd. There is no possibility of draining the biliary passages only through the ducts and only after a very difficult operation.

3rd. Redrainage of the biliary passages is extremely dangerous and difficult.

In regard to the first objection offered by Richardson the writer has corresponded with twenty-two surgeons in this country, and finds that with two exceptions their mortality in uncomplicated cases has been as good as after cholecystotomy and all expressed themselves that their mortality rate had fallen materially in disease condition of the biliary passages.

I agree with Dr. Lilienthal who says that drainage of the biliary passages by a tube at one sitting with a cholecystectomy is not so difficult and quite satisfactory.

Lilienthal thinks the third objection offered by Richardson might be valid but has never found it necessary to redrain, which experience corresponds with that of the writer.

W. J. Mayo in the Medical Record of February, 1903, collected 2,000 operations with

no instance of recurrence of stones which would have necessitated drainage.

Cholecystectomy is in the majority of cases not difficult of performance. It is usually performed through the Mayo-Robson incision in the following manner.

If any adhesions are present they are carefully separated. I might add here that cases are sometimes encountered where the bladder is imbedded in a dense mass of adhesions and the difficulty seem insurmountable but I believe any case can be handled where care and patience are used. After the gall bladder has been freed from adhesions its removal may be accomplished in one of two ways from behind forward or from before backward. It is easier to begin by separating the cystic duct and finding the cystic artery and vein, after this has been done the vessels are tied with Pagenstecher's linen or cat gut.

The cystic duct is provided with a cuff of peritoneum which is stitched over the ligated end of the duct. The separation of the gall bladder from the liver is now begun. This is easily accomplished by inserting the finger between the bladder and liver working toward the fundus. Where this has been done the peritoneum over the bladder is split. The bladder is now freed and all remains now to be done is to check bleeding from the liver surface which is easily done by hot sponges or very rarely by a suture or two and closure of the peritoneum with running cat gut suture.

If drainage is necessary it can be carried out by stitching a small rubber tube into the duct or it may be placed in the common duct.

In cases where the trouble is located entirely within the gall bladder and the ducts are free from stones, the wound may be closed and primary union be expected.

Case I. Mrs. H., white, age 40, previous history negative except for repeated attacks of gall stone colic which became more frequent. Last attack occurred April 10, 1903. Lasted some time followed by slight jaundice. Continued nausea. Was prepared in the usual way for operation which was performed through a straight incision, the gall bladder was exposed which contained one large stone. The bladder was slightly contracted over the stone. After palpating the ducts to ascertain the presence of other stones which were not found, cholecystectomy was decided upon. The gall bladder was removed entirely—patient made good recovery.

Case II. Mrs. J. B., white, age 48. Previous history, had typhoid fever 5 years before she came to me in August, 1903. Had never had an attack before she had typhoid. Since then she had two attacks which were diagnosed as appendicitis. She went to Chicago where her true condition was diag-

nosed. She continued to have attacks up to the time she was operated upon, was jaundiced twice, lost weight and complained of constant pain in region of gall bladder and under shoulder blade.

Operation was done through a straight incision. Gall bladder was found to contain a small amount of thick tarry bile. The cystic duct was found much elongated and contained two stones, the larger stone near the gall bladder. The smaller near the junction of common and cystic duct was milked back so a ligature could be thrown below, the cystic artery being ligated separately. The gall bladder together with cystic duct and stones were removed. A small eigarette drain was placed in for twenty-four hours and removed. Patient made a nice recovery.

Case III. Mrs. A., history of gall stone colic and had passed many large stones. This case is interesting because of the conditions present. There was found an opening between the gall bladder and duodenum as large as the middle finger, also the large size of the cystic duct and small size of the gall bladder. The latter condition may be accounted for by the fact that the bladder was so thoroughly drained through an opening so large that nothing could remain in the gall bladder to distend it; from the condition found it was deemed advisable to do cholecystectomy and closure of the opening in the duodenum. She was operated upon January 6, 1904, the wound healed nicely. She was confined to the hospital four weeks after which time she returned to her home entirely recovered and has since enjoyed good health.

Case IV. Mr. K., age 52, white. Was similar to Case I. Cholecystectomy was done, patient recovered and left hospital in five weeks. This patient suffered two mild attacks of colic, presumably due to either mucus or the pain may have been due to adhesions. The attacks came on within two and one-half months after the operations; it has now been nearly five years and he has had no pain and enjoys life.

Case V. Mr. P., white, age 29, was struck over the gall bladder two months before I saw him. He complained of pain continuously. His case had been diagnosed as abscess of the liver by the physician who first saw him, but an incision revealed the fact that the gall bladder was filled with pus and stones. Complete removal of the gall bladder was done, the cystic duct cut low down and tube placed in hepatic duct for drainage. This was removed after a few days and wound allowed to heal. Patient has been seen repeatedly since he left the hospital and is enjoying good health.

Cases VI-VII. Both were females ages 34 and 46 respectively. Gave clear histories of

gall stones with repeated jaundice. In these cases cholecystectomy was performed and both made good recoveries.

### INFLAMMATION OF THE ACCESSORY NASAL SINUSES AS A SEQUEL OF LA GRIPPE.\*

By GEORGE PURDY, NEW LIBERTY.

In dealing with this subject, which is one along lines that has not been often discussed by this society but, in the writer's opinion, is one, with many other similar subjects, which should call for more attention than is here given, it will be my first endeavor to get clearly before us just what the subject embraces.

By accessory nasal sinuses, we mean those cavities in the bones of the head and face which are connected by narrow aperatures with the main nasal fossa.

There are three bilateral single sinuses, the antrums of Highmore, or maxillary sinuses, the frontal sinuses and the sphenoidal sinuses and two bilateral groupes of sinuses, the anterior and the posterior ethmoidal sinuses.

The antrums of Highmore, or maxillary sinuses, are situated in the superior maxillary bones and connect with the nasal cavity by a fissure-like opening into the middle meatus of the nose, about its middle third. Posterior accessory openings are sometimes seen. They are bounded above by the orbits and below by the alveolar processes where the molars occasionally project upward into the floor. The frontal sinuses are located in the frontal bone above the inner canthus. Sometimes one is large and the other small but the average is about one inch in diameter at its most extended parts, both upward and backward. They are connected with the nasal cavity by what is known as the infundibulum, which is an irregular torturous canal leading to the middle meatus. The sphenoidal sinuses are located back of the nasal cavity in the sphenoid bone and open through the upper anterior wall. The ethmoidal cells are situated between the nasal processes of the superior maxillary and lachrymal bones and frontal sinuses in front and the sphenoidal and palate bones behind and below the frontal, sphenoid and cribriform plate of the ethmoid bones. They are separated by a partition into anterior and posterior cells. The anterior sometimes connect with the infundibulum or frontal sinus directly but the main opening is in the median wall of the ethmoidal bulla and frequently by another opening into the superior meatus. The posterior connect with the superior meatus. So much

\* Read before the Owen County Medical Society, November 7, 1907.

for the anatomy of these accessory sinuses, except that without a fair knowledge of the anatomy and physiology of these parts symptoms become confusing and treatment next to impossible.

There are a great many causes for disease in these organs but my subject binds me to the specific results of the introduction and invasion of the germ of influenza or la grippe. I will say that the bacillus of Pfeiffer may attack any of the mucosa between the external nares and the air cells, including, of course, the accessory nasal sinuses; in fact, these regions are its home.

The bacillus of influenza is extremely small and usually occurs singly but occasionally we may find it arranged in short chains. The ordinary methods of staining may be used in searching for it, especially the aniline dye and carbol-fuchsin, but Cram's method decolorizes. The ends of the bacillus stain deeper on account of being larger than the shaft. It is non-motile. May be cultivated upon blood serum and glycerine agar. The organisms decrease in quantity as the case advances, but in some cases the bacillus continues to flourish, especially in the frontal and ethmoidal sinuses. There is no especial lesion but an abundant excretion of mucus is produced.

In discussing the symptoms and treatment of these conditions it becomes necessary to take each separately.

The antrum of Highmore from its direct connection with the middle meatus is liable to be attacked by the Pfeiffer bacillus by a continuation of mucous membrane invasion (by continuity), again, the organism laden secretion from any part of the nasal cavity may drain into it and be the source of inflammation. When once this condition begins we have the symptoms of acute inflammation as found in any portion of the body. Pain is a marked symptom. There is a full peculiar feeling under the eye. On inspection a mucopurulent discharge is found coming into the middle meatus. Cases that have had secondary, or mixed infection with the formation of pus have more intense pain in this region, ringing in the ear, deafness and some may have asthmatic attacks. The pain, in my experience, has been generally present and when an acute empyema sets in becomes more severe, although some say that pain in this condition is very deceptive and may not occur at all. If there be doubt about the diagnosis transillumination by an electric light in the mouth with patient in dark-room is serviceable. During the acute attack of the sequel without stenosis the treatment should be similar to the treatment for a cold in the head or for la grippe proper but with the outlets becoming occluded and the formation

of pus drainage should promptly be resorted to, this is best accomplished by removing the superior canine and puncturing the alveolar floor, when this opening is once made the antrum should be thoroughly irrigated with some antiseptic solution and a tube put in to facilitate drainage. When much pus is found and the bones necrosed it may be wise to curette. The antiseptic irrigation should be kept up until the discharge ceases and the inflammation subsides. Some prefer making the opening for drainage through the walls of the inferior meatus, but, to me, the canine fossa opening seems the more plausible.

An invasion of this disease into the frontal sinuses probably takes place more often than into any one other of the accessory sinuses. Just why this is true I am unable to say, unless it is the bad drainage the frontal sinuses have through the infundibulum's torturous course. Pain over the eye or through the forehead is always present. When the infundibulum is entirely occluded pain becomes unbearable in these regions. Very often I find supraorbital neuralgia and tenderness over the eyes with an inclination to avoid light. One case, in particular, was very much worse, so far as the supraorbital neuralgia was concerned, during the hours of the day. Discharge from the infundibulum into the middle meatus and lack of transillumination with an electric bulb placed under the supraorbital margins are evidence of trouble in the frontal sinuses. In the treatment, local applications may be worth mentioning but as in the treatment of all these conditions disinfection and drainage are of paramount importance. If the infundibulum be patulous sprays or nebulizations of antiseptics may be advantageous but if it be not open entrance must be made either by catheterization or by operation. The former may be done by any of us by a little care and study. A silver instrument especially devised for this purpose is on the market. Many times great pain and continued suffering may be averted by this simple procedure. In cases where the infundibulum is swollen so catheterization is unadvisable or impossible and pus be present an operation is imperative for the welfare of the patient. The bone is chiselled away beneath the supraorbital ridge and entrance to and drainage had with subsequent irrigation as in similar conditions in the antrum.

Inflammation in the sphenoidal sinuses gives rise to headache, full, heavy feeling over and behind the eyes, and in severe cases pains in the temporal and occipital regions, discharge from the upper anterior sphenoidal wall above the superior turbinated body and disturbances of vision. The mucous membrane in this region will show the effects

of the constant discharge and, under favorable conditions, the opening may be seen discharging. In the management of these cases we may follow the line of treatment laid down in the treatment of the preceding conditions. However we should resort to surgical assistance very soon, removing the middle turbinated bone and puncturing the thin wall just below the opening and cutting upward, laying the sinns open. After this is done curett (if necessary), irrigate and drain, keeping this up as long as indications require it.

Inflamed conditions of the ethmoidal sinuses give rise to pains similar to the same conditions in the frontal sinuses with discharges through the rhino-pharynx and anterior nares. The pain is deep-seated, in the ethmoidal region and behind the eyes. Cases with free drainage have the discharge in the pharynx, larynx and bronchi. When stenosis exists mental dullness is often manifest. Any discharge in the superior meatus is suspicious of ethmoidal inflammation, although it might come from the sphenoidal sinuses or from bone necrosis. Sprays and douches should be used and in severe cases the walls of the cells may be broken down with impunity, after which curettment and irrigation can be done. Some one has recommended the ordinary burrow for breaking down the cell walls and it certainly seems to be a plausible idea, however there are numerous instruments for operations in this region.

In the treatment of all these conditions we must not forget the causative factor in infection which has spread from the general nasal chambers and that it behooves us to direct treatment toward the source. While we have no specific for influenza, in my experience, the salicylates, and especially some of the newer preparations have proven very satisfactory. Cases of long standing causing general debility necessarily need tonics and especial attention to diet, exercise in the fresh air and sunshine and other hygienic measures.

#### THE ACTION OF ARSENIC ON THE HUMAN ECONOMY FROM A THERAPEUTICAL STANDPOINT.\*

By J. F. MARRS, BOLES.

Arsenic itself is never employed in medicine. It is used in the form of arsenous acid or the arsenates of sodium, potassium or copper. In medicinal amounts the drug acts as a nervous excitant and as a stimulant to the trophic nervous apparatus.

According to lesser small doses act as a cardiac stimulant, large doses cause marked

decrease in the force and frequency of the pulse accompanied by a decided fall in arterial pressure and in these amounts it is to be regarded as a distinct cardiac depressant which depresses all the heart's component parts such as the ganglia muscles and nerves.

The fall in arterial pressure is due to vasomotor depression with relaxation of the general blood vessels more especially those of the abdominal cavity.

In modest amounts arsenic distinctly stimulates the respiratory centers also stimulates the peripheral ends of the vagi in the lungs, but in toxic quantities acting as a powerful respiratory depressant.

Arsenous acid applied to the normal skin produces no change of any moment whatever; but if the surface be broken or a wart or sore exists its action is very powerful, and the tissues are destroyed to a considerable extent, where large growths with wide surfaces are to be attached, arsenic must be used most boldly, or not at all, the danger of absorption is only escaped when the drug is used so generously as to destroy the tissues before they can carry on any absorption of the poison.

It should never be used in wet skin disease that is those associated with much proliferation of new cells and the exudation of serum and other liquids where the skin is affected in its lower layers arsenic is useless, its greatest value is in dry scaly skin diseases. In Psoriasis arsenic at first makes the skin more red and seemingly worse, but this passes off and the disease gets well.

In chorea arsenic is almost a specific—acting in an unknown way, small doses should be given at first, later on the dose should be increased rapidly as patients soon get accustomed to the drug, cases are on record, however, in which the too rapid increase of drug in medicinal doses has developed arsenical neuritis.

In leucocythemia and pseudo-leukaemia it is the remedy, and must be given up to the point of intolerance to be of value. In the latter disease, good results have followed its use when intraglandular, and intrasplenic injections of four drops of Fowler's solution were used, and ease of severe anaemia, where the stomach is disordered may be treated by giving three times the ordinary dose by the rectum in starch water.

In malaria it acts as a prophylactic, as a cure, and as an aid to convalescence. It is of great value for the improvement of depraved mucous membranes of the respiratory tract, especially in those persons who have not true tuberculosis, but phthisical tendencies, that is individuals who continually have colds in the head, chest or elsewhere.

In asthma, particularly where the mucus

\* Read before the Monroe County Medical Society, February 8, 1908.

membranes are at fault arsenic is one of the best remedies that we have either given internally or smoked in cigarettes.

Atonic dyspepsia associated with chronic diarrhoea and with evidences of dysentery, can be helped by the use of arsenic and in small amounts it is very valuable in frequently repeated doses in all forms of serous diarrhoea.

If arsenic is taken by a susceptible person it may cause a marked dermatitis with a sensation of severe burning in the skin, pustulations may occur, and Falek asserts, that an erysipelatous state may arise, almost any form of skin lesions may follow its use internally or externally, but nearly all show irritation of the true skin. Arsenic escapes from the body chiefly by the kidneys, bowels, and skin,—but usually does not appear far from fourteen to sixty hours after its ingestion in medicinal amounts, some traces may be found in the saliva and in the milk of nursing mothers.

#### TECHNIQUE OF NEW PERINEORRHAPHY (WALDO'S).\*

By M. CASPER, LOUISVILLE.

I do not wish to infer that we haven't already a sufficient number of operations for repairing a lacerated perineum. But I take the liberty of presenting in review, this new or rather late method of repair because, it is simple, practical and has in others as well as in my hands proven quite successful. The indications for and the benefits derived from secondary perineorrhaphy will be passed over. Not because they are not important but because they do not come under the scope of this paper and have been sufficiently gone over.

Waldo's technique is adaptable to both primary and secondary repair of the perineum. In secondary operations, the usual denudation is of course necessary before applying this suture. Also in case the tear extends into the rectum and through the sphincter ani, it should be closed as in any other method of repair. The material used for suture is preferably No. 4 plain catgut. I have used No. 2 chromic gut, it is not so large and unwieldy as the No. 4 plain, yet I am of the opinion that it is more uniform in strength and more time is required for absorption than the chromic gut. I very rarely employ silk worm gut now, but was slowest to discard it in perineal repairs and still I do not believe any material so good for perineal repairs as silk worm gut when any other form of technique is used. But absorbable suture-material is es-

sential to Waldo's operation. Other points of advantage are that cat gut if carried in hermetically sealed tubes, is always sterile and ready for immediate use, which is quite an item after being up all night with a tedious case of labor and find on final delivery a lacerated perineum. Also it is of some value by conducting towards the mental tranquility of the patient when you can insure her that the stitches do not require removal. We have all seen the patient worry and sometimes to a considerable extent after an operation of repair, premeditating the pain to be endured on removal of the stitches.

The suture is a sort of figure of eight stitch, folded on itself. Any long curved needle adapted to other perineorrhaphy operations is suitable for this method.

The close proximity of the rectum and the thinness of its wall require that the finger be placed in the rectum as a guide for accurate work. The needle is entered at the highest point of the tear, just externally to the caruncle of the left side (if the operator be right handed). The needle is carried inward to the upper end of the sulcus of the tear, that is the point of the tear furthest up the vagina. Then it is brought out and re-entered at a point of exit, if tear is too extensive to turn needle without taking a new hold on it. The needle is then brought out on the opposite side of the perineum, not however at a point exactly on the level with the entrance on the left side but at a point midway between the point opposite the first entrance and the angle of the tear nearest the sphincter ani. Thence cross over to the left side and enter the second time at a point directly opposite your point of last exit. Again carry to upper end of sulcus, turn and come back on the right side to a point exactly opposite to original entrance or to highest point of tear on the right side.

On tying you'll observe a very snug approximation of the tissues to their normal relation as before the tear. The suture does not require being tied extra tight to bring about this neat approximation. These tissues are prone to swell following the suturing and if the knot is already tight the circulation to the injured parts is sure to be interfered with, perhaps to a degree to delay or lessen union.

I might add here that cat gut being more resilient than silk worm gut is another advantage, for it will yield somewhat to the swelling of the tissues.

Before tying carefully sponge away all blood clots.

In using this particular suture it is just as important to take a deep bite into the muscle as in all other forms of perineal repair. No doubt failure to get union in any perine-

\* Read before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

orrhaphy is often due to overlooking this point. For if you do not get a deep hold on the muscle it is sure to retract and leave the raw surfaces unevenly approximated and hence non-union.

At times a small supplementary stitch may be taken at the upper angle but as a rule it is not necessary. The only form of tear that this stitch will appear awkward in is where the tear extends up both sides of the vagina leaving a double sulcus. This difficulty is easily overcome by taking an internal stitch or two in each sulcus and then apply the Waldo suture. It requires about seven days for No. 4 plain gut to become absorbed after the application of this stitch. When silk worm gut is used in Emmett's or any other operation, it should be removed by that time, for it begins to tear out if left longer and may thus lessen the strength of the union. So it is advisable to remove the stitches then whether there is union or not.

There is no after treatment to follow this operation, not even a dressing applied nor is it advisable to use pads against the perineum but rather placed just so as to prevent soiling of the bed clothes. Catheterization is not necessary, the perineum being intact normally as before tear the urine does not touch the repaired part or if at all very little, this being true of all perineums that are not torn, hence true in one properly united.

I have used this method several times in the past year and find it very efficacious and when once comprehended it is found to be quite simple and easy of performing. It can be performed quickly and is quite a time-saver as you are not required to tie more than a single knot and thread one needle as well as the avoiding of moving the rectal finger in and out which cannot remain long sterile.

The method itself is scarcely as difficult as the explaining of it and a great deal more quickly performed. However I trust I have been successful in making it clear to you.

I feel like it is just the thing for the general practitioner for it is he who does this work oftenest. Especially would I commend it to the practitioner who lives several miles from his patient and cannot visit them as often as those more closely in touch with the patient.

I believe it more suited to primary repair though I saw one case of secondary repair of a tear that extended into the rectum through the sphincter ani and the result was perfect following this technique.

In conclusion I wish to state that I claim no originality for this method or technique and only review it here because I believe it useful and beneficial to my fellow members

of this society and also because it has never been published either in the medical journals or text books, at least I have never seen it in print.

CUT I.

CUT II.

## EXPLANATION OF CUTS I AND II.

Cut I.—1, represents a point near caruncule of each side, 2, point of tear nearest anus; 3, highest point of tear in vagina or junction of the crest of the "Rectocele" with the tear. Needle first enters near Caruncula on left side at point 1, and is carried around tear deeply buried as per dotted line. Emerging at point 3 and is re-grasped and re-entered as per 2nd part of the dotted line, emerging at point midway between the points 1 and 2 on the right side. Observe that loop at 3 is abolished on drawing thread tight.

Cut II.—Needle is continued after emerging in Cut I to a point exactly opposite this emergence (namely midway between 1 and 2 on left side) and again re-entered, making the second emergence at point 3 and thence concluded by again re-entering at last point of exit (3) and coming out at point 1 on right side; this point corresponds to first (original) entrance on the left side.

NOTE.—If tear is not symmetrical the course of the suture also points of entrance and exit must vary accordingly.

## MEDIASTINAL TUMORS, WITH REPORT OF A CASE.\*

By W. H. COLEMAN, LOUISVILLE.

A brief anatomical description of the mediastinal spaces and their contents, I deem not out of order.

The mediastinum is a space extending from the sternum to the spine and bounded laterally by the pleura; and contains all the viscera of the thorax except the lungs. The upper mediastinal space is situated between the pleura, and above a plane running through the junction of the manubrium with the body of the sternum, back to the lower border of the fourth dorsal vertebra. This upper space contains a portion of the arch of the aorta; the innominate, subclavian, and left carotid arteries; the innominate veins, a part of the superior vena cava; the pneumogastric, phrenic and cardiac nerves; the oesophagus, trachea, remains of thymus gland and lymphatics.

The lower mediastinal space is situated below the upper border of the pericardium, and contains chiefly: the heart and pericardium, ascending aorta, part of superior vena cava, two bronchi and bifurcation of trachea, with lymphatic glands.

It will be readily observed therefore, that any form of tumor appearing in the mediastinal space, will encroach upon most vital organs and produce a train of symptoms of serious import.

The history of mediastinal tumors began with an English physician in 1621. In 1742 and in 1812 several cases were described but not till 1835 did a text-book description appear; after which cases multiplied and were reported by H. A. Hare, Wm. Pepper, Alfred Stengel and others.

H. A. Hare reported 520 cases in 1889. "Of 7566 autopsies at the Marine Hospital at Cronstadt, 158 were found to have tumors of the mediastinum, said to be malignant," so that even to-day with improved methods of medical diagnosis, mediastinal tumors fortunately are rarely found. Edwards places the frequency of such tumors at one in ten thousand medical cases.

The structures which are most likely to be the primary seat of new growths in this locality are, the lymph glands most frequently, connective tissue, the remains of the thymus gland, and even the thyroid gland.

The lungs, the pleura, stomach, breasts or bronchial glands, may originate a disease which will spread through the lymphatics to the glands of the mediastinum to originate a new growth. Dr. Allen, in the London Lancet for October 5th, 1907, reports a carcinoma originating in the glands of the left

bronchus. The remains of the thymus gland furnishes the starting point for most all tumors in the anterior mediastinal space.

The most common variety of tumor found in this locality, according to the observations of Tyson, Edwards, Milton Fagg, Wm. Pepper and others, is the lympho-sarcoma. Dermoid cysts are found and are soft fluctuating and may pulsate.

Benign tumors are not frequently observed. Inflammatory process with large abscess formation acute or chronic may take place.

Aortic aneurism with large tumor-like formation has been frequently pointed out.

Any kind or class of tumor endeavoring to locate itself within the mediastinum, will occupy space at the expense of the vital organs here situated; so that the signs and symptoms produced will be very similar, and in effect will be such as would arise from pressure.

I should like to describe the history and development of a case at hand, which will include most all of the classical symptoms of pressure in this locality, except a few special signs which develop in the course of abscess or aortic aneurism.

Male, aged 38, of Scotch descent, unmarried, and a boiler-maker by occupation; previous personal and family history very good. In January 1907 he fell suddenly ill with high temperature for ten days, which his doctor termed LaGrippe. He came to me in May, 1907 with temperature normal, pulse 100, respiration 24, slight emaciation, easily fatigued on account of dyspnoea, and a rasping cough which prevented sleep.

These symptoms have increased in severity until the present time. The dyspnoea is now very marked, and both inspiration and expiration are extremely labored. The eyes are bulging and stand out as in exophthalmic goitre, the expression is anxious and pitiable, as though begging for relief. He asked for a knife that he might open the throat in order to get air into his lungs easier. The cough is now constant, at intervals mild but usually loud and ringing. A neighbor describes this cough as "like the bark of a dog with a deep bass voice." The cough is said to be due to irritation of the vagus by pressure. Edwards attributes the cough in these cases to paralysis of the vocal cords from pressure on the laryngeal nerve. The dyspnoea may be due to pressure on the trachea, to an accumulation of mucus in the bronchi, or to partial closure of the glottis from pressure on the laryngeal nerve. The sputa is abundant, mucopurulent, with blood observed only twice. The "Currant-jelly-like" sputa of stakes often observed in cancer has not been present. Rapid heart action, which on exertion amounts to palpitation, has been a

\* Read before the Jefferson County Medical Society.

constant symptom, with no dissimilarity in the radial pulse. The pulse rate is now 120, respiration 40 and temperature 100 degrees.

This palpitation is usually attributed to irritation of the pneumogastric nerve, by pressure; though, in aortic aneurism it may as well be caused by obstruction to the blood current on account of the aneurismal tumor.

An almost constant sweating, at times cold and clammy has recently been present. Distention of the veins of the upper body is present, notably the external jugular veins, which are swollen and tortuous. The ends of the fingers are blue, swollen and clubbed in appearance; which is no doubt due to pressure on the vena cava and innominate veins. The feet and fore arms are slightly swollen.

Anemia and cachexia are now very marked, though loss of flesh was not notable till the last eight weeks.

This case has been walking about till the last two weeks when he has assumed a sitting posture with the head thrown forward and the chin on the sternum.

The physical signs have not been marked till recently. There is now dullness over the upper third of the sternum, and lately 3 inches to the left and 4 inches to the right. Dull also over the middle of the right clavicle but not over the left. Vocal resonance and respiratory murmur are not well transmitted over area of dullness, and no murmur is discernible, vocal fremitus is diminished, and no bulging of the chest or intercostal spaces is present, and pulsation is recently observed only in the supra-sternal fossa. The axillary and cervical glands are not enlarged.

The differential diagnosis in this case from aneurism of aorta, is based on the absence of the usual signs present in aortic dilatation; such as pain, expansile pulsation, tugging of the trachea, diastolic shock, and the age of the patient; it is said that aneurism usually runs a course of more than 18 months. So that I believe this case will reveal post-mortem a sarcoma, situated in the middle and posterior mediastinal spaces.

The treatment of mediastinal tumors either medical or surgical is symptomatic. R. S. Morris has performed a few successful operations. "In 20 cases of dermoid cyst, 70 per cent. recovered.

DaCosta states that "The posterior mediastinum has been entered to remove a foreign body from the bronchus, a set of false teeth from the oesophagus, or to puncture an abscess."

To quote: "There is no treatment for mediastinal disease" Tyson.

"Tumors of the mediastinum are beyond the reach of the surgeon, and the prognosis generally hopeless."—Wood and Fitz.

"I can find no records of successful surgical intervention."—Forscheimer.

*Necropsy:* Robert Pirtle and myself found the following post-mortem condition. There was an aneurism involving the ascending portion and arch of the aorta. It extends from a little below the bifurcation of the trachea to four inches up the trachea. The inside measurements of the sack formed by the dilatation of the vessel wall were: superior-inferior 4 1-2 inches; laterally, 3 1-2 inches, and antero-posterior 2 1-2 inches. There are layers of fibrous tissue in the sack which can be easily peeled off, and calcification of the walls of the whole sack is noted, so that there could be no resiliency in the walls themselves. The sack was not ruptured. Death was due to pressure upon the trachea, causing occlusion of the same, with a large accumulation of heavy mucopurulent secretion in the bronchi and lungs, which secretion poured out freely when the trachea was severed.

#### ACUTE NEPHRITIS.\*

By HUGH D. RODMAN, BARBSTOWN.

Acute nephritis is described as being an acute inflammation of the kidneys from whatever cause; or acute Bright's disease, it having been first described by Dr. Richard Bright, of London. The symptoms, pathologic anatomy and general conditions differ greatly but all of these conditions are grouped under the general term of Bright's disease, because in all of them the urine contains albumin.

I wish to speak only of the acute condition, which is the condition we meet most frequently, and which in my judgment is the only one which gives us any hope of recovery. The acute inflammation of the kidney is amenable to treatment and is often cured, but the chronic forms of Bright's disease are never cured.

The causes of acute nephritis are both infectious and toxic, the former being more common; they are all of the infectious diseases as, scarlet fever, diphtheria, other infections, sore throat, typhoid fever, smallpox, erysipelas, septicaemia, etc. The second group or toxic causes are to be found in those drugs which irritate the kidneys, such as cantharides, turpentine, copaiba, cubeb, the mineral acids, oxalic and carbolic acids, arsenic, chloride of mercury, etc.

Pregnancy is largely mentioned by many authors as a cause of acute nephritis which I am very greatly surprised to see. With me it has been the cause of more kidney diseases than all other causes combined, in fact preg-

\* Read before the Nelson County Medical Society, April 1st, 1908.

nancy and scarlet fever have been the prevailing causes. The kidneys of every pregnant woman should be carefully and closely watched for the first signs of nephritis. If we are not watchful this cause alone will give us more trouble than all others combined. If I were classing the various causes of this disease, I would put, as I said above pregnancy first and scarlet fever second on the list. For the pregnant woman we have always with us, but the other causes not always.

Like our pregnant woman, our scarlet fever patients can not be too closely watched, as soon as the temperature begins declining daily or by-daily chemical tests should be made of the patients' urine, until our little patient is well; and when shall we say that this is the case, and that we are justified in removing our guard? In answering this I will say that a good rule is to keep up our watch for at least one month after desquamation is complete and that there is no vestige of the poison left. As long as there is anaemia or the least evidence of disease an occasional chemical urine analysis should be made; this in my opinion is the only sure means at our command to prevent our patient from lapsing into a chronic and an incurable condition.

I wish to impress upon your minds, gentlemen, that we cannot be too vigilant in all such cases. Our watchful care will be rewarded by a large per cent. of perfect recoveries, and we will have less mortification in seeing our former patients drop into other hands and become chronic sufferers, caused frequently by our ignorance or our inattention, either of which is now criminal.

About thirty-five years ago, before we regarded urinary tests as a factor in diagnosis, I was taught a sad but impressive lesson, which I will never forget. I had a little patient with scarlet fever and failed to diagnose it as it was light, until desquamation was well under way, the little fellow got out and seemed well, and I was delighted to see my first case of scarlet fever get well, but wait, my joy was soon turned to sorrow, when in a few weeks I was called to see him and found him puffed and dropsical all over, which condition grew worse until death relieved him. With our present means of diagnosis and our knowledge of acute inflammation of the kidneys and its causes, I am not now likely to let such conditions confront me.

The symptoms of acute Bright's disease are usually light fever, dull pain in the lumbar region, general lassitude, sometimes nausea with vomiting, general anemia, loss of appetite, great drowsiness, finally dropsy begin-

ning in the face, and soon spreading over the whole system. Uremia may develop at any time accompanied by more or less coma. The urine is generally scanty and sometimes suppressed, is usually turbid with heavy precipitation on standing for a short time. Our diagnosis should always hinge on chemical and microscopical tests of the urine. Prognosis generally favorable, but should be guarded.

*Treatment:* The treatment of acute nephritis should vary according to cause and severity of the attack, but from whatever cause and no matter how severe there are certain well defined common sense rules which should be laid down in every case.

The patient should be put to bed and kept there, and kept as still and quiet as possible in a well ventilated room of an even temperature, uniform day and night, and should wear a good warm undershirt. The diet should be simple easy digested and nourishing with no irritating substances, milk in abundance is always to be recommended, large quantities of hot water should be taken, iced water never, the quantity of liquids in twenty-four hours should not be less than one gallon and more for an adult if the stomach will bear it and children in proportion. The rectum should be flushed at least twice daily with a normal salt solution, cupping is advised by many, I have never tried it. Hot flax-seed poultices over the renal region are always indicated they should be large and kept hot day and night, bottles and jugs filled with hot water should be placed near the patient under the cover to encourage free diaphoresis. If the patient is a child, a nurse should be continuously at the bedside so as to perpetuate our efforts to permit no removing of the bed clothes nor applications by the patient. This course should be continued until albumin has disappeared from the urine. My medication begins always with a good dose of calomel, ipecac and soda followed by a free saline cathartic; when catharsis is free and full I begin with infusion of digitalis and the alkaline diuretics and push them; my choice is the acetate of potash. If convalescence is slow and my patient needs iron I usually begin with Basham's mixture, changing as the case advances to some stronger iron tonic.

I have found this treatment usually satisfactory, there are, however, a number of other remedies used especially to produce sweating, such as pilocarpine, elaterium, etc., but I have never used them. In treating our pregnant women great care should be observed to protect the unborn and at the same time remove the toxic condition.

SOME IMPORTANT FEATURES IN THE  
PATHOLOGY AND TREATMENT  
OF DISEASED TONSILS  
AND ADENOIDS.\*

By G. C. HALL, LOUISVILLE.

At a meeting of the New York Academy of Medicine, Section on Laryngology and Rhinology, May 23rd, 1905, J. H. Abraham makes this statement as reported in the Laryngoscope: "This was the first instance in which he had completely removed the tonsil." This statement provoked no discussion and went unchallenged to the society impliedly at least acquiesced in the belief that as a rule it is not necessary to remove the whole growth, or that it is not wise to do so or is inexpedient.

From the earliest times the diseased tonsil has been the object of operative interference, though it remained to Meyer in comparatively recent times to show us the pathology involved in the hypertrophied adenoid.

The surgical history of these glands is a marked commentary on the diverse opinions held and urged by men of the greatest integrity arguing from the same premises to opposite conclusions; for broadly speaking through all these years two distinct procedures have been in vogue—one of which contemplates only the partial removal; the other and more radical their complete ablation.

Those advocating partial removal claim that the operation eures of course, that it is rapid and easy to perform—often requiring no anesthetic—there is little shock and no hemorrhage. They urge against the complete removal that it is dangerous on account of hemorrhage—it requires considerable anesthesia—produces more shock and robs the system of important lymphoid structures.

Those advocating complete removal claim that while the operation is more extensive and more difficult to perform that the results obtained justify the procedure—that it is not dangerous on account of hemorrhage—that shock is not decided—that partial removal is not only inefficient, but in most cases it is worse than useless for it submits the patient to the danger of operation with no certainty of relief, bringing both operator and operation into disrepute and further no ill effects are ever observed from ridding the system of the so-called important lymphoid structure that to the contrary the very opposite effects are shown.

Let us consider for a moment the various types these structures may present from a surgical aspect. Adenoids are fairly constant—in the young child they are soft and friable and made up almost entirely of lymphoid elements. As age advances they become

smoother, firmer and fibrous tissue becomes more prominent. Those confined strictly to the pharyngeal vaults being less troublesome and dangerous than those that spread to the lateral walls covering the fossae of Rosenmueller and the pharyngeal orifices of the Eustachian tubes.

The condition of fibrous bands and soft friable tissue in these situations giving rise to ear troubles spoken of by Brunk of Alabama, and Emerson, of Boston, deserve mention.

The hypertrophied tonsil, however presents several well defined and widely divergent types of which the following are representative.

1st. The completely projecting tonsil—not covered by the pillars, seen only in childhood, bulging widely into the pharynx almost meeting in the median line especially if the patient is made to gag.

These can be completely removed by the tonsillotome, but constitutes but a small percentage of cases.

2nd. Completely submerged variety, (a) large flat variety with many crypts filled with caseous material having often a pocket in the supratonsillar fossa filled with debris.

(b) Narrow submerged variety. Pillars almost in contact, area of redness defines the boundaries. No tonsil seen on simple examination. Gagging causes them to become prominent—caseous masses of large size may also be present in this variety, especially between the anterior surface and the pillar.

3rd. Projecting submerged variety—a combination of the other two and constitutes the largest percentage of all cases—may have large crypts 3-4 inch deep and caseous material as above.

This variety furnishes the greatest number that come for secondary operation for frequently only the projecting portion is removed at the first operation, leaving most of the tonsil behind. Peritonsillar abscess also is common in these cases.

The plica triangularis, a fold of mucous membrane derived from the anterior pillar and attached to the anterior surface of the tonsil is responsible for the buried condition of many of these cases. In other cases the submersion is apparently due to the contraction of fibrous structure thrown out by repeated inflammation surrounding the tonsil.

The necessity of removal in the submerged variety is just as urgent, in fact more so than the projecting variety since the products of decomposition are more deeply situated and absorption goes on unchecked.

He who removed the central mass of an adenoid leaving the lateral structures which by the way are of great importance in caus-

\* Read before the Muldraugh Hill Medical Society, April 9th, 1908.

ing deafness and otitis media is as much to be condemned as he who removed but the projecting portion of a tonsil leaving the submerged portion to continue to cause the original trouble and again hypertrophy.

Both operations are incomplete—both fail to relieve, they should therefore be put aside for other procedures more efficient.

The pathological condition arising from diseased tonsils and adenoids are as widespread as they are varied.

They cause lesions, not only in the nose, throat and immediate vicinity but serious general symptoms.

The appearance of these patients is so typical as to be familiar to every one. We recognize it at once in the open mouth, drawn condition of the nose, stupid expression, lack of lustre in the eyes and stooped shoulders. Such is the condition arising from oxygen starvation. This is farther supplemented by the restless tossing sleep, night cries, etc., arising from the indigestion the condition induces.

The literature of this particular field is so extensive that time forbids even a thorough resume of all the important facts that have been brought out in the last few years. I can do no more than but call your attention to some of the more important phases of the pathology of this region.

That tuberculosis is primary in diseased tonsils and adenoids in from five to ten per cent. of all cases is the conservative estimate of many observers. The relation of these glands to the general subject of tuberculosis becomes at once apparent.

The fact that under these circumstances the tuberculosis is not proliferative and cannot often be recognized except by microscopic examination makes the condition particularly dangerous, for any tonsil however innocent in appearance may deep in its structure be distinctly tuberculous and disseminate the disease throughout the body. The necessity of early and thorough removal under such conditions is also at once self evident.

That the virus of rheumatism gains an entrance into the system via the tonsils is the firm belief of many observers, though some contend to the contrary.

Ingals in a recent paper says he cannot convince himself of the relationship—though Godale of Boston shows conclusively that such a relationship does exist.

Cases of arthritis following tonsillar infection are fairly common. Acute endocarditis has been reported and albuminuria as a symptom of severe tonsillar infection is not infrequent, showing the serious work it imposes on the kidney. The further relationship between tonsillitis and rheumatism is borne out in the good results obtained by ad-

ministration of the salicylates and their derivatives in cases of tonsillitis.

The tonsils situated as they are at the head of both the respiratory and digestive tract contribute pathological lesions referable to each.

A persistent cough often referred to as a "bronchial affection" or even giving rise to the suspicion of incipient tuberculosis can be often diagnosed by palpating the tonsil with a probe thus exciting the cough. Removal cures the trouble.

By extension of the inflammation downward an attack of tonsillitis sometimes results in an attack of acute laryngitis or bronchitis, which may be exceedingly rebellious to treatment or which may continue to give trouble till the removal of the exciting cause.

The gastric and intestinal derangements existing in children with enlarged tonsils and adenoids is familiar to every one and is no doubt due to two causes. The first of which is oxygen starvation, caused by the obstruction to free respiration; the other is the absorption of toxins or ptomaines from the recesses of these glands.

The cheesy debris extracted from the tonsillar crypts has a most disgusting odor and the foul breath arising from this cause is often ascribed both in children and adults as due to a disordered stomach or bad teeth when in reality it is the diseased tonsil.

Deformity of the superior maxillary and the teeth due to obstructive lesions in the upper air passages is one of the newer lines of thought in connection with adenoids and a number of papers from both dentists and physicians have recently appeared. It is a subject worthy of farther study. While the subject is not wholly settled, much evidence is brought forward to show that adenoids are responsible for the high arched palate, narrow dental arches and subsequent deformity of the teeth through lack of space to develop.

Regarding the lesions produced in the immediate vicinity of the tonsil I shall say nothing of the various forms of tonsillitis for that subject is familiar to you all.

However, the infection of the peritonsillar tissues or quinsy deserves mention. It occurs frequently in adult life and is a severe form of infection giving rise to the most acute suffering. This usually occurs in the supratonsillar fossae and as this is the part of the tonsil most frequently left after the tonsillotomy operation it speaks more eloquently than all else for the complete operation.

There can be no doubt that enlarged tonsils and adenoids are a great factor in the acute exanthemata. Whether or not we admit that the infective agents of these diseases enter

through these organs we are all aware that these organs when diseases complicate matters exceedingly. The frequency of tonsillar infection in diphtheria, in scarlatina and in measles and the pathologic lesions lingering in this region long after the original disease is past is highly significant.

A farther fact might be urged that the acute exanthemata and the greatest activity of these glands are in the life of the child coincident.

Adenoids are an important factor not only in acute suppurative otitis media and its complicating inflammation of the mastoid but in the production later in life of the dreaded and persistent chronic catarrhal otitis media with changes in the Eustachian tubes and middle ear cavities.

These structures act by causing congestion and favoring infection in the first place and afterwards prolonging the disease by obstructing drainage.

The predisposition to such attacks, the cure of others when established may be brought about by thoroughly removing these offending structures. The close relationship existing between the membranous portion of the Eustachian tube and the supratonsillar fossae is also a factor in the production of deafness, each attack of inflammation of the tonsil causing closure of the tube.

It is a fact that when not diseased, tonsils and adenoids undergo atrophy as age advances and may in time practically disappear, but it is my firm conviction from numbers of cases seen not only early, but in late adult life that when these organs are diseased there is very little or no tendency for them to arrive at the cherished atrophic stage and that we do our patients a serious injustice when we advise delay in dealing with them; we expose the patients to repeated infections, which are bad enough in themselves, but the complications often arising from such neglect may seriously handicap a child in its growth and leave the marks of physical incompetency indelibly stamped upon it.

The prejudice that we often have to encounter when we advise operation in these patients arises almost wholly from bad results brought about by lack of thoroughness in doing the operation or in performing the incomplete removal.

I have never seen a case of recurrence of symptoms where thorough and complete removal of these glands was accomplished, but I have seen so many cases following the partial removal that I am convinced that in many cases it is worse than no operation at all.

Upon what has gone before I submit the following propositions. 1st. that tonsils and adenoids once hypertrophied and diseased

tend to diminish but little if at all—they do not atrophy at puberty and the patient carries the disease into adult life.

2nd. That the hypertrophy or hypertroplasia effects the whole of the gland, not the exposed or projecting portion above so that an operation which accomplishes but the removal of the projecting portion is incomplete and does not cure the patient. That the remaining portion does not shrink, but to the contrary hypertrophies again so that in but a little while the patient is just as bad or worse off than before the operation.

3rd. That as such a procedure is responsible for all the cases of recurrence and reoperation and as it brings both operation and operator into disrepute such a procedure should be unreservedly condemned on all sides.

4th. That thorough and complete removal of all diseased tissue is a highly satisfactory operation and will absolutely cure the condition without danger of recurrence, for if all the tissue is removed there is no starting point for a recurrence.

5th. That only in a very small per cent. of cases is the tonsilotome competent to remove a tonsil completely and then only when traction is made on it strongly outward by tenaculum.

6th. That to thoroughly remove a tonsil a preliminary dissection is necessary, freeing the tonsil not only from the anterior and posterior pillars, but below and especially from the supratonsillar fossa. After this is accomplished and the tonsil lies loosely attached only by the base its removal is best accomplished with a cold wire snare, traction being made outward by means of a tenaculum.

7th. That in older children and in adults this can be accomplished without pain under local anaesthesia, but that in young children a general anesthetic is imperatively demanded. The practice of holding a screaming and struggling child and attempting to operate under such conditions should be unreservedly condemned. It is unsurgical—you necessarily do poor work and an incomplete operation. And more than that, it has a very serious effect on the child's nervous system, causing them to hate all doctors and making them difficult to treat in any subsequent disorder.

8th. That in children both tonsils and adenoids should be removed at one sitting. That it is a mistake to remove the adenoids and allow the tonsils to remain or vice versa. That in patients well advanced into adult life, especially if there have been repeated attacks of quinsy and the tonsils are deeply buried it is safer to remove only one at a

time on account of the possibility of hemorrhage and reaction which is considerable.

9th. That the operation aside from the remote dangers of anesthesia is without mortality. That hemorrhage is very infrequent and not more common than by the old method. That shock is practically nil and that except in adults the reaction is never considerable. That in any event the longest stay in the house required will not exceed three days. That the results of the operation are excellent and that in probably no other operation in surgery are the results so uniformly good and such a change for the better brought about in the life of a patient.

### THE FORUM.

Bardstown, May 8th, 1908.

To the Editor:—

I write to congratulate you on the make-up of the May number of the KENTUCKY MEDICAL JOURNAL. It is by far the best number ever issued. For four or five months after the JOURNAL was first moved to its present location, there was considerable dissatisfaction and adverse criticism about the JOURNAL, but I am glad to say that this has all died away as far as I am able to judge and that the doctors generally appreciate the JOURNAL. For myself I will say that the JOURNAL has greatly improved in the last six months, and is now a thoroughly practical State journal, of which every doctor in the State should be proud. Keep up your good work. With congratulations, I am yours,

HUGH D. RODMAN.

To the Editor:

The thirty-fourth annual meeting of the Mississippi Valley Medical Association will be held in Louisville, Ky., October 13, 14, 15, 1908, under the presidency of Dr. Arthur R. Elliott, of Chicago,

Announcement has just been made of the selection of the orators for the coming meeting, by the President. The Address in Medicine will be delivered by Dr. George Dock, Professor of Medicine in the University of Michigan, Ann Arbor; and the Address in Surgery by Dr. Arthur Dean Bevan, Professor of Surgery in Rush Medical College, Chicago. The mere mention of these names is enough of a warrant that this feature of the program will be in every way first-class.

The local Committee of Arrangements in Louisville has selected The Seelbach hotel as headquarters, the general sessions and the section meetings being held in the hotel's large auditoriums.

One of the features of the entertainment projected is a smoker in the famous Rathskeller of the hotel—the finest of its kind.

The McDowell button, so much admired at the 1897 meeting in Louisville, will be reproduced in bronze for this meeting.

H. E. TULEY, Secretary.

To the Editor:

In the discussion of "Mastoiditis" in the KENTUCKY MEDICAL JOURNAL for April, 1908, I am represented as saying "Fever is far more unusual in children than in adults." This is exactly the opposite of what I said. It should read, "Fever is far more usual in children than in adults—it is nearly always present in them (children)."

A little further up the word, "otologist" instead of aurist is used—this odd mistake may also be worthy of correction.

I very rarely call attention to errors in medical reports, but fever in the mastoid disease of children, especially in the early stages, is a symptom of such importance that I should prefer not being directly misquoted in regard to it.

With best wishes for further success of the JOURNAL, and with kind regards for yourself, I am, very truly,

S. G. DABNEY.

To the Editor:

The second annual meeting of the Kentucky State Association of Graduate Nurses will be held in Louisville, June 9, 10, 11, 1908.

An interesting program is assured, and a large attendance is requested.

Information concerning hotel accommodations, etc., may be obtained by addressing the chairman of arrangements, Mrs. Ella C. Francis, 420 West St. Catherine street, Louisville.

LAURA A. WILSON, Chairman.

### JEFFERSON COUNTY MEDICAL SOCIETY MILK COMMISSION.

At the regular meeting of the Jefferson County Medical Society, March 23rd, papers were read by Henry L. Coit, of Newark, N. J., and Otto P. Geier, of Cincinnati, Ohio. Dr. Coit, in his paper dealt with the broad subject of the necessity for a clean, pure milk, which for infants and invalids could only be obtained by means of a Milk Commission, which certified to the product of a dairyman. Dr. Coit is the father of the Certified Milk idea, and has seen the work in the past fourteen years, grow until there are medical milk commissions in about thirty cities in the United States.

Dr. Geier in his paper dealt with the American Association of Medical Milk Commissions in supplying an absolutely pure milk with the work of pasteurizing which attempted to convert dirty milk into a milk fit for use by cooking. He also called attention to possibilities for philanthropists to do good work with their money by endowing the American Association of Medical Milk

Commissions so that it could spread its plans and aims and establish milk commissions everywhere.

On the evening of March the 24th at the Tavern Club, the Jefferson County Medical Society Milk Commission, the distributor and producers gave a Certified Milk dinner with Drs. Coit and Geier as the guests of honor. The following menu was served:

Certified Milk Punch.  
 Certified Milk Oyster Stew.  
 Baked Red Souper  
 Certified Cream Sauce  
 Cucumbers.  
 Certified Milk  
 Fried Chicken.  
 Certified Cream Gravy  
 Certified Cream Potatoes  
 Asparagus, Certified Cream Sauce  
 Certified Cream Smearcase.  
 Lettuce Salad  
 Mayonnaise Dressing.  
 Certified Ice Cream Cake  
 Certified Cream Cheese.  
 Bent's Crackers                      Cigars  
 Coffee with Certified Cream.

Dr. John G. Cecil, president of the Kentucky State Medical Association, delivered a short address of welcome, calling attention to the epoch-making occasion in which he emphasized the importance of the work being done by Commissions already over the country.

Dr. Coit, in a very interesting talk gave a history of the establishment of the first milk commission and spoke feelingly of the loss of his first born child, the sacrifice of which forced him into the study of infant feeding problems, the first one of which was the obtaining a pure milk supply for infants and invalids. He referred to the finding of Mr. Stephen Francisco and the fact that he had already such high ideals as to the production of milk, that he was looking for such a commission with the same longing, as the commission was looking for him. He referred to the good work which was being done by the local commission and complimented the dairymen present, on their enthusiasm and the excellence of their product.

Dr. Geier referred to the work which a few physicians had done in Cincinnati in their effort to have passed a bill in the Ohio Legislature, prohibiting the feeding of distillery slop to dairy cattle. He referred to the fact that one thing had been forcibly impressed upon him by this visit to Louisville, was that it was not necessary to have a marble palace to produce certified milk in, that modern stables could be converted readily into certified milk plants as had been demon-

strated by several of the dairies visited in Jefferson county.

Dr. George M. Whittaker, of the Dairy Division of Bureau of Animal Industry, Department of Agriculture, was sent to the banquet as a personal representative of Mr. Melvin, the chief of the Bureau. He brought with him a number of bromide enlargements of pictures of ideal dairy conditions prevailing in most cities which produce ordinary market milk. Dr. Whittaker spoke of the good work being done by department by the aid of municipalities, by obtaining better milk, and complimented the work of the Certified Milk Commission.

The toastmaster introduced Dr. Ben McClaskey, one of the dairymen, who referred to the fact that before he had begun the production of Certified Milk he had his herd tuberculin tested, 33 1-3 per cent. responded to the test and he forcibly realized that he had unwittingly been responsible for distribution of tuberculous milk to many infants and invalids. He spoke of the difficulties raised by the Commission and how discouraged the producer often is when his bacterial count runs up, but in spite of these difficulties, if his certificate were revoked he would discontinue the dairy business entirely as he believed that no market milk is fit to use.

A. T. McCormack referred to the model pure food bill which had been passed by the recent Legislature, and signed by the Governor, and complimented the milk commission in having included in this bill a course which prevented the use of the term "Certified Milk" by any dairyman except it be with the consent of a regularly appointed milk commission by the county medical society.

Dr. B. F. Zimmerman, president of the county society expressed his appreciation of the efforts of the milk commission, referred to the two children of the county society namely, the Milk Commission and the Medical Library. He admitted that there was a great deal more to Certified Milk than he had any idea of. Mr. Roach, the distributor referred to the difficulties which always beset the producer and distributor of Certified Milk and spoke of his gratification at the success of the unique Certified Milk dinner.

Squire Hollis, of the Jefferson County Fiscal Court referred to the pleasure it was to him to uphold the law in the cases of violation of the Pure Food Law, which had been presented to him for trial, and his pleasure at being present at the dinner.

Dr. Adolph O. Pfungst underwent an operation for ventral hernia April 4th. The hernia had developed in cicatrices, resulting from an operation for an appendical abscess, which occurred while pursuing post-graduate studies abroad. His many friends will be pleased to know of his satisfactory convalescence.

## COUNTY SOCIETY REPORTS.

**Anderson**—The Anderson County Medical Society met with C. W. Kavanaugh on the fourth of this month, the following members being present:—C. W. Kavanaugh, Lillard, Murdock, Toll, and Gilbert. No papers were read, but an interesting case of Ulcers of the Leg was sent in by Dr. Simpson.

The case of Dr. Murdock, that has been before the society several times, was presented. He operated on the case, and found several adhesions around the gall bladder. These were broken up and the case has almost entirely recovered.

The society adjourned to meet with Dr. Lillard in June.

J. W. GILBERT, Secretary.

**Barren**—The Barren County Medical Society met at Glasgow May 12, 1908. J. M. Taylor in the chair. Members present:—R. H. Porter, R. E. Garnett, J. S. Leech, S. T. Botts, W. C. Smith, and R. S. Plumlee.

**R. S. Plumlee** reported a case of tuberculous meningitis in a child 3 1-2 years old, which he thinks was contracted from the child's father, with whom it slept. Child lived only a week after medical aid was summoned. Father is still living, but is gradually sinking.

This started the ball rolling for a war on tuberculosis.

**R. E. Garnett** reported four cases in one family only, which he thinks might have been prevented.

**J. S. Leech** thinks the laity must be educated before we can accomplish much. Advises sleeping alone, also spitting in a receptacle.

**S. T. Botts** reported about 15 cases who died in the same family. All became infected so rapidly from the first cases that hygienic suggestions could not intercede until too late.

**J. M. Taylor** suggests the impression upon the laity of early treatment.

**W. C. Smith** approved the educational route. Also suggests that adenoids predispose to tuberculosis.

Motion carried that the chair appoint the county board of health to confer with the trustees of the schools in regard to a plan of sanitation to be carried out in the schools of the town and county.

**R. E. Garnett's** paper on "How to Prevent Piracy Among the Members of the Profession" was postponed till our June meeting, which is on the 12th. No further business, the society adjourned.

R. S. PLUMLEE, Secretary.

**Boyle**—The Boyle County Medical Society met last night at Danville, with about one-third of the members present; we had two scientific papers for discussion, one "The Differential Diag-

nosis of the More Common Acute Infectious Exanthematous Diseases."

**J. D. Jackson** read an interesting paper on "General Anesthesia."

W. H. SMITH, Secretary.

**Bullitt**—The Bullitt County Medical Society met at Shepherdsville, April 23. The following members were present:—Cook, Overall, Hill, Fryer, Dodds, Ridgway, Shafer, Coleman, Houck, Bates and Hackworth.

**S. W. Bates** read a paper on Pneumonia, which was discussed by all present.

**S. H. Ridgway** read a paper on "The Common Gastro-Intestinal Diseases of Infancy and Childhood."

Motion carried to submit the paper to the JOURNAL for publication.

The subject of unalpractice suit against Dr. Coleman was fully discussed by all present. It is the opinion of all present that Dr. Coleman was, and did perform his duties as a physician in a just and upright manner, and therefore no blame should be laid upon him. We also agreed to aid, help and assist all worthy physicians who might become the victim of unprincipled patients who are being encouraged to bring such suits by a set of hungry jack-leg lawyers.

No further business appearing the meeting adjourned.

R. L. HACKWORTH, Secretary.

**Casey**—The Casey County Medical Society met in Pierce Martin's office on the 23rd of April, 1908. In the absence of the president and vice-president, the society was called to order by the secretary, and J. T. Wesley was elected president pro tem.

**Pierce Martin** read a paper on "Summer Diarrhoea," which was a good one.

**C. B. Creech** said, in discussion, that he kept up elimination for 24 to 36 hours, and he usually gave astringents and intestinal antiseptics.

**J. T. Wesley:** The paper was a good one; These are cases that become very interesting at times. The older authors gave the cause as hot weather, but this has been exploded; the hot weather only favors the growth of the germ, and is not an underlying cause. The disease is of germ origin as all other diseases are, and anything that favors the formation and growth of the germ is a cause, as to the prevention brings us to sanitation. We, as medical men should educate the people as to sanitation, and hygiene, and as the people use better sanitation, we will not meet with so many of these cases. When we are called to these cases we often find the surroundings unhealthy, and we should point them out, no matter how unpleasant. We owe it to the parents and children, but of course we sometimes have to be very delicate about the matter, but we must do it. When we are called to see a

patient we should cleanse the child inside and out. I use minute doses of calomel for its anti-septic and eliminating effects, and diet the child, give pure and fresh milk. We often feed too much. I withhold food for 24 to 48 hours.

Sometimes buttermilk and limewater is good food for these patients.

**C. B. Creech:** In feeding young children cow's milk we must consider the age of the calf. No cow will give an ideal milk for the child, and we have to modify the cow's milk. Take milk rich in cream, and sweeten, dilute with water. One cause of this trouble in summer is because the child gets hold of food that is indigestible, and changes the juices of the stomach and they do not protect the child. Very few germs will live in both an alkaline and acid medium, and if the secretions are normal, they will be killed in either the stomach or bowels. We should instruct the mother in regard to regular feeding. Many a child is made sick by too much feeding. Castor oil is good to follow after the elimination, and is most suitable.

**J. T. Wesley:** These things are very interesting. The cow's milk is not the same at all ages of the calf, neither is the mother's milk at all ages of the child. They are changed as the needs call for.

**C. B. Creech** then read a paper on "Immunity," which was a fine paper.

**J. T. Wesley** said in this discussion: This is a very important subject, and but little has been known until recently. We have known that certain diseases rendered the subject immune from a second attack, but as to how it does it, but little was known, and probably but very little yet. Some other things we have learned; we know that vaccination renders the patient immune from small-pox, and antitoxines for diphtheria. We know that a patient will be immune at one time and not at another.

**C. B. Creech** in closing said: There are two laws, Colles Law, and Profeta's Law. A syphilitic mother carrying a child in the womb, will render the child immune from the disease. A child from a syphilitic father carried by the mother renders her immune from it. The immunity that one enjoys at times is on account of the protective forces being up too far. If all the forces of the body are up to par, we have the power to resist most diseases.

**L. F. Hammonds** then read a paper on "Eclampsia."

**C. B. Creech:** "I think the public should be educated of the fact pregnant women should place themselves under the care of her family physician as soon as she is aware of the fact that she is pregnant. He should examine the urine 2 or 3 times a month the first 4 or 5 months, and once a month thereafter. As to treatment, I have never had any experience, but good authors advise the use of Veratum Viridi,

given with Syrup of Squills, also, the use of chloroform.

**J. T. Wesley:** "They come when least expected. Most cases that I have had came up after delivery. As to the cause, many things have been claimed, as brought out in this paper. I think in a large per cent. of the cases we would find albumin urine, but this is not always the cause, as we sometimes find it and do not have the convulsions. We should look after the premonitory symptoms such as swelling of the limbs, etc. The people should be taught that every pregnant woman should place herself under the care of a physician. I made this statement in a society some years since, and was made sport of by some of the doctors. There are changes during pregnancy, and the doctor and woman should know it, and it should be looked after, especially in the latter months of pregnancy, and by so doing we may ward off an attack. There is nothing more frightful to all present, when everything is moving along nicely, and all of a sudden the patient is seized with a convulsion.

As to the treatment, this may be considered under two heads—prophylactic and curative. Prophylactic commences as soon as the woman becomes pregnant, and continued. Some doctors place a wonderful estimate on one drug, and one on another. Some veratrum, and some morphia, and some chloroform, and some claim no effect from any of them, some bleed, and some claim no effect from it. Some come through without any treatment whatever. I believe a large per cent. will recover. I do not believe any line of treatment will control the convulsions. Some claim the quick delivery is the method and should be done, but my advice is not to be in too much of a hurry, and everything will come around all right. Place the patient under comfortable surroundings and wait a while.

The Committee on Program reported the following:

Disease Due in Pregnancy—Pierce Martin.

Abortion—J. T. Wesley.

Extra Uterine Pregnancy—J. T. Gilbert.

Management of Pregnancy—C. B. Creech.

The society then adjourned to meet in Liberty, on the 28th day of May, 1908.

L. F. HAMMONDS, Secretary.

**Caldwell-Lyon**—The Caldwell-Lyon Medical Society met in Princeton on Tuesday, April 14, 1908, in the Council Chamber of the City Hall, and was called to order at 1 P. M. by the president, J. N. Todd. Minutes of the last meeting were read and approved. The following members were present:—C. H. Linn, and L. P. Mollay, Cuttawa; W. G. Kinsolving, Eddyville; J. N. Todd and J. N. Bailey, Fredonia; W. B. Moore, Crider; Frank Walker, Farmersville; J.

A. H. Miller, C. J. Pollard, I. Z. Barber, W. S. Stone, P. R. Shelby, W. L. Cash and R. W. Ogilvie, Princeton. H. G. Reynolds and H. T. Rivers, of Paducah, were pleasant visitors, and the society was favored by an interesting and thorough paper on "Appendicitis" by Dr. Rivers. After the discussion of this paper, a motion was made, seconded and carried unanimously, requesting that Dr. Rivers send it to the JOURNAL for publication.

**C. H. Linn**, then took charge of the exercises and proceeded with the disposal of the subjects "Abortion and Extra-Uterine Pregnancy" as outlined in the Post-Graduate Course of Study. The discussion proved to be quite interesting and many valuable points were elicited.

**W. G. Kinsolving** was selected to conduct the next monthly meeting, and upon investigation it was found that the date would conflict with the date of the Southwestern Kentucky Medical Society which meets at Paducah, so a motion was made and carried that we meet on the first Tuesday in May instead of the second, in order to avoid interference with the meeting at Paducah. There being no other business to transact, the Society adjourned.

R. W. OGILVIE, Secretary.

**Christian**—The Christian County Medical Society met in regular session in the city courtroom, President in the chair, and the following present:—Wright, House, Woodward, Sandbach, Rice, Gates, Harned, Paine, Backus, Haynes, Petrie, Anderson, Keith, Caudle, Beazley, J. F. Stone and Edwards.

**R. L. Woodward** moved that the society extend a vote of thanks to Senator Rives and Mr. Feland for the part they took in medical legislation in the recent meeting of the General Assembly. The motion passed unanimously.

**J. H. Rice** read a paper entitled "Cancer of Rectum," with a report of cases, which was one of the best of the year, and was freely discussed, the point being made by several that we often overlooked this condition until the diagnosis was forced on us, and an earnest appeal was made by several for closer examinations in all cases. And I believe every member present made a new resolve to do so in the future.

**R. L. Woodward** read a paper on "The Importance of Teaching Hygiene in the Public Schools." This paper, too, elicited quite a discussion, but all agreed that it was one important way of teaching preventive medicine, or the medicine of the future.

**B. A. Caudle** presented quite an interesting clinic in which a diagnosis of effusion into the pleural cavity was made, and proven by subsequent aspiration. There being no further business to come before the society, adjournment was in order. The society adjourned to meet again the third Tuesday in May. Every one went

away feeling that it was good to have been present, and expressing themselves freely that this was the best meeting of the year.

J. PAUL KEITH, Secretary.

**Harlan**—The Harlan County Medical Society met at Harlan, May 2nd, 1908. All the members were present.

**W. M. Martin** read a paper, entitled "The Importance of Consultation." It was discussed by N. S. Howard and W. T. Nolen.

**G. P. Bailey** read a paper; his subject was "The Technique of Mastoid Operation."

W. P. CAWOOD, Secretary.

**Jefferson County**—The Society met in 44th stated meeting at the Galt House, April 13th, 1908, B. F. Zimmerman presiding.

The Executive Committee, S. J. Meyers, C. G. Lucas, and G. A. Hendon, made its report on the application of the Louisville Academy of Medicine to become the Medical Section of the Jefferson County Society as follows:

That a medical section be created; that the Academy of Medicine be amalgamated with the county society and made its medical section; that the section elect its own officers, determine the dates of its meetings and fix its annual dues; that any member of the county society was eligible to membership upon the payment of the section dues; and finally, that the section shall be governed by the county society's Constitution and By-Laws. The report was unanimously carried and the committee directed to report the society's action to the academy's committee for final acceptance. The committee was further instructed to take steps to create a surgical section along similar lines.

The Eye, Ear and Throat Section has already been organized with J. M. Ray, chairman, and S. B. Hays secretary. Its first meeting will be held April 28th, 1908, and will meet every fourth Tuesday thereafter in the Atherton building.

Wm. Jenkins, chairman of a committee appointed to investigate feasibility of obtaining permanent quarters for the society in the Atherton building, read a report covering availability, accommodations and cost of such quarters.

A committee on ways and means composed of L. S. McMurtry, Cecil, and Ray, was appointed to formulate plans to raise funds for this purpose, and also to take the necessary steps to incorporate the society.

This meeting was "Field Day" and a total of eighty-nine was added to the society's membership. This makes the membership 57. There are about 475 eligible for membership in the city and county, leaving about 118 yet sinning. A committee of membership consisting of D. S. Wilson, H. A. Davidson, and Lee Kahn was created to continue the missionary work.

We invite the doctors out in the State to visit us and get a glimpse of a big horizon once.

VIRGIL E. SIMPSON, Secretary.

## PROGRAM.

### PATHOLOGICAL SPECIMENS.

Apparatus for the constant irrigation and drainage of the bladder,

DR. JAS. S. CHENOWETH.

Extirpation of Entire Rectum,  
Excision of half of Inferior Maxilla,

DR. AUGUST SCHACHNER.

Post-Puerperal Pelvic Abscess,  
Carcinoma of the Female Urethra,

DR. L. S. MCMURTRY.

Some Common Duct Stones,  
Pancreatitis,

DR. LOUIS FRANK.

Uterine Fibro-Myomata,

DR. A. M. CARLEDGE.

Intestinal Obstruction due to Carcinoma of the Sigmoid,  
Gangrenous Undescended Testicle due to Twisted Cord,

DR. W. O. ROBERTS.

Meckel's Diverticulum,

DR. J. GARLAND SHERRILL.

Two Cases of Carcinoma of the Intestine,

DR. AP. MORGAN VANCE.

Extirpation of Cancerous Breast,  
Hysterectomy for a Cancerous Uterus,

DR. W. H. WATHEN.

Volunteer Specimens and Clinical Case Reports Invited.

CASES REPORTED BY DR. AUGUST SCHACHNER.

### EXCISION HALF OF LOWER JAW.

Lillian H., age 17, white. Father and mother healthy, family history good, present condition, patient seems vigorous, well nourished, healthy young woman. One year ago had three teeth extracted from lower jaw on left side. Claims that enlargement was of two month's duration, but it is quite evident that in this, she is mistaken. No glandular enlargements upon palpation. The growth almost filled sub-maxillary triangle and extended from within about an inch and a half of the median line to the ramus and very apparent on the inside, pushing the tongue to the right.

*Operation:* Incision beginning in the median line at a point midway between lip and chin, extending downward and backward an inch below the body of the jaw to a point about an inch behind the border of the ramus. Preliminary ligation of the external carotid artery. The lower jaw was divided to the right of the median line by means of a gigli saw and the left half of the lower jaw dissected out. Soft parts readjusted with drainage below the ear. Preliminary loop about hyoid bone after the suggestion of Fenger, as well as loop through tip of tongue. The latter was very useful throughout the first night. Both were removed on the third day. By the fourth day, patient was able to swallow enough to satisfy thirst and hunger. By the eighth day was well nourished by

liquids only. Case referred by Dr. Peter S. Ganz.

*Recovery:* The diagnosis was sarcoma of the lower jaw.

In the Vol. xx, p. 35, Annals of Surgery, Dr. Charles McBurney describes a prosthetic arrangement to take the place of the excised lower jaw. Another description of a similar device can be seen in Archives Klin. Chirurg.

We have found in this and several other similar excisions of the lower jaw that the preliminary ligation of the external carotid to be a very desirable step in minimizing the hemorrhage, which would easily be controlled after this vessel was ligated. We have never practiced preliminary tracheotomy but relied upon the Trendelenburg position. In the use of the latter we would suggest that in the case of old subjects, that the position be not maintained too long. Otherwise, there is some danger of cerebral hemorrhage.

### EXCISION OF THE ENTIRE RECTUM.

Mary C., colored, age about 31. Had been operated upon at different times by other surgeons. When referred to me by Dr. Geo. F. Simpson, there was almost complete occlusion of the rectum. This was such that its extent could not be determined. For sometime prior her food was very much restricted. As the result of this, she was considerably emaciated. In view of the imperfect results of former operations, and the inability to determine the extent of the stricture, it was decided to open the abdomen and inspect from above. This revealed a stricture extending above the levator ani. In view of this, complete excision was decided upon. The bowel was divided at the lower end of the sigmoid. The proximal end was closed and brought through the fibres of the rectus, then across and through the external oblique attaching it externally to the skin. At the end of 48 hours it was opened. The distal end was likewise closed, the vessels ligated, and then stripped downward from the surface of the sacrum to the levator ani. The remainder of the operation was completed from below. The abdominal wound closed. She did nicely for five days. Then she developed several large abscesses, one about the attachment of the bowel, another higher up near the thorax and another below Poupart's ligament. This made the recovery slow and disturbed the abdominal closure sufficiently to permit some yielding at this point. Otherwise, however, her recovery was satisfactory. The bowel control is likewise satisfactory. It is now more than one year since the operation.

The cases for excision of the rectum can be divided into two classes. First, those in which the growth can easily be defined and is located entirely below the levator ani. The second class that cannot be defined or that clear-

ly extend above the levator ani. In the first class they are best approached from below, removing the coccyx and possibly the last piece of the sacrum, bringing the bowel out just a little above its former site. In these cases it is well to follow the suggestion of Gersuny and Gerster to rotate the bowel almost entirely upon its axis, thereby increasing the control.

In the second class of cases, the operation from above as suggested by Abbe, Hartwell, and others, is the one of choice. The advantages are that it not only enables the operator to more certainly define the outlines of the growth, but he is able to determine the possibility of secondary deposit in the liver, which is entirely impossible from below. Furthermore, the operation from above is more radical and less bloody because we attack the blood supply in the beginning of the operation. The objections to an artificial anus in front are based upon sentiment rather than sense.

In the upper operation, the bowel is entirely accessible and therefore more manageable. Furthermore, there is fairly good control through its passage between the muscular fibres, and lastly, and most important of all, the sigmoid flexure is not disturbed as it frequently is in drawing the proximal end of the bowel downward, effacing the curves of the sigmoid thereby seriously impairing its functions as faecal containers.

The extreme Kraske operation one might almost say is obsolete and deservedly so in view of its high mortality, its technical difficulties, the usually extensive hemorrhage, and the absence of control due largely to the absence of muscular fibres and the obliteration of the sigmoid curves which usually arrest the faeces and which now are not arrested in any way after leaving the splenic flexure.

#### DISCUSSION.

**J. G. Sherrill:** Dr. Schachner's case is a very interesting one. I wish to urge one objection to the step he took in operating on the lower jaw. I have done a great deal of surgery on the jaw, and in my early work I frequently resorted to tracheotomy and ligature of the carotid artery. In recent work, however, in both the upper and lower jaw, I have been able to accomplish good results, taking out the superior maxilla and doing the work carefully, without ligating either of the carotid arteries. In the lower jaw it is absolutely useless and unjustifiable to tie the carotid artery. You can tie the vessels as you come to them and enucleate it without any hemorrhage at all.

In regard to the operation for removal of the rectum, I think, in many cases, especially those which are malignant, it is exceedingly valuable to operate above and then below. In 1899 I op-

erated for the same condition upon a stricture of the rectum, in which a clear history of syphilis had been obtained. I did the Kraske operation and found the hemorrhage not difficult to control and an anus posteriorly was effected with the very best results.

I do not agree with Dr. Schachner in regard to placing the anus posteriorly. I believe the patient can more effectually care for the anus in the normal position than in any other portion of the body. In many cases where the stricture is short, where the amount of gut involved is not very long, we can put it back in the natural anus.

**W. C. Dugan:** Just a word in regard to the operation on the lower jaw. I wish to indorse what Dr. Sherrill said about not ligating the external carotid artery. I do not believe this is necessary. If we follow the steps outlined by Dr. Sherrill, we will have very little trouble from the blood getting into the patient's mouth. I have never found it necessary to ligate these vessels in this operation. The only real danger is to the internal maxillary artery where it passes in along by the internal lateral ligament of the jaw, and if you keep close to the bone, that risk is practically nothing, and the only danger is in the disarticulation, and by twisting the jaws and at the same time following the bone its attachment can be overcome without endangering that vessel in the slightest.

I was glad to hear the doctor suggest the use of the ligature in and of the tongue, as it does away with the tendency of the tongue to fall back and at the same time it enables you to draw the organ forward. However, I do not believe it is necessary to leave the suture in for two days, as the doctor suggested. I consider it far better to suture the strings of the tongue to tissue in front or to the floor of the mouth.

In regard to the rectum operation, I heartily agree with Dr. Williams and Dr. Sherrill that we should take out the rectum from below. Where the disease is high up, it might be necessary to make a section in order to inspect, but where you have a carcinoma of small size, it is best to make incision around the anus and preserve the external sphincter. I have had but little trouble in removing as much as eight inches of the rectum. The question of hemorrhage has been much exaggerated. I consider the excision of the rectum much neglected and its application is not limited to carcinoma alone. I don't think much of the Kraske method of rectal operation.

**J. M. Williams:** In 1896 I did my first colostomy. A large cancerous mass and about seven inches of the bowel were removed from below. The aerostic operation was done first, dividing the sphincter muscle at right angles, then dividing the rectum, dissecting it out, bringing it down and suturing it to the normal opening. This patient was an intelligent German, who had gone

the rounds of almost every surgeon in town. He is alive and well to-day, and lives in Germany. When he left here he promised to write to me every year, as I wished to know whether or not the trouble recurred; this he has done and there has been no recurrence. It was a year after the operation before this man had perfect control.

About a year after that I operated on a negro woman, which case I followed up for about three years after the operation and the results were satisfactory up to that time.

I believe the thing to do is to operate from below, and to establish the outlet at the normal anal orifice.

**August Schachner** (closing) I thank the gentlemen for their discussions. I think most of us were a little astonished at the objection made to ligating the carotid. I certainly would not ligate the common carotid, but I would ligate the external carotid. This is grounded on one of the first principles of surgery, which is to always attack a growth from the side of its blood supply if you can. This is a principle that is as old as surgery and is the commonest kind of common sense. By ligating the external carotid you control all the blood at once.

In the second case, I will say that the anus was ulcerated and discharging so that it was difficult to tell what the patient really had. For that reason, I made the remark that what I had to say applied to cancers of the rectum. If the cancer is where you can easily define its limits with the finger, or where it is below the levator ani, there is no doubt that the thing to do is the low operation. If, however, you cannot define the limits of the growth, you have first to determine whether or not there are any secondary deposits, in order that you may know whether to operate at all. If one does the Kraske operation, one cannot possibly determine whether there are any secondary deposits in the liver, and that is what we ought to determine. First, make an abdominal incision and determine whether or not you have any secondary deposits. If you find there are none, then you can attack the growth from above which is also the point of its blood supply, and what is usually a very bloody operation becomes a comparatively clean one.

I still think, gentlemen, that we have only two operations for cancer of the rectum.

#### CASE REPORTS.

**L. S. McMurtry:** As there is such a wealth of pathological material to be exhibited to-night, I shall endeavor to be very brief and not go into details of the symptomatology and operative procedure, but simply exhibit the pathological findings.

The case I present is rather an unusual pathological condition in a very common form of pelvic abscess. This specimen was removed in January, from a woman 32 years of age, white. In

September last this woman suffered an abortion, which I think was induced. After the abortion the woman was seriously ill for several weeks of septic infection, but finally got up and was able to go about, but was never well.

A few weeks later there were marked indications of suppuration in the pelvis, with the usual symptoms of fever, sweats, etc. The physical signs were very well marked. There was a very large mass occupying the pelvic space and the uterus was fixed by adhesions. The patient was very greatly emaciated and was very ill indeed when this operation was performed.

We all know that infections of this kind are, as a rule, tubal; here is the abscess sac, which is very greatly shrunken on account of having been in solution for more than two months. It is a very unusual condition of pelvic pathology following tubal infection.

I have here a kidney which is interesting only from a diagnostic standpoint. This was removed from a spinster, 42 years of age, it having grown very gradually. The urine, upon repeated examinations, gave very little evidence of the true character of the trouble. This patient was seen by several surgeons. We were all suspicious that it was a sarcoma. The abdominal wall was thin and it was very easy to determine that it was the kidney. The age of the patient and the general contour of the growth justified the suspicion that it was a sarcoma. However, the urinary findings did not so indicate, nor did the patient's systemic condition, as the emaciation was not of the marked character characteristic of sarcoma. Upon removing the kidney it was discovered that it was a case of inflammatory disease. There were stones in the kidney and that organ itself had undergone extensive degeneration. This is pronounced by pathologists to be an excessive growth of connective tissue, filling up all the spaces in between the tubules.

**J. G. Sherrill:** The first specimen I have to present was removed from a man about 31 years of age, on January 31st, 1908. In operating for the radical cure of hernia I found a Meckel's Diverticulum attached to the ilium and presenting in the hernial sac, the extremity being united to the sac of the hernia. This mass was almost as large as the ilium itself at that time. It was held so firmly in the hernial sac that I had some difficulty in reducing the hernial contents until I found the attachment and separated it. The diverticulum was cut away and the bowel sutured.

I have another specimen here which was removed from a child two years of age, which was born with an enlargement of the right side of the lip and left side of the tongue. The child grew and the tongue gave it very little trouble until the child hurt it by biting it, after which it became greatly inflamed and increased in size.

It was removed by placing a suture in the center of the tip of the tongue, making strong traction to the left side and ligating the lingual artery where it lies just beneath the mucosa. By cutting out the "V"-shaped piece two slips were left on either side and when these dropped together, the tongue was very nicely shaped.

The child made a good recovery, although some difficulty was experienced in keeping the mouth clean. At the present time there is no evidence of recurrence of the growth. The growth has been pronounced by pathologists to be an angioma.

**W. O. Roberts:** The first case I wish to present to-night is one of cancer of the sigmoid. I report this case because of the fact that there were no symptoms until two or three days before the patient was operated on. This was a man, 66 years of age, who told me he could not remember having a spell of illness, and that he had had very little trouble with his bowels, seldom having to take a purgative.

On a Thursday, in the early part of April, this man came home complaining of pain in the abdomen and said his bowels had not moved for forty-eight hours. His wife gave him a dose of oil, and, later, an enema, but neither had any effect. When I was called I gave him an enema and waited to see the result. He passed a considerable amount of liquid fecal matter. He then said he felt more comfortable. I gave him another dose of oil and saw him again the next day, and found that his bowels had responded a second time to an enema, but he was still very uncomfortable. Although there was considerable pain, there was no distension of the abdomen, no vomiting, and no elevation of pulse or temperature. This was on Friday. I saw him again on Saturday, about noon, and found the abdomen somewhat distended, and there had been no action of the bowels. Upon examination of the rectum I found it to be empty. The pain was general, not localized. I advised immediate operation and the patient was removed to the infirmary, where I opened him.

In the sigmoid I found that he had a malignant growth, which was removed, and the lower end of the descending colon was attached to the tumor in the left side. After removing the growth the opening was so small that I could not get my little finger through it, and in it was a lump of hard fecal matter.

This is the second case of acute obstruction, due to malignant disease of the sigmoid, that has come under my observation, the first being a case which I saw in consultation with Dr. Matthews. The patient, a man, weighed nearly two hundred pounds. He gave no history of any previous trouble with the bowels, and in this case we also found a cancer of the sigmoid.

The second specimen I have to present was re-

moved from a child, six months of age. The child was brought to me from a neighboring town in Indiana, with the history that, two days before I saw it, while the child was having an action of the bowels, it went into convulsions. The doctor was sent for and he discovered in the left groin a tumor which he took to be a hernia. He also found that the testicle on that side had not distended. He gave the child an anesthetic and attempted to reduce the supposed hernia, but was unsuccessful. The next day, when the child had another movement of the bowels, it again went into a convulsion, accompanied by vomiting. When I saw it, on the second day after the first attack, the enlargement in the groin was about the size of the end of my thumb and exceedingly sensitive to the touch, and the child lay with its limb drawn up. The bowels had moved that morning; this was about the middle of the day. I advised immediate operation, which was carried out. When I got down to the testicle I found it to be perfectly black. There was no hernia accompanying it.

In looking up the literature on the subject, I found a paper by Dr. Scudder, published in the *Annals of Surgery* for August, 1901. He says about 88 per cent. of these cases of twisted cord with gangrene of the testicle, result fatally. He reports 32 cases in which this condition had existed: in 31 operative interference was resorted to, and one was not operated on. All of them recovered. In six cases the testicle was not removed and in three of these it sloughed; in two, the testicle became atrophied. The symptoms of the condition are almost identical with those of strangulated hernia. The testicle swells, or hemorrhage occurs into it, and gangrene quickly results. In about one-half of the cases reported the testicle was either entirely undescended, or had only partially descended.

**Dr. W. H. Wathen:** The history of the case which I will present to-night is, briefly, as follows:

This gentleman first presented himself to me about four and one-half years ago, having come from a town about sixty-five miles from here, five miles of which he covered in a buggy. Upon his arrival here, he walked from the train to a carriage, then from the carriage to my office, back to the carriage, in which he was taken to the infirmary, and then through the halls to his ward.

On the preceding afternoon, about three hours after having eaten an ordinary meal, he suffered an attack of severe pain, which had continued up to the time I saw him. His abdomen on the right side was board-like. He was operated on about one o'clock in

the afternoon, just twenty-one hours after the sudden pain began.

When the abdomen was opened, probably half a gallon of yellowish green fluid escaped. There was no appendicular trouble, nor was there any indication whatever of acute inflammation of any part of the peritoneal cavity. Upon pushing the ligament away so I could see the stomach, I found an opening there about the size of a goose-quill. No food could be found in the peritoneal cavity, having apparently been washed out through the pylorus before rupture occurred. The tissues were thickened from chronic induration.

When the operation was performed the patient's pulse was practically normal and his temperature was but little elevated. He made an uninterrupted recovery, suffering no more pain and his temperature going only one degree above the normal, and his pulse was never above 75. He now feels better than for many years, drinks all sorts of liquids, eats milk toast and bread, and apparently has no trouble whatever from the passage of food from the stomach into the duodenum. Had I seen him at the beginning, I would have done gastro-enterostomy, attaching the stomach to the upper part of the duodenum, so that the food might go at once into the bowel without making the circuit of the duodenum, but I saw him so long after the attack that I deemed this inexpedient and the result proves the wisdom of the plan carried out.

This man tells me that for seven or eight years he has suffered with pain in the abdomen after eating, but has never vomited, either before or after eating, and has never vomited any blood. The operation showed that chronic ulceration of the pyloric end of the stomach had existed for a long time, culminating in this sudden rupture.

Report of the 54th stated meeting, Galt House, April 27, 1908:

Chas. W. Hibbitt, vice-president, presiding.

This session was devoted to a discussion of relations now existing and those which should exist between doctors and druggists. The retail druggists were the guests of the society and their representatives read essays. Counter-prescribing on the part of the druggists and promiscuous proprietary prescription writing on the part of the doctor were both justly condemned.

The society extended its courtesies to the following visitors: J. N. McCormack, Richmond, and A. T. McCormack.

The society voted to take up with its members the question of subscribing for but one telephone in their business. The Cumberland phone has recently raised its rates to \$8.00 per month, and the Home Company is preparing to raise its rates to \$7.00 per month, making a cost

of \$15.00 per month for office telephones. This, added to the combined cost of maintaining two residence telephones makes a cost almost prohibitive for men whose incomes are confined to the practice of medicine.

A committee of thirty was appointed to present the resolutions to the doctors for their signature and to report at the next meeting, May 11th.

VIRGIL E. SIMPSON, Secretary.

THE PHYSICIAN AND THE PHARMACIST.

BY W. S. ENRICH.

I would have felt more at home in discussing a topic along scientific lines, and I so stated to your chairman when accepting your invitation to be here this evening. What was my surprise when he replied: "You're all right, Doctor, just give them a nice little jolly. You're a crackerjack at saying nice things and that is the kind of stuff we want." Gentlemen, let me say right here, that I am not going to dispense any hot air, but I am going to speak right out in meeting and call a spade a spade. If my remarks strike home to some of you and I am able thereby to place the ethics of our respective professions on a higher plane, then my labors will not have been in vain.

I am glad that I count as a friend every druggist, it has been my pleasure to meet, since I became an adopted son of Kentucky. And since it is the prerogative of friends to criticize and to also stand criticism, I now claim that privilege. And should the coat fit you Mr. Physician or you Mr. Druggist, put it on and button it up tight.

First, are the physician and the druggist dependent upon one another? I am now speaking of the retail druggist. The question may be answered negatively or positively, but I prefer to consider that while for convenience to the physician the druggist is the greatest factor, still the physician can do without the druggist and the druggist without the physician.

Since the creation, food has been required to sustain life, and since Adam and Eve were driven from the Garden of Eden, clothing has been considered a necessity by the vast

majority. In primitive times man supplied his needs without the aid of his neighbor. He reaped with tools made by his own hands the harvest he had sown; the game and fish he ate were obtained through his own skill; he and his family were clothed with products of their own gathering and manufacture, and the hut in which they dwelt was the result of his own handiwork. There was no barter, no exchange, no division of labor.

But in pursuing these occupations, it became apparent that one man could do one thing better than another, and that his neighbor could perform a different labor better than he. This led to a realization of the fact that the faculties which men possess are not equally divided among them. The result was division of labor.

The needs of men were few and simple in that distant age and were crudely satisfied. It is probable that the first separation of classes was into hunters and fishers, each however, still tilling the ground for himself. With advancing intelligence, man discovered and adopted new foods and clothing, and welcomed luxuries which later became necessities; thus his wants increased and a further division of labor was the natural result. These changes and diversifications have continued until the present day and will continue as long as civilization continues.

The terms Druggist and Apothecary are used synonymously in this country, but in England the term Apothecary is applied to a general practitioner in medicine who supplies drugs to his patients. From early records we learn that the different branches of the medical profession were not regularly distinguished till the reign of Henry the Eighth, when separate duties were assigned to them and peculiar duties were granted to each. But, independently of the physicians and surgeons, there were a great number of irregular practitioners, who were more or less molested by their legitimate rivals, and it became necessary to pass an act in 1543 for their protection and toleration. As many of these practitioners kept shops for the sale of medicines, the term "apothecary" was used to designate their calling. But in 1843 Parliament passed a law that although an apothecary might have the right to prescribe drugs, yet his duties were more as an assistant to the physician and that he should thereafter act in conjunction with him. The laws of this country provide that only a licensed physician shall prescribe. And only a licensed pharmacist shall compound the prescription. There is not any doubt but what there is sufficient room for each of the respective professions without either usurping the rights of the other.

The physician while it is a great conven-

ience to write a R, could, in this day of tablets, triturates, alkaloids and other conveniences, dispense his own medicines and, in fact, many especially in the East, do so. Should the physician be too busy for such work he can easily train an assistant to do this for him. On the other hand the druggist by selling his toilet articles, patent medicines, etc., can make a living as legally as any other merchant who sells the customer what he asks for, provided that something is not under the ban of the laws of the country.

But for the benefit of the physician, pharmacist and public it is better that we should work together and should join in stamping out the various evils that work to the detriment of both professions and in many instances jeopardize the public. I frankly admit that I live in a glass house and should the stones act as a boomerang and break my windows I could not complain, but being a physician I will also take my own medicine. But as the pharmacists are our guests, courtesy demands that I attend to their case first and the physicians later.

The most dangerous and pernicious fault I find in my brother of the Mortar and Grindstone is the damnable habit of counter-prescribing. And I can assure you that this works far less injury to the physician than to the victim. Barring the illegality of this, is it fair to the patient? Has the Pharmacist knowledge of the etiology, pathology and symptoms of disease to enable him to make a correct diagnosis of the case so that he can remove the cause of the disorder if such a thing is possible, and to handle the case. If he has he certainly did not get that knowledge from any of the schools of pharmacy that I have investigated. If he has a sufficient knowledge to practice medicine then he should choose either one profession or the other as no man can serve two masters well.

For example: Mr. — conducts a pharmacy, but barring a few G. U. specialists, has probably the largest practice of this kind in the city. His method is as follows: When the victim arrives he gets some of the secretion or urine; places this on a marble slab and pours something over it. If it effervesces the patient has gonorrhoea. And in no case that has come under my observation has effervescence failed. Treatment is now begun—how I do not know, but I have had several chronic cases that had previously been treated by him, and the patients have my deepest sympathy. Nor is this all. I understand he does minor surgical operations and still worse, having secured possession of a red cross button he poses as an M. D., and G. U. Specialist.

Another interesting case that I have seen was that of a girl in the last stages of con-

sumption, who replied when asked who had treated her previously: Dr. — (a druggist) who she said gave her some medicine that stopped her cough and made her feel good. That girl now lies in her grave, a fitting monument to the practice of counter prescribing.

I recall a case of erysipelas of the scalp, where the patient, treated by the same man. This victim afterwards became so sick that he was obliged to send for a physician. I have asked several druggists why they prescribe and the answer has invariably been the same, "Well if I don't the other fellow will and I lose the sale." Now this puts it up to the physician to try and recompense the man who honestly tells his customer that he does not know what is the matter and refuses to drug him.

My opinion is that a physician should forbid his patients taking his R's to druggists who prescribe, because they are illegitimate competitors of both the physician and honest druggists. And by telling the patient that even though the counter prescriber charges less, that he is not honest, will bring good results. This doctrine will go a long way towards stamping out the pernicious evil of counter prescribing.

In regard to the matter of substitution, I do not think that there is as much of that today as formerly. The druggists, especially those who have large establishments, cannot afford to jeopardize their business by so doing. As exposures of this kind, I am sure, would kill any druggist, mean enough to stoop to such a practice.

I believe that such a thing should and I know would as far as I am personally concerned would be given the widest publicity in both the lay press as well as the medical journals.

One more point before I turn my attention to the physician, and that is the habit that some druggists have of criticising prescriptions, before those who bring them in to be filled. I was told recently by one of my patients who had occasion to go into a certain druggist's to have a prescription filled that the clerk made the remark that Dr. X., was a corker at writing prescriptions, that he wrote a beautiful R. but that Dr. Z., ought to be out on a farm hoeing potatoes. Now I presume Dr. X., probably sent a great many more prescriptions to that druggist than does Dr. Z., who may have patronized another pharmacy, but even so there was absolutely no need for the clerk to shoot off his mouth as he did. And if Dr. Z.'s R. was so terribly ambiguous the clerk should not have filled it. Nevertheless the evil was done by this two-spot clerk, although Dr. Z., probably did not deserve any such treatment.

Now what is good for the goose is also good for the gander. Mr. Physician do you think that you are giving the druggist a square deal when you dispense a dose of medicine? You certainly are not as you are simply depriving the druggist of a sale with the profit that is due him.

You know that when you dispense samples to your patients which have been left you by detail men you are not acting on the square. In the first place even if the medicine is what the patient needs it should be prescribed and not given to him. The patient will derive a better mental and physical affect from it if he has to pay for it. And he may also doubt the wisdom of the doctor if he sees that it is a sample. Gentlemen, the pharmacist is not in the business for his health any more than we are.

Now concerning our R's. About 60% of all R's seen in any drug store contain one or more proprietaries. Now I do not want to be misunderstood I do not object to using a proprietary provided that drug passes the requirements of the A. M. A., but I think we can here do a greater injustice to the pharmacist than almost anywhere else. We have the U. S. dispensatory and National Formulary to select our mixtures from and if the physician will bear in mind that the modern druggist is not a mere roller of pills but a man of science and should be treated as such then the big drug firms would cease waxing fat and our local pharmacists would be spurred on to take a pride in each mixture and would not have as much time to do their own prescribing across the counter.

Another place where the physician breeds trouble! Some physicians estimate the price of the prescription. As a matter of fact the physician does not know any more about that than the Pharmacist does about the pathology of disease. And he should let the pharmacist whose business it is to sell it make the price.

I have taken up a great amount of your time, perhaps more than I should have, but we all know that a man's life is full of crosses and temptations. He comes into this world without his consent and goes out against his will and the trip between the two is exceedingly rocky. The rule of contraries is one of the features of the trip. When he is little the big girls kiss him and when he is big the little girls kiss him. If he is poor he is a bad manager, if he is rich he is dishonest. If he needs credit he can't get it, if he is prosperous every one wants to do him a favor. Yes, the road is rocky, but man loves to travel in and after all there is a good deal of satisfaction especially, if we give each other a show.

THE RELATIONSHIP EXISTING BETWEEN THE  
PHYSICIAN AND PHARMACIST.

BY ADDISON DIMMITT, PH. G.

When Mr. Simon Jones, Chairman of our local Druggist Association, requested me to write a paper to be read before your Society on "The relationship existing between physicians and pharmacists." I demurred, not that I did not appreciate the honor of being selected, but because of the fact that my position is a dual one, I being both a retail druggist and a manufacturer of proprietary remedies. I told Mr. Jones he had better have some other member of our association defend the position of the retail druggist, as my defense might not be complimentary to some and he said that was the reason he wished me to write the paper as he wanted to bring out all points in the discussion, both pro and con; in other words, wanted a full confession of our faults. The physicians, no doubt, will do the same; then with mutual assurances of assistance and good will we shall try to correct all misdeeds and start anew. With that understanding, I respectfully submit for your consideration the following paper.

This subject has many angles and may be treated from the professional, the business and the social sides. Having talked to some of your members, I know we are going to hear some plain, unvarnished truths from the physicians of this "relationship," so I will forestall them somewhat by starting with a self-indictment of the druggists.

We are going to hear evidence that some druggists substitute, some counter-prescribe, some are incompetent pharmacists, while others advertise and push the sale of patent medicines and nostrums.

To the first charge—that some druggists substitute, I answer, we know only too well that this disreputable practice does exist among a certain class of druggists and do not hesitate to say it degrades and dishonors them. A physician in good faith writes a prescription for a drug indicated; his patient, in perfect confidence goes to a druggist to have it compounded, and the druggist, without conscience and impelled by desire for money, proceeds to dispense some inferior substitute. What is the result in most instances? The patient does not get the relief anticipated by the physician, but continues to suffer and has paid for something he has not received. The physician's reputation has been impaired, possibly he may lose a patient or a family practically, and all due to substitution by the druggist. My personal opinion is that such an act is thievery, pure and simple, and should be a felony in law. These druggists try and exense themselves by saying that the substitute is just as good. You,

as physicians, know better, as do all honorable druggists. Again, has the druggist any moral right to assume that he knows better than you what you want to use? Could we stand up before this representative body of physicians and defend one who thus dishonors our profession? No, but on the contrary, representing the element in our profession which aims to do an honest business, I say we want to go on record before you as maintaining in unmeasured terms, such a practice. As corroborating evidence of the intent and efforts of our city and state organizations along these lines, we can show that we have, year after year, by argument and resolutions, tried to stamp out such evil; for we know full well that the profession of pharmacy cannot command the respect and confidence of the medical profession unless we win it by our merits.

As further evidence of the efforts on the part of the druggists to correct this condition, I would remind you that at the last meeting of our state association we endorsed the National Pure Food and Drug Law unanimously and instructed our legislative committee to use the full influence of our state organization, as well as all of our available funds, to further the passage by our state legislature of a law governing pure foods and drugs, and it is a source of pride to us that we can say to you to-night, that our legislative committee drafted in its entirety, that part of our State Pure Food and Drug Law pertaining to drugs and even went further than the National Act by adding a most stringent section governing substitution. As the law now stands, it is considered, by persons familiar with such legislation and by both medical and pharmaceutical journals, as having the strongest section bearing on substitution, mis-branding and adulteration of any similar law in the country. It will be used as a model law by other states. I cite these facts to show that the better element of druggists in our city and state are earnest in their efforts to help elevate our profession to a higher plane and we believe this law will aid us by purging our business of this stain upon it.

It may be of interest to the physicians present to say that after the pure food and drug act had been drafted and was ready for introduction into the legislature it was closely inspected by a number of physicians, and nothing but words of commendation were heard from them.

Even the Secretary of your State Board of Health, Dr. J. N. McCormack, who has abused

the druggists for every crime in the calendar\* and from one end of this country to the other, had no adverse comments to make. How great must have been his surprise and how difficult for him to believe that the druggists themselves would draft and secure the passage of a law that carried such rigid requirements and heavy penalties against their own profession and at the same time was absolutely fair as to the method of enforcement. This law will become effective January 1st, 1909. It carries an annual appropriation of thirty thousand dollars for its enforcement, so it will only be a short time until the state food and drug inspectors will be among us, then the black sheep, the substitute, will be shown in his true colors. So much for substitution.

Apropos of this subject, however, I call your attention to the editorial columns of the Journal of the American Medical Association under date of March 21st, where the editor, by inference, does the druggists of Kentucky an injustice by referring to the excellent pure food and drug law of Kentucky having been passed by the combined efforts of the Kentucky State Medical Association, State Board of Health, State Pharmaceutical Association, Board of Pharmacy and the State Federation of Women's Clubs. It further says great credit is due not only to the physicians of Kentucky but also to the layman, in other words, there is apparently an intention on the part of the editor of the Journal or its correspondent in Kentucky, not to give credit for the enactment of this law pertaining to drugs, where it properly belongs. The Kentucky Pharmaceutical Association.

The writer who was in all conferences of the legislative committee of the Kentucky Pharmaceutical Association, where this law was drafted, and afterwards met with the State Experimental Officers to arrange to combine it with the other sections of the law, does not know of a single physician having any connection with it. Dr. McCormack did, after we had the law complete, suggest to the chairman of our legislative committee one amendment as follows,—“that no prescription shall be knowingly refilled except for the person for whom it was written.” and our committee readily agreed to same and had it inserted.

As to the second count of the indictment,

\* Address before the American Medical Association, Atlantic City, June 3-7, 1907.

Address before American Pharmaceutical Association, New York, Sept. 7, 1907.

The Union Signal, Nov. 9, 1907, Official Organ W. C. T. U.

Address at Towson, Md., Nov. 26, 1907.

The Apothecary, Nov. 1907.

that of druggists counter-prescribing, we will have to again plead guilty, but in many cases plead extenuating circumstances. I deeply regret to say that some druggists, loving too well, the almighty dollar, lose sight of the right and wrong side of such practice and unhesitatingly prescribe for any kind of ailment, knowing full well that they are not educated or qualified to diagnose and treat diseases. Then again, they do not seem to realize the fact that if they advise a person to see his physician, they are not only doing what is right by the customer and physician, but do not assume any responsibility for the action of the medication. In most instances the physician to whom he refers the patient usually writes one or more prescriptions, which the customer naturally brings back to the druggist, and from a monetary standpoint, the profit to the druggist on the prescriptions will be far greater than if he had given the customer some simple remedy for his ailment.

Counter-prescribing, as I said in starting this section, has its variations. When does a druggist counter-prescribe, is the question? From my standpoint, it is when a person comes into a drug store and tells the druggist his back aches or his head aches or pains in various parts of his body, without specifically stating his trouble, then if the druggist proceeds to question him and gives him medication it is counter-prescribing pure and simple, but when a customer diagnoses his own condition and asks the druggist for a remedy for headache, backache or stomach, and the druggist sells him some remedy recognized for such ailments, I question if this can be called counter-prescribing. In these I am referring to minor ailments. If a customer wants a remedy for gonorrhoea, syphilis, tuberculosis, fever, etc., the druggist has no moral or legal right to attempt to prescribe for him, but on the contrary, should try and impress the person with the necessity of going to his regular physician to be treated scientifically and properly, for by doing so it might save him from serious illness and expense. If the customer has no regular physician then it is optional with the druggist to whom he sends the patient. He usually refers to some physician or physicians who have been friendly to him in business. (This is reciprocity, I believe) but under no circumstances should a druggist try and divert a patient from one physician to another; on the contrary, the druggist should always speak well of the physician whom the customer has formerly employed and encourage his confidence in him.

In this connection I admit that irregular things will sometimes creep into any one's business even though every precaution is

taken to avoid them. In my own place of business, where we have tried faithfully and conscientiously not to counter-prescribe, I found, only a few days ago, one of our clerks had prepared and sold a gonorrhoea wash to a customer. He was a new clerk and had not listened to and followed closely the instructions given him by us. He told me he had been in the habit of doing such things in his former position. Then again sometimes a druggist is placed in an awkward position by a customer. I can cite a case that occurred in our place recently—a young lady, a patient of Dr. O. E. Bloch, also a customer of mine, had some acute throat trouble and seemed to be suffering intensely. She came to me, wanted me to look at her throat and give her something for it. I did not do so, but insisted that she should see her physician. This she tried to do but it was impossible that evening to see him as he was busy with some serious case elsewhere. She came back to me and insisted on my giving her something. I asked what she had at home in the way of a gargle or spray and she said listerine. I then suggested that she gargle her throat frequently with that and keep up the quinine which she was taking and in the morning go and see Dr. Bloch. This she did and we promptly had prescriptions to fill for the lady. Now suppose that young lady should have said to Dr. Bloch that we had prescribed listerine and quinine for her without any further explanation. Dr. Bloch would naturally think it was another case of counter-prescribing, when the truth was we did all we could to have the lady go to the Doctor. I cite this to show how easy it is for a physician to be misled sometimes about druggists counter-prescribing.

Both our city and state associations have discountenanced such practice and we are pleading continually with the members of our profession not to include in it. As a method of stopping it effectually, I suggested to Dr. McCormack that if he would have their attorney make up a few cases against druggists for the illegal practice of medicine it would probably put an end to it. But so far I have not heard of this being done. So much for counter-prescribing.

Now for the third charge of the indictment: Incompetency among druggists. Yes, strange as it may seem, even in our profession there the incompetent men are found as among physicians and every other profession. There are good, bad and indifferent druggists and the natural result is that each class soon seeks and finds its own level. If a druggist demonstrates to the physicians with whom he comes in contact that he is competent and honest, his worth is invariably recognized and

he is favored by them, if on the contrary, he proves incompetent and dishonest, the physicians, for the sake of protecting their own interest as well as their patients, will not permit their prescriptions to be filled by such a druggist, which is the only proper course for them to pursue.

Just as we see in all other callings, there are some druggists who have little education to start with and possibly no natural ability, yet by some hocus-pocus they break into our profession. But fortunately the standard of education necessary to become a pharmacist in this state is becoming higher each year. The writer who has been on the examining committee of the Kentucky Board of Pharmacy for the past ten years, is in a position to know this to be absolutely true. We examine an average of about 150 applicants each year, with about 40% passing; in other words we refuse license to two out of every three that come before the board.

Now for the fourth and last indictment, druggists endorsing and pushing patent medicines and nostrums. Yes, some do this but I am glad to say there are only a few who will permit their names to be used in the daily press guaranteeing and endorsing all kinds of cures for every ailment under the sun. The majority of us do not countenance this recognizing the evil of endorsing any remedy that we do not prepare or know absolutely its ingredients and any endorsement, even if limited to the statement that we believe it to contain just what is claimed for it, is thoroughly unethical and those that permit their names to be used or speak for such remedies, care little for the customer who buys it, and evidently less for the good will of the medical profession. In making this statement, I believe I voice the sentiments of the larger and better part of our profession.

As to druggists preparing and pushing the sale of proprietaries, this I will not avoid, but am ready to present my side of the question although it differ radically from the view of many druggists and some physicians.

In speaking of this subject I will quote from an article I read last June before the State Druggists meeting covering this point. I believe every physician and druggist who gives thought to this subject is fair minded enough to recognize that the legitimate proprietary preparation has its field. I am not speaking of frauds, impositions or cure-alls, but, only such products as have proven their worth. It is due to the pharmaceutical specialist of this country that a great many of our most valuable remedies and combinations have been placed before the medical profession, and it is also due to these same specialists that the National Formulary gives you similar combinations, as a large percentage of

the formulas contained therein were suggested by proprietary formulas. From another standpoint, if there had been no incentive to the pharmacist or chemist in the way of profit to originate these proprietaries, they would never have been placed before the medical profession, nor would we have similar preparations in the National Formulary. Therefore you must admit that proprietaries have accomplished some good by originating and developing new remedies and combinations which represent progressive and advanced pharmacy.

The study of medicine covers a wonderful and inexhaustible field. Its ramifications are endless; specialism is the order of the day, and why? because each specialty is an immense field within itself. It has become impossible for the physician to master all the details and technique of the entire subject. Therefore, if he chooses his line of work in the field of medicine, his time and mind will necessarily be completely occupied with it. Pharmacy is one of the branches of medicine, part and parcel of it, as much as surgery or any other specialty.

We represent the specialty of pharmacy in medicine with the distinction of having the material or trade interest connected with it. In other words, if the pharmacist must depend for a livelihood on the product of his mind and hands in *materia medica* while the physicians' livelihood depends on the application of their knowledge of the science of medicine to the subject and their fees increase in proportion to their increase of skill and usefulness, why then, on an equitable basis, are not pharmacists entitled to be remunerated for their special work? I mean when this work is honest and proves its value. I can see no reason under the sun why the manufacturer of a legitimate pharmaceutical specialty or proprietary should be condemned in unmeasured terms for using his knowledge to benefit mankind.

In an address by Dr. Geo. Dock, of Ann Arbor, Mich., (who, by the way, has lately been appointed by the American Medical Association on their staff of Clinical Consultants,) before the section on Practice of Medicine of the American Medical Association, Boston, June 1906, he says: "How to secure the really valuable new remedies is the problem now before all therapeutists. Repression by force or by enactment can never serve against such a condition. The right to investigate, to discover, if wished for, to patent new remedies, need not be curtailed. Authoritative bodies, governmental or otherwise, can do much to assist in determining the status of such products: but the final verdict must come from the great body of practical therapeutists, the physicians in actual charge of

sick people. Such a body as the Council on Pharmacy and Chemistry of this Association may perform an important function in making impartial examinations and reports on new substances of obscure compositions; but it can not determine whether or not such substances shall be used. The American Pharmacologic Society can also carry on an equally valuable work in making further tests; but no such body can be depended on to disclose all the good things and repress the bad, and just as far as it prevents the development of the spirit of responsibility and of criticism on the part of the physician will it do harm. Medicine has never been successful when bound down by tradition, schools and authorities. It has only flourished when it made use of every resource science or chance can bring whether the cinchona bark of the savage, the hydrotherapy of the peasant, or the synthetic compounds of the university professor testing all things, holding fast to the good."

But in deriding the legitimate proprietaries, I do not want to create the impression that I am depreciating the value of the U. S. P. or N. F. Preparations for, on the contrary, I think they have many advantages, and believe if the physicians will adhere as close as possible to their formulas it would be much better for all concerned, but I wish to go on record as protesting against the indiscriminate abuse of proprietaries.

Webster's definition of the pet word "Nostrum" so frequently used by persons abusing proprietaries, is "a medicine, the ingredients of which are kept secret, a quack or patent medicine." It is therefore manifestly unfair to class legitimate proprietaries whose formulas are laid bare and may be verified by the medical profession, with quack or patent medicines as "nostrums," etc. I would go further into this branch of the subject, were it not that you will hear from other members of our association on the subject of U. S. P. and N. F. products.

Now that we have pleaded guilty to a number of offenses, but claim some extenuating circumstances, I will try and outline some of the grievances the druggists think they have against physicians.

One of the greatest evils with which druggists generally have to contend, though I am glad to say, speaking from a local standpoint, this does not exist to a great extent, is self-dispensing by physicians. The absence of this deplorable custom here reflects great credit upon the intelligence of our medical profession, for beyond the question of a doubt, self dispensing by physicians is a retrograde movement and there is nothing to commend it. Nevertheless, for the benefit

of those who do dispense their own drugs, we will point out some of its worst features.

First, I contend that the average physician knows little of pharmacy. Where is he taught to prepare, compound and dispense medicines? Not at the medical college from which he graduated for, as I understand it, they do not attempt to teach practical pharmacy. The study of materia medica and chemistry in the schools of medicine is confined almost entirely to the therapeutic action of drugs, not to their physical identification, component parts, process of extracting their active principals, tests for purity, solubilities, incompatibilities and the hundred and one details which make up practical pharmacist's business. What is the result? When a physician starts to dispense his own drugs he has no recourse but to rely on the ready-made hand-me-down, and as a rule, cheap line of tablets and replacers, which, in many instances, by reason of the slow consumption of them by the one physician, become inert. This is due in liquids to precipitation of the effects of light and heat, while in the tablet form, which in most instances contain a dilutant of sugar of milk which, when exposed to air loses its water by crystallization, they become so hardened that it resists all solvents. Then again, if the tablet contains metallic salts, such as the mild chloride of mercury, it will, in presence of sugar and of alkali, be reduced to oxides.

As to the non-therapeutic effect of the tablet which has become hardened, I will quote in part from a paper written on "Aesthetic Medication" by the late Dr. I. N. Love, of St. Louis, who says: "The excipient necessary often hardens and renders the remedies indigestible, and they themselves may disturb and sometimes cause dangerous conditions; or if the vigor of the digestive canal is impaired, as it is in nearly all diseases, but particularly in typhoid fever, malaria and other infections, and when the tone of the nervous and general system has been lowered from any cause, the remedies may pass directly through the alimentary canal and their entire medical effect is lost. We thus lose valuable time, and sometimes I am sure lives have been sacrificed by this deceptive treatment, owing to the failure of the patient to receive and assimilate the remedial agent in the form intended.

Dangerously accumulative doses have sometimes resulted from giving powerful medicines in hard tablets slow to dissolve, and these have come together at some one point in the gut and been detained there, when a sudden dissolution and absorption of the mass occurring would overwhelm the patient hopelessly."

Now a word about replacers; they are usu-

ally base and cheap imitations of well known proprietary preparations. Their sale to the physician is accomplished by the manufacturer's representatives, who boldly assert that the preparation is the same as such and such a preparation and the principal reason for its purchase by the physician is that it is cheap. This kind of business is piracy in its truest sense and the physician who countenances it, is encouraging the very thing for which he condemns the druggists, substitution.

Now the worst feature, and the one which almost every dispensing physician admits to be true, is forcing his diagnosis of a disease to fit his drugs. This necessarily follows, since it is practically impossible for such physicians to carry in their offices a complete line of medicinal agents. What is the result? After a careful diagnosis, the doctor recognizing what drug is indicated, turns to his stock of medicine and finds that he is out of the agent best suited for the purpose. He then takes a chance with something else he happens to have. It may or may not do any good. It is also impossible for dispensing physicians, even if they be competent, to prepare many active agents which should only be prepared as they are needed, such as infusion of digitalis, spirits of mindercrus, diachylon ointment; in fact, I could name many which are absolutely worthless unless they are freshly prepared.

The rational conclusion to my mind is that it is decidedly inimical to the interest of the physicians, his patient and the pharmacist for him to dispense his own drugs. What a great advantage it gives the physician to have before him the entire materia medica from which to select his medication? He can then prescribe what is indicated, tell his patient to take the prescription to a reliable pharmacist, who by virtue of education and experience is competent to properly and accurately compound and dispense it.

I appeal to all right thinking physicians to lend their aid to stamp out this custom, which is detrimental to both physician and druggist and detracts from the dignity of the practice of medicine. I wish to qualify my remarks on this dispensing section by saying they do not apply to hypodermic tablets or other articles that a physician necessarily has to carry for emergency or office work.

Another complaint I have heard from a few druggists is that some physicians come to them for medicines buying on their own account for which the druggist usually charges cost, then supplying same to their patients, even when they are not charity cases. Do you think this is right? Again, some physicians have a habit of telling their patients what a prescription will cost them.

Is this just? Do druggists ever attempt to fix the fee a physician charges? It is also known that physicians write on prescription blanks for ten cents worth of tincture iron or phosphate of soda and gives it to his patient unsigned. Do you believe that is ethical? Then again, speaking of dark deeds, I know beyond a doubt of instances where several legally qualified physicians of this city have for a fee of fifty cents written prescriptions for cocaine for strangers. This was developed when we were trying to stop the criminal use and abuse of cocaine last year and was promptly reported to the board of health, who read the riot act to them and it was stopped.

Another point I would like to speak of is the legibility or illegibility of physicians' writing and their abbreviations in prescriptions. A druggist is frequently in a dilemma trying to decipher them and particularly is this true when we are not familiar with the physician's handwriting. Then again, when the directions on a prescription are not specific we are embarrassed by the patient asking how it is to be taken or used. We generally say "Did not the Doctor tell you?" their answer is "Yes, but I have forgotten" and they then insist that we should tell them and while we know the average dose or method of application, yet what we tell them may differ radically from what the physician intended and if we refuse to give them directions they conclude that we are ignorant and do not know our business.

Now a few suggestions to my fellow druggists: Never criticise a prescription in the presence of the patient. If there is anything wrong with it, *don't look it*, but tell the patient it will require some time to prepare it and they can call later or you will send it. If they insist on waiting and you have to reach the physician who wrote it, don't phone in the presence of the patient but go to a neighboring phone. Don't by word or action do anything that will create mistrust or suspicion in the mind of the patient. If the delay is due to a mistake or an oversight, incomplete prescription or an incompatibility, when you consult the physician he will gladly correct it and his confidence in you is materially strengthened.

As to your personal relationship with physicians, when you meet them socially or when they come into your place of business, be courteous and attentive, but do not gush and try to bestow upon them everything you have in your store. This is distasteful to most of them and savors of the idea that you are trying to bribe them. If they wish to do you a courtesy, charge them as near cost as pos-

sible; they are entitled to this and appreciate the concession you make.

Some of you may criticise my statements and question my views—as everything depends on the angle of vision—and as ours are doubtless not exactly alike, I expect wide differences of opinion. But I understand the intent of this meeting is to present unvarnished facts and plain truths. I have tried in a spirit of fairness and justice to all to do so, without the slightest attempt at veneering. It is only by this interchange of ideas that we can hope to overcome our faults and start on a new era of co-operation, confidence and good will between the two professions. This I know is the sincere wish of the pharmacists of this city.

#### COUNTER PRESCRIBING AND UNETHICAL ADVERTISING.

BY DR. C. H. HARRIS.

There is an old saying that druggists seldom agree, that doctors never agree, and if one should attempt to write a paper dealing with the things upon which *both should agree*, he would sure be up against proposition No. 23. So if after reading my paper I find myself undisturbed, with all members intact I will consider myself fortunate indeed.

I am happy in the reflection that, among those who know me best I enjoy the distinction of being a man of very few words and these words always conservatively selected. I hope still to maintain that reputation.

I am to discuss in a brief way, some of the things about which doctors and druggists disagree, and sincerely hope that in this joint meeting some seeds may be sown that will bring forth good fruit, of the kind that will be sweet and toothsome to all.

In the arrangement of my paper I desire to ask, and if possible answer, three questions.

*Question No. 1:* Have the druggists any good reasons for complaint because of the present day proprietary prescribing by the doctor? Or because some few physicians prefer to furnish their own medicines.

*Question No. 2:* Are the druggists ever justified in giving advice to, or prescribing medicine for the sick?

*Question No. 3:* Have the doctors any good reasons for complaint because of the attitude the druggist assumes toward him, by improperly advertising unethical medicines to the public.

In an analysis of *these* questions it seems to me may clearly bring out the main things about which the doctor and druggist are always ready to disagree.

Let us frankly admit in answering question No. 1, that the druggist has good grounds for complaint because of the fact that physie-

ians are continually prescribing every new proprietary with which he is sampled, compelling the family druggist to purchase a whole bottle, while it so often happens that the prescription will never be refilled and the doctor discarding the preparation or forgetting it entirely, the pharmacist finds at the end of the year his shelves laden with unsalable goods which of course to him is dead stock and therefore dead loss. This I know from my own experience as a pharmacist.

I want to read just here a paragraph from a paper by Mr. Addison Dimmitt, (one of our local druggists and a member of the State Board of Pharmacy) which was read before the Kentucky Pharmaceutical Association at its 30th annual meeting, 1907.

"Page 94: All druggists agree that from a standpoint of ethical pharmacy and from monetary considerations, proprietary preparations should be eliminated, as they have become a burden. In support of this assertion every druggist will testify by exhibiting shelf after shelf of partly consumed packages of proprietary and special makes of pharmaceuticals which represent a tremendous loss to each of us.

This is entirely unjust to the druggist and we doctors should make an effort to correct it. Let us remember that we can not believe always the flowery little story of the detail man whose business it is to create a demand for his particular specialties by inducing you to prescribe and in doing so compels the jobber to buy. He is in town to-day—leaves tomorrow, and if he has done his work well, in taking his departure he runs down the list of those he has caught then in the language of our German friends he says: *Du machst mich so glücklich fuhen.*

Then again the druggist has a kick against those of our brethren who are furnishing their patients with medicines thereby cheating him of that which justly belongs to him: Happily these are only a few and consist of those gentlemen who have straddled the fence between allopathy and homeopathy in giving those nonsensical alkaloids, or what I would term allopathic medicines in homeopathic doses. Come off the fence gentlemen either be a full-fledged allopath, rationalist or disciple of Hahnemann it is inconsistent to be all at once. Abbott may know some things but a great many physicians think he has yet a few to learn.

*Question No. 2:* Are the druggists ever justified in giving advice to or prescribing medicines for the sick? Here let me be frank again for the answer can only be "No."

In the first place it is not the business of the druggist to know the physiological action of medicines and of course he does not know,

therefore in prescribing medicines he can only use it in an empirical way. Besides not being acquainted with physiology, pathology, and symptomatology his advice can not spring from an intelligent understanding of these most essential things and may be misleading and bad.

Or if his advice happens to be good it is only luckily so. Generally it is bad, for symptoms seemingly turned and insignificant to him may mean to the trained and experienced physician, conditions of the gravest kind and dangerous order.

The following two cases coming under my own observation will explain what is meant by this:

A lady feeling weak and suffering with pronounced dyspepsia applied to her druggist for medicine and advice. She was informed that she had malaria and asthma and medicine was given her for same, as near as I could judge she was given quinine and elixir *Grindelia robusta*, failing to obtain any relief she again consulted the druggist whereupon she was given one of the smoking remedies generally used by asthmatics, this failing too, she concluded after a few days time to call a physician. Three hours after I first saw her I relieved her left pleural sac of five pints of serum.

Mr. S's., wife previously well, complained about bed time of severe pain in her lower abdomen with a feeling of faintness. The family druggist being consulted ventured the opinion that she had bellyache from indigestion and gave her some medicine. Failing to be relieved the druggist was again consulted and prescribed some morphine tablets. When I saw the woman at 5 a. m. she was collapsed, cold sweat on her face, hardly any radial pulse: Diagnosis ectopic pregnancy—rupture and hemorrhage, my diagnosis was confirmed by Dr. H. B. Ritter. Patient too far gone to consider operative measures and died in a few hours from blood loss. These are not fanciful cases, gentlemen, but actually occurred in my own practice. What lessons?

In the first case, I have often wondered if the druggist had made up his mind as to what variety of malaria the patient had and if by his quinine he hoped to stop the sporulation of the plasmodium of *Leveran*, or must we conclude that he did not know that malaria was divided into varieties, or that such a thing as plasmodium ever existed. Or did he know that several kinds of asthma existed, that the treatment of each kind was entirely different, or did he know then, or has he learned since that the various conditions associated with shortness of breath are not always asthma?

In the second case the outcome was so disastrous that it grieves one to think of it,

common sense alone should have told the druggist that pain so severe must mean something serious and he should have refused to give even the simplest thing.

Another deplorable thing is the fact that nearly every druggist attempts to treat gonorrhoea and syphilis, indeed some of them make it no secret that they do this, but rather advertise it. It would not be difficult to lead the way to several back rooms where fairly good clap and pox clinics are held almost daily. Of course their efforts in general is to stop the gonorrhoeal discharge, and heal the primary chancre, and when this is done pronounce the victim well. This leads the unsuspecting into an erroneous feeling of security only to suffer the more when secondary manifestations appear; and so it follows that when many of these unfortunates finally seek trained medical advice they are found with cystitis, epididymitis proctitis or folliculitis or the graver secondary or tertiary syphilitic lesions.

I have seen several rather ludicrous instances where druggists who never hesitating to treat these cases for others, but becoming victims themselves, hurry as quickly as possible to the best G. U. specialist obtainable. Would it not be a good thing to penalize them with their own medicines?

We must admit that there are occasionally times when the druggist is in a manner justified in giving medicine to the sick, *but never advice*. Should one apply to his druggist and say: I am suffering with rheumatism and desire to purchase something for it. The druggist would probably be justified in doing so, because he ventures no opinion as to diagnosis. He may offer what he has for sale with the remark that this is recommended for rheumatism *but he must make no promises*. The same principle may be applied where one calls "for croup medicine," "bowel medicine," "pile salve," or "skin ointments." But even under these circumstances it is safer for him to advise his customer to see the doctor for croup may be membranous, piles may be ulcerated or not piles at all, skin eruptions may be the signal of some dangerous constitutional condition, or perhaps tuberculous.

*Question No. 3:* Have the doctors any good reasons to complain because of the attitude the druggist assumes towards him by improperly and unethically advertising medicines to the public?

Here is where it occurs to me that the greatest inconsistency on the part of the druggist exists. While he expects and is clamoring for help and protection from the doctor, he is constantly failing to extend the same courtesy himself.

Let it be again recalled that in the para-

graph read from Mr. Dimmitt's paper, that the use of proprietaries by physicians is disliked because of the *money loss* it causes them, in crowding their shelves with the remainder of partly used bottles. Let us admit this to be true, and supposing we should make an effort to correct it, notwithstanding we may have to put aside our Gardner's Syr. Hydriodic Ac., Fairchild's Panapepton and Ess. Pepsin, Park Davis' Taka Diastase and Sol. Adrenalin, Fellow's Syr. Hypophosphites. I say suppose we make all these sacrifices to protect him from loss, have we not the same right to insist upon him protecting us from loss also?

There is hardly a druggist in this city who has not on the market and offers for sale at every opportunity his cough cures, blood medicines, liver pills, and spring tonics.

But the grossest inconsistency occurs to us when we read such advertisements as these which I cut only last week from our local daily papers:

#### ECZEMA ONLY SKIN DEEP.

##### Local Cure of Diseased Surface Now Recognized as Proper Treatment.

In gathering data for an address before the Pathological Club, Dr. D. D. Dennis, the skin specialist of Chicago, prepared a table of results on microscopical blood examinations of 433 sufferers from skin disease.

These tests were from the blood of persons who had called at his office within a period of two years. Less than 10 per cent. of all these cases showed anything at all the matter with the blood, and in not a single instance could the physicians present trace the slightest connection between the skin affection and the blood humor.

This personal experience furnished the Chicago physician with the basis for a brilliant exposition of his contention that Eczema, psoriasis, salt rheum, barber's itch and other skin diseases are first and last diseases of the skin and have nothing at all to do with the blood. At the conclusion of his paper, Dr. Dennis was congratulated on his demonstration by the prominent medical men present.

For several years Dr. Dennis has allowed a private company to manufacture and sell his celebrated compound of thymol glycerine and oil of wintergreen known as D. D. D. Prescription, and it was particularly gratifying to him that other first-class physicians, free from prejudice and jealousy, should recommend the D. D. D. Prescription to all skin sufferers.

It is simply wonderful—the instant relief—the complete taking away of the itch—the very moment this oil of wintergreen compound is applied to the skin. We know, we vouch for it! Taylor-Isaacs Drug Company, Third and Jefferson, T. P. Taylor & Co. (Inc.), 332 Fourth avenue and 582 Fourth avenue. Just try it. We recommend D. D. D. Prescription, especially when used with D. D. D. Soap. Call at our stores and we will tell you more about this scientific cure.

This Society should vote the great Dr. Dennis a vote of thanks for all his great help and send it to him through T. P. Taylor & Co.

These and some more for your inspection and delectation.

### 39c—RENZ'S BEEF, WINE AND IRON—39c

One of the most perfect spring tonics. Made under the exclusive Renz Formula from fresh beef, citrate of iron and glycerine, combined with high-grade sherry wine. It is a tonic that makes life worth living, gives you the vigor and nerve force to meet and complete the day's work. Makes rich, red blood, and builds up the weary and run-down man or woman.

### Walnutta Hair Stain.

Restores faded, streaked or gray hair to its natural color and softness. Gives a glossy, healthful, natural appearance and is a most agreeable hair tonic and dressing; Saturday only.

31c

### Roman Hair Tonic

Daily demonstration at our Third and Jefferson shop. An unsurpassed tonic for the hair and scalp, restoring vigor and vitality. Stops falling hair and clears the scalp of dandruff. On Saturday we will sell \$1 bottle at 50c each.

### GREEN TRADING STAMPS WITH ALL PURCHASES.

### "SOLOMON'S ELIXIR"

A tried remedy for the Nerves, Brain and Blood. Builds up the system. Greatest aid to repair the nervous system, giving power of endurance and capacity to enjoy every pleasure. A fine tonic for run-down men or women and who lack energy or ambition. The ingredients used in the prescription are: Solomon's Elixir, one ounce; Tincture Auk Vomical, one-half ounce; tincture Cinchona Co., enough to make eight ounces. The dose is a teaspoonful three times a day and at bedtime. This prescription is prepared best by THEO. RECTANUS, CO., Preston and Market streets.

### FACTS ABOUT NEW THEORY AS SECURED BY INTERVIEWS.

An article from the Nashville, Tenn. Banner, published during Dr. T. Cooper's visit to this city, throws some light on the remarkable success of the young man's theories and medicine in various cities, visited by him during the past year. The article is as follows:

"In view of the enormous sale of Cooper's preparations now going on in this city and the intense interest which Mr. Cooper has stirred up since his arrival, a representative of the Banner spent Thursday afternoon at the young man's headquarters, watching the swarm of humanity come and go.

"During the afternoon the reporter interviewed many of the callers and obtained statements from all who cared to give them as to their experience with Cooper and his preparations.

"The following are selected from those statements as being typical of the general expression of the people seen:

"Mr. B. B. Lasater, living at 124 North Fourth avenue, when interviewed, said: 'I have been troubled with my stomach for the past two years, and have had rheumatism for more than five years. Sometimes I could not walk, and there were times when I could not even move in bed. Hard knots would form on my muscles, which caused me intense pain. Gas formed on my stomach after eating, which gave me much pain and distress, and often I was restless and tossed all night, losing much sleep and rest.'

"Hearing of Mr. Cooper and the great work his medicine was accomplishing for others, I decided to try it. I have taken it

about two weeks, and had myself in a greatly improved condition. My stomach is in good shape, and does not trouble me at all. My rheumatism has nearly disappeared, and I expect to resume work shortly, for the first time in twelve months. Mr. Cooper certainly has a wonderful medicine, and I am grateful for what it has done for me.'

"Another caller was Mrs. T. J. Smith, of 65 Hudson street. She said: 'I have been a sufferer from bladder and kidney trouble for twenty-five years. In that time I have tried many prescriptions and various kinds of medicine, but received little or no benefit from them. I seldom had a sound night's sleep, my rest being broken at intervals throughout the night. I had pain in my back and burning sensations.'

"I heard so much of Mr. Cooper that I came to the conclusion he might be able to afford me some relief. I have now been taking the medicine about a week, and feel better every way. The pain has disappeared, and I have no distress whatever. I have come here today to express my appreciation to Mr. Cooper for his wonderful medicine and what it has done in my case. I will take pleasure in recommending it to others.'

"In spite of assertions by various physicians that Cooper is a fad who will soon die out, the young man seems to be gaining even greater headway as his visit draws to a close.

"The success of Cooper's celebrated medicine has been given to us. We are making a new record with them.—Taylor-Inscoe Drug Co., Incorporated, Third and Jefferson.

I don't know what "Solomon's Elixir" is. I can find nothing in the Dispensary or Kennington to enlighten me. Perhaps it is only a trade name, or may be something handed down from ancient times, and behind which is all the wisdom of the great "Master of the Temple."

# FRUITOLA

## THE NEW REMEDY FOR GALL STONE AND APPENDICITIS.

The Taylor-Isaacs Drug Company, north-east corner Third and Jefferson streets, Louisville, Ky., are exclusive agents in this territory for Fruitola. This wonderful new discovery in the field of medicine is curing people every day of appendicitis and gall stones.

### THIS LOUISVILLE MAN WAS CURED BY FRUITOLA.

Louisville, Ky., Oct. 1, '05.

Gentlemen: I have suffered with gall stones for about four years. Intervals of severe pain in the stomach and vomiting. Had tried numerous remedies without satisfactory result. Was induced to try Fruitola. The first bottle caused me to pass about one pint of gall stones, different sizes, including several very large ones. I feel better now than I have for many years, and can heartily recommend Fruitola to do all the manufacturers claim for it. Will take pleasure in verifying the above statement to anyone interested. MR. JOHN SCHLATER,  
No. 1304 Quincey St., Louisville, Ky.

Stop suffering today. Call or write to Taylor-Isaacs Drug Company, Third and Jefferson, or T. P. Taylor & Co. (Incorporated), 582 and 332 Fourth street, for free booklet about this great cure.

No more need of our surgeons for appendicitis and gall stones. Fruitola puts an end to all his ambitions.

## LOUISVILLE IN LUCK.

T. P. Taylor & Co. (Inc.) have received the first shipment of Dr. De Coursey's Famous Irish Liniment, ever made to this country. The article has been a God-send in the old country, and it will prove the same here with your help. It will do two things that will make happy homes. It will cure any case of Eczema that exists—to prove this, try it on one spot. It will cure any form of rheumatism, as true as the sun rises. It will stop a neuralgia pain in ten minutes. For a cut or burn it is an absolute wonder.

Irish Liniment is for sale in Louisville, as follows:

T. P. Taylor & Co. (Inc.), 332 and 332 Fourth Avenue, and Taylor-Isaacs Drug Co., Third and Jefferson.

Other druggists can get it from Bagby-Howe Drug Co. or Peter-Neat-Richardson Co.

### TAYLOR'S OPTICAL DEPT.

The above cut represents a pair of EYE GLASSES with GOLD FILLED FRAMES fitted with extra quality CRYSTAL LENSES, the popular price of which is \$7.00 (guaranteed 15 years).

## Our Cut Price, Fitted Properly, \$2.50

Our Optician, DR. RUSSELL, will test your eyes free of charge, and guarantee you satisfaction in every respect or refund your money.  
We give you GLASSES, AND FIT YOU PROPERLY at less than ONE-THIRD the price you would have to pay elsewhere.

### Know Digit Mounting.

This cut represents the surface glass fitted with the KNU DIGIT EYE GLASS MOUNTING; will not fall off; easy to wear.

## BUSCHEMEYER'S,

Fourth and Green. Ladies' Stopping Place.

Buschmeyers should be congratulated for telling us about this First and Last Kidney business. All kidney patients apply for literature.

# BEWARE OF IMITATIONS.

## Cheap Substitutes and "Just As Good As."

Unscrupulous dealers, mindful only of profit and caring nothing for the health of their patrons, are offering for sale low-grade, impure whiskey, which they tell you is as "good as Duffy's."

It is a cheap concoction and fraud, intended to deceive the people. Of course, when a remedy has been before the public so long, has been prescribed and used by the best doctors and in all the prominent hospitals, and has carried the blessing of health into so many thousands of homes as DUFFY'S PURE MALT WHISKEY has, imitations are bound to arise. But they can imitate the bottle and label only—no one can imitate the contents.

Duffy's Pure Malt Whiskey is an absolutely pure distillation of malted grain; great care being used to have every kernel thoroughly malted, thus destroying the germ and producing a predigested liquid food in the form of a malt essence, which is the most effective tonic stimulant and invigorator known to science; softened by warmth and moisture, its palatability and freedom from injurious substances renders it so that it can be retained by the most sensitive stomach.

Any firm that will sell imitation or substitution goods will sell impure drugs. The firm that is dishonest in one thing will not hesitate to be dishonest in another. Whenever you see imitation and substitution goods offered for sale by a firm, beware of anything and everything put up by that firm. You endanger your own life and the lives of your family and friends by dealing with them.

### BEWARE OF FRAUDS!

## Duffy's Pure Malt Whiskey

is sold in sealed bottles only—never in bulk. A facsimile of the genuine bottle, full size, is printed here so that you may easily recognize it. It is our own patented bottle—round, amber colored, and with the name "Duffy's Malt Whiskey Company" blown into the glass. The trade-mark—the Old Chemist's Head—is on the label, and over the cork there is an engraved paper seal. Be certain this seal is not broken.

### REFUSE IMITATIONS AND SUBSTITUTES.

When you ask for DUFFY'S PURE MALT WHISKEY be sure you get the genuine, which is the only absolutely pure malt whiskey containing medicinal, health-giving qualities. Imitations and substitutes, far from relieving the sick, are positively harmful. Demand DUFFY'S, and be sure you get it. Be on your guard against refilled bottles.

Duffy's Pure Malt Whiskey promotes health and longevity. **KEEPS THE OLD YOUNG—THE YOUNG STRONG.**

It is the only whiskey recognized by doctors everywhere as a family medicine.

The genuine is sold by all reliable druggists, grocers and dealers, or direct, \$1 a bottle. Write Dr R Curran, Consulting Physician, for free illustrated medical booklet and free advice. Duffy Malt Whiskey Co., Rochester, N. Y.

# COOPER TELLS REPORTER WHY HE ACCOMPLISHES SO MUCH

No man in recent years has been more successful in restoring human health than Dr. T. Cooper. During his stay in Chicago, and while he was meeting thousands of people daily, he gave the following reason for the remarkable demand for his medicine to a reporter:

"My New Discovery is successful because it corrects the stomach. My theory is that few can be sick if the digestive apparatus is working properly. It naturally follows that few can be well with a poor digestion.

"I know from experience that most of the tired, half-sick people that are so common nowadays, have indigestion. Put the stomach to sleep, and nature does the rest. The result is general good health. My medicine does this. That is why fifty thousand people here in Chicago are using it who never heard of me until a month ago."

Among the fifty thousand mentioned by Mr. Cooper who used his medicine in Chicago is Mrs. Mildie Fluoger, 1718 W. 122nd Avenue. This is the statement she makes concerning her experience with the medicine:

"I have been sick for six years with stom-

ach trouble. I was always hungry, but did not dare to eat much, as I had severe pain in my stomach, and also through my body. I could not sleep at night and was very restless. I was also very nervous, and would have severe headaches. I was constipated, and stomach felt bloated after eating.

"I had tried many remedies, but could secure no relief, until one day I applied in the newspapers what wonderful results Cooper's medicines were accomplishing in Chicago. I decided to try them, and shortly after commencing the treatment I began to feel better. I did not have those severe pains in my stomach, and I could sleep at night. My appetite improved, and I can now eat well. I am feeling like a new woman.

"I am very thankful to Mr. Cooper for what his remedies have done for me. They have restored me to good health, and I would advise anyone who suffers as I did to try them."

We sell the Cooper medicine. They are really the most celebrated preparations ever introduced in this country, growing in popularity daily.—The Taylor-Isaac Drug Company, Incorporated, Toledo, Ohio.

The greatest medical fakir living.

Please do not understand me to be hostile to this or that particular drug store. I use these adds simply to illustrate the thought I wish to convey. I could have found others no doubt but thought these sufficient.

Such misleading and unethical advertisements should be stopped—we have as much right to condemn such fake stories, cast broadside at the public, as we have to condemn the street fakirs and charlatan. Here is where the application of the Golden Rule is recommended.

What then in conclusion should be said. That there are faults to correct on both sides is very plain. While we can not concur altogether in the following statement, yet Mr. Simon N. Jones hit the key-note when he said, while discussing the Pure Food and Drug Act before the last Kentucky Pharmaceutical Association, "I fully concur with Mr. Cook in the suggestion that the druggist should be represented upon any Pure Food Commission that may be provided by the coming Legislature. \* \* \* The time has come when the doctor and the druggist must line up against each other or else lie down together. (Applause). We can not exist under present conditions if the doctor continues to humiliate the retailer, who is often his best friend, etc."

I don't know what he means by the doctor humiliating the druggist, unless it is that he questions his ability to compound, by prescribing proprietaries. But I do know this, we have both dropped into some bad habits and therefore we all have our faults, but, let each one make an effort to correct his own. We are all engaged in work that should call forth all of the best that is in us. We should work together in harmony, for after all is it not true that the doctor and the

druggist depend largely upon each other in our efforts to prolong life and alleviate human suffering.

Ours is a noble calling, and it is in the power of both doctor and druggist to do much good or harm as he wills, and will it not be better when our life's work is done and we appear before the Greatest of all Physicians for final examination, to hear our case favorably prognosticated?

SOME U. S. P. AND N. F. PREPARATIONS.  
BY WILLIAM VOTTELER, PH. G.

I have been requested to speak of some of the U. S. P. and N. F. preparations; in this connection a brief review of the scope and purposes of the Pharmacopoeia and the Convention formulating the same will not be amiss

The Board of Trustees of the Ph. Convention were directed to take out articles of incorporation for the Convention; this was done in July, 1900.

The particular objects and business of this Association are the encouragement and promotion of the science and art of medicine and pharmacy by selecting, by research and experiment and other proper methods and by naming such materials as may properly be used as medicines and drugs with formulas for their preparation; by establishing one uniform standard and guide for the use of those engaged in the practice of medicine and pharmacy in the United States whereby the identity, strength, and purity of all such medicines and drugs may be accurately determined.

Extracts from the Constitution of the United States Pharmacopoeial Convention.

### ARTICLE II. ON MEMBERSHIP.

The members of the U. S. Pharmacopoeial Convention, in addition to the incorporators and their associates, shall be delegates elected by the following organizations, in the manner they shall respectively provide; Incorporated Medical Colleges, and Medical Schools connected with Incorporated Colleges and Universities; Incorporated Colleges of Pharmacy, and Pharmaceutical Schools connected with Incorporated Universities; incorporated State Medical Association; Incorporated State Pharmaceutical Association; the American Medical Association; the American Pharmaceutical Association, and the American Chemical Society; provided that no such organization shall be entitled to representation unless it shall have been incorporated within, and shall have been in continuous operation in, the United States for at least five years before the time fixed for the decennial meeting of this corporation.

The Committee of Revision is authorized to admit into the Pharmacopoeia any product

of nature of known origin, any synthetic product of definite composition in common use by the medical profession, the identity, purity or strength of which can be determined. No compound or mixture shall be introduced, if the composition or mode of manufacture be kept secret, or if controlled by unlimited proprietary or patent rights.

As you are well aware, the standard Pharmacopoeia preparations constitute only a limited portion of the resources of the medical profession in the treatment of the sick. Numerous preparations of similar titles, but of variable compositions are used in the several States; yes, the same applies even in local communities. To rectify this, and bring about as much uniformity as possible, the National Formulary Committee was formed by the American Pharmaceutical Association.

The National Formulary represents largely such preparations as seem to meet the requirements and demands of the medical profession that have come into general use since the revision of the Pharmacopoeia. The N. F. Committee as a whole does not contemplate to devise imitations of popular secret remedies, and such preparations that bear resemblance, are constructed on rational principles, regardless of mere external appearance or taste and mainly with regard to uniform composition and reliable effect. In reading over Pharmacopoeia preparations, I find a very small portion of them in constant use, many are entirely foreign to our knowledge and I believe this is due to the fact that they are crowded out; its preparations being combined and exploited under fanciful names.

I have been requested to submit for your inspection a number of U. S. P. and N. F. preparations. These have been selected more or less at random, and of such will be my talk to-night, not knowing these items in which you might be most interested.

Diluted Hydriodic Acid, U. S. P. contains 10% by weight of the absolute acid and from it is prepared the official syrup containing 1%: this is the preparation usually prescribed but mostly under proprietary title; if such a preparation is desired it can be had by prescribing equal parts of Glys. Syr. and water with one-tenth part of the official dil. acid: the advantage of the dil. acid is its stability, and this permits of being combined with a number of expectorants, by its concentration its range of usefulness is increased.

Digestives: Comp. Digestive Elixir, N. F., this is undoubtedly one of the most used of the N. F. prep. judging from its frequent repetition in dispensing, this contains pepsin, pancreatin and diastase with lactic and HCl acid, it has a very pleasant taste and attractive in appearance, the present formula

contains a very small portion of free acid, this contributes greatly to its retaining for a much longer period the full effective value of the digestive ferments, and the physician can rely upon its medicinal usefulness, if not prepared for too great a length of time. All of the digestive enzymes lose more or less of their strength when held in solution for too great a length of time.

Pulvis Pepsin Comp., or Pulv. Digestive Comp. N. F., contains pepsin, pancreatin, diastase with lactic and HCl acid and sugar of milk.

Pulvis pancreatin compositus, peptonizing powder N. F. contains pancreatin and sodium bicarb., and in diluted form is used in preparing humanized milk.

Essentia Pepsini N. F., Ess. of Pepsin, is prep. from pepsin, rennin, glycerin, white wine, flavored with Tr. of sweet orange peel, contains 10 grs. of pepsin and 8 grs. of rennin to Fl. Oz. and one grain of rennin will curdle 15,000 to 20,000 times its weight of milk.

Pepsin, diastase rennet in powder form will appeal to you as being more permanent and by prescribing them in powders or solutions freshly prepared ought to give the best results if not quite so elegant in appearance, the addition of Aromatic Powder U. S. P., to the powder prescriptions or of the Arom. Tincture N. F., to the liquid prep. will enhance their stomachic qualities.

I shall not attempt to state more than in a cursory manner the uses of the several preparations, as this is entirely within the province of the physician, after informing you of their composition, you will readily discover their use and application, but I should like to offer a suggestion; although not in line with my subject and that is this: write each one of your prescriptions as far as possible "individual" by some slight change as the need may require, and you will find it redound much to your advantage.

Among the tonics, nerve nutrients and haematinics, you have the choice of a great many valuable U. S. P. and N. F. preparation.

Elix. Iron, Quinine and Strychnine in three different forms; combined with the phosphates, in one; the pyrophosphates in another and the tr. eit. chlor. of iron in another, this latter combination has a very attractive appearance.

Syr. Hyposphites Com. U. S. P., with I. Q. S. and Mang., will fully replace the often prescribed proprietary.

Solution Iron and Ammon. Acet. U. S. P. Bashams mixture, has been used successfully for thirty years, this is an active chalybeate, worthy of more frequent use, instead of the numerous proprietary prep. Another almost

forgotten, but never the less, one of the most useful of this class is Massa Ferri Carbonate U. S. P., this has a very slight astringent effect, and is readily absorbed by the secretion.

Sol. Iron Peptonate with Mang. is one of the later additions of the N. F.

Elix. Gentian and Tr. Cit. Chlor. Iron N. F., is a bitter tonic and haematinic.

Elix. Gentian Glycerinated, a sample of which is presented you contains gentian, dandelion, phosphoric acid with menstrum of white wine, has stomachic and tonic properties, and has a pleasant taste.

Elix. Celery Comp. N. F., is prep. from celery seed, coca, kola and viburnum prunifol., acts as a nerve stimulant and tonic.

*Antiseptics and Antipruritics:* The U. S. P. prep. Liquor Antisepticus, contains 2% boric acid combined with benzoic acid, thymol, eucalyptol, oils of peppermint, gaultheria and thyme, in a 25% alcoholic solution, this is a colorless prep. Adapted for internal and external use. (Spts. chloroform and F. E. batisia added to this fully replaces the much advertised prep. of this character.) (Sample.)

The N. F. prep. Liquor Antisepticus Alkalinus, is brightly colored and contains about 3% of potas. bicarb., sodium benzoate and nearly 1% of sodium borate, with thymol, eucalyptol, oil peppermint and wintergreen, in a menstrum of glycerine alcohol and water. (Sample.)

Liquor Antigerminarius, "Cermicide" is a strong alcoholic solution of thymol, oils of eucalyptus, and lavender, containing over 12% of the volatile oils, this should be a very pleasant and effective deodorant, and disinfectant in the sick room, applied by sprinkling on a cloth and allowed to evaporate spontaneously. (Sample.)

Liquor Cresolis Comp., composed of 50% of U. S. P. Cresol with a linseed oil soap. Cresol is said to be a far more active germicide than phenol. This prep. is used as an antiseptic deodorant and disinfectant, used in a strength of 1-2 to 1% solution, mixing readily with water.

Pulvis Antisepticus, N. F., soluble antiseptic powder, contains 12 1-2% of Zinc sulph. approximately 1% of salicylic acid, phenol, eucalyptol menthol, and thymol combined, the bulk consists of boric acid, about 85%. This is a soluble astringent antiseptic used as a dusting powder, or with a douche, this I consider a very meritorious formula. (Sample.)

I will name a few others of this class by title: Thymol iodide, cataplasma kaolin, unguentum resorcin comp. U. S. P. and N. F.

*Analgesics, antipyretic, anodynes, sedatives and hypnotics:* Allow me to call over

by title only a few of them: Acetphenetidin, antipyrin, phenyl salicylis, comp. acetanilid powder, ethyl carbonate (urethane), sulphoethylmenthan (trional), sulphonmethane (sulphonat), chloralamine, syrup bromides comp., mixt. chloral and bromides comp.

Tr. Opii deod., 80 minims to the ounce of a vehicle of your own choice will replace the exploited morphia free prep., that now has a label stating it contains 1 gr. of morphia to the oz. and will be less costly.

I show you a specimen of C. P. salicylate of sodium that I wish to call your especial attention too, notice the exceptional appearance and purity, if you will prescribe C. P. salicyl. soda, I know your patient will be put to considerable less expense than when the product from the oil of wintergreen is specified, as the cost is just one-tenth.

The following cough sedatives and expectorants of the N. F. will appeal to the busy prescriber:

Elix. terpin hydrate, simple or with codeine, or heroin;

Syrup pini strobi comp., mist. glycyrrhizae comp., syr. morphine, comp. syr. ipecac and opium.

Vehicles for prescribing bitter or saline drugs:

Syr. glycyrrhizae and syr. yerba santa comp. are two superior prep., the syr. of licorice disguises the taste of saline and acid drugs very thoroughly, also will cover the taste of quinine sulph. very well, but for the latter the arom. syr. yerba santa is preferable, as it forms the insoluble tannate, but as a caution I might add, never prescribe either prep. with acid salts, acids or acid solutions, Elix. glycyrr. comp. and elix. adjuvans widen the range of this class of preparations.

Tr. Viburnum Comp. N. F.: Contains viburnum opulus, dioscorea, skullcap, cloves and cinnamon prep. with a 75% alcoholic menstrum and contains about 20% of the drugs, a sample of this is submitted for your inspection, and if taste and appearance are any criterion, this should fully meet every indication, that may apply to the use of the much used proprietary viburnum comp.

Petrolatum saponatum liquidum N. F. is possibly one of the unknown N. F. preparations, and admits of wide range of usefulness as a means of external medication, it is a solvent for iodine, methyl salicylate, salicylic acid, atropine, morphine and other alkaloids, dissolves salol, menthol, mixes readily with chloroform, and volatile oils and oleo resin capsicum. This prep. will form a permanent emulsion with water in almost any proportion. I have prep. a 10% iodine solution, and a 25% methyl salicylate sol. as samples.

Consists of liq. petrolatum 100, oleic acid 50, and spt. ammo. 25 parts, there is also a solid form of this prep. which affords an admirable base for ointments, this is prepared from petrolatum.

Elix. buchn comp. N. F., contains 25% of comp. F. E. buchn. composed of buchu, eubebs, juniper and nva ursi. acts as a urinary sedative, and useful as a menstrum for prescribing hexamethyltetramine, sodium benzoate, potassium acet., lithium salts.

#### DISCUSSION.

**Dunning S. Wilson:** I believe I am qualified to speak from the standpoint of the druggist, by reason of the fact that, eighteen years ago, I started in the drug business, "washing off the windows, mopping up the floors, and polishing the handle of the big front door". I know the bad effects of counter-prescribing and I know also where the blame is to be placed. It is not to be laid altogether at the door of the druggists; the doctors come in for their share. In the first place, as Mr. Votteller has said, the druggists have gotten out of the practice of pharmacy; it has been a long time since they have compounded drugs. I am a teacher in the College of Pharmacy, and I will venture to say that very few of the students make use of the knowledge they acquire at that institution, because, from the very start, they get into the practice of using proprietary medicines.

Another unfortunate thing is the large number of physicians who have become interested in enterprising for the manufacture of proprietary medicines. I know that in one day one physician prescribed tincture of nux vomica and digestine eight ounces; iodide of potassium and digestine, eight ounces, and some other drug and digestine, eight ounces, all for the same patient. I do not know what we might infer from that; I leave it to you. We have no right, as professional men, to enter into a trade in which we are interested, and it ill behooves us to take part in the manufacture of any proprietary article.

One thing, in which both the doctors and druggists should be interested, is the education of young pharmacists. We do not insist that young men aspiring to be pharmacists shall attend a college of pharmacy for a certain number of years before being allowed to go before the State Board of Pharmacy. A diploma from a reputable college should be insisted upon. As the matter now stands, a young man may stay behind the counter for a certain number of years and then go before the State Board for examination irrespective of whether or not he is well-grounded in the theory and practice of pharmacy. Furthermore, men who fail in college frequently go before the State Board and pass the examination. Only to-day I was talking to a gentleman who failed in the senior class at college but who passed the examination of the State Board. I asked him if the examination questions were hard

and he replied: "Not nearly as hard as your questions in the junior class."

In the College of Pharmacy, out of 24 men who came up for examination, only 15 were allowed to pass, yet a great many of those who fail in college will pass the examination of the State Board.

As physicians and as pharmacists, we should insist upon the standard of pharmacy going upwards, and no man should be allowed to go before the State Board until he has been graduated in the theory and practice of pharmacy by a reliable college of pharmacy.

**A. R. Bizot:** Like Dr. Wilson, I feel that I am privileged to address you on this subject, as I spent thirteen years of my early life behind the counter of a drug-store before entering the field of medicine. The attitude of the physicians and druggists toward each other reminds me very much of the present status of the labor unions and the trusts, and it is only by meetings of this kind that we can hope to bring about a solution of all the troubles we have had in the past.

As I look back over some of the incidents which happened during that unlucky number of years I spent as a druggist, I recall that physicians were privileged characters about the store, and some doctors in the immediate neighborhood would make a practice of walking into the store and looking over the prescription file to see if his competitor was writing more prescriptions than he was, and the nature of those prescriptions. I believe this is one of the unethical privileges which some doctors seem to think is due them.

I know of what may be termed a trust which exists in this city, which is in cahoots with a couple of doctors. This trust makes a full line of preparations which these doctors prescribe. I have been told, and have reason to believe, that they are partially interested in a drug store, and if a patient lives so far away that they cannot send him to that particular drug store, one of these preparations is prescribed which the local druggist cannot fill, and the patient is referred to this pharmacy by the physician. This is grossly unjust to the druggists.

In regard to the sin of counter-prescribing, I have worked in drug stores in both the poor and the rich districts. Doctors who attend the better class of patients never fear that their patient will ask the druggist to prescribe for them; they always have a physician in attendance, but it is the poorer classes, who feel that they cannot afford to pay a doctor, and go to the drug store to get something to relieve their ailment. Of course, there may be a fatal termination in some of these cases, as Dr. Harris said. However, there are circumstances under which a druggist might properly prescribe for some trivial ailment.

**J. N. McCormack:** I have spoken of the relations between doctors and pharmacists, I believe, in every state in this Union and, in many

States, in a large percentage of the counties. In advance of nearly every meeting at which I have been scheduled to speak, patent medicine concerns have sent out circulars, and their representatives have distributed hand-bills advising the people of the community not to go to hear my address. I have always considered this a badge of honor. It has had the effect of bringing very large audiences to hear me where otherwise they might have been small. Clergymen and leading public men who knew that these circulars had been distributed took them as a text for remarks on the subject.

I was very much surprised to-night to find a member of the Kentucky State Board of Pharmacy discuss this subject from the standpoint of the quack druggist. He has evidently never heard me speak but has read these things from quack journals, or has received some of the circulars I have mentioned. In all of my talks I am very careful to differentiate between the class of pharmacists to which Mr. Dimmitt belongs and the quack druggists. In no speech that I have ever made have I improperly criticised the class of pharmacists which Mr. Dimmitt represents, but I have endeavored to blast the class of men who advertise in your papers a preparation made of morphine as a cure for the opium habit; who advertise alcoholic preparations as a cure for the whisky habit—I have blasted them and, if God gives me the voice to do it, I intend to continue to blast them.

Fifty per cent. of the operations done upon women in this country are more or less due to the fact that the same standard of morality is not recognized for men and women. Probably 75 per cent. of diseases in young men, resulting from immorality, are not treated scientifically, but are treated (or mis-treated) by clerks in quack drug stores. Usually they are not cured, but, having faith in what has been done for them, they go out and marry, and the poor young women who are thus affected with gonorrhoea fill our hospitals from one end of this land to the other. I have blasted these quack druggists and will continue to do it and I invite criticism, come from where it may.

On the other hand, in speaking before the American Pharmaceutical Association and other societies, I have made a plea for the doctors and druggists to come closer together, and the joint meeting between the two professions to-night, being in line with what I have been recommending, is very gratifying to me.

I have advised all my professional friends to carry a copy of the manual of the Pharmacopeia and National Formulary, published by the American Medical Association, in their pockets and let it be a guide in preparing medicines for the sick. In Philadelphia, Baltimore, and a good many other cities, the druggists have, upon my recommendation, put a copy of this manual in the hands of every doctor in the city. It ought to be

done within the next two or three weeks in this city. One of these manuals costs twenty-five cents and is worth hundreds of dollars to every doctor who will use it as a guide. In addition to this I am advising every sick person in this land that, when they take a prescription to a drug store to have it filled, if there is a sign indicating that it is a cut rate drug store, to avoid it as he would a pestilence.

I am much surprised at this criticism from Mr. Dimmitt, but if he would do me the honor to some time come to hear me speak, instead of giving credence to information received at second-hand from disreputable publications, he would be as thoroughly in sympathy with my work as is every other honorable doctor and druggist in this land.

What I have recommended is that we have a joint committee of the American Pharmaceutical Association and the American Medical Association, and endeavor to devise some standard remedies to take the place of these patent medicines. The time has come for us to get together in this great work. At times I have been criticised even by doctors, yet I have gone on hopefully, knowing that from one end of the land to the other, every reputable physician and pharmacist is heartily in sympathy with my work.

## PROGRAM.

### EXHIBITS

Clinical Case—Serous Cyclitis  
Pathological Specimens and New Instruments

### ESSAYS

#### GLAUCOMA

Etiology, Present Views on  
DR. G. C. HALL.

Treatment of  
DR. WM. CHEATHAM.

FIRST REGULAR MEETING OF THE OPHTHALMOLOGICAL AND OTO-LARYNGOLOGICAL SECTION  
AFTER ORGANIZATION, FOURTEEN  
MEMBERS PRESENT.

#### REPORT OF CASES.

G. C. Hall shows a case of injury to left eye by handle of a pitch fork, which eye was treated by collyrium only for a week. After treatment by an ophthalmologist for a few weeks the eye went totally blind, chemosis of conjunctiva developed, intense ciliary injection, pain, etc. An apparent wound over ciliary region at temporal side suggest a penetrating wound.

T. C. Evans suggests enucleation.

Wm. Cheatham, Pusey, Dabney and Hays agree that enucleation should be done.

Dr. Ray thinks sclera is perforated down and out.

G. C. Hall, closing, says had shown case to

another ophthalmologist who suggested that the eye should be left alone. The question of intra-ocular growth had been considered as existing before the injury.

S. B. Hays shows case of serous exudation with negative constitutional or traumatic history. Case O. S. first sluggish iris, pain and blurring; pupil readily widely dilated, fundus not to be seen. Later a slight rise of tension and a keratoglobus. Eye first affected in January, 1908; three or four weeks later relieved by weak eserine solution, was never any pain or much ciliary injection. After three months course the retina became detaching up and out and at present is more extensive. This is not a case of type so asks what the outcome may be; what is the cause or is any other treatment beyond atropine and local to be used.

Wm. Cheatham says there is annular detachment of retina and believes will lose the eye.

J. M. Ray says these are all bad cases. Has one protracted case who had iridectomy; both eyes later were affected. The best eye did worse after the operation and the worst eye before operation did better afterwards.

Dr. Cheatham says some years ago he made a plea for change of nomenclature as all uveal inflammations were necessarily chronic.

S. B. Hays closing, says but one other thing could have been done and that was an iridectomy early for the inflammatory process. This was refused by boy's mother. He thinks it a safe procedure when the medicinal treatment shows no immediate avail.

J. M. Ray shows case of removal of piece of steel from eyeball with the good result of a quiet eye, no apparent damage to the ciliary region and some vision restored. Piece of steel 5 mm in length and flat.

N. B. Pusey reports removal of pebble from external auditory meatus having remained therein for fourteen years.

#### CONCERNING THE ETIOLOGY OF GLAUCOMA.

By G. C. HALL.

The term glaucoma is one applied to several well recognized and different pathological conditions.

Any discussion therefore, dealing with the etiology of such conditions presupposes a classification of the different types of the disease.

We recognize Infantile Glaucoma, Buphthalmos; simple or non-inflammatory glaucoma, primary inflammatory glaucoma and secondary glaucoma.

It is not my purpose to discuss the infantile variety and the terms applied to the others are by no means inflexible, one variety

often assuming the characteristics of one of the other types.

All the symptoms of Glaucoma are fully explained in the increase of tension and since the time when Von Graefe, Mackenzie and Müller called attention to this fact various theories have been brought forward to explain the mechanism of its occurrence.

None of them however, are entirely satisfactory and free from objection, so that now though over fifty years have passed and an immense amount of work has been done on the subject the question is by no means settled.

While the subject of this paper is primarily to discuss the more recent work on the subject, a brief reference to some of the older theories may not be amiss.

Fuchs in his recent text book says: "The older theories of Glaucoma endeavored to account for the elevation of tension by attributing it to an increase in the volume of the eyeball due to an increase of the inflow.

Von Graefe assumed the existence of an increased excretion of fluid by the vessels of the choroid as a result of inflammation of the latter. Since the ophthalmoscopic symptoms of chorioiditis are generally wanting in glaucoma, Von Graefe, to get over this difficulty, assumed the existence of what he called a serous chorioiditis, the nature of which was supposed to consist in a serous transudation without any coarser anatomical changes.

Donders ascribed the increased secretion on the part of the choroid to the influence of the ciliary nerves. He looked upon glaucoma simplex as a typical form of glaucoma because it was not complicated with inflammation. Hence he could not consistently look for the cause of the increased excretion of fluid in an inflammation of the choroid. Rather, he supposed it to originate in an irritation of the choroidal nerves, being thus a sort of neurosis of secretion, just as, for example, increased secretion takes place in glands upon irritation of certain nerves.

Stellwag referred the elevation of tension not to increased excretion of fluid, but directly to the increase of blood-pressure in the vessels of the interior of the eye.

It makes its appearance in consequence of obstructions to the circulation, which affects mainly the region of the vasa vorticiosa, and are brought about by diminished elasticity and shrinkage of the sclera; for those sections of the vasa vorticiosa which pass with a very oblique course through the sclera are liable to compression whenever the latter shrinks.

Against these theories the objection must be made, primarily, that an increase in the inflow or an over-distention of the vessels can

not by themselves account for the elevation of tension, since, if the conditions are otherwise normal, an increase in the contents of the eyeball is immediately compensated for by the increased outflow.

If a few drops of liquid are injected into a healthy living eye, and the intra-ocular pressure is thus heightened, it returns to the normal again after a short time, since a correspondingly greater amount of liquid flows off through the lymph channels. If we ligate the vena vorticiosa at their points of exit from the eye, we get an increase of tension in the sense of Stelwag's theory, but it is not permanent.

The foundation for the views that now prevail were laid by Knies, who was the first to show that the peripheral adhesion of the iris which has been already known to exist, occurred quite regularly in the glaucomatous eye, so that he brought it into casual connection with the glaucoma. He explained the adhesion itself as being due to an adhesive inflammation in the vicinity of the sinus of the chamber. But almost simultaneously Weber by examining a recent case of glaucoma proved that the cause of the obliteration of the sinus was not inflammation but the pushing forward of the iris by the swollen ciliary processes.

Priestly Smith then demonstrated that glaucomatous eyes are on the average smaller than normal eyes, and have comparatively large lenses; he also was the first to recognize that the lens continues to grow even late in life. Czermak showed how the thickening of the iris, that occurs simultaneously with the dilatation of the pupil, acts. It is not the root of the iris that in this case is pushed against the cornea, for the root of the iris is very thin. But directly to the inner side of the root the iris attains its full thickness, so that here its anterior surface turns up and passes abruptly forward; and it is this point that first comes into contact with the posterior surface of the cornea when the iris is thickened. In this way the sinus is closed so as to form a ring-shaped space which no longer communicates with the anterior chamber. Then in both anterior and posterior chambers, the pressure rises and forces the most peripheral, or root portion of the iris against the sclera. The return to normal conditions, such as occurs in the case of the prodromal attacks, Czermak accounts for upon the supposition that owing to the increase of tension a state of irritation sets in, which by reflex action causes contraction of the pupil, so that the iris is again drawn away from the cornea. But in order for this to take place, it is necessary that the sphincter pupillae should be strong enough, and, more-

over, no adhesion must have formed between the iris and the cornea.

Up to this point therefore the etiology of glaucoma has been shown to be due not alone to an increase in intra ocular fluids, but rather to an interference with the outflow; by pressure of the iris forward against the posterior layer of the cornea shutting off the interstices, in the pectinate ligament and blocking up the spaces of Fontana and canal of Schlemm.

Now however, it is claimed by some that this is the effect and not the cause of glaucoma and that while this condition is present in practically all cases of long standing glaucoma it may be absent in fresh cases and that furthermore it fails to explain the mechanism of simple glaucoma.

Regarding Priestley Smith's observations, J. A. Tenney, of Boston, examined the eyes of two hundred persons with the Würdemann lamp to see to what extent the lens encroached on the ciliary processes as age advances. He concludes that the anterior chamber and circumferential space may both be shallow without causing trouble, on the other hand Robert Hesse, of Gratz, reports two cases of glaucoma caused by swelling of lens closing off the circumferential space and that uveitis serosa or inflammation of any kind is not necessary to produce an attack.

The observations of Troncoso are extremely interesting—having found that the aqueous in the eyes effected with glaucoma contained considerable albumin, he advanced the theory that the increase in tension was due primarily to the fact that whereas the pectinate ligament spaces of fontana and canal of Schlemm offered no resistance to the normal aqueous that the spaces become blocked by an aqueous loaded with albumin and filtration is interfered with, consequently causing a rise of tension.

This author has carried on an extensive controversy with Prof. Leber, of Heidelberg, who attacks his views on the albumin theory on the ground that other diseases of the eye, namely serous and plastic iridocyclitis have a much larger percentage of albumin in the aqueous than occurs in glaucoma.

To these observations Troncoso replies that we must distinguish two stages in inflammations, one a hypertonic, the other hypotonic and that in the diseases Leber mentions the hypertonic state is succeeded by an organization of exudates with atrophy of the ciliary aqueous and consequent atrophy and hypoprocesses and a much lessened secretion of tension due to interference with nutrition.

Raehlman, of Weimar, in an article on secondary glaucoma in traumatic cataract supports the views held by Troncoso that the increase of tension is caused by blocking up of

the filtration spaces by particles of albumin from the lens. These can be demonstrated with the ultra-microscope.

He farther demonstrated this by clearing up the aqueous by injecting normal saline in the chamber in traumatic cataract in animals eyes, thereby increasing the solubility of the globulins that filled the chamber. The process therefore is one of supersaturation of the aqueous with globulins with their precipitation and blocking of the filtration apparatus.

Erdmann, of Boestock, after producing glaucoma experimentally in the eyes of animals concludes that the increased tension is the result of the destruction of the anterior channel of filtration through obliteration of the angle of the anterior chamber.

The latter condition is brought about through a proliferating inflammation of the filtration tissue of the angle of the chamber excited by the fine granules of iron driven into the meshes of the tissue by electrolysis.

The atrophy of the choroid and retina in glaucomatous rabbits' eyes, which is almost entirely limited to the anterior segment of the eye, where the stretching is greatest, is a result of continued increased tension.

The more or less pronounced deep excavation which usually extends to the periphery of the nerve is to be considered as a pressure excavation.

Mydriatics produce an increase and myotics a decrease in tension in glaucomatous eyes of rabbits.

The aqueous of glaucomatous eyes is, in contrast with the normal eyes, rich in albumin. This increase must be considered as a result of the increase in tension.

Hemolysin apparently does not reach the "first" aqueous of glaucomatous eyes.

Henderson, Thomson, in the *Ophthalmic Review*, Sept. 1907, says: The underlying predisposing and causal factor of glaucoma exists in a primary obstruction and closure of the pectinate ligament. This occlusion is brought about by a sclerosis of the fibrous structure, composing that filtration area, which results in first a diminution and finally a complete obstruction of the outflow through that channel. All the other phenomena of glaucoma clinical as well as pathological follow as consequences of this primary closure of the pectinate ligament.

Glaucoma arises from a difficulty in the escape of the intraocular fluids. The hindrance to the aqueous outflow does not arise from the peripheral anterior synechia frequently met with but is brought about by the closing of the inter-spaces of the pectinate ligament in consequence of the fibrosis of the cells of its connective tissue stroma and continued formation of homogeneous membrane

around these fibrous bundles, leading to the endothelial cells being first brought into contact and then welding together the fibrous structure.

Acute glaucoma is precipitated by mydriasis or by mental or physical conditions which increase the general or local blood pressure in an eye predisposed to glaucoma. The raised intraocular pressure causes increased difficulty of venous return and as a result the iris becomes congested and applied to the pectinate ligament and so blocks the angle of the anterior chamber. In subacute glaucoma the same agencies are at work, only the balance between inflow and outflow is kept more even, each attack causes more of the swollen iris to become applied and then adherent to the posterior surface of the cornea. In chronic glaucoma the process of sclerosis is a slow one, and at the end such an eye may still show a perfectly open angle of the anterior chamber with a pectinate ligament which is sealed up.

The only difference between the various forms of glaucoma is one of degree, as the same pathological process underlies them all. In secondary glaucoma a similar obstruction is brought about by inflammatory products.

The pathogenesis of secondary glaucoma is easily understood as the condition which give rise to it—anterior and posterior synechia, swelling and dislocation of the crystalline lens, tumors and cysts at the angle of the anterior chamber—readily obstruct the outflow of the intra-ocular fluid and occasion its retention.

Intra-ocular tumors and hemorrhagic retinitis (thrombosis of the central retinal veins) tend to increase the pressure in the vitreous and thus cause secondary glaucoma.

Glaucomatous attacks brought on in people so disposed by gout, in connection with rheumatism, by worry, by over indulgence in food and drink, excitement or depressing news the so-called emotional mydriasis are too well known to need mention; recently however, de Schweinitz has reported a case of acute rise of tension due to a single subconjunctival injection of cyanide of mercury. *Oph. Rec.* Apr. 1907, and *A. Brav. Amer. Med. Journal*, July 1907, reports a case of glaucoma occurring in a cataractous eye following the instillation of adrenalin.

As both of these procedures are extremely common in ophthalmic practice it is well to take note of these cases and remembering such a possibility avoid the use of such measures in doubtful cases.

The writer has no desire to sit in judgment on the various theories brought forward to explain this condition. When a man as eminent in the profession as Dr. Risley says that there is no subject in ophthalmic practice

that he approaches with as much perturbation as this one, surely the present writer may be pardoned if he fails to reach any definite conclusions.

The widely divergent opinions held by different observers and the array of facts that each can bring forward in support of his contentions makes it appear probable at least that it is not one but several factors that are responsible.

It seems to be settled that a disturbance of outflow is the fundamental fault in glaucoma, it is the question as to how this is brought about that presents the stumbling block.

In one case the peripheral adhesion of the iris may be brought about by inflammation.

In another it may be due to a swollen lens.

In still another it may be due to pressure in the vitreous or a swollen ciliary process.

Particles of albumen may in reality block the spaces of filtration in a certain percentage of cases and in others the drainage system be closed by a progressive fibrosis.

Therefore, instead of hunting a hypothesis that would satisfactorily explain every case it bespeaks good judgment rather to sift down the facts now before us and accord to each the importance due in its role of causative agent.

#### DISCUSSION.

**Wm. Cheatham** talking on treatment of glaucoma, classified procedures as governed by whether primary or secondary. When secondary glaucoma occurs treatment is directed toward cause of the glaucoma and the improvement of the results of such causative conditions. In treating primary glaucoma, he considers the condition incident to the acute, subacute and simplex forms. He finds generally in glaucoma no substitutes for iridectomy which should be a pain-taking operation. He excludes sclerotomy except where anterior chamber is too shallow for safe corneal section. Eserine and pilocarpine are invaluable (better used in weak solution and oftener) regardless of operation or medical treatment. Has had insufficient justification in the use of adrenalin. He finds cocaine a valuable adjunct to myotics using in aqueous solution preceding the myotic or in the ointment. He performs iridectomy in all acute glaucomas. He corrects all refractive errors in the family of a glaucoma case and especially deems it important to make the glaucomatous eye emmetropic. Chronic inflammatory glaucoma may be nursed along fairly well on myotics, preferably pilocarpine. Use these in weak forms to better advantage. In business men have them use solutions of myotic at night so that there accommodation is as little interfered with their business hours. Removal of sympathetic ganglion (cervical has done little good.) Actual results of same do not justify it being listed with other remedial procedures. As the same etiology prevail in the causation of a

hemorrhage glaucoma (i.e. arterio sclerosis) should one eye be so affected a myotic should be used in the other eye. Here iridectomy would aid but little at best. In glaucoma simplex 50% are helped by iridectomy. Correction of gouty or nervous element, alterative treatment and salicylates are all of use.

**I. Lederman:** Would like to hear more of general treatment of glaucoma. He directs strong attention to the best constitutional condition and in chronic glaucomas does iridectomy. In a simplex it is hard to say what to do. Has seen one so-called optico-ciliary-neurotomy in Germany done in a blind eye.

**W. T. Bruner** says that anatomical conditions of a glaucomatous eye bear on the cause and guide him in his treatment. He finds most of glaucomas occur in hypermetropes.

**J. R. Wright** asks if glaucoma is not due to the occlusion of the filtration angle at the limbus, why don't we have more cases in myopia?

**W. B. Pusey** reports five cases in one family.

**Jessamine**—The Jessamine County Medical Society met at the office of J. A. VanArsdall, President Barnes in the chair. The following members were present:—Fish, Barnes, Matthews, Penick, Pentz and VanArsdall. Minutes of the last meeting were read and adopted. Dr. Pearson, who was to read the paper at this meeting, was absent.

**J. S. Barnes** reported an interesting case of pneumonia, in a man 65 years of age, in which resolution had not taken place.

**W. H. Fish** led the discussion and suggested that there might be a tubercular condition. The members discussed the case at length and in the main concurred in the opinion expressed by Dr. Fish. Dr. Barnes then read the chemical analysis of a sample of water taken from the well of W. D. Sharp, at Union Mills, near Nicholasville. Some of the members had used this water in the treatment of rheumatism and arteriosclerosis, and found it of signal benefit. Motion, that the secretary write a resolution indorsing this water, same to be signed by the members of the society.

**Pearson and Pentz** appointed to read papers at the next meeting.

Society adjourned to meet May 21, at 7:30 P. M. **J. A. VANARSDALL**, Secretary.

**Mercer**—The Mercer County Medical Society met at the Y. M. C. A. rooms, Horace Witherspoon, president, in the chair. The following members were present:—C. W. Sweeney, N. H. Rogers, E. V. Seay, C. B. VanArsdall, J. B. Robards, J. T. Price, M. L. Forsythe, A. U. Price, E. O. Eades.

**N. H. Rogers** read a very excellent paper on "The Management of Typhoid Fever."

**H. Witherspoon** read a short and interesting paper on "The Symptomatic Treatment of Tu-

berenosis." The discussion was entered into by all present, and a profitable meeting was enjoyed.

**E. O. Eades** was reported on favorably by the board of censors, and was unanimously elected a member.

The following resolution was presented in writing by **J. B. Robards** and **W. T. Forsythe**: "We, the members of the Mercer County Medical Society do agree, that we will not visit any delinquent, unless it be known charity; unless each delinquent pay cash in advance for each visit made."

Those who are able to pay, and refuse to make satisfactory settlement, shall be placed upon a list, and each doctor furnished with a copy.

Those industrial insurance holders, who have to have a certificate of health, for which we never receive a cent, we agree not to furnish, without cash in advance, or know to be reliable.

It was moved and seconded that the members have individual prescription blanks printed, containing a conspicuous notice: "Not to be refilled." The motion carried.

**J. Tom Price** moved that the members of the neighboring county societies be made honorary members, and that they be invited to attend, read papers and enter into the discussions. **Dr. Price** was appointed a committee to visit the societies and discuss the plan with them.

**J. B. Robards** was appointed secretary, vice **C. P. Price** resigned, to take effect June 1, 1908.

**C. P. PRICE**, Secretary.

**Russell**—At the last meeting of the Russell County Medical Society, our secretary, **J. S. Rowe**, being absent I was appointed secretary pro tem. We had a good meeting; three papers were read and discussed by the society, besides a number of cases reported. There was one application for membership, to be voted on at our next meeting, while three others who were in arrears, paid their dues—**L. D. Hammond**, **Irvine's Store**; **A. V. Neatherly**, **Russell Springs**; **W. G. D. Flanagan**, **Jamestown**.

**W. G. D. FLANAGAN**, Sec. pro tem.

**Washington**—The Washington County Medical Society met in its room at the court house on the 11th of May, 1908, with the following members present: **W. W. Ray**, **M. W. Hyatt**, **S. J. Smock**, **J. C. Mudd**, **J. N. Shehan**, **W. E. Crume**, **W. T. Barnett**, **D. A. Crosby**, **J. M. Spaulding**, **J. H. Hopper**, **Stallard**, and **A. G. Beam**.

**J. N. Shehan**, of **Wand**, read an interesting and instructive paper on "Cholera Infantum," which was well received and freely discussed.

**W. E. Crume**, of **Fredricksburg**, read a paper on "Constipation," which was a very able paper, and was discussed by the members present.

**J. C. Mudd**, **Hopper**, **Burnett**, and **Smock** re-

ported clinical cases, which were freely discussed, and it was necessary to call a meeting after lunch to finish the report of cases.

**JNO. M. SPAULDING**, Secretary.

**Warren**—The regular meeting of the Warren County Medical Society was held in the doctors' club-room Wednesday, April 29, 1908.

The following members were present: **J. H. Blackburn**, **Souther**, **South**, **McCormack**, **McCracken**, **Rau**, **Martin**, **Lewis**, **Rutherford**, and **Dr. Blakeman**, of **Glasgow**, was a guest of the society.

**J. H. Souther**: speaking on the treatment of typhoid fever, said: "Thirty years ago, in the fall, the first year of my practice an epidemic of typhoid fever occurred. Eight families used water out of a well, and the members of each family had the disease, amounting to 32 cases.

"The families that used a cistern did not have typhoid fever.

"I knew of no abortive or specific treatment then, nor has my knowledge increased along that line. As soon as I diagnose a case I put them to bed, use a bed pan. A physician to successfully treat a case must understand the history of the disease just the same as a captain of a boat on the placid stream of Barren must know the breakers and snags and steer clear of them.

"I limit the patient to liquid diet and use sponge bath if temperature is above 102 degrees. I never use coal tar products.

"After the initial dose of calomel, I continue to keep the bowels open.

"The usual intestinal antiseptics are employed. Lung, kidney and brain symptoms all receive appropriate treatment.

"I depend entirely on baths to control the fever. A high temperature in the morning is always an alarming symptom.

"Typhoid fever is an infectious, self-limiting disease. In regard to treatment we are yet no nearer the goal than our forefathers. Some things are impossible for men to attain, and I consider this as one of them.

"I have treated over 500 cases in thirty years, and at times I have congratulated myself that I aborted the disease—but after calmly thinking it over I realize I can do nothing to shorten the attack.

"There is no formulated treatment; individualize your cases and generalize the disease."

The subject was discussed by **Rutherford**, **Blackburn**, and **McCormack**, and **McCracken**.

**J. H. Blackburn** substituted for **Dr. Keen**, and spoke on "The Diagnosis of Typhoid Fever."

The society, with great enthusiasm ordered a vote of thanks to be sent to **Hon. Duncan Miliken**, who voted and actively supported all medical and health legislation during the past session of that honorable body at **Frankfort**.

**L. H. SOUTH**, Secretary.

# American Medical Association....

## CHICAGO, JUNE 2-5

---

---

### To Members:

For your information the arrangements planned by the MONON ROUTE for the delegation of members of the American Medical Association from Louisville and the South to the Chicago Convention, either from Louisville to Chicago direct or by way of French Lick Springs for the acceptance of Mr. Taggart's invitation to be the guests of the French Lick Springs Hotel Co. Sunday and Monday, May 31 and June 1, are as follows:

**RATE:** The round trip fare from Louisville to Chicago will be \$9.00; similar reduction from points South, which will be gladly furnished by your local Ticket Agent.

**DATES OF SALE:** From Louisville, May 28, 29, 30, 31 and June 1st; good returning till June 12th inclusive.

**STOP-OVER FRENCH LICK:** Tickets from wherever sold good to stop-over at Orleans, Ind., to enable holders to visit Springs. Fare Orleans to French Lick and return 68c.

**"THE DOCTORS' TRAINS":** Will leave Louisville, 10th Street Station, Sunday, May 31, at 8:30 A. M., arriving French Lick 11:15 A. M.; leave French Lick Monday, June 1st, at 9 P. M., arriving Chicago Tuesday, June 2nd, at 7:10 A. M. Other trains will leave Monday, 7:26 A. M., and 2 P. M., for French Lick Springs.

**REPLY IMPORTANT:** It is very necessary to know at your earliest convenience what train you will take from Louisville and what sleeping-car accommodations from French Lick to Chicago are wanted, as both adequate train and Pullman service must be arranged in advance. It is equally as necessary that Mr. Taggart should know in order to properly estimate for whom the Hotel shall provide.

You will, therefore, greatly oblige by advising the undersigned as promptly as possible.

Respectfully,

*E. H. BACON, D. P. A. Monon Route,  
Louisville, Ky.*

**McCracken**—The McCracken County Medical Society is following very interestedly the work as outlined in the *Journal A. M. A.* The doctors are taking great care in preparing the various subjects as it comes their turns, and meet every Tuesday night following the lectures by a fifteen minutes' quiz.

At our meeting with **E. B. Willingham** on the evening of March 3rd, he read a very thorough and interesting paper on Fractures, Their Varieties, Etiology, Symptoms, Diagnosis and Treatment."

March 10th the society met with **Jeff D. Robertson**, who gave a lecture on Fractures of Neck of Femur. He advised a bed or cot to be made with three separate mattresses, the smaller and middle mattress to have a small trap door attached directly under the buttocks for purpose of toilet. He advised a lateral extension weight of 15 pounds and a longitudinal of 25 pounds, the lateral weight to be supported by a pulley on a stand placed at the patient's side.

The resolution to amend Section 1 of By-Laws reading as follows: "Sec. 1 of By-Laws be amended to read as follows: Every reputable and legally qualified physician in McCracken County shall be entitled to membership." Was voted on and carried, ten votes for it, one against. This resolution had been before the society since January 21st, 1908, until through the secretary the society had secured authority from an authority on State Society and A. M. Society laws that such an amendment was not contrary to the medical spirit.

March 17, 1908, the society met at the office of **G. N. Murphy**, who reported a case of gall stone treated with chloroform and olive oil, followed by Hoffman's Anodyne, using castor oil to expel contents.

**H. T. Rivers** gave a very scholarly paper on Anatomy and Physiology of Blood, going into the subject intensively as outlined in *Journal A. M. A.* of February 29.

March 24, 1908, the society met with **Vernon Blythe**.

**C. E. Purcell** described by practical demonstration an anatomical specimen, a dissection showing carefully the operation for resection of the submucous membrane for deflected septum, pointing out with care the various important anatomical points and landmarks sphenoidal sinus, ethmoid cells, turbinated bones.

**Vernon Blythe** gave paper on "Chlorosis, Secondary Anaemia and Pernicious Anaemia," reporting a case of Carcinoma of Stomach with Dr. Duley, the blood staining had revealed a very interesting type of advanced secondary anaemia, with nucleated red cells, crenated and irregular in size and shape, a slight increase of polynuclear leucocytes and granular degenerations of red cells.

VERNON BLYTHE, Secretary.

**Muldraugh Hill**—The society was called to order in the City Hall at Elizabethtown, Thursday, April 9th, at 10 o'clock by President Basil M. Taylor. The minutes of the December meeting were read and approved. Members present were Basil M. Taylor, W. A. Ligon, S. T. Hobbs, C. T. Riggs, A. D. Willmoth, J. C. Mobley, Irvin Abell, W. H. Strother, J. M. English, W. Lucien Heizer, Emmitt Miller, J. W. O'Conner, J. D. Howell, J. W. Shacklett, I. T. Houck, M. S. Allen, J. W. Rogers, B. F. Zimmerman, J. R. Wathen, G. G. Thornton, John Glassecock, C. C. Carroll, R. C. McChord, F. P. Strickler, Hugh D. Rodman, C. Z. Aud, W. C. Dugan, S. N. Willis, H. C. Duvall, D. C. Bowen, G. C. Hall, H. S. Harned, and H. R. Nusz.

**Miss L. H. South**, of Bowling Green, was an interesting visitor.

#### Exhibition of Pathological Specimens.

**R. C. McChord** exhibited two specimens of Fibroid Tumors of the Uterus and reported the cases. His first case was one of the pedunculated variety, while second was interligamentary.

Discussions were by Dugan, Abell, and Willmoth, McChord closing the discussion.

**Jno. R. Wathen** exhibited five specimens of very large size, and reported the cases. They were: First, Pyo-Nephrotic Kidney; second, Hypertrophied Prostate Gland; third, Exophthalmic Goiter; fourth, Sarcoma of the Testicle, and fifth, Fibroid Tumor of the Uterus.

These cases and specimens were discussed by Dugan, Abell, Willmoth, McChord, and by Wathen in closing.

**Irvin Abell** reported cases and presented specimens of Enlarged Prostate Fibrous and Adenomatous, and Kidneys, Tubercular and Suppurative.

Discussions by Dugan and Wathen, and by Dr. Abell, closing.

**A. D. Wilmoth** exhibited specimens of Coley's Fluid for the cure of Sarcoma, Enlarged Prostate Gland and Varicose Ovary and Broad Ligament. Adjourned for dinner.

Afternoon Session.—The president called the society to order at 1:15 o'clock. Dr. Boggess being absent with his paper entitled "A Clinical Study of the Cardio-Vascular System," Dr. Heizer moved that Dr. Zimmerman give a talk along the lines of Dr. Boggess' paper. Motion carried.

**Dr. Zimmerman** made a very interesting talk on "Diseases of the Heart Muscle." Aud, Rodman and Heizer discussed Zimmerman's talk.

**C. Z. Aud** reported a case of Angine-Pectoris.

**Hugh D. Rodman** reported a case of Post-Partum Phlebitis, which was discussed by Drs. South, Riggs, Heizer, McChord, Aud, Willmoth, and Taylor.

**Bowen's** motion that the society proceed with the program carried.

**C. T. Riggs** read a paper on "Typhoid Fever and Its Treatment."

**G. C. Hall** presented a paper entitled "Some Important Features in the Pathology and Treatment of Diseased Tonsils and Adenoids."

**Hugh D. Rodman** read a paper entitled "Acute Nephritis."

A general discussion was indulged in by Drs. Thornton, South, Carroll, Heizer, Bowen, MeChord, Aud, Riggs, Rodman, Houick, and Hall.

**Aud's** motion to adjourn carried. Adjourned to meet at Elizabethtown Thursday, August 13th, 1908.  
H. R. NUSZ, Secretary.

**Pike**—The Pike County Medical Society met at the Pike Hotel in Pikeville, March 2nd, 1908, with the following members present: Booth, Lear, Thompson, and Walters. The following doctors are to lecture on the following subjects: Booth on "Rheumatism and Gout," Lear, "Diseases of Skin," Thompson on "Fractures and Dislocations," Walters on "Tumors," Campbell, "Diseases of Lungs," Vickers on "Intestinal Canal."

W. J. WALTERS, Secretary.

**Washington**—The Washington County Medical Society met in their room at the Court House, March 9th, being the regular monthly meeting.

The President, W. W. Ray was in the chair. Those present were: W. W. Ray, S. J. Smock, J. C. Mudd, A. L. Beam, J. M. Spaulding, D. A. Crosby, M. W. Hyatt, W. E. Crume, Dr. Thornton, of Lebanon, and Drs. G. S. Hanes, Geo. Shamity, of Nashville, Ky.

Dr. Grannelle S. Hanes, Louisville, Ky., read a paper on "The Value of the Proctoscope in the diagnosis and treatment of rectal and sigmoid diseases, also demonstrating the use of the proctoscope.

Dr. Hanes' paper was very interesting as well as the demonstration of the proctoscope, which was demonstrated on a clinical case.

Dr. Geo. Shamity, Louisville, Ky., read a paper on "Chronic Posterior Urthritis as a Result of Gonorrhoea." Dr. Shaunty had a very interesting paper and was discussed by Drs. Hyatt, Thornton, Ray and Hanes.

Dr. S. Anderson, of Louisville, Ky., had a paper on "The Surgical Treatment of Uterine Fibroid," but was detained on account of sickness.

It is hoped that the doctors will make us another visit soon.

There being no further business it was moved and seconded to adjourn to meet again at the next regular meeting, April 13th, 1908.

JNO. M. SPAULDING, Secretary.

**Woodford**—The Woodford County Medical Society met in regular session on Tuesday, March 3rd, 1908.

Present, President Steadman, Worthington, McCauley, Blackburn, Phelps, Crenshaw.

Dr. Crenshaw read a paper on the "Summer Diarrhoea in Children." The paper was kindly commented upon by several of the members. Dr. Blackburn thought much of the use of Epsom salts and as a stimulant when needed, cognac brandy weakened and sweetened with honey. The honey removing the pungency of the brandy better than any other sweet.

Dr. Steadman liked lavage administered high up in the bowel. Dr. Worthington thought that honey was very conducive to fermentation, a condition which we wish to antagonize and shaw discountenanced emphatically and idea which is, mostly already present. Dr. Crenshaw that honey was conducive to fermentation, but asserted that it was indisputably the most easily appropriated of all sweets, honey being already "grape sugar," into which form all "cane sugar must be converted before undergoing animal combustion.

The Committee on Papers assigned: "La Grippe and Its Sequela," to Dr. Anderson; "Ulcer of the Stomach," to Dr. Worthington, to be read and discussed at our next meeting, to be held on Tuesday, April 7th. The society adjourned.

J. W. CRENSHAW, Secretary.

**Fat-Free Milk in Infant Feeding.** — Townsend's considerations lead to the following conclusions: While it is necessary to the normal infant, it is more often given in excess than is generally supposed. Excess of fat may cause one or more of a number of symptoms, as, for example, constipation, white and "curdy" stools, a ravenous appetite with atrophy and convulsions. In gastrointestinal disturbances it is desirable to exclude fat. The proteids of undiluted fat-free milk appear to be remarkably well borne even by young infants, and there is an absence of so-called curds from the stools.—(Boston Medical and Surgical Journal).

**Indications for Theobromin.**—C. Alvarez publishes a clinical study of the action of theobromin in asystoly in the Revista de la Soc. Med., Argentina, October, 1907. He thinks there is nothing to be compared with it for recent asystoly free from complications, especially when the kidney is sound, and in all cases in which the pulse rate shows little modification. The theobromin does not accumulate in the system, and it is less dangerous than digitalis, he thinks. Unless the pulse is extremely irregular, he gives theobromin the preference in every case of asystoly, changing to digitalis in case the desired effect is not obtained with the theobromin.

# KENTUCKY MEDICAL JOURNAL.

BEING THE JOURNAL OF THE KENTUCKY STATE MEDICAL ASSOCIATION.

JULY, 1908.

\$2.00 YEARLY.

## ABOUT YOUR DUES.

We are receiving more than the usual number of complaints about members not receiving the JOURNAL. In every such instance in the past month we find that the dues have not been received at the office of the State Secretary. Nineteen twentieths of the membership is paid up. It is the last twentieth that is hard to get. If every member would assist the county secretaries in this matter by collecting from members as they see them, it would be of the greatest possible assistance. The roll of the Association has already been sent in to the American Medical Association. From this the Directory will be made up, and those who fail to pay their dues appear as non-members. From day to day as we receive remittances from the delinquents we are sending their names to Chicago. We are sure by this time that our members realize that reciprocity is dependent upon the recommendation of your county society at a regular meeting. County secretaries are requested by the Council to make all checks payable to the Kentucky State Medical Association.

## OFFICIAL BUTTON.

Members of the Association have been urging the manufacture of an official membership button, and in response to this popular demand the Council has had the Purdy Company of Rhode Island, to manufacture a supply of neat, distinctive buttons with the golden words "Kentucky State Medical Association" in the magic circle around the red cross. They are similar to but quite distinct from the A. M. A. buttons.

As a token of appreciation of the interest shown, the Council will have one of these buttons sent to every member of the State Association who induces a physician who has never been affiliated with his county society to join it. The button will be sent by mail,

postpaid, as soon as the name and address of the new member and his annual dues are received at the office of the State Association from the County Secretary. Of course this does not include the reinstatement of old members, or of members who remove from other counties.

The Council desires to make it plain that these buttons are in no sense intended as a reward to members for doing a duty which has already been so well done that there are less than 800 non-members in Kentucky eligible to society membership but as a simple token of its pleasure at the active participation of another physician in the great work of our county and state societies.

Members desiring to purchase these buttons may do so by sending \$1.00 for a gold plated button or \$2.00 for a solid gold one to the KENTUCKY MEDICAL JOURNAL, Box 98, Bowling Green, Ky. We are sure every member will want one.

## THE ANNUAL ADDRESS.

The general interest already being manifested in the Annual Session of the Association which will be held in Winchester, September 23, 24 and 25, will be greatly increased by the official announcement of the Council that it has secured Professor Torald Sollmann, of Cleveland to deliver the Annual Address. Dr. Sollmann is a member of the Council on Pharmacy and Chemistry of the American Medical Association, and is Professor of Pharmacology and Materia Medica at the Medical Department of Western Reserve University, and it was felt particularly appropriate at this time when the attention of the whole medical world is being turned to the practical study of drug therapy in its clinical and scientific as distinguished from its purely empirical aspect that our Association should have one of the great leaders in modern pharmacology to tell us of its pro-

gress and its aims. His subject will be "The Mechanical Prescription," and we assure him an audience that will inspire him in the good city of Winchester.

#### THE PROGRAM.

The Committee on Scientific Work will announce next month the Preliminary Program for the Winchester Session. In so far as possible members will be asked to prepare essays for this session who did not appear on the program in 1906 or 1907. Fewer papers will be on the program, and it is the intention of the Committee to afford the greatest possible opportunity for that extemporaneous discussion which is the most pleasant and profitable part of our annual gatherings. It will be noticed that most essays will be grouped in symposia, and that abundant opportunity will be given for work in each of the great subdivisions of our science. Symposia in obstetrics, mental and nervous diseases, the diseases of children, pure milk, the practice of medicine, therapeutics and surgery will invite your attention and participation. The Committee has asked the Clark County Society not to arrange for social entertainments, as the time will be fully occupied by scientific work. A limited number of voluntary papers will be added to the program.

#### A. M. A.

Every member of the Kentucky State Medical Association has a large share in the wonderful meeting held last month in Chicago of the American Medical Association. The largest and strongest delegation of physicians which ever left Kentucky was in attendance, and took an active part in the various sections. The record for attendance was broken—6422 members being registered as present. The best previous attendance was in Boston, where 4701 were registered. However, it was neither from number nor from the high character of the attainments of those present, as remarkable as were both of these, that this session will merit its place in the history of our profession but on account of the scientific and practical work accomplished—on account of the uplift to the doctor everywhere especially in that part of his work that is nearest the people of the country, the prevention and cure of disease. No one man, nor any dozen for that matter, could see and hear it all, and the detailed proceedings which will be published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION from week to week will receive the closest attention from every medical man alive to his own or his patient's interests.

In the House of Delegates a continuation of the splendid work done in previous years was

noted. Kentucky was represented by Drs. McMurtry and Richmond and your secretary. On account of his experience both as a former Trustee and as President of the National Association, Dr. McMurtry gave the delegation a strength and influence that will be appreciated by all who know him.

The reports of the various officers must be read to be appreciated. Action was taken looking to more active work for the development of a Department or Bureau of Public Health at Washington which will help to conserve the greatest of all national resources—the health of the people, for more and better work by the Bureau of Public Information, in publishing matters of interest both to the profession and public about the altruistic aims and purposes of the organization and the best methods for their attainment, and the Council on Medical Education was heartily commended and directed to continue their efforts for the improvement of medical education. The retiring President, Dr. Bryant, of New York, especially emphasized the importance of teaching moral philosophy and medical ethics to the student while still in college. This same plan was elaborated and endorsed in the report of the Committee on Organization which is published in another page of this issue. The House of Delegates as a Committee of the Whole visited the JOURNAL office and inspected its great plant, after which a resolution expressing confidence in Dr. Simmons and his work was unanimously adopted by a rising vote. It was pleasing to Kentuckians that Dr. J. N. McCormack was requested to continue his work by a unanimous vote in spite of his request that he be relieved from it.

In the election of the officers the high standard of former years was maintained. Col. Wm. C. Gorgas, of the Medical Department of the Army was elected President. Dr. Gorgas is a native of Alabama and is the man who cleaned yellow fever out of Cuba and who has made it possible to dig the Panama Canal by making the Canal Zone habitable. Dr. Thomas Jefferson Murray, of Montana, was elected first Vice President. Dr. Murray had been a member of the House of Delegates for a number of years and is one of the most able and distinguished members of the Association. Drs. Woodruff, of Chicago, Hatchett, of Oklahoma, and E. N. Hall, of Kentucky, are the other Vice Presidents. In nominating Dr. Hall, Dr. Campbell, of Montana said that he nominated him as a worthy representative of the best type of the American physician—the country family doctor; that he came from a State which had done the best work of any because its profession was composed of men of whom Dr. Hall is a fair sample and that he was not only an

active member of the post-graduate club of his county society but that he had served his State Association and the American Medical Association with credit and honor. Dr. Hall was elected by acclamation. This is a great honor both to Dr. Hall and to Kentucky, and his friends feel that it reflects equal honor on the national body.

A surprise came with the election of three new members for the Board of Trustees to succeed Drs. Montgomery, of Pennsylvania, Johnson, of the District of Columbia, and Wright of Iowa. These gentlemen had been honored by two previous reelections and they retire from the Board with the gratitude and affection of the entire profession. Dr. Wright was an especial favorite with the Southern members, many of whom voted for him in spite of the fact that his friends made little effort for his re-election, feeling that he had served the profession in this capacity as long as it was fair to ask him to do so. This was the first session for years when it was possible to add new members to the Board, as previous to the last few sessions attacks reflecting on the integrity of all the Association and especially its officers were coming from every section of the venal press owned or controlled by the proprietary medicine people.

Drs. Wisner R. Townsend, Secretary of the New York State Medical Association, Phillip Mills Jones, Secretary of the California State Medical Association, and W. T. Sarles, of Wisconsin, are the newly elected Trustees. They are all men of the highest and best type and their numerous friends and admirers feel that they will help push the practical workings of our Association on to a better and larger usefulness. Dr. Jones' prominence as editor of the *JOURNAL OF THE CALIFORNIA ASSOCIATION* in the fight against dishonest proprietaries and the disreputable medical journals which advertise them made of his election an especial victory for all that is best in the A. M. A.

The attendance at our State meeting in Louisville last fall was 643, which was 1-10 of the Chicago session of the A. M. A. It is to be greatly regretted, however, that every medical man in Kentucky is not a member of the great parent body. Twelve hundred of our physicians already receive the *JOURNAL A. M. A.* If you do not, fill out and send in the application blank in this number and join to day.

#### TWO NEW BEVERAGES.

In this number of the *JOURNAL* will be found the announcement by the Lexington Brewing Company that they are now manufacturing and offering for sale two non-intoxicating alcoholic beverages which they call

Malt-Mead and Maltina. These products are one of the first good results of the local option sentiment which is so prevalent in the South, offering as they do beverages which taste and look like beer and yet contain such small percentages of alcohol as not only to be non-intoxicating but to be really beneficial with most people. Before accepting this advertisement we have had these preparations analyzed by the Council on Pharmacy and Chemistry of the American Medical Association and by the Division of State Food Inspection of the Kentucky Agricultural Experiment Station. The alcohol content is found to vary in Malt-Mead from 1.20 to 1.25 per cent. absolute alcohol by volume, in Maltina from 0.16 to 0.30 per cent absolute alcohol by volume. These preparations are made from barley, rice and malt, which are boiled at the proper time to prevent the formation of the larger percentage of alcohol found in our American beers. They comply with our pure food law, and are pleasant, nourishing, harmless beverages.

As we said above the manufacture of such products may well be called one of the good results of local option. Rectified whiskies, vile gins and high percentage beers sold in low dives, and not only stimulating all that was morally bad in the lowest grades of society, but actually poisoning their habits, is the real cause of the all but universal uprising against the saloon. Some sensible reasonable beverages containing the physiological amount of alcohol in a pure, nourishing medium had to be found. Whether the products whose announcement we carry will be the best to be made as far as taste and all goes remains to be seen. They are certainly unobjectionable on account of their alcoholic content, and we present them to the profession as pleasant beverages.

#### THE DOCTOR'S DUTY TO THE STATE.

It has just been our pleasure to read a brochure by Dr. John B. Roberts, of Philadelphia, on "The Doctor's Duty to the State." It is a pity that it cannot be read and digested by every physician in the Union. From the first page to the last Dr. Robert's high practical conception of the function of the doctor is one which does him great honor.

The first article in the book was delivered as the President's address before the American Academy of Medicine. The opening paragraph is the key to the address: "The doctor's highest duty is to be honest and to fight for honesty in his profession and in his State. He should abhor cowardice in others as in himself, for cowardice is the parent of dishonesty. The professional coward and the commercial coward have aided efficiently, if perchance unwittingly, the pres-

ent degradation of the body politic and the body medical." \* \* \* "The doctor must fight for honesty in others also and strike real knockdown blows at political and professional chicanery, if he wishes to do his whole duty to the public. There are in all vocations weaklings who do nothing but accept the benefits which their environment brings them. They make no return to their generation and when dead leave no special vacancy in the economic household." \* \* \* "A physician does not do his duty to his fellow citizens by merely treating their typhoid fevers, while making no effort to compel the local rulers to supply purer drinking water to the home. He knows the cause of this disease, and it is his bounden duty to actively labor for a pure water supply. \* \* \* If he is mentally or physically lazy, let him select some position in the world, where such inactivity and uselessness are less censurable."

At another place Dr. Roberts well says: "It is clearly improper for a doctor to prescribe a certain remedy for a patient, when he does not know, and is not permitted to find out, the character and amount of the powerful drugs it contains. It is also, in my opinion detrimental to professional integrity for medical journals, conducted under professional auspices, to accept advertisements of pharmaceutical products of secret composition. \* \* \* As to the first proposition there can be but one answer—which is that a doctor has no right to use a powerful therapeutic weapon, unless he knows its possibilities for good and evil. These possibilities he cannot know unless he is able to learn how much acetanilid, strychnine, arsenic, mercury, or other active ingredients it contains. The propriety of medical journals, published by doctors, increasing the dangerous use of these secret remedies by accepting their advertisements cannot be successfully maintained. \* \* \* If the vice of prescribing medicines of unknown composition is to be rooted out, honest doctors must jointly repudiate any such illicit combination with commercial journalism, and individually refuse to prescribe remedies of whose composition they are kept in ignorance." \* \* \* "Osler spoke of these nostrums being 'foisted on the profession by men who trade on the innocent credulity of the regular physician, quite as much as any quack preys on the gullibility of the public.' It must be a very ignorant or dishonest doctor, and not an innocent credulous one, who treats his patients with the secret nostrums brought to his notice by interested salesmen."

Again he speaks of a problem as solved which is still confronting the profession of many states, when he says, "The secret remedy evil is degrading the medical faculty

at this hour very much as the low grade medical school debauched the profession. The cause is the same—laziness and love of money. The case is the same—an aroused professional sentiment. It was the leaven of honesty in the hearts of the doctors at large, which compelled avaricious professors and low grade medical schools to cease deluding the public with unsafe and ignorant medical practitioners. It took energy, courage, and unselfishness to carry on the work. Honest men were compelled to antagonize friends, to fight against their *alma matres*, to relinquish opportunity of professional position, and to be misunderstood by other honest men. What matter, when the goal was to preserve the State and uphold the honor of the medical guild!"

Many more quotations of as great or greater value can be read on all of the hundred pages of this valuable collection of the utterances of a great man. We trust Dr. Roberts will make his work available to the many men now interested in medical economics.

## SCIENTIFIC EDITORIALS.

### ABDOMINAL CONTUSIONS ASSOCIATED WITH VICERAL INJURIES THEIR DIAGNOSIS AND TREATMENT.

When the abdominal wall has been subjected to trauma there is often produced a class of injuries which in the early stages offer much difficulty in distinguishing between the trivial and the severe internal injuries.

Most often these contusions are associated with other lesions, as fractures and dislocations, which later distract our attention, and are very liable to be overlooked in our first examinations. Brewer has said: "The results of an uncomplicated abdominal contusion may vary from a slight feeling of soreness or general discomfort, with or without an insignificant bruise or ecchymosis of the skin, to a rapidly fatal collapse."

They result from a variety of accidents, embracing blows, kicks and crushes, and the trauma may be either confined to a small area, or widely spread over the whole abdominal cavity. The extent of damage will usually depend upon the amount of the force, the condition of relaxation, or rigidity of the belly muscles, and whether the hollow organs contain fluid as well as the particular area affected.

All the organs of the abdominal cavity suffer, but those deeply seated, as the pancreas and the kidneys, receive less damage.

Movnihan says: "The injury to the intestine is of different kinds. The bowel may

be crushed between the offending object and the spinal column or pelvic wall; it may burst when full of its normal contents; it may be torn away from one of its fixed points; it may be damaged, though not completely ruptured by the blow, and sloughing and gangrene at the injured area may lead to secondary perforation, or the mesentery with its vessels may be so injured that gangrene of the gut supplied from the vessels will in time result. The injury may be limited to the mucous coat or to the peritoneal coat, or it may, and most frequently does, involve the whole thickness of the wall. When the force is diffused, a rupture occurs as a rule, at one of the fixed points of the bowel, at the duodenojejunal flexure or at the ileocecal junction, or the mesentery is torn."

It is generally agreed that the ileum and the jejunum are the parts of the intestine most often injured.

In rupture of the liver, spleen or kidneys, the fracture or fissure is along the line of the blood vessels, and if not deep and limited only to the cortex of these organs, the hemorrhage is not profuse; but when large arteries are torn, an enormous amount of blood escapes to spread over the peritoneum, unless by clotting within the fissure its flow is checked.

A distended gall or urinary bladder is liable to rupture when the blow received is over those parts.

In former years, surgeons regarded shock as a prominent or chief symptom of internal injury, but the modern statistics have clearly shown that this is only present to a great extent in those cases where much hemorrhage or great extravasation has taken place. It has been demonstrated by Crile that injuries to the upper abdominal cavity, especially those involving the diaphragm, give rise to more shock than those in the lower or pelvic region, and he further adds that "the more specialized and abundant the nerve supply to a part the more will it contribute to the production of shock when subjected to injury."

Korfe, writing in von Bergman's Surgery, says: "If the shock is due to hemorrhage and not to the injury itself, it will not decrease as time goes on, but will rather increase, and the patient will further exhibit the symptoms of increasing anemia a pulse growing weaker and faster, exhaustion and restlessness."

"In the presence of shock," says LeConte, "we cannot make a diagnosis of intestinal injury, no matter how profound the shock may be or how slowly reaction takes place. We may diagnose hemorrhage, which would lead to an immediate operation, and at the same time presume the presence of a lacerated gut, but primary shock is of itself no

aid to our diagnosis. I would therefore wait for reaction to take place. No one symptom is pathognomonic of intestinal injury, but the two most reliable are gradually increasing rigidity and the facial expression."

Moynihan has well described the symptoms which lead to a diagnosis when he says: "To sum up, one may say that when a patient has sustained such an injury to the abdomen as is likely to produce a serious lesion; if the abdomen soon becomes rigid and tender; if the rigidity steadily increases and affects the whole abdominal wall; if the vomiting is repeated at short intervals; if the patient by his facial appearance conveys the impression of serious illness, then an exploratory operation is not only justified but is imperative."

Having reached a conclusion that our patient is suffering from severe internal rupture due to an abdominal contusion without a perforation of the belly wall, what should be our treatment? Only until recent years when a diagnosis of this condition was reached, was any radical treatment advocated, and the patient was formerly left to take his chances with a non-interfering policy, rather than resort to operation, assuming that the case was practically hopeless if much damage was done.

Petry collected statistics of 160 cases of ruptured intestine without operation, having a mortality of 93 per cent.

A later series of 376 cases collected by Siegel show a mortality of about one-half the former, 51.6 per cent following operative interference. The cases operated upon within the first four hours after injury had a mortality of 15.2 per cent.; those within 5 to 8 hours, 44.4 per cent.; those within 9 to 12 hours, 70 per cent. mortality.

These figures clearly demonstrate the wisdom of early surgical interference in severe abdominal contusions associated with grave visceral injuries.

When a decision to operate has been reached, the abdomen should be opened in the median line by an incision of ample length and near the area where the greatest damage is suspected. If hemorrhage has occurred, the fluid of the cavity will readily show the discoloration, and if mixed with fecal matter, will indicate a perforation of the intestinal canal.

In the presence of very profuse hemorrhage, it is necessary to work with great rapidity in handling the viscera in order to reach the bleeding point and prevent further shock.

Arteries of the mesentery can be easily clamped, but wounds in the solid organs, as the liver and spleen, are often very difficult to manage.

It was formerly considered impossible to

stitch large wounds of the liver owing to its great friability, but if the chief bleeding points are first clamped and ligated, and then a blunt-pointed needle threaded with a catgut suture, is introduced slowly through the soft tissue some distance from the cut edge, the wounded edges can be nicely approximated. But all this often requires much delay and experience, and the average operator would save much valuable time and do better to introduce a gauze tampon within the fissure, and bring the ends of the gauze through the abdominal wound, to be subsequently removed. This latter treatment affords good drainage, and has been used with much success in stab wounds of the liver and spleen.

The most difficult and hopeless class of abdominal contusions are those where the injury is principally confined to the nervous system, and traumatism here produce conditions which often lead to confusion as to diagnosis.

Von Bruns, as quoted by Star, has called attention to the fact that while two-thirds of his cases of nerve injury recovered, only one-fourth of the cases of injuries of the plexuses were cured.

JOHN R. WATHEN.

## ORIGINAL ARTICLES.

### A FEW REMARKS ON TUBERCULOSIS OF BONE.\*

BY BENJ. F. VAN METER, LEXINGTON.

An early diagnosis of tuberculosis of bone is the paramount issue. I do not propose to take up the subject in an exhaustive way for fear of obscuring with figures and statistics a few cardinal signs and symptoms of the disease, and two or three advances in treatment to which I wish to call your attention.

All of us see tuberculosis of the knee and hip treated as rheumatism until abscess-formation, and tuberculosis of the spine treated as indigestion or something else until there is loss of tissue and the everlasting knuckle or kyphosis. We all know there is absolutely no excuse for this. We don't do it, but the absent brother, who is too busy to come to this meeting, does do it and has always done it. I am sorry he is not present. We've always been sorry that he wasn't present.

The pathology of tuberculosis of bone is the same as of that of all tissues. Tubercle bacilli, whether dead or alive, seem to possess the capacity to kill live cells in their immediate proximity. These dead cells undergo a process of cheesy degeneration, and from

them flocculent masses, found as a characteristic of tubercular pus, are formed. Immediately surrounding the focus of infection or tubercle is a process of great activity, proliferation of cells, which forms a zone of granulation tissue. This is an effort on the part of Nature to surround the enemy. Now one of two things takes place. The periphery of the focus of infection is slowly melted away by the killing effect of the bacillus on the granulation tissue, as an apple rots from the core toward the surface. Then we have abscess-formation, which deadens its way to the surface of the bone, and burrows in the way of the least resistance. When the diagnosis is made by the absent brother, and often by his neighbors, and the patient has lost his golden opportunity. For the other thing that could happen would be for the doctor to come to the aid of that surrounding cordon of granulated-tissue with an early diagnosis, good food and rest (meaning fixation) fresh air, an enforced blood-supply, or congestion where practicable. When this is done, in the overwhelming majority of cases the granulation tissue wins the fight, and surrounds the focus of infection with a hard and impenetrable wall. With an early diagnosis, and the aid of Mother Nature, you are able to pass on the bacilli in that tubercle a sentence of life-imprisonment, where they are doomed to die, harmless to their host.

When it is remembered that the cancellous tissue of the articulate ends of the long bones and the bodies of the vertebra are the favorite places of attack by the bacillus, I will only take up in a general way the diagnosis of tuberculosis of knee, hip and spine, and mention what I believe to be a few advances made in treatment.

The symptomatology is based on the pathology, and runs a course more nearly parallel thereto than in almost any other condition in medicine, certainly more so than in pulmonary tuberculosis. The old debatable question of trauma has never been settled. There are some few who believe that injury prepares the way for invasion, and stands in the foreground of etiology. As for myself, I doubt it. One can get a history of a fall to go with any ailment of childhood. I don't remember ever having seen a case of anterior polio-myelitis where the mother was not positive of some injury, and in her mind there is usually a dark suspicion that a careless nurse has let the baby fall and injured its back. The hereditary tendency is the same as that for tuberculosis of other parts. The early symptoms are few, and easy to remember. Pain is not a constant or cardinal symptom, and is usually referred. The hip is supplied by the anterior crural, sciatic, and obturator nerves. The pain, if any, is usually referred

\* Read by title before the Kentucky State Medical Association, Louisville, October 15-17, 1907.

to the distribution of the abductor, the inner side of the knee.

Night-cry is a very important symptom, and is usually present, occurs oftenest in the early part of the night, and is caused by a temporary relaxation of the voluntary muscles about the hip, then a sudden involuntary muscular spasm, which jams the articular surfaces together. Typical night-cries are of two kinds; one a sudden scream, when the patient wakes up conscious of pain, and of having cried out, the other the patient gives a sudden cry, followed by some mumbling and restlessness, but does not wake, and if awakened, is not conscious of having cried out, or of pain.

Loss of appetite, and de-toning of general condition are about the same as in early tuberculosis of the other parts, though I think as a rule a little less pronounced. Limp is usually the earliest and most important symptom, and by the practiced observer it can nearly always be detected very early. Though it is sometimes transient, and is usually more pronounced in the morning, or after rest. With the limp and physical signs we make the diagnosis. The cardinal physical signs are muscular rigidity, change of contour, and atrophy. Reflex muscular spasm which is the cause of limitation of motion is an infallible sign of a diseased or inflamed joint. In children, when not traceable to actual injury, and limited to a single joint, is practically always tubercular. Limitation of extension is usually first to occur. With the patient lying prone, with the hand on the sacrum, to steady the pelvis, if a full range of extension can be had easily without pain, hip-disease can be excluded. Limitation of motion at the hip also occurs with low Pott's disease. I have seen more than once a diagnosis of hip-disease based upon the limitation of extension where, as a matter of fact, the disease was of the lower lumbar vertebra. Here the differentiation should have been made by finding a full range of flexion and the limitation of all motion in the spine. Limitation of flexion is then next to occur, and often occurs co-incident with that of extension. Following these early signs we have general rigidity, when the body moves with the thigh, and the so-called "stage of apparent lengthening" exists.

*Change of Contour.*—This is an old and very trustworthy sign, and one that the father of orthopaedic surgery, Lewis A. Sayre, was fond of laying great stress on. It's a striking sign, and perfectly apparent. The gluteal fold is lowered, and shortened, the buttock is broader and flatter. You will see by a moment's consideration, that the sign is brought about and is necessarily following on account of the attitude of the limb

in the "position of apparent lengthening," which is abduction, flexion and outward rotation.

Atrophy does not occur early, but is a valuable sign to sustain an early diagnosis, and to give some idea as to the duration of the disease it is always present sooner or later. The inguinal glands on the affected side are enlarged fairly early.

*Knee and Spine.* The knee being a much more superficial joint is subject to a more direct observation, but the cardinal symptoms hold good. Limitation of motion, pain, change of contour, night-cries; with the addition of tender points on pressure, and the constant tendency toward flexion and a subluxation of the tibia backward. Later, swelling, fluid, and local heat.

*Spine.* The same symptoms and signs, with the pain, if any, referred to the belly. The deformity is that of flexion at a very acute angle forming a knuckle due to the destruction of the bodies of one or more vertebra. The angle is short and acute, or long and oval, as one or more vertebra are involved.

Shame be it said that the diagnosis is not usually made by the absent brothers until the kyphosis puts in its appearance, which means that the disease has progressed to the point of destruction of tissue. Far beyond the stage of inflammation which has usually lasted for weeks, the granulation tissue is losing the fight against the killing influence of the bacillus. Why haven't you made the diagnosis? The child has had a rigid spine, with limitation of motion especially that of extension, has been holding out a hand to every object in his surroundings for support; walking from chair to table, and to chair with a hand ever on something, even on the good doctor's knee, while he shakes hands with him with the other. He squats with upright spine to pick up his playthings from the floor instead of stooping. He has cried out in his sleep, and when awake, to every inanimate object in his environment, including the knee of the doctor. But until the mother finds that everlasting (because it is never corrected) knuckle, the absent brother has supported him on calomel, pepsin and worm medicine.

Why is this? A very simple reason. The absent brother hasn't stripped the patient, and laid him prone on a smooth table, and caught him by his two legs, and tested his spine as to limitation of motion and muscular rigidity. For this there is absolutely no excuse on the part of the doctor, and no ultimate end but failure.

To recapitulate, the cardinal symptoms and signs of tuberculosis of articulate ends of bone are, impaired function, reflex muscular spasm, limitation of motion, pain, change of

contour, night cries, atrophy, a tendency toward a fixed and definite deformity, and the running of a chronic course.

*Treatment* is operative, mechanical and general. Operative treatment is confined to the extremities in adults, and in children only indicated after abscess and sinus formation. Excision of knees, elbows, ankles and shoulders in adults after a thorough trial and failure of mechanical treatment, has yielded good results. There are even cases in the working classes where a short period of disability only is demanded, where an excision might be indicated primarily. In children it is almost never indicated, because of destroying the epiphysis. Dead bone should be removed, sinuses curetted, and thorough drainage established. A sharp and definite excision at the hip has proven a failure; that which almost amounts to an excision, done with a curette, is often indicated and has saved many lives. The advantages of the curette excision are; it leaves fragments of sound bone, and shreds of periosteum, which produce new bone, save shortening, and give a firm, solid, ultimate fixation. It is a safe statement, that no cutting operation should ever be undertaken in children, until after sinus-formation. In the great majority of cases, conservative mechanical treatment accompanied by, where practicable, Biers' congestion, will give the best results. In the acute cases, where an early diagnosis has been made, good food, fresh air, and mechanical treatment only is indicated. Mechanical treatment implies three things: fixation, support and traction. As soon as the very acute stage with muscular spasm has passed, fixation and congestion only is indicated. In my opinion, when the countless number of braces and apparatus of all descriptions are tried and compared with plaster, they have been found wanting. A combination of a simple brace to walk on, with plaster for fixation, has given me the best results. As soon as the case is convalescent, or, if you choose as soon as the acute symptoms have subsided, the brace is discarded, and he is allowed to walk on his feet, while fixation is maintained by a short spike.

In disease of the knee during the convalescent stage, an ordinary plaster-cast from the middle of the thigh to the middle of the calf. When one has learned what really can be done with plaster of Paris, he can go a long way without the instrument-maker.

*Pott's Disease.* There is no brace that has ever been made for the back that compares with a plaster jacket. In cervical Pott's or high dorsal, we must needs have a jury-mast incorporated in our plaster jacket. For disease from the mid dorsal down, the compara-

tively modern way, that of putting on the jacket with the patient lying prone, resting his extended arms and chin on one table, and his thighs on another table of the same height, is a distinct improvement on the old method of suspension by head-gear. In this position the spine is extended and the bodies of the vertebra are separated and the weight is borne on the posterior articular processes instead of anteriorly on the bodies of the vertebra, which is the location of the disease. The whole story of the treatment is written in plaster, and to my mind, braces do not fill the indications. I believe the leather jacket is worthless, worse than worthless, because it gives the patient a sense of security that something is being done for him that the leather jacket doesn't do.

The Biers' congestion treatment has been used sufficiently where I believe I can say, it is a distinct advance in our methods and is invaluable in the joints where it can be properly brought about. In sinus cases it is invaluable.

As to the opsonic index; we have not gone far enough with this and the therapy treatment to say definitely as to what its true scope and value will ultimately be. It would seem that it bids fair to give us a means of an early and positive diagnosis. Hollister has said if the patients' tuberculo-opsonic index is consistently below that of normal he has tuberculosis, if much higher or very variable he also probably has tuberculosis. L. S. McArthur has maintained that in the tuberculo-opsonic index of a patient we have a positive and absolutely reliable means of determining whether a patient is tubercular or not and this by a simple examination of the blood.

John Ridlon, of Chicago, in preliminary report of ten cases of tubercular infection treated by Wright's method, concludes, first, a low tuberculo-opsonic index with a local joint symptoms may be accepted as evidence that it is tubercular, but a normal opsonic index neither proves nor disproves joint tuberculosis. "When a diagnosis has been made a high opsonic index should be maintained if possible. With a high opsonic index an operation for the removal of all or part of the diseased focus may be undertaken, not so with low index. If use of the joint lowers the opposite index the joint must be protected, that is fixed, if it does not, motion at the joint and weight bearing may be permitted—if it raises the index, use of the joint must be insisted upon.

He believes and so do I, that we have not gone far enough with vaccine therapy, and the opsonic index to be positive if its range of usefulness but that the outlook is very en-

couraging and there is a fair chance that we may be able to control joint tuberculosis eventually almost as well as we now control diphtheria with anti-toxine.

### THE PRESENT DAY STATUS OF TUBERCULOSIS.\*

BY DELIA CALDWELL, PADUCAH.

In presenting this paper I have no thought of offering anything new or startling for your consideration. It is only my intention that we "take stock," as it were, of our present knowledge of this the most prevalent and destructive of all the diseases which we have to contend with.

If we accept the statement as we usually must, of Dr. Frank Billings, an ex-president of the American Medical Association—and one of the foremost medical authorities in this country, we must admit that one in five or twenty per cent, of our population, is afflicted with some form of tuberculosis. This statement was made within the past six months before a body of laymen in Chicago, but I feel sure the percentage is not materially less in Paducah than it is in Chicago.

In trying to review the literature of the past year bearing on this subject I was reminded of the small boy who, in writing his first composition at school, chose for his subject, "The World and Its Inhabitants." My subject almost covers the same ground of such wide-spread prevalence is this disease.

There are two aspects of this subject which I wish especially to present to you: First: what I shall call the individual doctor's interest in, and use of, our knowledge of tuberculosis. Second: the interest of the general public in this disease and its great responsibility in regard to its spread or limitation, in the light of our present knowledge of the characteristic manner of its propagation.

Under the first division: The individual doctor has been gradually learning many valuable facts about tuberculosis. First and foremost of these is, that it is not directly transmitted as a disease from the parents or ancestors of the patient, that is, it is not hereditary. Second: It is *infectious*. This we have learned by observation in our own practice as well as by the many and exhaustive researches of biologists and microscopists. From these two facts we deduce the third: It is *preventable*. The fourth is it is curable. This we know by our own and the experience of many other physicians all over the world.

Consider for a moment the revolution which these four facts, (which by the way, are not yet thoroughly realized by even all of

the medical profession), have wrought in our attitude towards this disease. Of course it is curable only when recognized early and treated rationally. But think of the difference from the days when every person afflicted with consumption was absolutely doomed to die.

In regard to its curability we say roughly speaking, in the "early stages." To be more specific I quote from the requirements of one of the most benignant charitable institutions in our country, The National Jewish Hospital for Consumptives at Denver, Colorado, "Only patients in the early stages of pulmonary tuberculosis are admitted—with such signs as dullness at one or both apices, with some modification of respiratory note, slight changes of temperature, without much loss of strength, and absence of all laryngeal and severe digestive disturbances."

"Patients with more or less continued fever extending over a prolonged period, rapid, weak pulse, marked anorexia, rapid loss of weight, obstinate diarrhoea or general weakness even though there are but few adventitious signs in the lungs, should not be sent. Patients having the above symptoms, together with signs of marked consolidation or excavation or those with fibroid phthisis of many years standing are not admitted."

This institution gives statistics of 60% of those sent to the hospital since its beginning cured or sufficiently improved to again become bread-winners. Many of these were not incipient cases, as the institution has found it difficult to effectually exclude the advanced cases on account of either carelessness or mistaken kindness of medical examiners. Of true incipient cases 85% are estimated to have been completely restored to health.

I have thus quoted these statistics to give an accurate idea of the curability of this disease in order to show you what we may definitely promise our patients.

From the foregoing we see the great necessity of determining the presence of the disease at the earliest possible moment. Not only does this apply to pulmonary tuberculosis but to those forms found in bones, joints, glands, in fact practically every organ and tissue of the body, in order to prevent destruction of tissue with consequent disability and deformity, if not absolute loss of life.

Our main reliance in the past has been on a careful physical examination and, where possible, as in pulmonary and intestinal forms, a microscopical examination to determine the presence of the bacillus of tuberculosis.

In the past few years, and especially within this past year, however, pathologists and bacteriologists have been working diligently to supplement these two methods, which are

not available as early as desirable and not always entirely reliable. These efforts have resulted in two new procedures, I mean relatively new. The tubercular test and the test by means of the opsonic index.

Tuberculin is the product which Koch exploited prematurely a number of years ago as a "cure" for tuberculosis; as the diphtheritic serum is a cure for diphtheria. This tuberculin fell into disrepute because, being prematurely extensively advertised it was rashly and ignorantly used and its use was followed by many disastrous results.

Investigators continued its use cautiously and carefully and it became recognized as a legitimate and valuable means of diagnosis in bovine tuberculosis and is used, as such, in most of our states in dairy inspection. It is generally considered perfectly reliable and entirely harmless to non-infected cattle.

In the past few months it has been employed very carefully as a means of diagnosis of human tuberculosis, especially in children. Its use for this purpose is authorized by so good an authority as Roche, of Boston, and the dose is a very small fraction of a grain for sub-cutaneous injection. In a healthy child this produces very slight reaction, while if the child be tubercular, fever and other constitutional symptoms are marked. Even yet the use of this agent is not without danger, as instances are still given of deaths resulting from excessive doses either ignorantly or carelessly given. Roche also advocates its use for curative purposes and states that in some instances he has obtained good results.

A modification of the use of tuberculin as a means of diagnosis is the ophthalmo-tuberculin test in which one drop of a very dilute tuberculin solution is instilled into the eye in suspected cases. A reaction, which is strictly localized, is obtained in infected subjects, and none in the healthy. This reaction consists of a reddening of the conjunctiva and caruncle and the production of a profuse sero-fibrinous secretion. It is claimed that it is painless and harmless as well as perfectly reliable. It is greatly to be hoped that further investigations will thoroughly substantiate these claims.

The second new diagnostic agent is the utilization of recent researches into the behavior of the opsonins in the blood. By using the properly prepared pure culture of tubercle bacilli and testing the patient's ability to destroy these organisms, not only is it possible to make an accurate diagnosis but it is also practicable to judge of the progress of the disease under the tuberculin or other recognized treatment.

The opsonic test can be used more safely,

from what I gather, than the so-called tuberculin tests except the ophthalmo-tuberculin test.

So much for the newer methods of diagnosis.

I think most of us will stick to our physical examination and the verdict of the microscope pretty closely but I hope we will not be so conservative as to fail to try these recent methods and to use them after proving them, or seeing them proved reliable.

Having made our diagnosis it now remains to prescribe the treatment.

I scarcely realized till I came to write it, how thoroughly the treatment of this disease has been revolutionized, even since I began to practice medicine twelve or fifteen years ago.

What is the recognized treatment of all forms of tuberculosis in the opinion of the best, most enlightened physicians to-day? Outdoor air, sunshine, and nourishing, suitable food. These must be used abundantly, yes according to all old standards, superabundantly.

Drugs are scarcely used at all except for special symptoms, or temporarily to assist the patient to make the best possible use of the three vitally necessary agents named above.

We add rest or exercise and vary the climate to suit individual cases. In this disease, as in all others it is the patient not the disease which must be treated.

As a consequence of this accepted theory of treatment our medical literature is filled with descriptions of appliances rendering it possible for even the most delicate patient to live out of doors. We have sleeping tents and shelters and hovels in great number and many sanatoria where the outdoor life is compulsory. And the wide-spread fear which consumptives and their friends have cherished carefully for years against "drafts" and "taking cold" is gradually but laboriously being proven groundless.

In considering the second aspect of this subject—the interest of the public and its responsibility in regard to this disease the two essential facts here to be considered are its infectiveness and consequently its preventability.

All over the world public spirited citizens, instructed, stimulated and encouraged by our profession are inaugurating campaigns of education in regard to the frightful ravages of this disease, its contagiousness and preventability.

The best way to dispel the horror most people have of this most distressing malady is to teach them about it, talk about it freely as about any other contagious disease. Take it in a matter of course manner as you would the grippe or typhoid fever. In most of our

cities this is done by some regularly organized body composed of physicians and laymen, called variously "Anti-tuberculosis Leagues," "Societies for Prevention of Tuberculosis," etc.

These bodies look after the spread of accurate, scientific information on the subject; provide "exhibits" showing various facts in regard to it especially in the way of illustrating its spread by unsanitary and infected houses. They also look after state and local legislation in regard to provision of public sanatoria, anti-spitting laws, isolation of advanced cases in our public charitable and penal institutions, etc. In these institutions as you know, few inmates have an opportunity of living out the allotted time of life because so thoroughly are the buildings infected and so unsanitary are the surroundings that consumption carries off its victims by scores.

In some states notably Kansas, a colony of tents has been established in connection with its prisons, for those who become tubercular.

In our state I do not know how many of these societies for the study and prevention of tuberculosis exists but I am sure that however many there are, in such a necessary work there is always room for one more and I suggest that we take steps immediately to organize such a society in Paducah.

#### RELATION OF BOVINE TO HUMAN TUBERCULOSIS.\*

By THOMAS STONE LEWIS, LEXINGTON.

Historically bovine tuberculosis is one of the oldest diseases which has been mentioned in animals. Moses, in his laws, forbade the consumption of animals affected with tuberculosis. The Talmud contains numerous measures relative to this disease. During the eleventh and twelfth centuries it was described by the Arabian rabbi, Alfasi and the Hebrew doctor, Mainonides. There is a collection of Jewish writings upon tuberculosis which dates upon the sixteenth century. In the ninth century, in the Franconian portions of Germany, the church laws forbade use of tuberculous meats. The sale of tuberculous meat was forbidden in Wurzburg in 1343, in Munich in 1379, in Pasau in 1394, Landshut in 1401, in Wurtenburg in 1558, in Platinaf in 1582. Twelve scholars of a Leipsic school died in 1677 of tuberculosis contracted by consumption of infected meat. In 1702 Florinus called it "French disease" because it resembled syphilis and believed that the animals were infected through sodomy. All tuberculous animals had to be destroyed. Grauman, in 1784, stated that the animal loss from this cause in Prussian countries was \$4,-

000, and that a non-observance of this law was followed by severe outbreaks. In 1783 the Sanitary College of Berlin criticised the relation between tuberculosis and syphilis. As a consequence tuberculous meat was allowed to be eaten. Kersting of Hanover, Franck of Baden, gave a similar opinion the same year. Grauman, in 1784, stated that tuberculous meat had no noxious property. All the edicts which forbade the sale of tuberculous meat were repealed in 1785. Austria took the same measures in 1788. In 1816 Tschendin divided tuberculous meats into three classes and advised the following rules: In cases of the first degree tubercles were removed; in the second, the affected organs must be destroyed, and consumption of non-affected meat allowed; in the third the whole carcas must be destroyed. Until recently these measures were enforced in Southern Germany, Switzerland, Austria, France, Belgium, Spain and Italy. In 1700 Magnetus described for the first time miliary tubercles. Following him, came a host of investigators, Bayle, Lannee, Meissner, Rokitansky, Virchow, Lebert and others endeavoring to solve the problem of tuberculosis by anatomical and microscopical research. Von Preuss, Simon and Lehman and Vogel made numerous chemical researches with the purpose of explaining the so-called dyscrasia. These threw no light upon the subject. The most important result of this investigation was BULL'S discovery in 1857, that acute miliary tuberculosis was as a rule, traceable to a pre-existing cheesy foci whose infectious products were taken up by the blood and so gave origin to disseminate miliary foci in the various organs. He thus had the conception of miliary tuberculosis as a specific disease due to absorption and infection. Another important result of these extended researches was the conclusion of Cruveillhier in 1862 that scrofula and tubercular diathesis were identical. So after a hundred years untiring labor by investigators the problem of tuberculosis remained unsolved.

We now enter the stage of experimental investigation. The earlier attempts to produce the disease artificially by Kortum in 1789, Hebreart in 1802, Sahnade in 1805, Lepelletier in 1816 and others were failures. They inoculated themselves, healthy children and animals with serofulous pus, but with no effect. To disprove its infectious nature Cruveillhier injected quicksilver into the trachea of animals and produced tubercle like nodules, so the theory of infection found at first no foothold. In 1843 Klenke was the first to get results, but his contribution was forgotten. Villimin published in 1865 his brilliant series of experiments. He injected and fed rabbits and cows with tuberculous material

\* Read before the Fayette County Medical Society, May 14, 1907.

from human and bovine sources and caused tubercles in the lungs. Rabbits inoculated with the pus showed no trace of tuberculosis. This brought him to the conclusion that phthisis was a specific disease, virulent in type and produced by an inculcable agent. That same year Chauveau produced the disease in cows. These results were confirmed by Klebs, Conheim, and Gerlach in 1869 and Baumgarten in 1870. Villimin, Chauveau and Gerlach proved clinically that bovine tuberculosis was introduced into their stables by a purchased animal and spread through the entire herd. They looked upon this as a confirmation of their inoculation experiment and it appeared to them further that there was often a remarkable coincidence between the use of milk from tuberculous cows and the development of the disease in mankind. By these brilliant experiments the infectious nature of bovine and human tuberculosis was thoroughly established. It now remained to discover the nature and quality of the specific virus. The first attempt in this direction was made by Klebs in 1877, by cultivating tuberculous material upon the white of eggs. Inoculations with this produced lesions similar to tubercles. Schuller and Reinstadler confirmed his results, but neither of these investigations or those of Touissant in 1881, in which he cultured bacteria from tuberculous blood, capable of producing tuberculosis were able to settle the question. It was reserved for Robert Koch to bring the problem to a final solution. After many unsuccessful attempts he was able to demonstrate fine rod-like structures, in sections of the fresh grey tubercles of recently killed animals. These were found by Koch in miliary tubercles, in tuberculous intestinal abscesses, in scrofulous cervical glands, in fungous bone and joint disease, in lupus, in sputum, in consumption of cattle, in beef, in all diseases which by their course as well as their microscopical structure and infectious nature of their products, must be regarded as tuberculous. He further demonstrated that they were found exclusively in tuberculous, never in other diseases, nor in healthy tissues and that they could be recognized in the very inception of the disease. Further he succeeded in growing them in coagulated blood serum. The keystone of Koch's demonstration was the inoculation test whereby he showed that pure cultures produced tuberculosis as typical as that due to inoculation with cheesy glands, cattle tubercles, lupus, etc. Simultaneous injections of various substances containing no tubercle bacilli are always negative. The announcement of this classical demonstration was made before the physiological society of Berlin in 1882. A few weeks after Baumgarten during a course of experimental re-

search on tuberculosis had occasion to examine unstained tissues in a weak solution of caustic potash. He detected bacilli that did not stain by Weigerts method. Basing his opinion on this 'negative reaction' he considered them pathognomonic of tuberculosis. Shortly after he had opportunity at one of the meetings of the medical society of Berlin to submit his preparation to Koch who pronounced the bacilli as identical with his bacillus tuberculosis. As a natural outcome of the discovery of tubercle bacillus much attention has been given to the bacteriology of tuberculosis. The new field made possible by the investigations of Villimin and opened up with results so brilliantly realized by Koch has been assiduously cultivated by a host of workers. No other subject has witnessed the same development and perfection in method of study. Babes, Petrone, Noard, and Roux were among the first to note variations in form Metchnikoff in 1888 found that in old cultures bacilli remarkable for their small size and resembling cocci. Coppen Jones described long branching forms and some that showed the characteristic form of actinomyces. Most of the earlier investigators used avian and bovine tubercle bacilli, though a few used bacilli from human source. It seemed that change of environment is one of the most potent factors in altering the morphological characters. So Krahl and Dubar have completely changed the tubercle bacilli of human and avian origin by growth in cold-blooded animals. Differences have been insisted on by Theobald Smith between bovine and human bacilli according to him bovine bacilli tend to remain short, while others, especially the human variety remain slender. Another important discovery was variation in virulence. As early as 1883 Air-long of Lyons showed that differences existed between bacilli from scrofulous surgical lesions and tuberculous lungs. Lartigau mentioned variations in virulency observed in human tubercle bacilli obtained under different clinical conditions. Theobald Smith and Dinwiddie reiterate a fact already noted by Villimin that bovine tubercle bacilli are more virulent than the human variety for cattle, sheep, goats and rabbits, while no distinction can be established in the case of horses, pigs, cats, dogs and monkeys. However, these experiments in which the disease is produced in one species with tuberculous material from another, led to the view that tuberculosis in all species of mammals was identical. Koch, himself at that time considered them identical, especially the bovine and human variety.

The interesting experiments of Noard with avian tuberculosis add confirmation to this view. He filled small collodian sacks with human tuberculous sputum and intro-

duced them into the peritoneal cavity of fowls. At the end of five months they were killed and it was found that the cultural characters had been so profoundly modified that instead of growing like human tubercle bacilli they possessed the characteristics of fowl tubercle bacilli.

This modification was not limited to the cultural side only, for the pathogenic differences were pronounced, the animals dying of typical lesions of avian tuberculosis. Kruse and others found avian tubercle bacilli in human sputum, having the same cultural characteristics and pathogenic qualities. The investigation of Terre, Bataillon and Dubard in 1897 concerning tuberculosis in cold-blooded animals furnishes the last link of evidence necessary to prove the unity of all tubercle bacilli. The variations observed are merely accidents of long habit in certain environments. If, therefore, the avian bacilli could be made to produce tuberculosis in mammals and the mammalian bacillus to produce this disease in fishes and frogs there appeared no reason to doubt that the bovine bacillus could produce tuberculosis in man; since the human and bovine bacilli resembled each other more closely than do the avian and mammalian or the mammalian and piscine forms.

Now comes an explosion: At the London Congress in July 1901 Koch took an opposite position stating that as a result of further experiments he had concluded that the bacilli of bovine tuberculosis were not capable of producing ordinary tuberculosis in the human and that he did not believe either meat or milk from tuberculous cattle were dangerous to man; also that he had found it impossible to infect calves with tubercle bacilli from man. Since the above statement was made many investigations have been made with the view of establishing the exact relation of these two forms. The weight of evidence and the weight of opinion are against the doctrine of the strict duality of tuberculosis as maintained by Koch and confirm the view that the two forms of the disease are interchangeable.

Before the publication of Koch's statement several observers had obtained positive results by inoculating human tuberculosis upon cattle; such as Chauveau, Frothingham, Sidney Martin, Airlong, Behring, Delapine, Ravenel, de Jong, and others. These furnished positive proof that human tuberculosis is inoculable upon cattle.

Koch's proposition that bovine tuberculosis is not pathogenic for human beings is much less susceptible of direct investigation.

Many cases have been reported in which there is a fairly clear history of direct inoculation of bovine tuberculous material result-

ing in a tuberculous lesion have been reported. L. Pfeiffer reports that a veterinary surgeon developed a cutaneous tubercle as a result of an autopsy of a tuberculous cow and died in one and one-half years of pulmonary tuberculosis. A similar infection in a powerful butcher's apprentice resulted in the formation of lupus of the arm. The form of tuberculosis of the skin described by Riehl and Paltauf was most often found by them in individuals who had to handle animals and animal products, such as butchers, inn-keepers, coachmen and cooks. In Thuringia according to Wahl excoriations are washed with new milk and in many parts of France with cream. Leloir publishes a case of a farmer's wife who in the bloom of health developed lupus of the face by this means. Stang reports a case of a boy without hereditary taint, born of healthy parents, dying of miliary tuberculosis of the lungs. It was afterwards found that the mesenteric glands were enormously enlarged and further that the boy had used milk from a tuberculous cow. Ollivier and Boulay report six cases of tuberculosis in an institution where milk from tuberculous cows was used. McFaydyen and McConkey took mesenteric glands from children who had died of non-tuberculous diseases and who were found at autopsy not to be tuberculous 25% contained virulent tubercle bacilli.

Behring found that the toxicity of cultures of tubercle bacilli depended upon their origin and their treatment during growth, but that only one kind of toxin can be found in all preparations. He employs human bacilli for immunizing cattle.

Ravenel isolated from the mesenteric glands of a child who died of primary tuberculosis a bacillus which had the most intense pathogenic power for cattle. He also succeeded in intensifying for cattle the pathogenic power of a human culture of moderate virulence by passing it successively through calves.

Behring suggests that the pulmonary tuberculosis is the result of an infection acquired through the intestine at an early age through milk. This remains latent till called into activity by subsequent circumstances which diminish resistance. This view is based upon his observation that in early life the uninjured membrane permits passage of bacteria with great readiness.

Salmon, chief of the animal industry in this country had DeScheinitz and Mohler conduct two sets of experiments. DeScheinitz isolated nine pure cultures of human tuberculosis. Two were from sputum, three from generalized tuberculosis in adults, and four from cases of generalized tuberculosis in children. These cultures were compared with newly isolated virulent bovine tubercle bacil-

ii Two of the cultures from children were found to be identical in cultural and morphological characteristics with the bovine bacilli. They also killed rabbits, guinea pigs, etc., in a short time as did the bovine bacillus. Two calves weighing 300 pounds developed general tuberculosis after subcutaneous inoculation. So 50% of cultures from children were virulent for cattle.

Mohler obtained three very virulent bacilli from the human subject. A goat, an animal almost immune to human tuberculosis died in 27 days after inoculation. This culture came from the mesenteric glands of a boy. Of still greater interest is a bacillus obtained from human sputum. A goat after inoculation died in 95 days. A rabbit injected with bovine bacilli lived ten days longer than the one inoculated with this sputum germ. In 1905 Calmette and Guerin proved by a brilliant series of experiments on cattle and goats that in the majority of cases pulmonary tuberculosis is caused by intestinal absorption of tubercle bacilli. They find it impossible to produce the typical lung lesion by an infection through the respiratory tract and they further proved that in the experiments of Cornet, Noard and Rossingnot the infection which was supposed to be directly respiratory was in fact intestinal and brought about by spasmodic coughing caused by bronchial irritation followed by subsequent swallowing of the bacilli. Romer has shown that true albumins could penetrate unchanged the intestinal mucosa of young animals whereas in adults they must be changed to peptones. From this it was an easy step to show that bacteria have the power of penetrating the apparently intact mucosa of the young owing to a lack of continuous epithelial covering of the intestinal glands in early life. Since this has been established it offers the irresistible conclusion that the bacteria pass directly through the lacteals into the chyle ducts, thence to the right heart and from here are distributed throughout the capillaries of the lungs. Taking into consideration the fact that the gastric juice is incapable of destroying tubercle bacilli it is miraculous how the bottle-fed baby runs the gauntlet of countless of millions and billions of tubercle bacilli ingested in each feeding.

In my search for tuberculous literature it has been my great good fortune to procure the April number of *The Veterinary Journal* for this year containing the second report of the Royal Commission on human and animal tuberculosis which is now at work in England conducting an experimental research concerning tuberculosis. This report is devoted to the solution of the relations of human and bovine tuberculosis. It is the most painstaking comprehensive and conclusive experi-

mental research that has ever been undertaken to settle this vexed question. I wish that this report could be placed in the hands of every board of health, doctor, dairyman, and lastly the person most concerned, the layman. It is impossible in the short time that remains to give anything but a brief synopsis of this report.

Two parallel investigations were carried out, an investigation into the effect produced in the bovine body by the introduction of human tubercle bacilli and an investigation into the effect produced in the bovine body by the introduction under similar conditions of bovine tubercle bacilli. These were carried on at two separate establishments which were a mile apart by two different sets of investigators. Each animal was thoroughly tested with tuberculin and otherwise to exclude tuberculosis from natural sources. In the experiments with bovine tuberculosis emulsions of lesions and cultures from this source injected into bovines produced first fatal generalized tuberculosis; second limited retrogressive tuberculosis; third results between the two. These variations were due to variations in natural resistance and variations in dose. It was found that 50 mgs. of emulsion of tuberculous lesions or of cultures was uniformly fatal, 10 mgs. is often fatal but left room for the play of natural resistance. In striking contrast to the ease with which fatal tuberculosis was produced by inoculation, is the difficulty of producing the same result by feeding.

Turning to the effects on other animals it can be produced either by injection or feeding in guinea pigs, rabbits, pigs, goats, cats, dogs and monkeys. The question naturally presents itself; Is the bacillus of bovine tuberculosis as effective on these other animals as it is in the bovine animal itself? Guinea pigs, pigs and monkeys seem to be more susceptible to bovine tubercle bacilli than the bovine animal itself. They call it the bovine tubercle bacilli merely because it is found most frequently in the bovine body. The fact that the bacillus of the bovine tuberculosis can readily give rise to the generalized tuberculosis in the anthropoid ape, so nearly related to man and produces this more readily than in the bovine body itself has an importance so obvious that it need not be dwelt upon.

In the experiments with human tubercle bacilli from sixty cases, results divided them into two distinct groups. Group one is far smaller than the other containing only fourteen cases. One was obtained from sputum, three from cervical glands, ten from primary tuberculous intestinal glands. In some of these cases which had died of generalized tuberculosis, lesions remote from the

gland were used, such as lungs and meninges. In ten cases the injection into bovines gave rise to generalized tuberculosis, four proving fatal, four others though generalized did not prove fatal within the period of observation. The other had a mild form of tuberculosis. The question naturally presents itself: Were the cases of lesser effect due to the small dose in relation to the resistance of the animal? The truth of this was established by injection of tuberculous emulsion from these animals originally infected into other animals producing fatal generalized tuberculosis. Cultures and emulsions taken from these fourteen bovines were now injected in the same doses mentioned in the experiment on bovine tuberculosis. Injections of 50 mgs., 10 mgs., 5 mgs., produced exactly the same result. There can be no doubt that the bacillus in each case or group one resembled the bovine bacillus in being capable of producing generalized tuberculosis in bovines. The effects on other animals were the same as was produced by the bovine tubercle bacilli. Both were equally virulent.

Group two contained forty cases from most diverse forms of tuberculosis. The injections with emulsions from this group produced local lesions, sometimes a few scattered tubercles in organs, but always in a retrogressive state. Injections of large doses, for instance 3000 mgs., of culture from these animals gave rise only to limited retrogressive lesions. Testing other animals, it produced generalized tuberculosis in guinea pigs, monkeys and apes. Pigs and goats were almost immune.

The results obtained by feeding two heifers for two hundred days were in one a few tuberculous mesenteric and hepatic glands. An emulsion made from these and injected into a calf produced severe general tuberculosis. The other heifer had a few calcareous mesenteric glands. Emulsion from these proved fatal to guinea pigs. The emulsion taken from the guinea pigs and injected into a calf produced only limited tuberculosis. They seem to have introduced by feeding in the first heifer, bacilli of group one and in the second heifer, bacilli of group two.

Histologically the lesions are the same differing only in degree.

In the experiments concerning the bacteriology of the tubercle bacilli it was found that they could be divided into two classes: One which grows with difficulty on artificial media called *dysgonic* and the other which grew readily on the same media called *eugonic*. In the first class they placed the bovine tubercle bacilli and the bacilli of group one of human tuberculosis. They exhibited the same range of growth, and the same variations in microscopical features. They are in

all respects one and the same. In the second class they placed the bacillus of group two of human tuberculosis, but the demarcation between these two is not a sharp or broad one. The members of the former class are not equally dysgonic nor are those of the second equally eugonic. In each the least dysgonic of the former differs but slightly, if at all from the least eugonic of the latter. Hence the real difference is slight. They now describe the behavior of some cases that do not fall in group one or two. In group one and two the cases differ so little that they are almost homogenous. In one case of this latter group tuberculous synovial membrane injected into two calves gave only limited retrogressive tuberculosis. A culture from these two calves was distinctly eugonic; a culture obtained from a guinea pig inoculated with the original material, injected into calves in doses of 50 mgs. produced limited tuberculosis. The bacillus in this case clearly belonged to group two of human tuberculosis. When, however, this material was passed through a series of calves, emulsions from the organ of the fifth and sixth passage calves injected into other calves gave rise to fatal generalized tuberculosis. The cultures from these fatal cases moreover were markedly dysgonic. One of them was the most dysgonic obtained from human source.

They briefly sum up the bearings of the results at which they have already arrived as follows:

There can be no doubt that in a certain number of cases the tuberculosis occurring in the human subject, especially in children, is the direct result of the introduction into the human body of the bacillus of bovine tuberculosis, and there also can be no doubt that in the majority at least of these cases the bacillus is introduced through cows' milk. Cows' milk containing bovine tubercle bacilli is clearly a cause of tuberculosis, in man.

Of the sixty cases of human tuberculosis investigated by them, fourteen of the viruses belonged to group one, that is to say, contained the bovine bacillus. If instead of taking all these sixty cases, they confine themselves to cases of tuberculosis in which the bacilli were apparently introduced into the body by way of the alimentary canal, the proportion of group one becomes very much larger. Of the total sixty cases investigated by them twenty-eight possessed clinical histories indicating that in them the bacillus was introduced through the alimentary canal. Of these thirteen belonged to group one. Of the nine cases in which the cervical glands were studied by them, three, and of the nineteen cases in which the lesions of abdominal tu-

berculosis were studied by them, ten belong to group one.

These facts indicate that a very large proportion of tuberculosis contracted by ingestion is due to tubercle bacilli of bovine source.

A very considerable amount of disease and loss of life, especially among the young, must be attributed to the consumption of cows' milk containing tubercle bacilli. The presence of tubercle bacilli in cows' milk can be detected, though with some difficulty, if the proper means be adopted, and such milk ought never to be used as food. There is far less difficulty in recognizing clinically that a cow is distinctly suffering from tuberculosis, in which case she may be yielding tuberculous milk. The milk coming from such a cow ought not to form part of human food and indeed ought not to be used as food at all.

Their results clearly point to the necessity of measures more stringent than those at present enforced being taken to prevent the sale or the consumption of such milk.

In conclusion the mass of evidence just presented refutes in its entirety the amazing stand of Koch in 1901; re-establishes the unity of all tubercle bacilli from whatsoever source obtained; proves that its infectiveness for mammals and some cold blooded animals is interchangeable, and that this is more especially the case with the bovine and human varieties. Hence any means of eradicating tuberculosis in animals or preventing the consumption of the products and meats of such tuberculous animals, will confer a great boon upon humanity by eventually stamping out the Great White Plague.

#### CONCERNING THE OPSONIC INDEX AND BACTERIAL VACCINES.\*
